70481 R&D General economic, commercial, and labor affairs (CS)

- Administration and operation of government agencies engaged in applied research and experimental development related to general economic, commercial, and labor affairs
- Grants, loans, or subsidies to support applied research and experimental development related to general economic, commercial, and labor affairs undertaken by nongovernment bodies, such as research institutes and universities.

Excludes: basic research (70140).

70482 R&D Agriculture, forestry, fishing, and hunting (CS)

- Administration and operation of government agencies engaged in applied research and experimental development related to agriculture, forestry, fishing, and hunting

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

- Grants, loans, or subsidies to support applied research and experimental development related to agriculture, forestry, fishing, and hunting undertaken by nongovernment bodies, such as research institutes and universities.

Excludes: basic research (70140).

70483 R&D Fuel and energy (CS)

- Administration and operation of government agencies engaged in applied research and experimental development related to fuel and energy
- Grants, loans, or subsidies to support applied research and experimental development related to fuel and energy undertaken by nongovernment bodies, such as research institutes and universities.

Excludes: basic research (70140).

70484 R&D Mining, manufacturing, and construction (CS)

- Administration and operation of government agencies engaged in applied research and experimental development related to mining, manufacturing, and construction
- Grants, loans, or subsidies to support applied research and experimental development related to mining, manufacturing, and construction undertaken by nongovernment bodies, such as research institutes and universities.

Excludes: basic research (70140).

70485 R&D Transport (CS)

- Administration and operation of government agencies engaged in applied research and experimental development related to transport
- Grants, loans, or subsidies to support applied research and experimental development related to transport undertaken by nongovernment bodies, such as research institutes and universities.

Excludes: basic research (70140).

70486 R&D Communication (CS)

- Administration and operation of government agencies engaged in applied research and experimental development related to communication
- Grants, loans, or subsidies to support applied research and experimental development related to communication undertaken by nongovernment bodies such as research institutes and universities.

Excludes: basic research (70140).

70487 R&D Other industries (CS)

- Administration and operation of government agencies engaged in applied research and experimental development related to other sectors
- Grants, loans, or subsidies to support applied research and experimental development related to other sectors undertaken by nongovernment bodies, such as research institutes and universities.

Includes: distributive trades, storage, and warehousing; hotels and restaurants; tourism and multipurpose development projects.

Excludes: basic research (70140).

7049 ECONOMIC AFFAIRS N.E.C.

70490 Economic affairs n.e.c. (CS)

- Administration, operation, or support activities relating to general and sectoral economic affairs that cannot be assigned to (7041), (7042), (7043), (7044), (7045), (7046), (7047), or (7048).

705 ENVIRONMENTAL PROTECTION

The breakdown of environmental protection is based upon the Classification of Environmental Protection Activities (CEPA) as elaborated in the European System for the Collection of Economic Information on the Environment (SERIEE) of the Statistical Office of the European Communities (Eurostat).

7051 WASTE MANAGEMENT

This group covers collection, treatment, and disposal of waste.

Waste collection includes sweeping of streets, squares, paths, markets, public gardens, parks, etc.; collection of all types of waste, whether selective by type of product or undifferentiated covering all waste, and their transport to place of treatment or discharge.

Waste treatment includes any method or process designed to change the physical, chemical, or biological character or composition of any waste so as to neutralize it, to render it nonhazardous, to make it safer for transport, to make it amenable for recovery or storage, or to reduce it in volume.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Waste disposal includes final placement of waste for which no further use is foreseen by landfill, containment, underground disposal, dumping at sea, or any other relevant disposal method.

70510 Waste management (CS)

- Administration, supervision, inspection, operation, or support of waste collection, treatment, and disposal systems
- Grants, loans, or subsidies to support the operation, construction, maintenance, or upgrading of such systems.

Includes: collection, treatment, and disposal of nuclear waste.

7052 WASTE WATER MANAGEMENT

This group covers sewage system operation and waste water treatment.

Sewage system operation includes management and construction of the system of collectors, pipelines, conduits, and pumps to evacuate any waste water (rainwater, domestic, and other available waste water) from the points of generation to either a sewage treatment plant or to a point where waste water is discharged to surface water.

Waste water treatment includes any mechanical, biological, or advanced process to render waste water fit to meet applicable environment standards or other quality norms.

70520 Waste water management (CS)

- Administration, supervision, inspection, operation, or support of sewage systems and waste water treatment
- Grants, loans, or subsidies to support the operation, construction, maintenance, or upgrading of such systems.

7053 POLLUTION ABATEMENT

This group covers activities relating to ambient air and climate protection, soil and groundwater protection, noise and vibration abatement, and protection against radiation.

These activities include construction, maintenance, and operation of monitoring systems and stations (other than weather stations); construction of noise embankments, hedges, and other anti-noise facilities including the resurfacing of sections of urban highways or railways with noise reducing surfaces; measures to clean pollution in water bodies; measures to control or prevent the emissions of greenhouse gases and pollutants that adversely affect the quality of the air; construction, maintenance, and operation of installations for the decontamination of polluted soils and for the storage of pollutant products; transportation of pollutant products.

70530 Pollution abatement (CS)

- Administration, supervision, inspection, operation, or support of activities relating to pollution abatement and control
- Grants, loans, or subsidies to support activities relating to pollution abatement and control.

7054 PROTECTION OF BIODIVERSITY AND LANDSCAPE

This group covers activities relating to the protection of fauna and flora species (including the reintroduction of extinct species and the recovery of species menaced by extinction), the protection of habitats (including the management of natural parks and reserves), and the protection of landscapes for their aesthetic values (including the reshaping of damaged landscapes for the purpose of strengthening their aesthetic value and the rehabilitation of abandoned mines and quarry sites).

70540 Protection of biodiversity and landscape (CS)

- Administration, supervision, inspection, operation, or support of activities relating to the protection of biodiversity and landscape
- Grants, loans, or subsidies to support activities relating to the protection of biodiversity and landscape.

7055 R&D ENVIRONMENTAL PROTECTION

Definitions of basic research, applied research, and experimental development are given under (7014) and (7015).

70550 R&D Environmental protection (CS)

- Administration and operation of government agencies engaged in applied research and

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

experimental development related to environmental protection

- Grants, loans, or subsidies to support applied research and experimental development related to environmental protection undertaken by nongovernment bodies, such as research institutes and universities.

Excludes: basic research (70140).

7056 ENVIRONMENTAL PROTECTION N.E.C.

70560 Environmental protection n.e.c. (CS)

- Administration, management, regulation, supervision, operation, and support of activities such as formulation, administration, coordination, and monitoring of overall policies, plans, programs, and budgets for the promotion of environmental protection; preparation and enforcement of legislation and standards for the provision of environmental protection services; production and dissemination of general information, technical documentation, and statistics on environmental protection.

Includes: environmental protection affairs and services that cannot be assigned to (7051), (7052), (7053), (7054), or (7055).

706 HOUSING AND COMMUNITY AMENITIES

7061 HOUSING DEVELOPMENT

70610 Housing development (CS)

- Administration of housing development affairs and services; promotion, monitoring, and evaluation of housing development activities regardless of whether the activities are under the auspices of public authorities; development and regulation of housing standards
- Slum clearance related to provision of housing; acquisition of land needed for construction of dwellings; construction or purchase and remodeling of dwelling units for the general public or for people with special needs
- Production and dissemination of public information, technical documentation, and statistics on housing development affairs and services
- Grants, loans, or subsidies to support the expansion, improvement, or maintenance of the housing stock.

Excludes: development and regulation of construction standards (70443); cash benefits and benefits in kind to help households meet the cost of housing (71060).

7062 COMMUNITY DEVELOPMENT

70620 Community development (CS)

- Administration of community development affairs and services; administration of zoning laws and land-use and building regulations
- Planning of new communities or of rehabilitated communities; planning the improvement and development of facilities such as housing, industry, public utilities, health, education, culture, recreation, etc. for communities; preparation of schemes for financing planned developments
- Production and dissemination of general information, technical documentation, and statistics on community development affairs and services.

Excludes: plan implementation—that is, the actual construction of housing, industrial buildings, streets, public utilities, cultural facilities, etc. (classified according to function); agrarian reform and land resettlement (70421); administration of construction standards (70443) and housing standards (70610).

7063 WATER SUPPLY

70630 Water supply (CS)

- Administration of water supply affairs; assessment of future needs and determination of availability in terms of such assessment; supervision and regulation of all facets of potable water supply including water purity, price, and quantity controls
- Construction or operation of nonenterprise-type of water supply systems
- Production and dissemination of general information, technical documentation, and statistics on water supply affairs and services
- Grants, loans, or subsidies to support the operation, construction, maintenance, or upgrading of water supply systems.

Excludes: irrigation systems (70421); multipurpose projects (70474); collection and treatment of waste water (70520).

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

7064 STREET LIGHTING

70640 Street lighting (CS)

- Administration of street lighting affairs; development and regulation of street lighting standards
- Installation, operation, maintenance, upgrading, etc. of street lighting.

Excludes: lighting affairs and services associated with the construction and operation of highways (70451).

7065 R&D HOUSING AND COMMUNITY AMENITIES

Definitions of basic research, applied research, and experimental development are given under (7014) and (7015).

70650 R&D Housing and community amenities (CS)

- Administration and operation of government agencies engaged in applied research and experimental development related to housing and community amenities
- Grants, loans, or subsidies to support applied research and experimental development related to housing and community amenities undertaken by nongovernment bodies, such as research institutes and universities.

Excludes: basic research (70140); applied research and experimental development into construction methods or materials (70484).

7066 HOUSING AND COMMUNITY AMENITIES N.E.C.

70660 Housing and community amenities n.e.c. (CS)

- Administration, operation, or support of activities such as formulation, administration, coordination, and monitoring of overall policies, plans, programs, and budgets relating to housing and community amenities; preparation and enforcement of legislation and standards relating to housing and community amenities; production and dissemination of general information, technical documentation, and statistics relating to housing and community amenities.

Includes: administration, operation, or support activities relating to housing and community amenities that cannot be assigned to (7061), (7062), (7063), (7064), or (7065).

707 HEALTH

Government expenditure on health includes expenditure on services provided to individual persons and services provided on a collective basis. Expenditure on individual services is allocated to groups (7071) through (7074); expenditure on collective services is assigned to groups (7075) and (7076).

Collective health services are concerned with matters such as formulation and administration of government policy; setting and enforcement of standards for medical and paramedical personnel and for hospitals, clinics, surgeries, etc.; regulation and licensing of providers of health services; and applied research and experimental development into medical and health-related matters. However, overhead expenditure connected with administration or functioning of a group of hospitals, clinics, surgeries, etc. is considered to be individual expenditure and is classified to groups (7071) through (7074) as appropriate.

7071 MEDICAL PRODUCTS, APPLIANCES, AND EQUIPMENT

This group covers medicaments, prostheses, medical appliances and equipment, and other health-related products obtained by individuals or households, either with or without a prescription, usually from dispensing chemists, pharmacists, or medical equipment suppliers. They are intended for consumption or use outside a health facility or institution. Such products supplied directly to outpatients by medical, dental, and paramedical practitioners or to in-patients by hospitals and the like are included in outpatient services (7072) or hospital services (7073).

70711 Pharmaceutical products (IS)

- Provision of pharmaceutical products such as medicinal preparations, medicinal drugs, patent medicines, serums and vaccines, vitamins and minerals, cod liver oil and halibut liver oil, oral contraceptives
- Administration, operation, or support of the provision of pharmaceutical products.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

70712 Other medical products (IS)

- Provision of medical products such as clinical thermometers, adhesive and nonadhesive bandages, hypodermic syringes, first-aid kits, hot-water bottles and ice bags, medical hosiery items such as elasticized stockings and knee-pads, pregnancy tests, condoms, and other mechanical contraceptive devices
- Administration, operation, or support of the provision of prescribed other medical products.

70713 Therapeutic appliances and equipment (IS)

- Provision of therapeutic appliances and equipment, such as corrective eyeglasses and contact lenses, hearing aids, glass eyes, artificial limbs and other prosthetic devices, orthopedic braces and supports, orthopedic footwear, surgical belts, trusses and supports, neck braces, medical massage equipment and health lamps, powered and unpowered wheelchairs and invalid carriages, "special" beds, crutches, electronic and other devices for monitoring blood pressure, etc.
- Administration, operation, or support of the provision of prescribed therapeutic appliances and equipment.

Includes: dentures but not fitting costs; repair of therapeutic appliances and equipment.

Excludes: hire of therapeutic equipment (70724).

7072 OUTPATIENT SERVICES

This group covers medical, dental, and paramedical services delivered to outpatients by medical, dental, and paramedical practitioners and auxiliaries. The services may be delivered at home, in individual or group consulting facilities, dispensaries, or the outpatient clinics of hospitals and the like.

Outpatient services include the medicaments, prostheses, medical appliances and equipment, and other health-related products supplied directly to outpatients by medical, dental, and paramedical practitioners and auxiliaries.

Medical, dental, and paramedical services provided to in-patients by hospitals and the like are included in hospital services (7073).

70721 General medical services (IS)

This class covers the services provided by general medical clinics and general medical practitioners.

General medical clinics are defined as institutions that chiefly provide outpatient services that are not limited to a particular medical specialty and that are chiefly delivered by qualified medical doctors. General medical practitioners do not specialize in a particular medical specialty.

- Provision of general medical services
- Administration, inspection, operation, or support of general medical services delivered by general medical clinics and general medical practitioners.

Excludes: services of medical analysis laboratories and x-ray centers (70724).

70722 Specialized medical services (IS)

This class covers the services of specialized medical clinics and specialist medical practitioners.

Specialized medical clinics and specialist medical practitioners differ from general medical clinics and general medical practitioners in that their services are limited to treatment of a particular condition, disease, medical procedure, or class of patient.

- Provision of specialized medical services
- Administration, inspection, operation, or support of specialized medical services delivered by specialized medical clinics and specialist medical practitioners.

Includes: services of orthodontic specialists.

Excludes: dental clinics and dentists (70723); services of medical analysis laboratories and x-ray centers (70724).

70723 Dental services (IS)

This class covers the services of general or specialist dental clinics and dentists, oral hygienists, or other dental operating auxiliaries.

Dental clinics provide outpatient services. They are not necessarily supervised or staffed by dentists; they may be supervised or staffed by oral hygienists or by dental auxiliaries.

- Provision of dental services to outpatients
- Administration, inspection, operation, and support of dental services delivered by general or

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

specialist dental clinics and by dentists, oral hygienists, or other dental auxiliaries.

Includes: fitting costs of dentures.

Excludes: dentures (70713); services of orthodontic specialists (70722); services of medical analysis laboratories and x-ray centers (70724).

70724 Paramedical services (IS)

- Provision of paramedical health services to outpatients
- Administration, inspection, operation, or support of health services delivered by clinics supervised by nurses, midwives, physiotherapists, occupational therapists, speech therapists or other paramedical personnel and of health services delivered by nurses, midwives, and paramedical personnel in nonconsulting rooms, patients' homes, or other nonmedical institutions.

Includes: acupuncturists, chiropodists, chiropractors, optometrists, practitioners of traditional medicine, etc.; medical analysis laboratories and x-ray centers; hire of therapeutic equipment; medically prescribed corrective-gymnastic therapy; outpatient thermal bath or sea-water treatments; ambulance services other than ambulance services operated by hospitals.

Excludes: public health service laboratories (70740); laboratories engaged in determining the causes of disease (70750).

7073 HOSPITAL SERVICES

Hospitalization is defined as occurring when a patient is accommodated in a hospital for the duration of the treatment. Hospital day care and home-based hospital treatment are included, as are hospices for terminally ill persons.

This group covers the services of general and specialist hospitals, the services of medical centers, maternity centers, nursing homes, and convalescent homes that chiefly provide in-patient services, the services of military base hospitals, the services of institutions serving old people in which medical monitoring is an essential component, and the services of rehabilitation centers providing in-patient health care and rehabilitative therapy where the objective is to treat the patient rather than to provide long-term support.

Hospitals are defined as institutions that offer in-patient care under direct supervision of qualified medical doctors. Medical centers, maternity centers, nursing homes, and convalescent homes also provide in-patient care, but their services are supervised and frequently delivered by staff of lower qualification than medical doctors.

The group does not cover facilities such as military field hospitals (7021), surgeries, clinics, and dispensaries devoted exclusively to outpatient care (7072), institutions for disabled persons and rehabilitation centers providing primarily long-term support (71012), or retirement homes for elderly persons (71020). Neither does it cover payments to patients for loss of income due to hospitalization (71011).

Hospital services include medicaments, prostheses, medical appliances and equipment, and other health-related products supplied to hospital patients. It also includes nonmedical expenditure of hospitals on administration, nonmedical staff, food and drink, accommodation (including staff accommodation), etc.

70731 General hospital services (IS)

- Provision of general hospital services
- Administration, inspection, operation, or support of hospitals that do not limit their services to a particular medical specialty.

Excludes: medical centers not under the direct supervision of a qualified medical doctor (70733).

70732 Specialized hospital services (IS)

Specialized hospitals differ from general hospitals in that their services are limited to treatment of a particular condition, disease, or class of patient—for example, diseases of the chest and tuberculosis, leprosy, cancer, otorhinolaryngology, psychiatry, obstetrics, pediatrics, and so forth.

- Provision of specialized hospital services
- Administration, inspection, operation, or support of hospitals that limit their services to a particular medical specialty.

Excludes: maternity centers not under the direct supervision of a qualified medical doctor (70733).

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

70733 Medical and maternity center services (IS)

- Provision of medical and maternity center services
- Administration, inspection, operation, or support of medical and maternity center services.

70734 Nursing and convalescent home services (IS)

Nursing and convalescent homes provide in-patient services to persons recovering from surgery or a debilitating disease or condition that requires chiefly monitoring and administering of medicaments, physiotherapy, and training to compensate for loss of function or rest.

- Provision of nursing and convalescent home services
- Administration, inspection, operation, or support of nursing and convalescent home services.

Includes: institutions serving old people in which medical monitoring is an essential component; rehabilitation centers providing in-patient health care and rehabilitative therapy where the objective is to treat the patient rather than to provide long-term support.

7074 PUBLIC HEALTH SERVICES

70740 Public health services (IS)

- Provision of public health services
- Administration, inspection, operation, or support of public health services, such as blood-bank operation (collecting, processing, storing, shipping), disease detection (cancer, tuberculosis, venereal disease), prevention (immunization, inoculation), monitoring (infant nutrition, child health), epidemiological data collection, family planning services, and so forth
- Preparation and dissemination of information on public health matters.
- *Includes*: public health services delivered by special teams to groups of clients, most of whom are in good health, at workplaces, schools, or other non-medical settings; public health services not connected with a hospital, clinic, or practitioner; public health services not delivered by medically qualified doctors; public health service laboratories.

Excludes: medical analysis laboratories (70724); laboratories engaged in determining the causes of disease (70750).

7075 R&D HEALTH

Definitions of basic research, applied research, and experimental development are given under (7014) and (7015).

70750 R&D Health (CS)

- Administration and operation of government agencies engaged in applied research and experimental development related to health
- Grants, loans, and subsidies to support applied research and experimental development related to health undertaken by nongovernment bodies, such as research institutes and universities.

Includes: laboratories engaged in determining the causes of disease.

Excludes: basic research (70140).

7076 HEALTH N.E.C.

70760 Health n.e.c. (CS)

- Administration, operation, or support of activities such as formulation, administration, coordination, and monitoring of overall health policies, plans, programs, and budgets; preparation and enforcement of legislation and standards for the provision of health services, including the licensing of medical establishments and medical and paramedical personnel; production and dissemination of general information, technical documentation, and statistics on health.

Includes: health affairs and services that cannot be assigned to (7071), (7072), (7073), (7074), or (7075).

708 RECREATION, CULTURE, AND RELIGION

Government expenditure on recreation, culture, and religion includes expenditure on services provided to individual persons and households and expenditure on services provided on a collective basis. Individual expenditure is allocated to groups (7081) and (7082); expenditure on collective services is assigned to groups (7083) to (7086).

Collective services are provided to the community as a whole. They include activities such as formulation

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

and administration of government policy; formulation and enforcement of legislation and standards for providing recreational and cultural services; and applied research and experimental development into recreational, cultural, and religious affairs and services.

7081 RECREATIONAL AND SPORTING SERVICES

70810 Recreational and sporting services (IS)

- Provision of sporting and recreational services; administration of sporting and recreational affairs; supervision and regulation of sporting facilities
- Operation or support of facilities for active sporting pursuits or events (playing fields, tennis courts, squash courts, running tracks, golf courses, boxing rings, skating rinks, gymnasia, etc.); operation or support of facilities for passive sporting pursuits or events (chiefly specially equipped venues for playing cards, board games, etc.); operation or support of facilities for recreational pursuits (parks, beaches, camping grounds and associated lodging places furnished on a noncommercial basis, swimming pools, public baths for washing, etc.)
- Grants, loans, or subsidies to support teams or individual competitors or players.

Includes: facilities for spectator accommodation; national, regional, or local team representation in sporting events.

Excludes: zoological or botanical gardens, aquaria, arboreta, and similar institutions (70820); sporting and recreational facilities associated with educational institutions (classified to the appropriate class of Division 709).

7082 CULTURAL SERVICES

70820 Cultural services (IS)

- Provision of cultural services; administration of cultural affairs; supervision and regulation of cultural facilities
- Operation or support of facilities for cultural pursuits (libraries, museums, art galleries, theatres, exhibition halls, monuments, historic houses and sites, zoological and botanical gardens, aquaria, arboreta, etc.); production, operation, or support of cultural events (concerts, stage and film productions, art shows, etc.)
- Grants, loans, or subsidies to support individual artists, writers, designers, composers, and others working in the arts or to organizations engaged in promoting cultural activities.

Includes: national, regional, or local celebrations provided they are not intended chiefly to attract tourists.

Excludes: cultural events intended for presentation beyond national boundaries (70113); national, regional, or local celebrations intended chiefly to attract tourists (70473); production of cultural material intended for distribution by broadcasting (70830).

7083 BROADCASTING AND PUBLISHING SERVICES

70830 Broadcasting and publishing services (CS)

- Administration of broadcasting and publishing affairs; supervision and regulation of broadcasting and publishing services
- Operation or support of broadcasting and publishing services
- Grants, loans, or subsidies to support the construction or acquisition of facilities for television or radio broadcasting; the construction or acquisition of plant, equipment, or materials for newspaper, magazine, or book publishing; the production of material for, and its presentation by, broadcasting; the gathering of news or other information; the distribution of published works.

Excludes: government printing offices and plants (70133); provision of education by radio or television broadcasting (709).

7084 RELIGIOUS AND OTHER COMMUNITY SERVICES

70840 Religious and other community services (CS)

- Administration of religious and other community affairs
- Provision of facilities for religious and other community services, including support for their operation, maintenance, and repair
- Payment of clergy or other officers of religious institutions; support for the holding of religious

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

services; grants, loans, or subsidies to support fraternal, civic, youth, and social organizations or labor unions, and political parties.

7085 R&D RECREATION, CULTURE, AND RELIGION

Definitions of basic research, applied research, and experimental development are given under (7014) and (7015).

70850 R&D Recreation, culture, and religion (CS)

- Administration and operation of government agencies engaged in applied research and experimental development related to recreation, culture, and religion
- Grants, loans, and subsidies to support applied research and experimental development related to recreation, culture, and religion undertaken by nongovernment bodies, such as research institutes and universities.

Excludes: basic research (70140).

7086 RECREATION, CULTURE, AND RELIGION N.E.C.

70860 Recreation, culture, and religion n.e.c. (CS)

- Administration, operation, or support of activities such as formulation, administration, coordination, and monitoring of overall policies, plans, programs, and budgets for the promotion of sport, recreation, culture, and religion; preparation and enforcement of legislation and standards for the provision of recreational and cultural services; production and dissemination of general information, technical documentation, and statistics on recreation, culture, and religion.

Includes: affairs and services relating to recreation, culture, and religion that cannot be assigned to (7081), (7082), (7083), (7084), or (7085).

709 EDUCATION

Government expenditure on education includes expenditure on services provided to individual pupils and students and expenditure on services provided on a collective basis. Expenditure on individual services is allocated to groups (7091) through (7096); expenditure on collective services is assigned to groups (7097) and (7098).

Collective educational services are concerned with matters such as formulation and administration of government policy; setting and enforcement of standards; regulation, licensing, and supervision of educational establishments; and applied research and experimental development into education affairs and services. However, overhead expenditure connected with administration or functioning of a group of schools, colleges, etc. is considered to be individual expenditure and is classified to groups (7091) through (7096) as appropriate.

The breakdown of education is based upon the level categories of the 1997 International Standard Classification of Education (ISCED-97) of the United Nations Educational, Scientific and Cultural Organization (UNESCO).

This division includes military schools and colleges where curricula resemble those of civilian institutions, police colleges offering general education in addition to police training, and the provision of education by radio or television broadcasting. Expenditure so incurred is classified to groups (7091) to (7095) as appropriate.

7091 PRE-PRIMARY AND PRIMARY EDUCATION

70911 Pre-primary education (IS)

- Provision of pre-primary education at ISCED-97 level 0
- Administration, inspection, operation, or support of schools and other institutions providing pre-primary education at ISCED-97 level 0.

Excludes: subsidiary services to education (70960).

70912 Primary education (IS)

- Provision of primary education at ISCED-97 level 1
- Administration, inspection, operation, or support of schools and other institutions providing primary education at ISCED-97 level 1.

Includes: literacy programs for students too old for primary school.

Excludes: subsidiary services to education (70960).

7092 SECONDARY EDUCATION

70921 Lower-secondary education (IS)

- Provision of lower-secondary education at ISCED-97 level 2

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

- Administration, inspection, operation, or support of schools and other institutions providing lower-secondary education at ISCED-97 level 2
- Scholarships, grants, loans, and allowances to support pupils pursuing lower-secondary education at ISCED-97 level 2.

Includes: out-of-school lower-secondary education for adults and young people.

Excludes: subsidiary services to education (70960).

70922 Upper-secondary education (IS)

- Provision of upper-secondary education at ISCED-97 level 3
- Administration, inspection, operation, or support of schools and other institutions providing upper-secondary education at ISCED-97 level 3
- Scholarships, grants, loans, and allowances to support pupils pursuing upper-secondary education at ISCED-97 level 3.

Includes: out-of-school upper-secondary education for adults and young people.

Excludes: subsidiary services to education (70960).

7093 POST-SECONDARY NONTERTIARY EDUCATION

70930 Post-secondary nontertiary education (IS)

- Provision of post-secondary nontertiary education at ISCED-97 level 4
- Administration, inspection, operation, or support of institutions providing post-secondary nontertiary education at ISCED-97 level 4
- Scholarships, grants, loans, and allowances to support students pursuing post-secondary nontertiary education at ISCED-97 level 4.

Includes: out-of-school post-secondary nontertiary education for adults and young people.

Excludes: subsidiary services to education (70960).

7094 TERTIARY EDUCATION

70941 First stage of tertiary education (IS)

- Provision of tertiary education at ISCED-97 level 5
- Administration, inspection, operation, or support of universities and other institutions providing tertiary education at ISCED-97 level 5
- Scholarships, grants, loans, and allowances to support students pursuing tertiary education at ISCED-97 level 5.

Excludes: subsidiary services to education (70960).

70942 Second stage of tertiary education (IS)

- Provision of tertiary education at ISCED-97 level 6
- Administration, inspection, operation, or support of universities and other institutions providing tertiary education at ISCED-97 level 6
- Scholarships, grants, loans, and allowances to support students pursuing tertiary education at ISCED-97 level 6.

Excludes: subsidiary services to education (70960).

7095 EDUCATION NOT DEFINABLE BY LEVEL

70950 Education not definable by level (IS)

- Provision of education not definable by level (i.e., educational programs, generally for adults, that do not require any special prior instruction, in particular, vocational training and cultural development)
- Administration, inspection, operation, or support of institutions providing education not definable by level
- Scholarships, grants, loans, and allowances to support students pursuing education programs not definable by level.

7096 SUBSIDIARY SERVICES TO EDUCATION

70960 Subsidiary services to education (IS)

- Provision of subsidiary services to education
- Administration, inspection, operation, or support of transportation, food, lodging, medical and dental care, and related subsidiary services chiefly for students regardless of level.

Excludes: school health monitoring and prevention services (70740); scholarships, grants, loans, and allowances in cash to defray the costs of subsidiary services (7091), (7092), (7093), (7094), or (7095).

7097 R&D EDUCATION

Definitions of basic research, applied research, and experimental development are given under (7014) and (7015).

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

70970 R&D Education (CS)

- Administration and operation of government agencies engaged in applied research and experimental development related to education
- Grants, loans, and subsidies to support applied research and experimental development related to education undertaken by nongovernment bodies, such as research institutes and universities.

Excludes: basic research (70140).

7098 EDUCATION N.E.C.

70980 Education n.e.c. (CS)

- Administration, operation, or support of activities such as formulation, administration, coordination, and monitoring of overall educational policies, plans, programs, and budgets; preparation and enforcement of legislation and standards for the provision of education, including licensing of educational establishments; production and dissemination of general information, technical documentation, and statistics on education.

Includes: education affairs and services that cannot be assigned to (7091), (7092), (7093), (7094), (7095), (7096), or (7097).

710 SOCIAL PROTECTION

Government expenditure on social protection includes expenditure on services and transfers provided to individual persons and households and expenditure on services provided on a collective basis. Expenditure on individual services and transfers are allocated to groups (7101) through (7107); expenditure on collective services is assigned to groups (7108) and (7109).

Collective social protection services are concerned with matters such as formulation and administration of government policy; formulation and enforcement of legislation and standards for providing social protection; and applied research and experimental development into social protection affairs and services.

The social protection functions and their definitions are based on the 2008 European System of Integrated Social Protection Statistics (ESSPROS) of the Statistical Office of the European Communities (Eurostat).

In ESSPROS, social protection includes health care, but this division does not include health care. Health care is covered by Division 707. Hence, medical goods and services provided to persons who receive the cash benefits and benefits in kind specified in groups (7101) through (7107) are classified under (7071), (7072), or (7073) as appropriate.

7101 SICKNESS AND DISABILITY

71011 Sickness (IS)

- Provision of social protection in the form of cash benefits or benefits in kind that replace in whole or in part loss of earnings during a temporary inability to work due to sickness or injury
- Administration, operation, or support of such social protection schemes
- Cash benefits, such as flat-rate or earnings-related sick leave payments and miscellaneous payments provided to help persons temporarily unable to work due to sickness or injury
- Benefits in kind, such as assistance with daily tasks provided to persons temporarily unable to work due to sickness or injury (home help, transport facilities, etc.).

71012 Disability (IS)

- Provision of social protection in the form of cash benefits or benefits in kind to persons who are fully or partially unable to engage in economic activity or lead a normal life due to a physical or mental impairment that is either permanent or likely to persist beyond a minimum prescribed period
- Administration, operation, or support of such social protection schemes
- Cash benefits, such as disability pensions paid to persons below the standard retirement age who encounter a disability that impairs their ability to work, early retirement benefits paid to older workers who retire before reaching the standard retirement age due to reduced capacity to work, care allowances, allowances paid to disabled persons undertaking work adapted to their condition or undergoing vocational training, and other periodic or lump-sum payments paid to disabled persons for social protection reasons
- Benefits in kind, such as lodging and possibly board provided to disabled persons in appropriate establishments, assistance provided to disabled persons to help them with daily tasks (home help, transport facilities, etc.), allowances paid to the person who looks after the disabled person, vocational and other training provided to further the occupational and social rehabilitation of disabled persons, and miscellaneous services and goods provided to disabled persons to enable them to

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

participate in leisure and cultural activities or to travel or to participate in community life.

Excludes: cash benefits and benefits in kind paid to disabled persons on reaching the standard retirement age (71020).

7102 OLD AGE

71020 Old age (IS)

- Provision of social protection in the form of cash benefits and benefits in kind against the risks linked to old age (loss of income, inadequate income, lack of independence in carrying out daily tasks, reduced participation in social and community life, etc.)
- Administration, operation, or support of such social protection schemes
- Cash benefits, such as old-age pensions paid to persons on reaching the standard retirement age, anticipated old-age pensions paid to older workers who retire before the standard retirement age, partial retirement pensions paid either before or after the standard retirement age to older workers who continue working but reduce their working hours, care allowances, and other periodic or lump-sum payments paid upon retirement or on account of old age
- Benefits in kind, such as lodging and sometimes board provided to elderly persons either in specialized institutions or staying with families in appropriate establishments, assistance provided to elderly persons to help them with daily tasks (home help, transport facilities etc.), allowances paid to the person who looks after an elderly person, and miscellaneous services and goods provided to elderly persons to enable them to participate in leisure and cultural activities or to travel or to participate in community life.

Includes: pension schemes for military personnel and for government employees.

Excludes: early retirement benefits paid to older workers who retire before reaching standard retirement age due to disability (71012) or unemployment (71050).

7103 SURVIVORS

71030 Survivors (IS)

- Provision of social protection in the form of cash benefits and benefits in kind to persons who are survivors of a deceased person (such as the person's spouse, ex-spouse, children, grandchildren, parents, or other relatives)
- Administration, operation, or support of such social protection schemes
- Cash benefits, such as survivors' pensions, death grants, and other periodic or lump-sum payments to survivors
- Benefits in kind, such as payments toward funeral expenditure and miscellaneous services and goods provided to survivors to enable them to participate in community life.

7104 FAMILY AND CHILDREN

71040 Family and children (IS)

- Provision of social protection in the form of cash benefits and benefits in kind to households with dependent children
- Administration, operation, or support of such social protection schemes
- Cash benefits, such as maternity allowances, birth grants, parental leave benefits, family or child allowances, and other periodic or lump-sum payments to support households and help them meet the costs of specific needs (e.g., those of the lone parent families or families with handicapped children)
- Benefits in kind, such as shelter and board provided to preschool children during the day or part of the day, financial assistance toward payment of a nurse to look after children during the day, shelter and board provided to children and families on a permanent basis (orphanages, foster families, etc.), goods and services provided at home to children or to those who care for them, and miscellaneous services and goods provided to families, young people, or children (holiday and leisure centers).

Excludes: family planning services (70740).

7105 UNEMPLOYMENT

71050 Unemployment (IS)

- Provision of social protection in the form of cash benefits and benefits in kind to persons who are capable of work and available for work but are unable to find suitable employment
- Administration, operation, or support of such social protection schemes
- Cash benefits, such as full and partial unemployment benefits, early retirement benefits paid to

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

older workers who retire before reaching the standard retirement age due to unemployment or job reduction caused by economic measures, allowances to targeted groups in the labor force who take part in training schemes intended to develop their potential for employment, redundancy compensation, and other periodic or lump-sum payments to the unemployed, particularly the long-term unemployed

- Benefits in kind, such as mobility and resettlement payments, vocational training provided to persons without a job or retraining provided to persons at risk of losing their job, and accommodation, food, or clothes provided to unemployed persons and their families.

Excludes: general programs or schemes directed toward increasing labor mobility, reducing the rate of unemployment or promoting the employment of disadvantaged or other groups characterized by high unemployment (70412); cash benefits and benefits in kind paid to unemployed persons on reaching the standard retirement age (71020).

7106 HOUSING

71060 Housing (IS)

- Provision of social protection in the form of benefits in kind to help households meet the cost of housing (recipients of these benefits are means-tested)
- Administration, operation, or support of such social protection schemes
- Benefits in kind, such as payments made on a temporary or long-term basis to help tenants with rent costs, payments to alleviate the current housing costs of owner-occupiers (i.e., to help with paying mortgages or interest), and provision of low-cost or social housing.

7107 SOCIAL EXCLUSION N.E.C.

71070 Social exclusion n.e.c. (IS)

- Provision of social protection in the form of cash benefits and benefits in kind to persons who are socially excluded or at risk of social exclusion (such as persons who are destitute, low-income earners, immigrants, indigenous people, refugees, alcohol and substance abusers, victims of criminal violence, etc.)
- Administration and operation of such social protection schemes
- Cash benefits, such as income support and other cash payments to the destitute and vulnerable persons to help alleviate poverty or assist in difficult situations
- Benefits in kind, such as short-term and long-term shelter and board provided to destitute and vulnerable persons, rehabilitation of alcohol and substance abusers, and services and goods to help vulnerable persons, such as counseling, day shelter, help with carrying out daily tasks, food, clothing, fuel, etc.

7108 R&D SOCIAL PROTECTION

Definitions of basic research, applied research, and experimental development are given under (7014) and (7015).

71080 R&D Social protection (CS)

- Administration and operation of government agencies engaged in applied research and experimental development related to social protection
- Grants, loans, and subsidies to support applied research and experimental development related to social protection undertaken by nongovernment bodies, such as research institutes and universities.

Excludes: basic research (70140).

7109 SOCIAL PROTECTION N.E.C.

71090 Social protection n.e.c. (CS)

- Administration, operation, or support of activities such as formulation, administration, coordination, and monitoring of overall social protection policies, plans, programs, and budgets; preparation and enforcement of legislation and standards for the provision of social protection; production and dissemination of general information, technical documentation, and statistics on social protection.

Includes: provision of social protection in the form of cash benefits and benefits in kind to victims of fires, floods, earthquakes, and other peacetime disasters; purchase and storage of food, equipment, and other supplies for emergency use in the case of peacetime disasters; other social protection affairs and services that cannot be assigned to (7101), (7102), (7103), (7104), (7105), (7106), (7107), or (7108).

7 The Balance Sheet

This chapter and the following three chapters are concerned with the stock position and flows of assets and liabilities. This chapter defines assets, liabilities, and net worth, and describes their classification and the various balance sheet memorandum items.

Introduction

7.1 A **balance sheet** is a statement of the values of the stock positions of assets owned and of the liabilities owed by an institutional unit or group of units, drawn up in respect of a particular point in time.[1] A balance sheet is typically compiled at the end of each reporting period, which is also the beginning of the next reporting period. In a macroeconomic statistics balance sheet, a distinction is made between nonfinancial assets, financial assets, liabilities, and net worth. The **net worth** of an institutional unit (or grouping of units) is the total value of its assets minus the total value of its liabilities. As for all other balance sheet items, net worth can also be viewed as a stock position resulting from the transactions and other economic flows of all previous periods. A highly abbreviated version of a balance sheet is shown in Table 7.1.[2]

7.2 The existence of a set of balance sheets integrated with the flows enables analysts to take a comprehensive view when monitoring and assessing economic and financial conditions and the behavior of public sector units. Balance sheet information on financial assets held by, and liabilities owed to, other entities supports the analysis of the financial risks and vulnerabilities of the general government or public sector. Similarly, with regard to claims and liabilities on nonresidents, balance sheets support the assessment of the general government's share in the external debtor and creditor position of a country. For public corporations, balance sheets permit the computation of widely used financial ratios, while data on the stock position of fixed assets are useful in studies of their investment behavior and needs for financing.

7.3 This chapter first defines assets and liabilities in general and the two major types of assets, financial and nonfinancial assets. The following section describes the principles used to value assets and liabilities. The chapter then describes the detailed classification of assets and liabilities and the types of assets and liabilities included in each category of the classification. The final sections describe net worth, recommended memorandum items, and a supplemental cross-classification of financial assets or liabilities by sector of the counterparty.

Defining Assets and Liabilities

7.4 This section describes economic and legal ownership of an asset, as well as the asset boundary used in GFS and other macroeconomic statistics. These concepts are then used to define liabilities, financial assets, and nonfinancial assets.

Ownership and the Asset Boundary

7.5 Two types of ownership can be distinguished in macroeconomic statistics: legal ownership and economic ownership (see paragraphs 3.38–3.41). Legal and economic ownership are usually the same but differ in a few cases (e.g., financial leases discussed in paragraph 7.158).

- The **legal owner of resources**, such as goods and services, natural resources, financial assets, and liabilities, is the institutional unit entitled by law and sustainable under the law to claim the

[1] A balance sheet can be compiled for an individual unit or any collection of units, such as the general government or public sector, or their subsectors. It is often convenient to describe a balance sheet in reference to a single institutional unit, but any such statement applies equally to the balance sheet of a sector or subsector.
[2] Table 4.4 shows a presentation of a balance sheet that displays the same information presented in an alternative format.

benefits associated with the resources. Only if such resources have a legal owner, either on an individual or collective basis, are they recognized in macroeconomic statistics.

- The **economic owner of resources**, such as goods and services, natural resources, financial assets, and liabilities, is the institutional unit entitled to claim the benefits associated with the use of these resources by virtue of accepting the associated risks.

7.6 As defined in paragraph 3.42, an **asset** is a store of value representing a benefit or series of benefits accruing to the economic owner by holding or using the resource over a period of time. It is a means of carrying forward value from one reporting period to another. Only economic assets are recorded in the macroeconomic statistical systems (i.e., included within the asset boundary), and they appear in the balance sheet of the unit that is the economic owner of the asset. Economic assets are those resources (i) over which economic ownership rights are enforced by institutional units, individually or collectively, and (ii) from which economic benefits may be derived by their owners by holding them or using them over a period of time (see paragraph 4.43).

7.7 Every economic asset provides benefits by functioning as a store of value. In addition:

- Some benefits are derived by using assets, such as buildings or machinery, in the production of goods and services.
- Some benefits consist of property income, such as interest, dividends, and rent receivable by the owners of financial assets, land, and other nonproduced assets.

7.8 When ownership rights are established and enforced, the resource is an economic asset regardless of who receives the benefits. For example, a government may own land in a national park with the intention that its benefits accrue directly to the community at large.

7.9 To be an economic asset, a resource must also be able to supply economic benefits given the technology, scientific knowledge, economic infrastructure, available resources, and relative prices existing at a given time or expected in the foreseeable future. Thus, a known deposit of minerals is an economic asset only if it is already commercially exploitable or is expected to become commercially exploitable in the foreseeable future.

7.10 Some resources are not economic assets if ownership rights over them have not been established or are not enforced. For example, it may not be feasible to establish ownership rights over the atmosphere and certain other naturally occurring assets. In other cases, ownership rights may be established, but it may not be feasible to enforce them, such as government-owned land that is so remote or inaccessible that the government cannot exercise effective control over it or the government chooses not to enforce its ownership rights. In such cases, it can be a matter of judgment as to whether the degree of control exercised by the government is sufficient for the land to be classified as an economic asset. Nonetheless, even if ownership rights can be enforced, if the assets are not capable of bringing any economic benefits to their owners, they should be excluded.

7.11 Governments use assets to produce goods and services much like corporations. For example, office buildings, together with the services of government employees, office equipment, and other goods and services, are used to produce collective or individual services, such as general administrative services. In addition, however, governments often own assets whose services are consumed directly by the general

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

public and assets that need to be preserved because of their historic or cultural importance. Thus, when the asset boundary is applied to the general government sector, it often incorporates a wider range of assets than is normally owned by a private organization. That is, government units frequently own:

- General-purpose assets, which are assets that other units would be likely to possess and use in similar ways, such as schools, road-building equipment, fire engines, office buildings, furniture, and computers
- Infrastructure assets, which are immovable nonfinancial assets that generally do not have alternative uses and whose benefits accrue to the community at large; examples are streets, highways, lighting systems, bridges, communication networks, canals, and dikes
- Heritage assets, which are assets that a government intends to preserve indefinitely because they have unique historic, cultural, educational, artistic, or architectural significance.

7.12 In some cases, governments can create economic assets by exercising their sovereign powers or other powers delegated to them. For example, a government may have the authority to assert ownership rights over naturally occurring assets that otherwise would not be subject to ownership, such as the electromagnetic spectrum and natural resources in international waters subject to designation as an exclusive economic zone.[3] These assets are economic assets only if the government uses its authority to establish and enforce ownership rights.

7.13 Only actual (outstanding) liabilities (and their corresponding assets) are included in the balance sheet. Contingent assets and liabilities are not recognized as financial assets and liabilities prior to the condition(s) being fulfilled. Explicit contingent liabilities are discussed in paragraphs 7.251–7.260.

- Amounts set aside in business accounting as provisions to provide for a unit's future liabilities, either certain or contingent, or for a unit's future expenditures, are not recognized in the macroeconomic statistical systems. However, amounts accrued and not yet due for payment (such as employment-related pension "provisions") are liabilities.
- No liability is recognized on the balance sheet for government's implicit obligations to pay social security benefits, such as unemployment, old age pensions, and health care, in the future (see Appendix 2). However, it is recommended to include net implicit obligations for social security benefits as a memorandum item to the balance sheet (see paragraph 7.261).
- Lines of credit, letters of credit, and loan commitments assure funds will be made available in the future, but no financial asset (and liability) in the form of a loan is created until funds are actually advanced.
- Uncalled share capital is contingent until there is an obligation to pay the amount.
- Environmental liabilities, which are probable and measurable estimates of future environmental cleanup, closure, and disposal costs other than those included in costs of ownership transfer (see paragraphs 8.6–8.8), are not recognized.[4]

Deriving Definitions for Assets and Liabilities

7.14 This section defines liabilities and financial claims, from which it then derives the definitions of financial and nonfinancial assets.

7.15 As defined in paragraph 3.45, a **liability** is established when one unit (the debtor) is obliged, under specific circumstances, to provide funds or other resources to another unit (the creditor). Normally, a liability is established through a legally binding contract that specifies the terms and conditions of the payment(s) to be made, and payment according to the contract is unconditional. Whenever a liability exists, the creditor has a corresponding financial claim on the debtor. A **financial claim** is an asset that typically entitles the owner of the asset (the creditor) to receive funds or other resources from another unit, under the terms of a liability. Like liabilities, financial claims are unconditional. Financial claims consist of

[3] Exclusive economic zones are the area of sea and seabed extending from the shore of a country claiming exclusive rights to them.

[4] An example is an agreement to perform cleanup (i.e., removal, containment, and disposal) of hazardous waste that resulted from government operations. Where terminal costs are part of costs of ownership transfer, these costs are written off through consumption of fixed capital over the whole life of the asset. Terminal costs are discussed in paragraphs 6.60 and 8.6.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

debt instruments (see paragraph 7.236), financial derivatives and employee stock options, and equity and investment fund shares.

- Debt instruments are financial instruments that typically are created when one unit provides funds or other resources (e.g., goods in the case of trade credit) to a second unit and the second unit agrees to provide a return in the future. Debt liabilities can also be created by the force of law,[5] and by events that require future transfer of payments.[6] For a liability to be considered debt it must exist and be outstanding.
- In contrast, financial derivatives are financial instruments of which the underlying contracts involve risk transfer. Thus, rather than supplying funds or other resources, a derivative contract shifts the exposure to the effect of a change in the value of an item between the parties, without a change in ownership of that item. Employee stock options share some of the risk elements of financial derivatives, but are also designed to be a form of remuneration.
- Equity and investment fund shares issued by corporations and similar legal forms of organization are treated as liabilities of the issuing units even though the holders of the claims do not have a fixed or predetermined monetary claim on the corporation. Equity and investment fund shares do, however, entitle their owners to benefits in the form of dividends and other ownership distributions, and they often are held with the expectation of receiving holding gains. In the event the issuing unit is liquidated, shares and other equities become claims on the residual value of the unit after the claims of all creditors have been met. If a public corporation has formally issued shares or another form of equity, then the shares are a liability of that corporation and an asset of the government or other unit that owns them. If a public corporation has not issued any type of share, then the value of other equity is estimated (see paragraph 7.173).
- Monetary gold in the form of bullion is not a financial claim, because it is not the liability of any other unit. Monetary gold does, however, provide economic benefits by serving as a store of value and a means of international payment to settle financial claims and finance other types of transactions. As a result, monetary gold in the form of bullion is, by convention, treated as a financial asset. Monetary gold in the form of unallocated gold accounts is a financial claim and, therefore, a liability of another unit in the form of currency and deposits (see paragraph 7.139).

7.16 Financial assets consist of financial claims plus gold bullion held by monetary authorities[7] as a reserve asset.

7.17 Nonfinancial assets are economic assets other than financial assets. The main categories of nonfinancial assets are: produced assets (such as fixed assets, inventories, and valuables) and nonproduced assets (such as natural resources, contracts, leases, and licenses, and goodwill and marketing assets). Nonfinancial assets are stores of value and provide benefits either through their use in the production of goods and services or in the form of property income. Unlike financial claims, nonfinancial assets have no counterpart liability—that is, the owner of the nonfinancial asset does not have a claim on another institutional unit. Nonfinancial assets may come into existence as the output from a production process, or in other ways, such as natural occurrences.

7.18 Produced assets are classified as fixed assets, inventories, or valuables:

- **Fixed assets** are produced assets that are used repeatedly or continuously in production processes for more than one year. Fixed assets are discussed in paragraphs 7.35–7.74.
- **Inventories** are produced assets consisting of goods and services, which came into existence in the current period or in an earlier period, and that are held for sale, use in production, or other use at a later date. Inventories are discussed in paragraphs 7.75–7.86.
- **Valuables** are produced assets of considerable value that are not used primarily for purposes of production or consumption, but are held primarily

[5] These liabilities could include those arising from taxes, penalties (including penalties arising from commercial contracts), and judicial awards at the time they are imposed.

[6] These include claims on nonlife insurance companies, claims for damages not involving nonlife insurance companies, and claims arising from lottery and gambling activity.

[7] Government units typically do not fulfill functions of monetary authorities and thus would not hold financial assets in the form of gold bullion.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

as stores of value over time. Valuables are discussed in paragraphs 7.87–7.89.

7.19 Naturally occurring assets and constructs of society are both referred to as nonproduced assets (see paragraph 7.90). Naturally occurring assets include land, subsoil mineral deposits, fish in open but territorial waters, and the radio spectrum when ownership rights are enforced. Constructs of society that are assets include some contracts, leases, and licenses, as well as goodwill and marketing assets.

Valuation of Assets and Liabilities

7.20 As discussed in paragraph 3.113, stock positions of assets and liabilities should be valued at market value—that is, as if they were acquired in market transactions on the balance sheet reporting date (reference date). Therefore, the value of an asset at any given time is its current market value, which is the amount that would have to be paid to acquire the asset on the reporting date, taking into account its age, condition, and other relevant factors. This amount depends on the economic benefits that the owner of the asset can derive by holding or using it. The remaining benefits expected to be received from most assets diminish with the passage of time, which will reduce the value of the asset. The remaining benefits of some assets, such as valuables, may increase with the passage of time. The value of the remaining benefits may also increase or decrease because of changes in economic conditions.

7.21 In addition to current market value, the nominal value (see paragraph 3.115) of financial instruments is also useful for some purposes. This value is typically established by reference to the terms of a contract between the debtor and creditor. The nominal value of a debt instrument reflects the value of the debt at creation plus any subsequent economic flows, such as transactions (e.g., accrual of interest or repayment of principal) plus exchange rate and other valuation changes other than market price changes.[8]

7.22 The current market value for nonfinancial assets (except land) includes all costs of ownership transfer and for financial assets excludes these costs. For more details, see paragraphs 8.6–8.8.

[8] Accumulated revaluations arising from market price changes reconcile nominal value with market value.

7.23 The value of financial assets and liabilities denominated in foreign currencies should be converted to the domestic currency as discussed in paragraph 3.119.

7.24 Ideally, observable market prices should be used to value all assets and liabilities in a balance sheet. However, in estimating the current market price for balance sheet valuation, a price averaged over all transactions in a market can be used if the market is one on which the items in question are regularly, actively, and freely traded. When there are no observable prices because the items in question have not been purchased or sold on the market in the recent past, an attempt has to be made to estimate what the prices would be were the assets to be acquired on the market on the date to which the balance sheet relates. Such estimates may be obtained by (i) accumulating and revaluing transactions, or (ii) estimating the present value of future returns. These two methods, together with values observed in markets, are discussed in paragraphs 7.26–7.33.

7.25 The following paragraphs describe possible methods of estimating current market prices. Additional guidance on the valuation of specific types of assets and liabilities is included in the relevant parts of the section that describes the classification of assets and liabilities. Because the valuation of liabilities is the same as the valuation of the corresponding financial assets, in most cases, the remainder of this chapter will refer only to financial assets, but such references should be read as including liabilities equally. GFS compilers are typically not expected to independently derive the market values of assets and liabilities; they should evaluate what is available and how that information could be used in the GFS balance sheet.

Value Observed in Markets

7.26 The ideal source of price observations for valuing balance sheet items is a market, like the stock exchange, in which each asset traded is completely homogeneous, is often traded in considerable volume, and has its market price listed at regular intervals. Such markets yield data on prices that can be multiplied by indicators of quantity in order to compute the total market value of different classes of assets held by sectors and of different classes of their liabilities.

7.27 For securities quoted on a stock exchange, for example, it is feasible to gather the prices of individual assets and of broad classes of assets and, in addition,

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

to determine the global valuation of all the existing securities of a given type. Debt securities traded (or tradable) in organized and other financial markets—such as bills, bonds, debentures, negotiable certificates of deposits, asset-backed securities, etc.—should be valued at market value and, in the case of liabilities, at nominal value as well.[9] In some countries, another example of a market in which assets may be traded in sufficient numbers to provide useful price information is the market for existing dwellings.

7.28 If assets of the same kind are being produced and sold on the market, an existing asset may be valued at the current market price of a newly produced asset adjusted for consumption of fixed capital in the case of fixed assets, and any other differences between the existing asset and a newly produced asset. This adjustment for consumption of fixed capital should be calculated on the basis of the asset prices prevailing on the balance sheet reference date rather than the actual amounts previously recorded as an expense.[10]

7.29 In addition to providing direct observations on the prices of assets actually traded there, information from such markets may also be used to price similar assets that are not traded. For example, information from the stock exchange also may be used to price unlisted shares by analogy with similar, listed shares, making some allowance for the inferior marketability of the unlisted shares. Similarly, independent appraisals of assets for insurance or other purposes generally are based on observed prices for items that are close substitutes, although not identical, and this approach can be used for balance sheet valuation.

7.30 Debt instruments other than debt securities (as well as the corresponding financial assets in the form of debt instruments) are normally not traded and, therefore, lack generally observable market values. This means that these values have to be estimated by using the nominal value as a proxy (see paragraph 7.122).[11]

- Nontraded debt instruments: Debt instruments (as well as the corresponding financial assets in the form of debt instruments) not generally traded (or tradable) in organized or other financial markets—namely, loans, currency and deposits, and other accounts payable/receivable—should be valued at nominal value. The nominal value of a debt instrument could be less than the originally advanced amount if there have been repayments of principal, debt forgiveness, or other economic flows (such as arising from indexation) that affect the value of the amount outstanding. The nominal value of a debt instrument could be more than originally advanced because of, for example, the accrual of interest or other economic flows.
- Debt instruments that do not accrue interest: For debt instruments (as well as the corresponding financial assets in the form of debt instruments) that do not accrue interest—for example, most trade credit and advances—the nominal value is the amount owed by the debtor to the creditor at the balance sheet date. If there is an unusually long time before payment is due on an outstanding debt liability on which no interest accrues, the value of the principal should be reduced by an amount that reflects the time to maturity and an appropriate existing contractual rate, such as for similar debt instruments (see also paragraph 3.118).
- Repayment specified in terms of commodities or other goods: For some instruments, such as a loan, repayment may be specified in a contract in terms of commodities or other goods deliverable in installments over a period of time. At inception, the value of the debt (as well as the corresponding financial assets in the form of debt instruments) is equal to the principal advanced. When payments are made in the form of the good or commodity, the value of the principal outstanding will be reduced by the market value of the good or commodity at the time the payment is made.
- Extinguishing a trade credit under barter arrangements: The value of the commodities, other goods, or services to be provided for extinguishing a trade credit liability (and the corresponding financial asset) under barter arrangements is established at the creation of the debt—that is, when the exchange of value occurred. However, as noted earlier, if there is an unusually long time before payment, the value of the principal should be reduced by an amount that reflects the time to

[9] Nominal and market valuation are discussed in paragraphs 3.113–3.117. For a numerical examples on the calculation of interest and nominal value, see Boxes 2.3–2.5 in the *PSDS Guide*.
[10] Amounts previously recorded as expense are based on the average prices of the asset over the reporting period.
[11] See the *PSDS Guide*, Chapter 2.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

maturity and an appropriate existing contractual rate, and interest should accrue until actual payment is made.

- Nontraded debt instruments with uncertain nominal values: For nontraded debt instruments (as well as the corresponding financial assets in the form of debt instruments) where the nominal value is uncertain, the nominal value can be calculated by discounting future interest and principal payments at an appropriate existing contractual rate of interest.

Value Obtained by Accumulating and Revaluing Transactions

7.31 In the absence of observable market prices, the balance sheet value of an asset may be obtained by accumulating and revaluing transactions. The values of most nonfinancial assets change, reflecting changes in market prices. At the same time, initial acquisition costs are reduced by consumption of fixed capital[12] (in the case of fixed assets) or amortization or depletion[13] (in the case of other nonfinancial assets) over the expected life of the asset. In principle, the value of such a nonfinancial asset at a given point in its life is given by the current acquisition price of an equivalent new asset minus the accumulated consumption of fixed capital, amortization, or depletion. This valuation is referred to as the written-down replacement cost. When reliable, directly observed market prices for used assets are not available, applying this method gives a reasonable approximation of what the market price would be, were the asset offered for sale. For example, the principle could be applied as follows for these assets:

- In the absence of observed market values, most fixed assets are recorded in the balance sheet at their written-down replacement cost.
- Intangible nonproduced assets, such as goodwill and marketing assets, are typically valued at their initial acquisition costs minus an allowance for amortization. For this method, a pattern of decline must be chosen, which may be based on tax laws and accounting conventions.
- It may be possible to value subsoil and other naturally occurring assets at their initial acquisition costs (appropriately revalued using a relevant specific or commodity price index) minus an allowance for depletion.

7.32 The perpetual inventory method (PIM) is commonly used to estimate the written-down replacement cost of a category of assets, especially tangible fixed assets. With this method, the value of the stock is based on estimates of acquisitions and disposals that have been accumulated (after deduction of the accumulated consumption of fixed capital, amortization, or depletion) and revalued over a long enough period to cover the acquisition of all assets in the category. The PIM may be viewed as the macro equivalence of an asset register: the PIM does these calculations for large groups of assets, while an asset register does them for individual assets or asset types.[14]

Present Value of Future Returns

7.33 In some cases, current market prices may be approximated by the present value[15] of the future economic benefits expected from a given asset. This method may be feasible for a number of financial assets, naturally occurring assets, and intangible assets. For example, timber and subsoil assets are assets whose benefits are normally receivable well in the future and/or spread over several years. Current prices can also be approximated by net present value when there are costs of bringing assets to the market. The economic benefit and costs can be discounted to estimate the net present value of the asset.

Classification of Assets and Liabilities

Nonfinancial Assets (61)[16]

7.34 At the first level of classification, there are four categories of nonfinancial assets. The first three categories are produced assets—*fixed assets* (611), *inventories* (612), and *valuables* (613)—and the fourth consists of all *nonproduced assets* (614). The summary

[12] See Box 6.1 for guidance on the calculation of consumption of fixed capital.
[13] See paragraph 10.52.
[14] For details on the PIM, see Organisation for Economic and Cooperation and Development, *Measuring Capital—OECD Manual: Measurement of Capital Stocks, Consumption of Fixed Capital and Capital Services* (Paris, 2001).
[15] Present value is the value today of a future payment or stream of payments discounted at some appropriate compounded interest rate. It is also referred to as the "time value of money" or "discounted cash flow."
[16] The numbers in parentheses after each classification category are the GFS classification codes. Appendix 8 provides all classification codes used in GFS.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Table 7.2 Summary Classification of Nonfinancial Assets	
61	**Nonfinancial assets**
611	**Fixed assets**
6111	Buildings and structures
61111	Dwellings
61112	Buildings other than dwellings
61113	Other structures
61114	Land improvements
6112	Machinery and equipment
61121	Transport equipment
61122	Machinery and equipment other than transport equipment
6113	Other fixed assets
61131	Cultivated biological resources
61132	Intellectual property products
6114	Weapons systems
612	**Inventories**
613	**Valuables**
614	**Nonproduced assets**
6141	Land
6142	Mineral and energy resources
6143	Other naturally occurring assets
61431	Noncultivated biological resources
61432	Water resources
61433	Other natural resources
6144	Intangible nonproduced assets
61441	Contracts, leases, and licenses
61442	Goodwill and marketing assets

classification of nonfinancial assets is shown in Table 7.2; more detailed classifications of these categories are provided in the discussions of the various types of fixed assets, where relevant.[17]

Fixed assets (611)

7.35 ***Fixed assets*** (611) are produced assets that are used repeatedly or continuously in production processes for more than one year. The distinguishing feature of a fixed asset is not that it is durable in some physical sense, but that it may be used repeatedly or continuously in production over a long period of time, which is taken to be more than one year (by convention). Some goods, such as coal used as fuel, may be highly durable physically but cannot be fixed assets because they can be used only once. Fixed assets are further classified as *buildings and structures* (6111), *machinery and equipment* (6112), *other fixed assets* (6113), and *weapons systems* (6114).

7.36 In general, in the absence of observable market prices for used assets, the written-down replacement cost is used as a proxy for the current market value of fixed assets. In the remainder of this section, it is noted when a particular type of fixed asset is likely to be more accurately valued by another method.

7.37 The production of some fixed assets may span two or more reporting periods. These nonfinancial assets should be reflected on the balance sheet, in principle, when economic ownership changes, as evidenced by the transfer of risks and benefits associated with the asset. For high-value fixed assets such as ships, heavy machinery, and other equipment, ownership changes are recorded at the time agreed between the parties; for example, it could be a progressive change in line with stage payments, or in full on delivery. When a contract of sale is agreed in advance for the construction of buildings and structures, incomplete structures are being acquired in each period through progress payments and classified as fixed assets on the purchaser unit's balance sheet (i.e., the structure is being sold by the construction contractor to the purchaser in stages as the latter takes legal possession of the structure). When progress payments exceed the value of the incomplete asset, the excess should be recorded as a trade advance that will be exhausted as work proceeds. In the absence of a contract of sale, the incomplete structure is recorded as work in progress, and completed structures are recorded as finished goods, on the balance sheet of the unit doing the construction until ownership of the asset changes. Fixed assets being constructed on own account are treated as fixed assets rather than inventories of work in progress. These general principles also apply to the production of cultivated assets (see paragraph 7.62).

7.38 Fixed assets acquired under a financial lease—most likely machinery and equipment—are treated as if purchased and owned by the user or lessee (the economic owner) rather than the lessor (the legal owner). The acquisition is treated as being financed by a financial claim, classified as a loan. For example, if a bank purchases an airplane and then leases it to the national airline, the airplane is recorded as an asset of

[17] The classification of assets and liabilities in this chapter is supplemented by description of transactions in Chapters 8 and 9, while other economic flows related to these assets and liabilities are described in Chapter 10.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

the airline and a loan is recorded as a liability of the airline and an asset of the bank. Financial leases are discussed in detail in paragraphs A4.10–A4.15.

7.39 A further consideration to be taken into account in determining ownership concerns fixed assets built under a public-private partnership (PPP) or a build, own, operate, and transfer (BOOT) scheme, sometimes also described as a private finance initiative (PFI), or some other similar shorthand. The statistical treatment is based on the economic ownership of the asset involved (see paragraph 7.5). PPPs are discussed in detail in paragraphs A4.58–A4.65. Also, immovable fixed assets, such as buildings and other structures within the economic territory, are deemed, by convention, to be owned by resident units (see paragraph 2.13).

7.40 Small/hand tools are excluded from the fixed asset boundary. Costs incurred on these inexpensive durable goods are recorded as *use of goods and services* (22) when such expenses are incurred regularly and are small compared with the costs incurred for the acquisition of machinery and equipment. But there can be circumstances when such small/hand tools are recorded as fixed assets (see paragraph 6.43).

Buildings and structures (6111)

7.41 ***Buildings and structures*** (6111) consist of *dwellings* (61111), *buildings other than dwellings* (61112), *other structures* (61113), *and land improvements* (61114), as shown in Table 7.3. The value of buildings and structures includes the costs of site clearance and preparation and the value of all fixtures, facilities, and equipment that are integral parts of the structures.

7.42 Public monuments in the form of buildings and structures are included here. **Public monuments** are identifiable because of particular historical, national, regional, local, religious, or symbolic significance. They are accessible to the general public, and visitors are often charged for admission to the monuments or their vicinity. Public sector units typically use public monuments to produce cultural or entertainment-type services. In principle, public monuments should be included in dwellings, buildings other than dwellings, and other structures, as appropriate; in practice, it may be desirable to classify them with other structures when such a breakdown is not available. Consumption of fixed capital on new monuments, or on major improvements to existing monuments, should be calculated on the assumption of appropriately long service lives.

Table 7.3 Classification of Buildings and Structures

6111	Buildings and structures
61111	Dwellings
61112	Buildings other than dwellings
61113	Other structures
61114	Land improvements

7.43 Public monuments can be valued directly, however, only when their significance has been recognized by someone other than the owner, typically by a sale or a formal appraisal. Newly constructed public monuments are valued at written-down replacement cost. Other than newly constructed monuments should be valued at the most recent sale price, updated, if need be, by a general price index. If no sale price is available, then an alternative valuation, such as an insurance appraisal or replacement cost (see paragraph 7.31), should be used.

Dwellings (61111)

7.44 ***Dwellings*** (61111) are buildings, or designated parts of buildings, that are used entirely or primarily as residences, including any associated structures, such as garages, and all permanent fixtures customarily installed in residences. Houseboats, barges, mobile homes, and caravans that are used as principal residences are also included, as are public monuments identified primarily as dwellings. Dwellings acquired by government for military personnel are included in this category because they are used in the same way as dwellings acquired by civilians. Incomplete dwellings are included to the extent that the ultimate user is deemed to have taken economic ownership, because the construction is on own account, the ultimate user assumed the risks and benefits of the asset, or as evidenced by the existence of a contract of sale or purchase.

7.45 For dwellings, there may be adequate information available from the sale of both new and existing buildings in equivalent private markets to assist in making balance sheet estimates of comparable price movements in the total value of public sector dwellings. However, these house prices depend to a

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

considerable extent on location and may include land values. The geographical pattern of sales in the period may not cover all areas adequately, in which case a technique such as a PIM will have to be used (see paragraph 7.32). This technique will probably also apply to many other public buildings and structures since their characteristics are often specific to the structure concerned.

Buildings other than dwellings (61112)

7.46 ***Buildings other than dwellings*** (61112) include whole buildings or parts of buildings not designated as dwellings. Fixtures, facilities, and equipment that are integral parts of the structures are included. For new buildings, costs of site clearance and preparation are included.

7.47 Examples of types of buildings included in this category are office buildings, schools, hospitals, buildings for public entertainment, warehouses and industrial buildings, commercial buildings, hotels, and restaurants. Public monuments identified primarily as nonresidential buildings are also included. Prisons, schools, and hospitals are regarded as buildings other than dwellings despite the fact that they may shelter institutional households. Buildings and structures acquired for military purposes are included to the extent that they are used repeatedly, or continuously, in processes of production for more than one year.

Other structures (61113)

7.48 ***Other structures*** (61113) consist of all structures other than buildings. The costs of site clearance and preparation are also included. Public monuments are included if identification as dwellings or buildings other than dwellings is not possible. Also included are the construction of sea walls, dikes, flood barriers, etc. intended to improve the quality and quantity of land adjacent to them. The infrastructure necessary for aquaculture, such as fish farms and shellfish beds, is also included. Further examples are:

- Highways, streets, roads, bridges, elevated highways, tunnels, railways, subways, and airfield runways
- Sewers, waterways, harbors, dams, and other waterworks
- Shafts, tunnels, and other structures associated with mining mineral and energy resources
- Communication lines, power lines, long-distance pipelines, local pipelines, and cables
- Outdoor sport and recreation facilities
- Structures acquired for military purposes are included to the extent that they are used repeatedly, or continuously, in processes of production for more than one year.

Land improvements (61114)

7.49 ***Land improvements*** (61114) are the result of actions that lead to major improvements in the quantity, quality, or productivity of land, or prevent its deterioration. Activities such as land reclamation, land clearance, land contouring, and creation of wells and watering holes that are integral to the land in question are to be treated as resulting in land improvements. Seawalls, dikes, dams, and major irrigation systems that are in the vicinity of the land but not integral to it, which often affect land belonging to several owners and which are often carried out by government, are classified as *other structures* (61113).

7.50 Land improvements represent a category of fixed assets distinct from the nonproduced asset *land* (6141) as it existed before improvement. Unimproved land remains a nonproduced asset and as such is subject to holding gains and losses separately from price changes affecting the improvements. In cases where it is not possible to separate the value of the land before improvement and the value of those improvements, the asset should be allocated to the category that represents the greater part of the value.

7.51 The value of land improvements is shown as the written-down replacement cost of the improvements as originally carried out, suitably revalued to market prices. This is conceptually equal to the difference in value between the land concerned in an unimproved or natural state and its value after the improvements have been made, taking into account price changes. The costs of ownership transfer on all land are, by convention, included with land improvements. Consumption of fixed capital and the costs of ownership transfer are discussed in paragraphs 6.53–6.60.

Machinery and equipment (6112)

7.52 ***Machinery and equipment*** (6112) cover transport equipment, machinery for information, computer, and telecommunications (ICT) equipment,

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

and machinery and equipment not elsewhere classified. Machinery and equipment forming an integral part of a building or other structure are included in the value of the building or structure rather than in machinery and equipment. Tools that are inexpensive and purchased at a relatively steady rate, such as hand tools, are not considered fixed assets unless they form a large share of the stock of machinery and equipment. As explained in paragraph 7.38, machinery and equipment under a financial lease are classified here because they are treated as being acquired by the user (lessee). Machinery and equipment acquired for military purposes other than weapons systems are classified under this category; *weapons systems* (6114) form a separate category (see paragraph 7.74).

7.53 Machinery and equipment are classified in two main categories: *transport equipment* (61121) and *machinery and equipment other than transport equipment* (61122), with a further breakdown of other machinery and equipment, as shown in Table 7.4.

Transport equipment (61121)

7.54 ***Transport equipment*** (61121) consists of equipment for moving people and objects, including motor vehicles, trailers and semitrailers, ships, railway locomotives and rolling stock, aircraft, motorcycles, and bicycles. Markets for existing automobiles, aircraft, and some other types of transportation equipment may be sufficiently representative to yield price observations that are superior to valuations at written-down replacement cost.

Machinery and equipment other than transport equipment (61122)

7.55 This category consists of all machinery and equipment other than transport equipment. A distinction is made between *information, computer, and telecommunications (ICT) equipment* (611221) and *machinery and equipment not elsewhere classified* (611222).

Table 7.4 Classification of Machinery and Equipment

6112	Machinery and equipment
61121	Transport equipment
61122	Machinery and equipment other than transport equipment
611221	Information, computer, and telecommunications (ICT) equipment
611222	Machinery and equipment not elsewhere classified

Information, computer, and telecommunications equipment (ICT) (611221)

7.56 ***Information, computer, and telecommunications equipment*** (611221) consists of devices using electronic controls and also the electronic components forming part of these devices. Examples are products that form part of computing machinery and parts and accessories thereof, television and radio transmitters, television, video, and digital cameras, and telephone sets. In practice, this narrows the coverage of ICT equipment mostly to computer hardware and telecommunications equipment.

Machinery and equipment not elsewhere classified (611222)

7.57 This category includes all machinery and equipment not classified in any of the other machinery and equipment categories.[18] Types of assets that would be included are general- and special-purpose machinery; office and accounting equipment; electrical machinery; medical appliances; precision and optical instruments; furniture; watches and clocks; musical instruments; and sports goods. It also includes paintings, sculptures, other works of art or antiques, and other collections of considerable value that are owned and displayed for the purpose of producing museum and similar services. Similar items owned primarily as stores of value that are not intended for use in production would be classified as valuables (see paragraphs 7.87–7.89). Also excluded from this category are inexpensive durable goods such as small/hand tools that are recorded as *use of goods and services* (22) (see paragraph 6.43).

Other fixed assets (6113)

7.58 Other fixed assets consist of *cultivated biological resources* (61131) and *intellectual property products* (61132), as shown in Table 7.5.

[18] All items under the United Nations' *Central Product Classification (CPC)*, version 2.0, categories 43–48, are included here, except for categories 452 and 472, which are classified under Information, Computer, and Telecommunications (ICT) Equipment. For more details, see http://unstats.un.org/unsd/cr/registry/cpc-2.asp.

Table 7.5 Classification of Other Fixed Assets	
6113	Other fixed assets
61131	Cultivated biological resources
611311	Animal resources yielding repeat products
611312	Tree, crop, and plant resources yielding repeat products
61132	Intellectual property products
611321	Research and development
611322	Mineral exploration and evaluation
611323	Computer software and databases
6113231	Computer software
6113232	Databases
611324	Entertainment, literary, and artistic originals
611325	Other intellectual property products

Cultivated biological resources (61131)

7.59 ***Cultivated biological resources*** (61131) cover animal resources yielding repeat products and tree, crop, and plant resources yielding repeat products whose natural growth and regeneration are under the direct control, responsibility, and management of institutional units.

7.60 *Animal resources yielding repeat products* (611311) include breeding stocks, dairy cattle, draft animals, sheep, or other animals used for wool production, animals used for transportation, racing, or entertainment, and aquatic resources yielding repeat products. Immature cultivated assets are excluded unless produced for own use. Animals raised for slaughter, including poultry, are not fixed assets but inventories.

7.61 *Tree, crop, and plant resources yielding repeat products* (611312) include trees (including vines and shrubs) cultivated for fruits and nuts, for sap and resin, and for bark and leaf products. Trees grown for timber that yield a finished product once only when they are ultimately felled are not fixed assets, but are included as inventories, just as grains or vegetables that produce only a single crop when they are harvested cannot be fixed assets.

7.62 In general, when the production of fixed assets takes a long time to complete, those assets for which production is not yet completed at the end of the reporting period are recorded as inventories in the form of work in progress. These general principles also apply to the production of cultivated assets, such as animals or trees that may take a long time to reach maturity. Two cases need to be distinguished from each other: the production of cultivated products by specialized producers, such as breeders or tree nurseries, and the own-account production of cultivated assets by their users:

- In the case of the specialist producers, animals or trees whose production is not yet complete and are not ready for sale or delivery are recorded as work in progress.
- However, when animals or trees intended to be used as fixed assets are produced on own account on farms or elsewhere, incomplete assets in the form of immature animals, trees, etc. not ready to be used in production are treated as the acquisition of fixed assets by the producing public sector unit in its capacity as eventual user and not as work in progress.

7.63 Only animals and plants cultivated under the direct control, responsibility, and management of institutional units are cultivated assets or inventories. Otherwise, they are nonproduced assets. Animals classified as cultivated biological resources usually can be valued on the basis of the current market prices for similar animals of a given age. Such information is less likely to be available for plants; more likely they will have to be valued at the written-down replacement cost.

Intellectual property products (61132)

7.64 ***Intellectual property products*** (61132) are the result of research, development, investigation, or innovation leading to knowledge that the developers can market or use to their own benefit in production because use of the knowledge is restricted by means of legal or other protection. The knowledge may be embodied in a free-standing product or may be embodied in another product. When the latter is the case, the product embodying the knowledge has an increased price relative to a similar product without this embodied knowledge. The knowledge remains an asset as long as its use can create some form of monopoly profits for its owner. When it is no longer protected or becomes outdated by later developments, it ceases to be an asset. Intellectual property products can be classified as:

- *Research and development* (611321)
- *Mineral exploration and evaluation* (611322)

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

- *Computer software and databases* (611323)
- *Entertainment, literary, and artistic originals* (611324)
- *Other intellectual property products* (611325).

7.65 Some intellectual property products are used solely by the unit responsible for their development or by a single unit to whom the product is transferred. Mineral exploration and evaluation are an example. Other products, such as computer software and artistic originals, are used in two forms. The first is the original copy. This is frequently controlled by a single unit but exceptions exist, as explained in the remainder of this section. The original is used to make copies that are, in turn, supplied to other institutional units. The copies may be sold outright or made available under a license:

- A copy sold outright may be treated as a fixed asset if it satisfies the necessary conditions—that is, it will be used in production for a period in excess of one year.
- A copy made available under a license to use may also be treated as a fixed asset if it meets the necessary conditions—that is, if it is expected to be used in production for more than one year and the licensee assumes all the risks and rewards of ownership. A good indication, but not a necessary one, is if the license is purchased with a single payment for use over a multiyear period.
- If the acquisition of a copy with a license to use is purchased with regular payments over a multiyear contract and the licensee is judged to have acquired economic ownership of the copy, then it should be regarded as the acquisition of a fixed asset.
- If regular payments are made for a license to use without a long-term contract, then the payments are treated as payments for a service.
- If there is a large initial payment followed by a series of smaller payments in succeeding years, the initial payment is recorded as the net acquisition of a fixed asset and the succeeding payments are treated as payments for a service.
- If the license allows the licensee to reproduce the original and subsequently assume responsibility for the distribution, support, and maintenance of these copies, then this is described as a license to reproduce and should be regarded as the sale of part or whole of the original to the unit holding the license to reproduce.

7.66 ***Research and development*** (611321) consists of the value of expenditure on creative work undertaken on a systematic basis in order to increase the stock of knowledge, including knowledge of man, culture, and society, and use of this stock of knowledge to devise new applications. It does not extend to including human capital as assets within GFS and other macroeconomic statistics. The value of research and development should be determined in terms of the economic benefits it is expected to provide in the future. This value includes the provision of public services in the case of research and development acquired by government. In principle, research and development that does not provide an economic benefit to its owner does not constitute a fixed asset and should be treated as an expense. Only research and development that meets the criteria to be a nonfinancial asset should be included in this category.[19]

7.67 Unless the market value of the research and development is observed directly, it may, by convention, be valued at the sum of costs, including the cost of unsuccessful research and development. More specifically, research and development undertaken by government units, universities, nonprofit research institutes, etc. is nonmarket production and should be valued on the basis of the total costs incurred, excluding a return to capital used. Research and development expenditure carried out on contract is valued at the contract price. If carried out on own account, it is valued as cumulated costs. If it is carried out by a public corporation, the costs include a return to capital. These valuations need to be increased for changes in prices and reduced because of consumption of fixed capital over the life of the asset. With the inclusion of research and development in the asset boundary, patented resources are no longer considered as a form of nonproduced assets.[20]

[19] For further guidance on the practical measurement of research and development, see Organisation for Economic and Co-operation and Development, *Handbook on Deriving Capital Measures of Intellectual Property Products* (Paris, 2010).

[20] The patent agreement is to be seen as the legal agreement concerning the terms on which access by third parties to research and development is granted. The patent agreement is a form of license to use, which is treated as payments for service or the acquisition of assets. See discussions on *contracts, leases, and licenses* (61441) in paragraph 7.105 and in Appendix 4.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

7.68 ***Mineral exploration and evaluation*** (611322) consist of the value of expenditure on exploration for petroleum and natural gas and for nonpetroleum deposits and subsequent evaluation of the discoveries made. The information obtained from exploration influences the production activities of those who obtain it over a number of years. Mineral exploration and evaluation should be valued either on the basis of the amounts payable under contracts awarded to other institutional units for the purpose or on the basis of the costs incurred for exploration undertaken on own account. These costs should include a return to the fixed capital used in the exploration activity. In addition to the costs of actual test drilling and boring, mineral exploration includes any prelicense, license, acquisition, and appraisal costs, the costs of aerial and other surveys, and transportation and other costs incurred to make the exploration possible. The value of the resulting asset is not measured by the value of new deposits discovered by the exploration but by the value of the resources allocated to exploration during the reporting period. Exploration undertaken in the past whose value has not yet been fully written off should be revalued to the prices and costs of the current period.

7.69 ***Computer software and databases*** (611323) are grouped together because a computerized database cannot be developed independently of a database management system that is itself computer software. This category can be further divided into *computer software* (6113231) and *databases* (6113232).

7.70 ***Computer software*** (6113231) includes computer programs, program descriptions, and supporting materials for both systems and applications software that is expected to be used for more than one year. The software may be purchased from other units or developed on own account and may be intended only for own use or may be intended for sale by means of copies. ***Databases*** (6113232) consist of files of data organized in such a way as to permit resource-effective access and use of the data. These expenditures on the purchase, development, or extension of computer databases are assets when expected to be used in production for more than one year.

7.71 The value of *computer software and databases* (611323) should be based on the amount payable if acquired from another unit or on the costs of production (including a return to capital if produced by a public corporation) if produced on own account. Software and databases acquired in previous years and not yet fully written off should be revalued to current prices.

7.72 ***Entertainment, literary, and artistic originals*** (611324) are original films, sound recordings, manuscripts, tapes, and models in which drama performances, radio and television programming, musical performances, sporting events, and literary and artistic output are recorded or embodied. They should be valued at their current market price when they are actually traded. Otherwise, they should be valued either on the basis of their acquisition price or costs of production (including a return to capital if produced by a public corporation), revalued to the prices of the current period and written down, or on the basis of the present value of the expected future receipts.

7.73 ***Other intellectual property products*** (611325) consist of new information and specialized knowledge not elsewhere classified, the use of which is restricted to the units that have established ownership rights over the information or to other units licensed by the owners. The assets should be valued at their current written-down replacement cost or the present value of expected future receipts.

Weapons systems (6114)

7.74 ***Weapons systems*** (6114) include vehicles and other equipment, such as warships, submarines, military aircraft, tanks, missile carriers and launchers, etc. Weapons systems are treated as fixed assets. The military weapons systems comprising specialized vehicles and other equipment, such as warships, submarines, military aircraft, tanks, missile carriers and launchers, etc., are used continuously in the provision of defense services, even if their peacetime use is simply to provide deterrence. Therefore, military weapons systems should be classified as fixed assets and this classification of military weapons systems as fixed assets should be based on the same criteria as for other fixed assets—that is, produced assets that are themselves used repeatedly, or continuously, in processes of production for more than one year. Most single-use weapons they deliver, such as ammunition, missiles, rockets, bombs, etc., are treated as *military inventories* (61225) (see paragraphs 7.86 and 6.49). However,

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

some single-use items, such as certain types of ballistic missiles with a highly destructive capability, may provide an ongoing service of deterrence against aggressors and therefore meet the general criteria for classification as fixed assets. Weapons systems are valued at their written-down replacement cost.

Inventories (612)

7.75 ***Inventories*** (612) are produced assets consisting of goods and services, which came into existence in the current period or in an earlier period, and that are held for sale, use in production, or other use at a later date. Inventories are classified as *materials and supplies* (61221), *work in progress* (61222), *finished goods* (61223), *goods for resale* (61224), and *military inventories* (61225), as shown in Table 7.6. Each of these types of inventories has a different economic function.

7.76 Inventories consist of stocks of:

- Goods that are still held by the units that produced them prior to their being further processed, sold, delivered to other units, or used in other ways
- Products acquired from other units that are intended to be used in the production of market and nonmarket goods and services by units, or for resale without further processing
- Strategic stocks that are goods held for strategic and emergency purposes, goods held by market regulatory organizations, and other goods of special importance to the nation, such as grain, military inventories, and petroleum.

7.77 Inventories may include services consisting of work in progress or finished products—for example, architectural drawings that are in the process of completion or are completed and waiting for the building to which they relate to be started.

7.78 Inventories should be valued at their current market prices on the balance sheet date rather than their acquisition prices. In principle, current market prices should be available for most types of inventories, but in practice, the values of inventories frequently are estimated by adjusting book or acquisition values of inventories with the aid of price indexes.

Table 7.6 Classification of Inventories

612	Inventories
61221	Materials and supplies
61222	Work in progress
61223	Finished goods
61224	Goods for resale
61225	Military inventories

Materials and supplies (61221)

7.79 ***Materials and supplies*** (61221) consist of all goods held with the intention of using them as inputs to a production process. Public sector units may hold a variety of goods as materials and supplies, including office supplies, fuel, and foodstuffs. Every public sector unit may be expected to hold some materials and supplies, if only office supplies. Materials and supplies often can be valued on the basis of the current market prices for the same goods.

Work in progress (61222)

7.80 ***Work in progress*** (61222) consists of goods and services that are not yet sufficiently processed to be in a state in which it is normally supplied to other institutional units. General government units that primarily produce nonmarket services are likely to have little or no work in progress, as the production of most such services is completed in a short time span or continuously. Work in progress must be recorded for any output that is not complete at the end of the reporting period, such as construction. The only exceptions to recording incomplete work as work in progress are for partially completed projects for which the ultimate owner is deemed to have taken economic ownership in stages (see paragraph 7.37). Economic ownership conveys in stages when the production is for own use, the new owner assumes the risks and benefits associated with the incomplete asset, or when evidenced by specific clauses in a contract of sale or purchase. In these exceptions, the partially complete products are recorded as the acquisition of fixed assets rather than work in progress.

7.81 Work in progress can take a wide variety of different forms, ranging from growing crops to developing computer programs. Although work in progress is output that has not reached the state in which it is normally supplied to others, its ownership is nevertheless transferable, if necessary.[21]

[21] For example, it may be sold under exceptional circumstances, such as the liquidation of a public sector unit.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

7.82 Work in progress inventories are valued on the basis of the cost of production at current prices as of the balance sheet date. The value of standing timber and other cultivated crops may be estimated by discounting the future proceeds of selling the final product at current prices and the expenses of bringing the product to maturity.

Finished goods (61223)

7.83 ***Finished goods*** (61223) consist of goods that are the output of a production process, are still held by their producer, and are not expected to be processed further by the producer before being supplied to other units. Finished goods may be held only by the units that produce them. General government units will have finished goods only if they produce goods for sale or transfer to other units. Inventories of finished goods are valued at their current sales value (before adding any taxes, transport, or distribution charges) or at the cost to produce them currently (i.e., their current replacement prices).

Goods for resale (61224)

7.84 ***Goods for resale*** (61224) are goods acquired for the purpose of reselling or transferring to other units without being further processed. Goods for resale may be transported, stored, graded, sorted, washed, or packaged by their owners to present them for resale in ways that are attractive to their customers or beneficiaries, but they are not otherwise transformed. Any general government unit that sells goods for economically significant prices, such as a museum gift shop, is likely to possess an inventory of goods for resale. This category also includes goods purchased by general government units for provision free of charge or at prices that are not economically significant to other units. Goods acquired by government for distribution as social transfers in kind but that have not yet been so delivered are also included in goods for resale.

7.85 Inventories of goods intended for resale are valued at their current replacement prices.

Military inventories (61225)

7.86 ***Military inventories*** (61225) consist of single-use items, such as ammunition, missiles, rockets, bombs, etc., delivered by weapons or weapons systems. As noted in paragraph 7.74, in the discussion of weapons systems as fixed assets, most single-use items are treated as inventories, but some types of missiles with highly destructive capability may be treated as fixed assets. Military inventories are valued at their current replacement prices.

Valuables (613)

7.87 ***Valuables*** (613) are produced assets of considerable value that are not used primarily for purposes of production or consumption but are held as stores of value over time. They are expected to appreciate, or at least not to decline, in real value, and they do not deteriorate over time under normal conditions.

7.88 Included in valuables are:

- Nonmonetary gold and other precious stones and metals that are not intended to be used as materials and supplies in the processes of production
- Paintings, sculptures, and other objects recognized as works of art or antiques held primarily as stores of value over time
- Jewelry of significant value fashioned out of precious stones and metals, collections, and miscellaneous other valuables.

Many items fitting the description of a valuable that are owned by general government units will be classified as *machinery and equipment not elsewhere classified* (611222) because they are not held primarily as stores of value but used in production, such as by being displayed in government museums. (See also paragraph 7.57.)

7.89 To the extent that there are well-organized markets for valuables, they can be valued at current market prices, including any costs of ownership transfer, such as agents' fees or commissions. Otherwise, the amounts for which they are insured against fire, theft, and other risks may be appropriate.

Nonproduced assets (614)

7.90 Nonproduced assets consist of tangible, naturally occurring assets—natural resources—over which ownership rights are enforced, and *intangible nonproduced assets* (6144) that are constructs of society. Natural resources comprise *land* (6141), *mineral and energy resources* (6142), and *other naturally occurring assets* (6143). If ownership rights have not or cannot be enforced over naturally occurring resources, then they are not economic assets.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

7.91 All immovable nonproduced assets such as land and other natural resources within the economic territory are deemed, by convention, to be owned by resident units (see paragraph 2.13).

Land (6141)

7.92 ***Land*** (6141) consists of the ground, including the soil covering and any associated surface waters, over which ownership rights are enforced and from which economic benefits can be derived by their owners by holding or using them. The associated surface water includes any reservoirs, lakes, rivers, and other inland waters over which ownership rights can be exercised and that can, therefore, be the subject of transactions between units. However, water bodies from which water is regularly extracted, against payment, for use in production (including for irrigation) are included not in water associated with land but in *water resources* (61432).

7.93 Land excludes the following:

- Buildings and other structures constructed on the land or through it, such as roads, office buildings, and tunnels
- Land improvements and the costs of ownership transfer on land
- Cultivated components of vineyards, orchards, and other plantations of trees, animals, and crops
- Subsoil assets
- Noncultivated biological resources
- Water resources below the ground.

7.94 Land is valued at its current price that would be payable by a new owner, excluding the costs of ownership transfer. By convention, the costs of ownership transfer on land are recorded as the net investment in fixed assets as part of land improvements and are subject to consumption of fixed capital. The value of land can vary enormously depending on its location and the uses for which it is suitable or sanctioned. As a result, these factors must be taken into account when the current market price for the land is determined. In a number of instances, it may be difficult to separate the value of land from the value of structures erected on the land:

- One method of estimating the value of land separately is to calculate ratios of the value of the site to the value of the structure from valuation appraisals and to deduce the value of land from the replacement cost of the buildings or from the value on the market of the combined land and buildings.
- When the value of land cannot be separated from the building, structure, plantation, vineyard, etc., above it, the composite asset should be classified in the category representing the greater part of its value.
- Similarly, if the value of the land improvements (which include site clearance, preparation for the erection of buildings or planting of crops, and costs of ownership transfer) cannot be separated from the value of land in its natural state, the value of the land may be allocated to one category or the other, depending on which is assumed to represent the greater part of the value.

7.95 Land appears on the balance sheet of the legal owner except when the land is not separable from other assets that are subject to a financial lease. This may most often occur in connection with a financial lease over a building or plantation on the land, when the inseparable assets, including land, are on the balance sheet of the economic owner.[22]

7.96 By convention, where the legal owner of a building is not the legal owner of the land on which the building stands, but the purchase price of the building includes an upfront payment of rent on the land beneath, without any prospect of further payments being due in future, land is recorded on the balance sheet of the owner of the building on the land.

Mineral and energy resources (6142)

7.97 ***Mineral and energy resources*** (6142) consist of mineral and energy reserves located on or below the earth's surface that are economically exploitable, given current technology and relative prices. Ownership rights to the mineral and energy resources are usually separable from those to the land itself. The deposits may be located on or below the earth's surface, including deposits under the sea, but they must be economically exploitable. Mineral and energy resources are known reserves of oil, natural gas, coal, metallic ores (including ferrous, nonferrous, and precious metal ores), and nonmetallic mineral reserves (including

[22] See paragraphs 3.38–3.41 and 7.5, for a description of the distinction between legal and economic ownership.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

stone quarries, clay and sand pits, chemical and fertilizer mineral deposits, and deposits of salt, quartz, gypsum, natural gem stones, asphalt, bitumen, and peat). Mine shafts, wells, and other subsoil extraction facilities are fixed assets in the form of *other structures* (61113) rather than subsoil assets.

7.98 The value of the resources is usually estimated as the present value of the expected net returns resulting from their commercial exploitation, but if the ownership of subsoil assets changes frequently on markets, then it may be possible to obtain appropriate prices. In practice, it may be necessary to use the valuations that the owners of the assets place on them in their own accounts.

7.99 It is frequently the case that the enterprise extracting a resource is different from the owner of the resource. In many countries, for example, oil resources are the property of government. However, it is the extractor who determines how fast the resource will be depleted, and since the resource is not renewable on a human time scale, it appears as if there has been a change of economic ownership to the extractor even if this is not the legal position. Nor is it necessarily the case that the extractor will have the right to extract until the resource is exhausted. Because there is no wholly satisfactory way in which to show the value of the asset split between the legal owner and the extractor, the whole of the resource is shown on the balance sheet of the legal owner and the payments by the extractor to the owner shown as rent. (This treatment is, therefore, an extension of the concept of a resource lease applied in this case to a depletable asset, as described in paragraphs 5.130 and A4.16–A4.17.)[23]

Other naturally occurring assets (6143)

7.100 *Other naturally occurring assets* (6143) comprise *noncultivated biological resources* (61431), *water resources* (61432), and *other natural resources* (61433), as shown in Table 7.7.

Table 7.7 Classification of Other Naturally Occurring Assets

6143	Other naturally occurring assets
61431	Noncultivated biological resources
61432	Water resources
61433	Other natural resources
614331	Radio spectrum
614332	Natural resources not elsewhere classified

7.101 ***Noncultivated biological resources*** (61431) consist of animals, birds, fish, and plants that yield both once-only and repeat products over which ownership rights are enforced but for which natural growth or regeneration is not under the direct control, responsibility, and management of any institutional units. Examples are virgin forests and fisheries that are commercially exploitable. Only those resources that have economic value that is not included in the value of the associated land are included. As observed prices are not likely to be available, such assets are usually valued at the present value of expected future returns (see paragraph 7.33).

7.102 ***Water resources*** (61432) consist of surface and groundwater resources used for extraction to the extent that their scarcity leads to the enforcement of ownership or use rights, market valuation, and some measure of economic control. As observed prices are not likely to be available, such assets are usually valued at the present value of expected future returns.

7.103 The category *other natural resources* (61433) includes the electromagnetic spectrum, which includes the range of radio frequencies used in the transmission of sound, data, and television. The value of the spectrum is usually determined as the present value of expected future returns. If a long-term contract to use the spectrum exists, its value could be used as a basis for estimating the total value of the asset. Given the tendency to implement environmental policy by means of market instruments, it may be that additional natural resources will come to be recognized as economic assets. (See also paragraphs A4.18–A4.40 and A4.48–A4.50 on the treatment of permits and licenses to use natural resources.)

Intangible nonproduced assets (6144)

7.104 ***Intangible nonproduced assets*** (6144) are constructs of society evidenced by legal or accounting actions. Such assets entitle their owners to engage in certain specific activities or to produce certain specific goods or services and to exclude other units from doing so except with the permission of the owner. The owners of the assets may be able to earn monopoly

[23] See Appendix 4, Box A4.1, for a description of the criteria to distinguish between rent and asset sales of natural resources.

Table 7.8	Classification of Intangible Nonproduced Assets
6144	Intangible nonproduced assets
61441	Contracts, leases, and licenses
614411	Marketable operating leases
614412	Permits to use natural resources
614413	Permits to undertake specific activities
614414	Entitlement to future goods and services on an exclusive basis
61442	Goodwill and marketing assets

profits by restricting the use of the assets to themselves. Two types of intangible nonproduced assets are distinguished: *contracts, leases, and licenses* (61441) and *goodwill and marketing assets* (61442), as shown in Table 7.8. Whenever possible, contracts, leases, and licenses, should be valued at current prices when they are actually traded on markets. Otherwise, it may be necessary to use estimates of the present value of expected future returns. Goodwill and marketing assets are typically valued at their initial acquisition costs minus allowances for amortization (see paragraph 10.55).

Contracts, leases, and licenses (61441)

7.105 ***Contracts, leases, and licenses*** (61441) are treated as assets only when both the following conditions are satisfied:

- The terms of the contract, lease, or license specify a price for the use of an asset or provision of a service that differs from the price that would prevail in the absence of the contract, lease, or license.
- One party to the contract must be able legally and practically to realize this price difference.

7.106 These kinds of contracts are regarded as assets only if the existence of the legal agreement confers benefits on the holder in excess of the price payable to the lessor, owner of the natural resource, or permit issuer,[24] and the holder can realize these benefits legally and practically (i.e., if a market for the contract exists). It is recommended that in practice, *contracts, leases, and licenses* should be recorded only when the value of the asset is significant and if holders can actually exercise the right to realize the price difference by on-selling the asset. In this case, a suitable market price necessarily exists. The asset does not exist beyond the length of the contract agreement, and its value must be reduced accordingly as the remaining contract period shortens (see paragraph 10.53).

7.107 Contracts, leases, and licenses may be *marketable operating leases* (614411), *permits to use natural resources* (614412), *permits to undertake specific activities* (614413), and *entitlement to future goods and services on an exclusive basis* (614414).[25]

Marketable operating leases (614411)

7.108 ***Marketable operating leases*** (614411) are third-party property rights relating to fixed assets. The lease confers economic benefits to the holder in excess of the fees payable and the holder can realize these benefits legally and practically, through transferring them. An example is where a tenant of a building has a fixed rental but the building could fetch a higher rental in the absence of the lease. If, in these circumstances, the tenant is able both legally and practically to sublet the building, then the tenant has an asset of the type of a marketable operating lease.

Permits to use natural resources (614412)

7.109 ***Permits to use natural resources*** (614412) are third-party property rights relating to natural resources. An example is where an institutional unit holds a fishing quota and is able, again both legally and practically, to sell this to another unit. Payment for a mobile phone license constitutes the sale of an asset, not payment for rent, when the licensee acquires effective economic ownership rights over the use of the spectrum. To decide whether ownership is effectively transferred, the six criteria quoted in Box A4.1 are to be considered.

Permits to undertake specific activities (614413)

7.110 A ***permit to undertake a specific activity*** (614413) is an asset for the holder when: (i) the permits are limited in number and so allow the holders to earn monopoly profits, (ii) the monopoly profits do not come from the use of an asset belonging to the permit-issuer, and (iii) a permit holder is able both legally and practically to sell the permit to a third party.

[24] Also see *2008 SNA*, Chapter 17, part 5.

[25] For a description of the recording of these permits issued by government see paragraphs A4.18–A4.52.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Such permits are issued mainly by government but may also be issued by other units.

7.111 When governments restrict the number of cars entitled to operate as taxis or limit the number of casinos by issuing permits or licenses, they are in effect creating monopoly profits for the approved operators and recovering some of the profits as the "fee." For government, such proceeds are recorded as *other taxes on the use of goods and on permission to use goods or perform activities* (11452) (see paragraph 5.81). For the permit holder, the incentive to acquire such a license is that the licensee believes that it will thereby acquire the right to make monopoly profits at least equal to the cost of the license. This permission to create monopoly profits creates an asset for the holder if the licensee can realize these profits by on-selling the asset—that is, the license is tradable. The value of this asset is determined by the value at which it can be sold or, if no such information is available, is estimated as the present value of the future stream of monopoly profits (see also paragraphs A4.42–A4.45).

Entitlement to future goods and services on an exclusive basis (614414)

7.112 ***Entitlement to future goods and services on an exclusive basis*** (614414) relates to the case where one party that has contracted to purchase goods or services at a fixed price at a time in the future is able to transfer the obligation of the second party to the contract to a third party. These entitlements relate to footballers' contracts and a publisher's exclusive right to publish new works by a named author or issue recordings by named musicians (see also paragraph A4.51). For example, when a football player contracted his or her services to a club, the latter has an asset with the ability to sell this contract to another club.

Goodwill and marketing assets (61442)

7.113 Potential purchasers of an enterprise are often prepared to pay a premium above the net value of its individually identified and valued assets and liabilities. This excess is described as goodwill and reflects the value of corporate structures and the value to the business of an assembled workforce and management, corporate culture, distribution networks, and customer base. It may not have value in isolation from other assets, but it enhances the value of those other assets. Looked at another way, it is the addition to the value of individual assets because they are used in combination with each other.

7.114 Goodwill cannot be separately identified and sold to another party. The value has to be derived by deducting the value of assets and liabilities classified elsewhere within the asset boundary of GFS from the sale value of the corporation. (In practice, since it is estimated as a residual, an estimate of goodwill will also reflect errors and omissions in the valuation of other assets and liabilities.)

7.115 As well as residual errors, the value of goodwill may include the value to the corporation of items known as marketing assets. **Marketing assets** consist of items such as brand names, mastheads, trademarks, logos, and domain names. A brand can be interpreted as far more than just a corporate name or logo. It is the overall impression a customer or potential customer gains from his or her experience with the company and its products. Interpreted in that wider sense it can also be seen to encompass some of the characteristics of goodwill, such as customer loyalty.

7.116 The value of goodwill and marketing assets is the difference between the value paid for an enterprise as a going concern and the sum of its assets minus the sum of its liabilities, each item of which has been separately identified and valued. Although goodwill is likely to be present in most corporations, for reasons of reliability of measurement it is recorded in GFS only when its value is evidenced by a market transaction, usually the sale of the whole corporation. In some exceptions, identified marketing assets may be sold individually and separately from the whole corporation, in which case their value should also be recorded under this item.

7.117 The balance sheet entry for goodwill and marketing assets is the written-down value of the entry that appears as a transaction in financial assets and liabilities when an enterprise is taken over or when a marketing asset is sold.[26] These entries are not revalued.

Financial Assets (62) and Liabilities (63)

7.118 Financial assets and liabilities were defined in paragraphs 7.15–7.16. The classifications of financial assets and liabilities are based primarily on the

[26] As explained in paragraph 10.55, the amortization of goodwill and marketing assets over their service or legal lives is an other economic flow.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

liquidity and legal characteristics of the instruments that describe the underlying creditor-debtor relationships. The liquidity of a financial instrument embraces characteristics such as negotiability, transferability, marketability, and convertibility.

7.119 Securities are debt and equity instruments that have the characteristic feature of negotiability. That is, their legal ownership is readily transferred from one unit to another unit by delivery or endorsement. While any financial instrument can potentially be traded, securities are designed to be traded, usually on organized exchanges or "over the counter." (The over-the-counter market involves parties negotiating directly with one another, rather than on a public exchange.) Negotiability is a matter of the legal form of the instrument. Some securities may be legally negotiable, but there is not, in fact, a liquid market where they can be readily bought or sold. Listed financial derivatives, such as warrants, are sometimes considered to be securities.

7.120 In addition to classifying financial assets and liabilities by the characteristics of the financial instrument, they can also be classified according to the residence of the other party to the instrument (the debtors for financial assets and the creditors for liabilities).[27] Residence is defined in paragraphs 2.6–2.21. The classifications of financial assets and liabilities by instrument are shown in Table 7.9.

7.121 Because a given financial instrument creates both a financial asset and a liability, the same descriptions of instruments can be used for both. For simplicity, the descriptions will refer only to financial assets unless there is a specific need to refer to liabilities.

7.122 As discussed in paragraphs 3.113 and 7.20–7.25, in principle, all financial assets should be valued at market value.[28] Because the creditor can dispose of the asset on the date of the balance sheet at its current market price, it is that price that is relevant for the balance sheet. In practice, valuing debt instruments[29] at market value on the balance sheet date means that:

- Debt securities are valued at market prices.
- Insurance, pension, and standardized guarantee schemes are valued according to principles that are equivalent to market valuation.
- All other debt instruments are valued at nominal prices, which are considered to be the best generally available estimates of their market prices.

7.123 Some financial assets and liabilities, most typically deposits, debt securities, loans, and other accounts payable/receivable, require the debtor to pay interest. The interest accrues continuously and increases the total amount that the debtor will be required to pay (see paragraph 6.64).

7.124 To calculate the overall balance (see paragraph 4.57) financial assets acquired by government units in support of their fiscal policies[30] are classified differently from financial assets acquired for liquidity management. The distinction between financial assets acquired for public policy purposes and financial assets acquired for liquidity purposes is not included in the GFS classification of financial assets. This distinction rests on the judgment of the analyst of the particular purpose for employing financial assets.[31]

Monetary gold and Special Drawing Rights (SDRs) (6201, 6221, 6301, 6321)

7.125 On the financial assets side, this category comprises monetary gold and SDRs, and on the liabilities side it comprises only SDRs (see paragraph 7.128). The counterparties to this financial asset and liability are nonresidents.

Monetary gold (62011, 62211)[32]

7.126 Monetary gold is gold to which the monetary authorities (or others who are subject to the effective control of the monetary authorities) have title and is held as a reserve asset. It comprises gold bullion (including gold held in allocated gold accounts)

[27] A discussion of Islamic banking instruments and how they can be treated in terms of the classification of financial assets and liabilities can be found in the *MFSM*, Appendix 2.
[28] That value, however, may differ from an asset's nominal value, which is a measure of value from the viewpoint of the debtor: at any moment in time the nominal value is the amount that the debtor owes to the creditor. See paragraph 3.115.
[29] Debt instruments are all liabilities, except equity and investment fund shares and financial derivatives and employee stock options.
[30] This is often referred to as "public policy lending" or "policy lending" and is treated akin to expenditure in the calculation of the overall balance.
[31] As explained in Box 6.3, under some circumstances, "capital or equity injections" are considered to be expense—that is, they do not result in a financial claim on the debtor.
[32] There is no liability in the form of monetary gold; the counterpart liability to monetary gold in the form of unallocated gold accounts with nonresidents that give title to claim the delivery of gold is classified under deposits. Gold bullion has no counterparty liability.

Table 7.9 Classification of Financial Assets and Liabilities by Instrument and Residence of the Counterparty

62	**Financial assets**	**63**	**Liabilities**
6201	Monetary gold and Special Drawing Rights (SDRs)	6301	Special Drawing Rights (SDRs)
62011	Monetary gold		
62012	Special Drawing Rights (SDRs)		
6202	Currency and deposits	6302	Currency and deposits
6203	Debt securities	6303	Debt securities
6204	Loans	6304	Loans
6205	Equity and investment fund shares	6305	Equity and investment fund shares
62051	Equity	63051	Equity
62052	Investment fund shares or units	63052	Investment fund shares or units
6206	Insurance, pension, and standardized guarantee schemes [GFS]	6306	Insurance, pension, and standardized guarantee schemes [GFS]
62061	Nonlife insurance technical reserves	63061	Nonlife insurance technical reserves
62062	Life insurance and annuities entitlements	63062	Life insurance and annuities entitlements
62063	Pension entitlements [GFS]	63063	Pension entitlements [GFS]
62064	Claims of pension funds on pension manager	63064	Claims of pension funds on pension manager
62065	Provisions for calls under standardized guarantee schemes	63065	Provisions for calls under standardized guarantee schemes
6207	Financial derivatives and employee stock options	6307	Financial derivatives and employee stock options
62071	Financial derivatives	63071	Financial derivatives
62072	Employee stock options	63072	Employee stock options
6208	Other accounts receivable	6308	Other accounts payable
62081	Trade credit and advances	63081	Trade credit and advances
62082	Miscellaneous other accounts receivable	63082	Miscellaneous other accounts payable
621	**Domestic debtors**	**631**	**Domestic creditors**
6212–6218	*Same instrument breakdown as above, but excluding monetary gold and SDRs*	6312–6318	*Same instrument breakdown as above, but excluding SDRs*
622	**External debtors**	**632**	**External creditors**
6221–6228	*Same instrument breakdown as above*	6321–6328	*Same instrument breakdown as above*

and unallocated gold accounts with nonresidents that give title to claim the delivery of gold.[33] All monetary gold is included in reserve assets or is held by international financial organizations. Only gold that is held as a financial asset and as a component of reserve assets is classified as monetary gold. Therefore, except in limited institutional circumstances,[34] gold bullion is a financial asset only for the central bank or central government. Deposits, loans, and securities denominated in gold are treated, respectively, as deposits, loans, and securities denominated in foreign currencies, and not as monetary gold, unless held as unallocated gold accounts by monetary authorities as reserve assets.

7.127 Allocated gold accounts provide ownership of a specific piece of gold. The ownership of the gold remains with the entity placing it for safe custody. When held as reserve assets, allocated gold accounts are classified as monetary gold. Otherwise, allocated gold accounts are treated as representing the ownership of a nonfinancial asset. In contrast, **unallocated gold accounts** represent a claim against the account custodian to deliver gold. For these accounts, the account provider holds title to a reserve base of physical gold and issues claims to account holders denominated in gold. When held as reserve assets, unallocated gold accounts are classified as monetary gold. Unallocated

[33] See the *BPM6*, paragraphs 5.74–5.78, for a detailed discussion of gold bullion and gold accounts.
[34] For example, gold held by a commercial bank but under the control of the monetary authorities.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

accounts not held as reserve assets, and all unallocated gold account liabilities, are classified as deposits.

7.128 Gold bullion takes the form of coins, ingots, or bars with a purity of at least 995 parts per 1,000, including such gold held in allocated gold accounts. Gold bullion is usually traded on organized markets or through bilateral arrangements between central banks. Gold bullion held as a reserve asset is the only financial asset with no corresponding liability.

7.129 Any gold held by a government unit that does not satisfy the definition of monetary gold is not a financial asset and is included in nonmonetary gold as a nonfinancial asset, most likely *valuables* (613) but possibly *inventories* (612).[35] In some cases, a central bank may own gold bullion that is not held as reserves, such as sometimes occurs when it acts as a monopoly reseller of mined gold. A gold swap is treated as a loan (see paragraph 7.161).

7.130 Monetary gold is valued at the price established in organized markets or when traded through bilateral arrangements between central banks.

Special Drawing Rights (SDRs) (62012, 62212, 63012, 63212)

7.131 Special Drawing Rights (SDRs) are international reserve assets created by the International Monetary Fund (IMF) and allocated to its members to supplement reserve assets. The Special Drawing Rights Department of the IMF allocates SDRs among member countries of the IMF (collectively known as the participants). The allocation of SDRs is a liability of the member country and interest accrues on this liability.[36]

7.132 SDR holdings represent each holder's unconditional right to obtain foreign exchange or other reserve assets from other IMF members. These financial assets represent claims on the participants in the IMF's SDR Department collectively and not on the IMF. A participant may sell some or all of its SDR holdings to another participant and receive other reserve assets, particularly foreign exchange, in return. Participants may also use SDRs to meet liabilities.

[35] Nonmonetary gold is a good and classified under nonfinancial assets as valuables, if held primarily as a store of value, and classified as inventories of materials and supplies, if used in a production process (such as jewelry or dentistry).
[36] The IMF has also designated a limited number of international financial institutions as holders of SDRs.

7.133 SDR allocations constitute a (debt) liability of the recipients (and part of the public sector's debt liabilities) and the SDR holdings are part of the public sector's financial assets. The allocation and holdings are recorded on a gross basis. The macroeconomic statistical guidelines do not specify on whose balance sheet SDR holdings and allocations should be recorded (e.g., the central bank or a general government entity such as the ministry of finance or treasury). This is because SDR allocations are made to IMF members that are participants in the SDR Department of the IMF, and it is for those members to follow domestic legal and institutional arrangements to determine the ownership and recording of SDR allocations and SDR holdings in the public sector. Given that financial claims on and liabilities to members in the SDR system are attributed on a cooperative basis, a residual partner category—other nonresidents—is used as the counterparty to SDR holdings and allocations.

7.134 In addition to SDRs as a type of financial instrument, SDRs may also be used as a unit of account in which other debt instruments can be expressed. The value of the SDR is determined daily by the IMF on the basis of a selected basket of currencies. To ensure consistency, the SDR rates against domestic currencies are obtainable from the IMF. Both the basket and the weights of the currencies that make up the SDR basket are revised from time to time.

Currency and deposits (6202, 6212, 6222, 6302, 6312, 6322)

7.135 Currency consists of notes and coins that are of fixed nominal values and are issued or authorized by the central bank or government. All sectors may hold currency as assets, but normally only central banks and government may issue currency. In some countries, commercial banks are able to issue currency under the authorization of the central bank or government. Currency constitutes a liability of the issuing units. Unissued currency held by a public sector unit is not treated as a financial asset of the public sector or a liability of the central bank. Gold and commemorative coins that are not in circulation as legal tender, or as monetary gold, are classified as nonfinancial assets in the form of valuables or inventories of materials and supplies, as appropriate, rather than currency.

7.136 A distinction should be drawn between domestic currency that is a liability of a resident unit

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

and foreign currency that is the liability of nonresident units. (See paragraph 3.134 for the definitions of domestic and foreign currency.) Domestic currency has a fixed nominal value. The value of foreign currency is converted to the domestic currency at the exchange rate valid on the date to which the balance sheet relates. The rate used should be the midpoint between the buying and selling spot rates for currency transactions.

7.137 Deposits are all claims, represented by evidence of deposit, on the deposit-taking corporations (including the central bank) and, in some cases, general government or other institutional units. A deposit is usually a standard contract, open to the public at large, that allows the placement of a variable amount of money. Public sector units may hold a variety of deposits as assets, including deposits in foreign currencies. It is also possible for a government unit to incur liabilities in the form of deposits. For example, postal offices or other government units may accept deposits from the public, acting like a sort of rural financial institution as a secondary activity. Public financial corporations (e.g., the central bank) typically incur liabilities in the form of deposits, including to government units.

7.138 Claims on the IMF that are components of international reserves and are not evidenced by loans should be classified as deposits. (Claims on the IMF evidenced by loans should be included in loans.) Repayable margin payments in cash related to financial derivative contracts (see paragraph 7.219) can also be classified under deposits.

7.139 Unallocated accounts for precious metals, such as unallocated gold accounts, are also deposits, except for unallocated gold accounts held by monetary authorities for reserves purposes, for which the asset holding is included in monetary gold, with the counterpart liability being recorded as a deposit (as also mentioned in paragraph 7.15).

7.140 Deposits may be transferable or nontransferable. Transferable deposits comprise all deposits that are (i) exchangeable (without penalty or restriction) on demand at par, and (ii) directly usable for making third-party payments by check, draft, giro order, direct debit/credit, or other direct payment facility. Nontransferable deposits comprise all other financial claims, other than transferable deposits, represented by evidence of deposit. Examples of other deposits are sight deposits that permit immediate cash withdrawals but not direct third-party transfers, savings and fixed-term deposits, overnight and very short-term repurchase agreements that are included in the national measures of broad money, and foreign currency deposits that are blocked because of the rationing of foreign exchange as a matter of national policy.

7.141 It may be useful to further classify deposits according to whether they are denominated in the domestic currency or a foreign currency.

7.142 Deposits should be recorded at nominal value. They give rise to the same issues as loans with respect to nominal and fair values (see paragraph 7.163). Deposit assets at banks and other public deposit-taking corporations in liquidation also should be recorded at their nominal value until they are written off. If the difference between the nominal and fair values is significant, the fair value of such deposits could be shown as an additional memorandum item to the balance sheet. The same treatment is applicable for any other cases of impaired deposits (i.e., where the public deposit-taking corporation is not in liquidation but is insolvent).

Debt securities (6203, 6213, 6223, 6303, 6313, 6323)

7.143 Debt securities are negotiable financial instruments serving as evidence of a debt. The security normally specifies a schedule for interest and principal payable. Examples of debt securities are:

- Bills
- Bonds and debentures, including bonds that are convertible into shares
- Loans that have become negotiable from one holder to another
- Nonparticipating preferred stocks or shares
- Asset-backed securities and collateralized debt obligations
- Similar instruments normally traded in the financial markets.

7.144 Bills are defined as securities (usually short-term) that give holders the unconditional rights to receive stated fixed sums on a specified date. Bills are issued and usually traded in organized markets at discounts to face value that depend on the rate of

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

interest and the time to maturity. Examples of bills are treasury bills, negotiable certificates of deposit, bankers' acceptances, promissory notes, and commercial paper.

7.145 A **banker's acceptance** is created when a financial corporation endorses, in return for a fee, a draft or bill of exchange and the unconditional promise to pay a specific amount at a specified date. International trade is often financed in this way. A banker's acceptance is classified under the category of debt securities. A banker's acceptance represents an unconditional claim on the part of the holder and an unconditional liability on the part of the accepting financial corporation; in turn, the financial corporation acquires an asset because it has a claim on its customer. A banker's acceptance is treated as a financial asset from the time of acceptance, even though funds may not be exchanged until a later stage.[37]

7.146 Bonds and debentures are securities that give the holders the unconditional right to fixed payments or contractually determined variable payments on a specified date or dates. The earning of interest is not dependent on earnings of the debtors. Bonds and debentures could have various characteristics and uses. For example, bonds may be issued to recognize a liability for government employee pensions (often called recognition bonds). Bonds can be issued at a deep discount or with no coupons (zero-coupon bonds).

7.147 Zero-coupon bonds are long-term securities that do not involve periodic payments during the life of the bond. Similar to short-term securities, zero-coupon bonds are sold at a discount, and a single payment, that includes accrued interest, is made at maturity.[38] **Deep-discount bonds** are long-term securities that require periodic coupon payments during the life of the instrument, but the amount is substantially below the market rate of interest at issuance.

7.148 Instruments with embedded derivatives[39] are not classified as financial derivatives. If a primary instrument, such as a security or loan, contains an embedded derivative, the instrument is valued and classified according to its primary characteristics—even though the value of that security or loan may well differ from the values of comparable securities and loans because of the embedded derivative. Examples are corporate bonds that are convertible into shares of the same corporation at the option of the bondholder and securities with options for repayment of principal in currencies that differ from those in which the securities were issued. If the conversion option is traded separately, then the option is treated as a separate instrument, classified as a financial derivative, and it is not debt.

7.149 Loans (see paragraph 7.157) that have become negotiable from one holder to another are to be reclassified (through other changes in the volume of assets) from loans to debt securities under certain circumstances. For such reclassification, there needs to be evidence of secondary market trading, including the existence of market makers, and frequent quotations of the instrument, such as provided by bid-offer spreads.[40]

7.150 Nonparticipating preferred stocks or shares are those that pay a fixed income but do not provide for participation in the distribution of the residual value of an incorporated enterprise on dissolution. These shares are classified as debt securities. Bonds that are convertible into equity should also be classified as debt securities prior to the time that they are converted.

7.151 Asset-backed securities and collateralized debt obligations are arrangements under which payments of interest and principal are backed by payments on specified assets or income streams. This process is also described as securitization (for more details, see paragraph A3.59–A3.66). Asset-backed securities are backed by various types of financial assets—for example, mortgages and credit card loans. A general government unit may issue debt securities backed by specific streams of earmarked revenue. This is not an asset-backed security, as in macroeconomic statistical systems, the ability to raise taxes or other government revenue is not recognized as a government asset that could be used for securitization. Nevertheless, the

[37] Appendix 1 of the *EDS Guide* provides a glossary of financial instruments, including banker's acceptances.

[38] For a discussion of the accrual recording of interest on zero-coupon and deep-discounted bonds, see paragraphs 6.71–6.72 and the annex to Chapter 2 of the *PSDS Guide*.

[39] An **embedded derivative** arises when a derivative feature is inserted in a standard financial instrument and is inseparable from the instrument.

[40] An example is a syndicated loan, which is provided by a group of lenders and is structured, arranged, and administered by one or several commercial or investment banks. If parts of a syndicated loan become traded in secondary markets, the loan may meet the criteria to be reclassified as a security.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

earmarking of future revenue, such as receipts from toll roads, to service debt securities issued by a general government (or public sector) unit may resemble securitization.

7.152 Stripped securities are securities that have been transformed from a principal amount with coupon payments into a series of zero-coupon bonds, with a range of maturities matching the coupon payment date(s) and the redemption date of the principal amount(s). The function of stripping is that investor preferences for particular cash flows can be met in ways different from the mix of cash flows of the original security. There are two cases of stripped securities:

- When a third party acquires the original securities and uses them to back the issue of the stripped securities; then new funds have been raised and there is a new financial instrument.
- When no new funds are raised and the payments on the original securities are stripped and marketed separately by the issuer or through agents (such as strip dealers) acting with the issuer's consent; in this case, there is no new instrument.

7.153 Index-linked securities are instruments for which either the coupon payments (interest) or the principal or both are linked to another item, such as a price index, an interest rate, or the price of a commodity. Issues in the measurement of interest on index-linked securities are discussed in paragraphs 6.75–6.78.

7.154 Debt securities traded (or tradable) in organized and other financial markets—such as bills, bonds, debentures, negotiable certificates of deposits, asset-backed securities—should be valued at both market and nominal value. Debt securities are shown in the balance sheet at market value. The nominal value is used to determine gross debt at nominal value, which is shown as a memorandum item to the GFS balance sheet. For a traded debt security, nominal value can be determined from the value of the debt at creation and subsequent economic flows, while market value is based on the price at which it is traded in a financial market.

7.155 For debt securities that are tradable but for which the market price is not readily observable, the market value can be estimated by the discounted present value method provided an appropriate discount rate can be used (see paragraph 3.125). This and other methods of estimating market value are explained in the *PSDS Guide*, Box 2.2.

7.156 When securities are quoted on markets with a buy-sell spread, the midpoint should be used to value the instrument. The spread is an implicit service fee of the market platform or dealer payable by buyers and sellers.

Loans (6204, 6214, 6224, 6304, 6314, 6324)

7.157 A **loan** is a financial instrument that is created when a creditor lends funds directly to a debtor and receives a nonnegotiable document as evidence of the asset.[41] This category includes overdrafts, mortgage loans, loans to finance trade credit and advances, repurchase agreements, financial assets and liabilities created by financial leases, and claims on or liabilities to the IMF in the form of loans. Trade credit and advances and similar accounts payable/receivable are not loans (see paragraph 7.225). Loans that have become marketable in secondary markets should be reclassified under *debt securities* (see paragraph 7.149). However, if traded only occasionally, the loan is not reclassified under debt securities.

7.158 A financial lease involves imputing a loan. A **financial lease** is a contract under which the lessor, as legal owner of an asset, conveys substantially all risks and rewards of ownership of the asset to the lessee. When goods are acquired under a financial lease, the lessee is deemed to be the owner, even though legally the leased good remains the property of the lessor. This is because the risks and rewards of ownership have been, de facto, transferred to the lessee. This change in ownership is deemed to have been financed by an imputed loan, which is an asset of the lessor and a liability of the lessee.

7.159 A **securities repurchase agreement** (repo) is an arrangement involving the sale of securities for cash, at a specified price, with a commitment to repurchase the same or similar securities at a fixed price either on a specified future date (often one or a few days hence) or with an open maturity.[42] The economic nature of the transaction is that of a collateralized loan

[41] A loan is distinguished from a deposit on the basis of the representation in the documents that evidence them.
[42] An open maturity exists when both parties have the option to agree daily to renew or terminate the agreement.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

(or a deposit[43]) because the risks and rewards of ownership of the securities remain with the original owner (security provider). Thus, the funds advanced by the security taker (cash provider) to the security provider (cash taker) are treated as a loan and the underlying securities remain on the balance sheet of the security provider, despite the legal change in ownership.

7.160 Securities lending is an arrangement whereby a security holder transfers securities to another party (security taker), subject to the stipulation that the same or similar securities be returned on a specified date or on demand. As with a securities repurchase agreement, the risks and rewards of ownership remain with the original owner. If the security taker provides cash as collateral, then the arrangement is a repo (see paragraph 7.159). If the security taker provides noncash collateral, then no stock position changed. In either case, the securities involved remain on the balance sheet of the original owner.

7.161 A **gold swap** involves an exchange of gold for foreign exchange deposits with an agreement that the transaction be reversed at an agreed future date at an agreed gold price. The gold taker (cash provider) should not record the gold on its balance sheet, while the gold provider (cash taker) should not remove the gold from its balance sheet. Gold swaps are similar to securities repurchase agreements, except that the collateral is gold, and should therefore be recorded as a collateralized loan or deposit. Gold loans occur in the same form as securities lending and should be treated in the same way.

7.162 An **off-market swap** is a swap contract[44] that has a nonzero value at inception as a result of having reference rates priced differently from current market values—that is, "off-the-market." Such a swap results in a lump sum being paid, usually at inception, by one party to the other. The economic nature of an off-market swap is equivalent to a combination of borrowing (i.e., the lump sum), in the form of a loan, and an on-market swap (financial derivative).[45]

[43] Repurchase agreements that are included in the national definition of broad money should be classified as nontransferable deposits. All other securities repurchase agreements should be classified under loans.

[44] A swap contract involves the counterparties exchanging, in accordance with prearranged terms, cash flows based on the reference prices of the underlying items.

[45] For more details, see the *PSDS Guide*, paragraphs 4.127–4.131.

7.163 Loans are recorded at nominal value (i.e., the amount advanced plus interest accrued and not paid minus any repayments). The use of nominal values is partly influenced by pragmatic concerns about data availability. In addition, because loans are generally not intended for trading on the secondary market, estimating a market price can be subjective. Nominal value is also useful because it shows actual legal liability and the starting point of creditor recovery behavior. In some cases, loans may be traded, often at discount, or a fair value may exist or could be estimated. It is recognized that nominal value provides an incomplete view of the financial position of the creditor, particularly when the loans are nonperforming. In such cases, information on the nominal value, as well as the fair value, of nonperforming loan assets should be included as a memorandum item to the GFS balance sheet—see paragraph 7.262.

Equity and investment fund shares (6205, 6215, 6225, 6305, 6315, 6325)

7.164 Equity and investment fund shares have the distinguishing feature that the holders own a residual claim on the assets of the institutional unit that issued the instrument. Equity represents the owners' funds in the institutional unit. In contrast to debt, equity does not generally provide the owner with a right to a predetermined amount or an amount determined according to a fixed formula. Investment fund shares have a specialized role in financial intermediation as a kind of collective investment in other assets, and should be identified separately. When an institutional unit's net worth is calculated, equity and investment fund shares are, by convention, included in total liabilities (see paragraphs 7.228–7.233).

Equity (62051, 62151, 62251, 63051, 63151, 63251)

7.165 Equity consists of all instruments and records that acknowledge claims on the residual value of a corporation or quasi-corporation, after the claims of all creditors have been met. Equity is treated as a liability of the issuing institutional unit (a public corporation or other government unit).

7.166 Ownership of equity in legal entities is usually evidenced by shares, stocks, participations, depository receipts, or similar documents. Shares and stocks have the same meaning. Participating preferred

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

shares are those that provide for participation in the residual value on the dissolution of an incorporated enterprise. Such shares are also equity securities, regardless of whether the income is fixed or determined according to a formula. (For nonparticipating preferred shares, see paragraph 7.150.) In addition to the purchase of shares, the value of equity can be affected by a range of factors, such as share premiums, accumulated reinvested or retained earnings, or revaluations. In addition, a direct investor may increase its equity in an affiliate by providing goods and services or assuming debt.

7.167 Depository receipts are securities that represent ownership of securities listed in other economies. Depository receipts listed on one exchange represent ownership of securities listed on another exchange, and ownership of the depository receipts is treated as if it represents direct ownership of the underlying securities. Depository receipts facilitate transactions in securities in economies other than their home listing. The underlying securities may be equity or debt securities.

7.168 Equity may be subdivided into listed shares, unlisted shares, and other equity. Both listed and unlisted shares are equity securities (securities are defined in paragraph 7.119). **Listed shares** are equity securities listed on an exchange and may be referred to as quoted shares. **Unlisted shares** are equity securities not listed on an exchange. Listed and unlisted shares tend to be issued by different types of corporations (unlisted shares are often issued by subsidiaries and smaller businesses) and typically have different regulatory requirements.

7.169 Other equity is equity that is not in the form of securities. This can include equity in quasi-corporations, such as branches, trusts, limited liability and other partnerships, unincorporated funds, and notional units for ownership of real estate and other natural resources. The ownership of many international organizations is not in the form of shares and should be classified as other equity (although equity in the Bank for International Settlements is in the form of unlisted shares). Ownership of currency union central banks is included in other equity.[46]

7.170 Most general government units do not have liabilities in the form of equity and investment fund shares. However, in two cases, it is possible to show a general government unit with liabilities for equity and investment fund shares. The first relates to some units (usually special purpose entities) that are established legally as public corporations but carry out only fiscal and quasi-fiscal activities—they are treated as part of general government (regardless of their legal status) because they are not considered to be separate institutional units, unless they are nonresident. Second, when a unit under the control of government is legally established as a corporation but functions as a nonmarket producer, such a unit is also part of general government, as explained in paragraph 2.41.

7.171 The general principles of valuation at market prices given in paragraphs 7.20–7.33 apply to equity. Equity can be readily valued at its current market prices when it is regularly traded on stock exchanges or other financial markets.

7.172 However, there may be no observable market prices for unlisted shares and other equity positions (e.g., for equity in direct investment enterprises, unlisted and delisted companies, listed but illiquid companies, joint ventures, and unincorporated enterprises).

7.173 When actual market values of equity are not available, an estimate is required. One approach is to use information from the stock market on a similar listed share, as described in paragraph 7.29. Alternative methods of approximating the market value of shareholders' equity are outlined in *2008 SNA*, paragraphs 13.71–13.73, and include the following: recent transaction price, net asset value, present value/price to earnings ratios, book values reported by enterprises with macro-level adjustments by the statistics compilers, own funds at book value, and apportioning global value. The value of other equity is equal to the value of the unit's assets minus the value of its liabilities. So for unincorporated enterprises, such as quasi-corporations, net worth is zero and the estimated value of other equity can be negative if the value of liabilities exceeds the value of the assets.[47]

Investment fund shares or units (62052, 62152, 62252, 63052, 63152, 63252)

7.174 Investment funds are collective investment undertakings through which investors pool funds for

[46] See the *BPM6*, paragraph A3.44.

[47] Incorporated corporations have a limited liability toward their shareholders so that the minimum value of their equity is zero.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

investment in financial or nonfinancial assets. These funds issue shares (if a corporate structure is used) or units (if a trust structure is used). Investment funds include money market funds (MMF) and non-MMF investment funds.[48] Investment fund shares or units refer to the shares issued by mutual funds and unit trusts, rather than the shares they may hold.

7.175 MMFs are investment funds that invest only or primarily in short-term money market securities, such as treasury bills, certificates of deposit, and commercial paper. MMF shares and units sometimes are functionally close to transferable deposits—for example, accounts with unrestricted check-writing privileges. If MMF shares are included in broad money in the reporting economy, they should be recorded as a separate item in the balance sheet to allow reconciliation with monetary statistics.

7.176 Investment funds invest in a range of assets, such as debt securities, equity, commodity-linked investments, real estate, shares in other investment funds, and structured assets.

7.177 Shares (or units) in money market funds or in other investment funds should be valued in a manner similar to the methods under equity:

- Listed shares should be valued using the market price of the share.
- Unlisted shares should be valued according to one of the methods described in paragraph 7.172 for unlisted equity and other equity.

Insurance, pension, and standardized guarantee schemes [GFS] (6206, 6216, 6226, 6306, 6316, 6326)

7.178 Insurance, pension, and standardized guarantee schemes comprise:

- Nonlife insurance technical reserves
- Life insurance and annuities entitlements
- Pension entitlements [GFS]
- Claims of pension funds on pension manager
- Provisions for calls under standardized guarantee schemes.

7.179 These reserves, entitlements, and provisions for calls represent liabilities of a public sector unit as the insurer, pension fund, or issuer of standardized guarantees, and corresponding assets of the policyholders or beneficiaries. In the public sector, it is usually public financial corporations that engage in insurance schemes. General government units may incur liabilities for these reserves, entitlements, and provisions as operators of nonlife insurance schemes, nonautonomous or unfunded pension schemes, and standardized guarantee schemes.[49]

7.180 The value of a public sector unit's assets in the form of insurance, pension, and standardized guarantee schemes—as a policyholder—is determined by the amount of prepaid premiums plus estimates for claims established but not yet received by the public sector unit. The value of a public sector unit's liabilities in the form of each of these instruments is discussed under the relevant instrument.

7.181 In general, insurance companies and operators of pension funds and standardized guarantee schemes make actuarial estimates of their liabilities under these schemes. These estimates will be the usual source to compile statistics for this instrument.

7.182 The following paragraphs briefly define the types of reserves, entitlements, and provisions applicable to insurance, pension, and standardized guarantee schemes.[50]

Nonlife insurance technical reserves (62061, 62161, 62261, 63061, 63161, 63261)

7.183 **Nonlife insurance**[51] **technical reserves** consist of (i) prepayments of net nonlife insurance premiums and (ii) reserves to meet outstanding nonlife insurance claims. In other words, nonlife insurance technical reserves consist of premiums paid but not

[48] These are discussed further in the *BPM6*, paragraphs 4.73–4.75.

[49] It is unlikely that a general government unit would incur liabilities with respect to life insurance and annuities, unless it provides such schemes to its employees.

[50] These issues are discussed in detail in the *2008 SNA*, paragraphs 17.76–17.224.

[51] Nonlife insurance covers all risks other than life insurance, such as accidents, sickness, fire, etc. A policy that provides a benefit in the case of death within a given period but in no other circumstances, usually called term insurance, is regarded as nonlife insurance because, as with other nonlife insurance, a claim is payable only if a specified contingency occurs and not otherwise. In practice, because of the way in which insurance corporations keep their accounts, it may not always be possible to separate term insurance from other life insurance. In these circumstances, term insurance may have to be treated in the same way as life insurance for practical reasons.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

yet earned (called unearned premiums) and claims incurred but not yet settled.

7.184 Prepayments of net nonlife insurance premiums arise because premiums are usually payable at the beginning of the period covered by the policy. However, on an accrual basis, the premiums are earned through the policy period, so that the initial payment involves a prepayment or advance. At any given time, part of the insurance premiums already paid has not yet been earned by the insurance enterprise because these prepaid premiums provide coverage against risks in the future. The value of the prepaid or unearned premiums should be determined proportionally. For example, if an annual policy with a premium of 120 currency units comes into force on April 1 and accounts are being prepared for a calendar year, the premium earned in the calendar year is 90. The prepaid or unearned premium is the amount of the actual premium received that relates to the period past the reporting point. In the example just given, there will be an unearned premium of 30 at the end of December. This unearned premium is intended to provide coverage for the first three months of the next year.

7.185 Reserves to meet outstanding nonlife insurance claims are amounts arising from events that have occurred but for which the claims are still pending. They also include reserves for unexpired risks. The liability incurred by the insurer to meet outstanding claims represents the present value of the amounts expected to be paid out in settlement of claims, including disputed claims, as well as allowances for claims for incidents that have taken place but have not yet been reported.

7.186 Other reserves, such as equalization reserves, may be identified by insurers. However, these are recognized as liabilities (and corresponding assets) only when there is an event that gives rise to a liability. Otherwise, equalization reserves are internal accounting entries by the insurer that represent saving to cover irregularly occurring catastrophes, and thus do not represent any existing corresponding claims for policyholders.

Life insurance and annuities entitlements (62062, 62162, 62262, 63062, 63162, 63262)

7.187 Life insurance and annuities entitlements are financial claims policyholders have against an enterprise offering life insurance or providing annuities. This category consists of liabilities of life insurance companies and annuity providers for prepaid premiums and accrued liabilities to life insurance policyholders and beneficiaries of annuities. Life insurance and annuity entitlements are the obligation to provide benefits to policyholders, or to compensate beneficiaries upon the death of policyholders,[52] and thus are kept separate from shareholders' funds. These entitlements are regarded as liabilities of the insurance companies and assets of the policyholders and beneficiaries. Annuities entitlements are the actuarial calculation of the present value of the obligations to pay future income until the death of the beneficiaries.

7.188 The amount to be recorded as the stock positions for life insurance and annuities entitlements is similar to that for nonlife insurance technical reserves in that it represents obligations to meet future claims already accrued. However, in the case of life insurance, the level of the entitlements is considerable and represents the present value of all expected future benefits.[53]

Pension entitlements [GFS][54] (62063, 62163, 62263, 63063, 63163, 63263)

7.189 As explained in paragraphs A2.5–A2.7, entitlements to social insurance benefits are divided between those relating to pensions and those relating to all other forms of benefits (i.e., nonpensions). The distinction between the two is important because the GFS recognizes liabilities for employment-related pensions, regardless of whether there are actually assets set aside to meet the entitlements, but recognizes reserves for employment-related nonpension benefits only when these reserves actually exist (see paragraph 7.195). Furthermore, a distinction is made between social security schemes and employment-related schemes. This section deals with entitlements to employment-related pension schemes.

7.190 Pension entitlements are financial claims that existing and future pensioners[55] hold against

[52] This is distinct from term insurance, which is regarded as nonlife insurance (see footnote 51).

[53] In the commercial accounts of insurance corporations, some of these obligations will be described as provisions for bonuses and rebates. This is the result of the insurance industry's practice of smoothing benefits over time and retaining some benefits until the policy matures.

[54] [GFS] indicates that an item has the same name but different coverage in the *2008 SNA*.

[55] Existing and future pensioners include past and current employees, as well as existing pensioners, but exclude future employees.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

either their employer or a fund designated by the employer, to pay pensions earned as part of a compensation agreement between the employer and employee. The nature of these claims, and the corresponding liabilities of the units operating the pension funds, depends on the type of benefit promised.

7.191 The two main types of pension schemes are defined-benefit schemes and defined-contribution schemes.[56] In a **defined-benefit scheme**, the level of pension benefits promised by the employer to participating employees and other family members is determined by an actuarial formula based on participants' length of service and salary. In a **defined-contribution scheme**, the level of contributions to the fund is set, but the benefits that will be payable depend on the assets of the fund.

7.192 A pension fund for public sector employees can be managed on behalf of the public sector unit by a public or private insurance corporation, or it can be organized and managed by the public sector unit as an autonomous or nonautonomous pension fund. A nonautonomous pension fund is not a separate unit and the assets of the fund belong to the employer. The employees have a claim against the employer who operates the nonautonomous fund, and the employer has a liability equal to the present value of the promised benefits. For a description of the typology of social protection arrangements, see Appendix 2.

7.193 The liabilities of unfunded pension schemes should also be included in pension entitlements. By its nature, an unfunded employment-related pension scheme must be organized and managed by the employer, which may be a general government unit or a public corporation.

7.194 No liability is recognized in the primary accounts of macroeconomic statistical systems for benefits under social security schemes.[57] The implicit obligation for future social security benefits are reported as a memorandum item to the balance sheet (see paragraph 7.261), regardless of the level of assets in a social security fund or other segregated accounts. Liabilities for the payment of social security benefits that were due to be paid but have not yet been paid are classified as *other accounts receivable/payable* (6308, 6318, 6328). If a social security fund also administers an employment-related pension scheme, those pension obligations are included under pension entitlements, and not as implicit social security obligations.

7.195 As well as pensions, some employment-related schemes may have other related liabilities, such as for health benefits, which are included under entitlements to nonpension benefits.[58] Liabilities for these nonpension entitlements are recorded in macroeconomic statistics only when and to the extent that they exist in the employer's accounts—that is, when reserves for these nonpension entitlements actually exist. For pragmatic reasons, such liabilities for nonpension entitlements may be included with those for pension entitlements.

7.196 In addition to its pension entitlement liabilities to its beneficiaries, a pension fund may sometimes have a claim on the employer, as the pension manager of the scheme. On the other hand, the pension manager may have a claim on the surplus of the pension fund. Such claims are excluded from pension entitlements and are classified as *claims of pension funds on pension manager* (62064, 62164, 62264, 63064, 63164, 63264) (see paragraphs 7.199–7.200).

7.197 Pension entitlements are valued as follows:

- The liability of a defined-benefit pension scheme (including nonautonomous pension funds and unfunded pension schemes) is the present value of the promised benefits.
- The liability of a defined-contribution pension fund is the current market value of the fund's net assets, which is determined according to the performance of the assets acquired with the pension contributions.[59]

7.198 Because the measurement of defined-benefit pension fund entitlements rests on various assumptions and methods, the nature of coverage and estimation should be described in metadata accompanying the balance sheet and other data reports.

[56] Defined-benefit schemes are sometimes referred to as "final salary schemes," while defined-contribution schemes are sometimes referred to as "money-purchase schemes."
[57] Social security schemes are defined in paragraphs 2.100–2.102.
[58] Funded schemes for social insurance other than pensions are not common.
[59] The basis on which pension entitlement is calculated is described in detail in the *2008 SNA*, Chapter 17.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Claims of pension funds on pension manager (62064, 62164, 62264, 63064, 63164, 63264)

7.199 An employer may contract with a third party to administer a pension fund for its employees. If the employer continues to determine the terms of the pension scheme and retains the responsibility for funding any deficit, as well as the right to retain any excess funding, the employer is referred to as the pension manager and the unit working under the direction of the pension manager as the pension administrator. If the agreement between the employer and the administrator is such that the employer passes the risks and responsibilities for any deficit in funding to the administrator in return for the right of the administrator to retain any excess, the latter becomes the pension manager as well as the administrator.

7.200 When the pension manager is a unit different from the administrator, and the responsibility for any deficits, or claims on any excess, rests with the pension manager, the following are recorded in the balance sheet of the pension manager:

- A liability for claims of pension funds on the pension manager, in the case of deficits
- A financial asset in the form of a claim on the pension fund, if the pension fund generates more investment income from the assets it holds than is necessary to cover the increase in pension entitlements
- A counterpart entry should be recorded in imputed social security contributions on a net basis (i.e., an expense to increase the liability and a reduction in the expense when the liability reduce or when government acquires an asset).

Provisions for calls under standardized guarantee schemes (62065, 62165, 62265, 63065, 63165, 63265)

7.201 Standardized guarantees are those kinds of guarantees that are issued in large numbers, usually for fairly small amounts, along identical lines.[60] Operators of standardized guarantee schemes incur liabilities equal to the present value of the expected calls under outstanding guarantees, net of any recoveries the guarantor expects to receive from the defaulting borrowers, a similar approach as for nonlife insurance. This liability is called provisions for calls under standardized guarantees.

7.202 There are three parties involved in these arrangements: the borrower (debtor), the lender (creditor), and the guarantor. Either the borrower or lender may contract with the guarantor to repay the lender if the borrower defaults. Examples are export credit guarantees, deposit guarantees, and student loan guarantees. Standardized guarantees are based on the same paradigm as that for nonlife insurance, and a similar treatment is adopted for these guarantees, as discussed in paragraphs A4.66–A4.80.

Financial derivatives and employee stock options (6207, 6217, 6227, 6307, 6317, 6327)

7.203 Financial derivatives and employee stock options are financial assets and liabilities that have similar features, such as a strike price and some of the same risk elements. However, although both transfer risk, employee stock options are also designed to be a form of remuneration.

Financial derivatives (62071, 62171, 62271, 63071, 63171, 63271)

7.204 A **financial derivative contract** is a financial instrument that is linked to another specific financial instrument, indicator, or commodity and through which specific financial risks (e.g., interest rate risk, foreign exchange risk, equity and commodity price risks, and credit risk) can be traded in their own right in financial markets. Transactions and positions in financial derivatives are treated separately from the values of any underlying items to which they are linked. Financial derivatives are valued at market prices prevailing on balance sheet recording dates. If market price data are unavailable, other fair value methods (e.g., option models or present values) may be used to value them. Compilers are generally constrained to use the parties' own accounts.

7.205 The risk embodied in a financial derivative contract can be traded either by selling the contract itself, as is possible with options, or by creating a new contract embodying risk characteristics that match, in a countervailing manner, those of the existing contract. The latter practice, which is termed offsetability, occurs in forward markets. Offsetability means that it is often

[60] In contrast, one-off guarantees are individual, and guarantors usually cannot reliably estimate the risk of calls. As a result, in most cases, one-off guarantees are considered a contingent liability (unless and until such guarantees are called). For a discussion of contingent liabilities, see paragraphs 7.251–7.260.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

possible to eliminate the risk associated with a derivative by creating a new but reverse contract having characteristics that countervail the risk underlying the first derivative. Buying the new derivative is the functional equivalent of selling the first derivative because the result is the elimination of the underlying financial risk. The ability to countervail the underlying risk in the market is therefore considered the equivalent of tradability in demonstrating value. The outlay that would be required to replace the existing derivative contract represents its value; actual offsetting is not required.

7.206 In many cases, derivatives contracts are settled by payments of net amounts in cash, rather than by the delivery of the underlying items. Once a financial derivative reaches its settlement date, any unpaid overdue amount is reclassified as other accounts receivable/payable, as its value is fixed, and thus the nature of the claim becomes debt.

7.207 The following types of financial arrangements are not financial derivatives:

- A fixed-price contract for goods and services is not a financial derivative unless the contract is standardized so that the market risk therein can be traded in financial markets in its own right. For example, an option to purchase an aircraft from the manufacturer is not classified as a financial derivative; if the option to purchase is transferable, and is in fact transferred, the transaction is recorded under contracts, leases, and licenses, discussed in paragraph A4.52.
- Insurance and standardized guarantees are not financial derivatives. Insurance involves the collection of funds from policyholders to meet future claims arising from the occurrence of events specified in insurance policies. That is, insurance and standardized guarantees are used to manage event risk primarily by the pooling, not the trading, of risk (see paragraph 7.201). However, some guarantees other than standardized guarantees meet the definition of financial derivatives. Those guarantees protect, on a guarantee-by-guarantee basis, the lender against certain types of risk arising from a credit relationship by paying the guarantor a fee for a specified period—these are known as credit derivatives (see paragraph 7.218).
- Contingent assets and liabilities, such as one-off guarantees and letters of credit, are not financial assets (as discussed in paragraph 7.251).
- Instruments with embedded derivatives are not financial derivatives (see paragraph 7.148). If the owner of the primary instrument subsequently creates a new but reverse financial derivative contract to offset the risk of the embedded derivative, the creation of this new financial derivative contract is recorded as a separate transaction, which does not affect the recording of transactions and positions in the primary instrument. However, detachable warrants are treated as separate financial derivatives, because they can be detached and sold in financial markets.
- Timing delays that arise in the normal course of business and may entail exposure to price movements do not give rise to financial derivatives. Timing delays include normal settlement periods for spot transactions in financial markets.

7.208 There are two broad types of financial derivatives—options and forward-type contracts.

Options

7.209 In an **option contract** (option), the purchaser acquires from the seller a right to buy or sell (depending on whether the option is a call (buy) or a put (sell)) a specified underlying item at a strike price on or before a specified date. The purchaser of an option pays a premium to the writer of the option. In return, the buyer acquires the right but not the obligation to buy (call option) or sell (put option) a specified underlying item (real or financial) at an agreed-on contract price (the strike price) on or before a specified date. (On a derivatives exchange, the exchange itself may act as the counterparty to each contract.)

7.210 Options can be contrasted with forward-type contracts in that:

- At inception, there is usually no up-front payment for a forward-type contract and the derivative contract begins with zero value, whereas there is usually a premium paid for an option that reflects the nonzero value of the contract.
- During the life of the contract, for a forward-type contract, either party can be creditor or debtor, and it may change, whereas for an option, the buyer is always the creditor and the writer is always the debtor.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

- At maturity, redemption is unconditional for a forward-type contract, whereas for an option it is determined by the buyer of the option.

7.211 Warrants are a form of financial derivative option giving the owner the right but not the obligation to purchase from the issuer of the warrant a fixed amount of an underlying asset, such as equities and bonds, at an agreed contract price for a specified period of time or on a specified date. Although similar to other traded options, a distinguishing factor is that the exercise of the warrants can create new securities, thus diluting the capital of existing bond- or shareholders, whereas traded options typically grant rights over assets that are already available.

Forward-type contracts

7.212 A **forward-type contract** (forward) is an unconditional contract by which two counterparties agree to exchange a specified quantity of an underlying item (real or financial) at an agreed-on contract price (the strike price) on a specified date. Forward-type contracts include futures and swaps (other than as discussed in paragraph 7.215). The term forward-type contract is used because the term forward is often used more narrowly in financial markets (often excluding swaps).

7.213 Futures are forward-type contracts traded on organized exchanges. The exchange facilitates trading by determining the standardized terms and conditions of the contract, acting as the counterparty to all trades, and requiring a margin to be deposited and paid to mitigate risk. Forward rate agreements and forward foreign exchange contracts are common types of forward-type contracts.

7.214 At the inception of a forward-type contract, risk exposures of equal market value are exchanged, so a contract typically has zero value at that time. As the price of the underlying item changes, the market value will change, although it may be restored to zero by periodic settlement during the life of the forward. The classification of a forward-type contract may change between asset and liability positions.

Other issues associated with financial derivatives

Swap contracts

7.215 A **swap contract** involves the counterparties exchanging, in accordance with prearranged terms, cash flows based on the reference prices of the underlying items. Swap contracts classified as forward-type contracts include currency swaps, interest rate swaps, and cross-currency interest rate swaps. Under a swap contract, the obligations of each party may arise at different times—for example, an interest rate swap for which payments are quarterly for one party and annual for the other. In such cases, the quarterly amounts payable by one party prior to payment of the annual amount payable by the other party are recorded as transactions in the financial derivative contract. Other types of arrangements also called swaps but not meeting the foregoing definition include gold swaps (see paragraph 7.161 for a discussion of their treatment), central bank swap arrangements,[61] and credit default swaps (see paragraph 7.218).

7.216 For foreign currency financial derivative swap contracts, such as currency swaps, it is necessary to distinguish between transactions in a financial derivative contract and transactions in the underlying currencies. At inception, the parties exchange the underlying financial instruments (usually classified as currency and deposits or loans). At the time of settlement, the difference in the values of the currencies swapped, as measured in the unit of account at the prevailing exchange rate, is allocated to a transaction in a financial derivative, with the values swapped recorded in the relevant item (usually currency and deposits, or loans).

7.217 As mentioned in paragraph 7.162, the economic nature of an off-market swap is equivalent to a combination of borrowing (i.e., the lump sum), in the form of a loan, and an on-market swap (financial derivative).

Credit derivatives

7.218 Credit derivatives are financial derivatives whose primary purpose is to trade credit risk. They are designed for trading in loan and security default risk. In contrast, the financial derivatives described in paragraphs 7.215–7.217 are mainly related to market risk, which pertains to changes in the market prices of securities, commodities, interest, and exchange rates. Credit derivatives take the form of both forward-type (total return swaps) and option-type contracts (credit default swaps). Under a credit default swap, premiums are paid in return for a cash payment in the event of a default

[61] See the *BPM6*, paragraphs 6.102–6.104.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

by the debtor of the underlying instrument. Like other financial derivatives, credit derivatives are frequently drawn up under standard master legal agreements and involve collateral and margining procedures, which allow for a means to make a market valuation.

Margins

7.219 Financial derivatives are often subject to margin calls. **Margins** are payments of cash or deposits of collateral that cover actual or potential obligations incurred. The required provision of margin reflects market concern over counterparty risk, especially in markets for futures and exchange-traded options. The classification of margins depends on whether they are repayable or nonrepayable:

- Repayable margin consists of cash or other collateral deposited to protect counterparties against default risk. Ownership of the margin remains with the unit that deposited it. Repayable margin payments in cash are classified as transactions and stock positions in deposits (particularly if the debtor's liabilities are included in broad money) or in other accounts receivable/payable. When a repayable margin deposit is made in an asset other than cash (such as securities), no transaction nor change in stock position is recorded because no change in economic ownership has occurred.
- Nonrepayable margin payments reduce the financial liability position in a derivative. In organized exchanges, nonrepayable margin (sometimes known as variation margin) is paid daily to meet liabilities recorded as a consequence of the daily marking of derivatives to market value. The entity that pays nonrepayable margin no longer retains ownership of the margin nor has the right to the risks and rewards of ownership. Nonrepayable margin payments are classified as transactions in financial derivatives.

7.220 These principles for the classification of margins also apply more generally to margin calls relating to positions in other financial assets.

Employee stock options (62072, 62172, 62272, 63072, 63172, 63272)

7.221 **Employee stock options** are options to buy the equity of a company, offered to employees of the company as a form of remuneration. Employee stock options have similar pricing behavior to financial derivatives, but they have a different nature—including arrangements for the granting and vesting dates—and purpose (i.e., to motivate employees to contribute to increasing the value of the company, rather than to trade risk). If a stock option granted to employees can be traded on financial markets without restriction, it is classified as a financial derivative.

7.222 In some cases, stock options may be provided to suppliers of goods and services to the enterprise. Although these are not employees of the enterprise, for convenience they are also recorded under employee stock options because their nature and motivation is similar. (Whereas the corresponding entry for stock options granted to employees is *wages and salaries in kind* (2112) as discussed in paragraph 6.17, the corresponding entry for stock options granted to suppliers is *use of goods and services* (22).)

7.223 Employee stock options should be valued at fair value at grant date[62] using a market value of equivalent traded options (if available) or using an option pricing model (binomial or Black-Scholes) with suitable allowance for particular features of the options.[63] After the vesting date, employee stock options are valued at market prices.

Other accounts receivable/payable (6208, 6218, 6228, 6308, 6318, 6328)

7.224 **Other accounts receivable/payable** consist of trade credit and advances and miscellaneous other items due to be paid or received. If an economic event requires a subsequent cash flow, for example, goods and services are sold on credit provided by the supplier and the length of time between the economic event and the time of the cash flow is bridged by an entry in other accounts receivable/payable.

7.225 *Trade credit and advances* (62081, 62181, 62281, 63081, 63181, 63281) include (i) trade credit extended directly to purchasers of goods and services and (ii) advances for work that is in progress or to be undertaken, such as progress payments made during

[62] The terms grant date, vesting date, and exercise date are defined in paragraph 9.77.

[63] The International Accounting Standards Board provides detailed recommendations on how employee stock options may be valued, and its recommendations are likely to be followed by corporations using employee stock options as a form of compensation for their employees. The value of the employee stock options varies between grant date and vesting date and then between the vesting date and exercise date, as the value of the shares covered changes.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

construction in advance for work being performed, or for prepayments of goods and services. Such credit arises both from normal delays in receiving payment and from deliberate extensions of vendor credit to finance sales. Trade credit extended by the seller of goods and services does not include loans, debt securities, or other liabilities that are provided by third parties to finance trade. If a government unit issues a promissory note or another type of security to consolidate the payment due on several trade credits, the note or security should be classified as a debt security. Trade credit and advances exclude trade credits that meet the definition of a loan.[64]

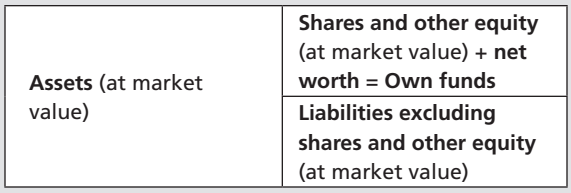
7.226 *Miscellaneous other accounts receivable/payable* (62082, 62182, 62282, 63082, 63182, 63282) include accrued but unpaid taxes, dividends, payment for purchases and sales of securities paid or received before the instrument is issued, rent, wages and salaries, social contributions, social benefits, and similar items. They also include payments due under financial derivative contracts that are in arrears and payments of amounts that have not yet accrued, such as prepayments of taxes. Some of these prepayments, often called "deposits," should be recorded here rather than in currency and deposits. These "deposits" are repayable only when specific conditions are met. Examples of this type of "deposit" included under miscellaneous other accounts receivable/payable are deposits held by court or tax authorities pending resolution of a dispute, deposits payable in advance to cover breakages or nonpayment for the use of goods and services, and bail deposits. In principle, accrued but unpaid interest should be added to the principal of the underlying asset rather than included in this category. Taxes receivable and/or compensation of employees payable should be separately identified if the amounts are substantial.

[64] A supplier of goods or services may have a claim on a government unit in the form of a trade credit. When the supplier transfers this claim completely and irrevocably to a financial institution (notably a unit engaged in factoring activity), the original liability of the government unit recorded as trade credit in other accounts payable should be reclassified (by way of other changes in the volume of assets) as a loan when the following two conditions are both met: (i) the government unit has no longer any payment obligation to its supplier, and (ii) the financial institution has no direct or indirect recourse on the supplier (transferor of the claim) if the government unit does not meet its payment obligations in due time. Also, if a trade credit is restructured in such a way that it meets the definition of a loan, it should be reclassified as a loan.

7.227 Other accounts receivable/payable should be recorded at nominal value. By definition, other accounts receivable/payable are accrual concepts and do not exist in an accounting system that uses a pure cash basis of recording.

Net Worth

7.228 As defined in paragraph 7.1, ***net worth*** (6) of an institutional unit (or grouping of units) is the total value of its assets minus the total value of its liabilities. Net worth is a balancing item that stems from valuing assets and liabilities (including equity and investment fund shares) at their market prices on the balance sheet date. Net worth can be positive, negative, or zero. As with other balancing items in GFS, net worth cannot be measured independently of the other entries.



7.229 For most government units, the net worth is the economic value of the unit because they usually have no issued shares and other equity. In the case of quasi-corporations, net worth is zero, because the value of the owners' equity is assumed to be equal to its assets minus its liabilities. Even when general government units have liabilities in the form of equity (see paragraph 7.170), the net worth of such government units is zero, similar to that of quasi-corporations, if these shares are not traded or the value of the shares cannot be determined independently. For other corporations, net worth is a component of own funds. In macroeconomic statistics, own funds and net worth have a specific meaning, which may differ from the understanding of these terms within the context of accounting.

7.230 When an autonomous pension fund operates as a defined contribution scheme, the net worth will be zero, because by definition the claims on the pension fund are equal to the assets of the fund. However, a defined-benefit pension scheme operated by an insurance corporation or as an autonomous pension fund can have a net worth, positive or negative, if the assets of the fund exceed or fall short of the fund's liability for the pension benefits, unless there is a claim of the pension fund on the pension manager—in which instance the net worth is also zero (see paragraphs 7.199–7.200).

7.231 Own funds are defined as the difference between total assets (at market values) and total liabilities excluding shares and other equity (at market value). From the foregoing, it follows that the value

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Figure 7.1 Net Worth in a Macroeconomic Statistics Balance Sheet

of own funds is equal to the value of shares and other equity (at current market prices on the balance sheet date) plus net worth, as illustrated in Figure 7.1.

7.232 In the case of quasi-corporations, their imputed shareholders' equity is equal to their own funds. Public corporations are seen to have a net worth (which could be positive or negative) in addition to the value of the shareholders' equity, if shares are traded in the market or the value can be determined independently. This is because shares are included in the public corporation's balance sheet at their current market price on the balance sheet date.

7.233 If the current market value of equity and investment fund shares cannot be determined independently or they do not trade in the market, an alternative calculation is similar to the treatment of quasi-corporations (see paragraph 7.232). This calculates the value of equity and investment fund shares in such a way that the net worth of the public corporation is zero.

Memorandum Items

7.234 It may be desirable to record memorandum items to provide supplemental information about items (such as aggregates and balancing items) related to, but not included on, the balance sheet. Table 7.10 shows the memorandum items to the balance sheet proposed in the GFS framework (additional items and subitems may be added, as needed).

Net Financial Worth (6M2)

7.235 The ***net financial worth*** (6M2) of an institutional unit (or grouping of units) is the total value of its financial assets minus the total value of its liabilities. This balancing item is often cited because of the general government and public sectors' influence on the financial system and also because of the difficulties in valuing government-unique nonfinancial assets.

Table 7.10 Classification of Memorandum Items to the Balance Sheet

6M2	Net financial worth
6M3	Gross debt at market value
6M4	Gross debt at nominal value
6M35	Gross debt at face value
6M36	Net debt at market value
6M37	Net debt at nominal value
6M38	Net debt at face value
6M391	Concessional loans at nominal value
6M392	Implicit transfers resulting from loans at concessional interest rates
6M5	Arrears
6M6	Explicit contingent liabilities[1]
6M61	Publicly guaranteed debt
6M62	Other one-off guarantees
6M63	Explicit contingent liabilities not elsewhere classified
6M7	Net implicit obligations for social security benefits[1]
6M8	Nonperforming loan assets at fair value
6M81	Nonperforming loan assets at nominal value

[1]The contingent liabilities are shown in the *Summary Statement of Explicit Contingent Liabilities and Net Implicit Obligations for Future Social Security Benefits* (Table 4.6).

Debt[65]

Gross debt

7.236 Total **gross debt**—often referred to as "total debt" or "total debt liabilities"—consists of all liabilities that are debt instruments. A **debt instrument** is defined as a financial claim that requires payment(s) of interest and/or principal by the debtor to the creditor at a date, or dates, in the future. The following instruments are debt instruments:

- Special Drawing Rights (SDRs)
- Currency and deposits
- Debt securities
- Loans
- Insurance, pension, and standardized guarantee schemes [GFS]
- Other accounts payable.

[65] For a detailed discussion on the compilation of public sector debt, see the *PSDS Guide*.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

7.237 From the foregoing list, it follows that all liabilities included in the GFS balance sheet are considered debt, except for liabilities in the form of *equity and investment fund shares* and *financial derivatives and employee stock options*. Equity and investment fund shares are not debt instruments because they entitle the holders to dividends and a claim on the residual value of the unit. Financial derivatives are not debt instruments because they do not supply funds or other resources, but rather shift the exposure to risks from one party to another.

7.238 As recommended in the *PSDS Guide*, debt instruments should be valued on the reference date at nominal value, and, for traded debt securities, at market value as well. Both valuation bases provide useful information about debt. If the nominal and market values of debt instruments are not available, gross debt is at face value. Deviations from these valuation principles should always be specified in the footnotes to the balance sheet.

7.239 These valuations of gross debt are discussed, in turn, in paragraphs 7.240–7.242. For more details on valuation, see paragraphs 3.107–3.129.

Gross debt at market value (6M3)

7.240 *Gross debt at market value* (6M3) means that debt securities are valued at market prices; insurance, pension, and standardized guarantee schemes are valued according to principles that are equivalent to market valuation; and all other debt instruments are valued at nominal prices, which are considered to be the best generally available proxies of their market prices.

Gross debt at nominal value (6M4)

7.241 *Gross debt at nominal value* means that debt securities are valued at their nominal values. The nominal value of a debt instrument at any moment in time is the amount that the debtor owes to the creditor. This is a measure of value from the viewpoint of the debtor.

Gross debt at face value (6M35)

7.242 The **face value** of a debt instrument is the undiscounted amount of principal to be repaid at (or before) maturity and has been called nominal value in some cases. The use of face value as a proxy for nominal value in measuring the gross debt position can result in an inconsistent approach across all instruments and is not recommended, unless nominal and market values are not available.

Net debt

7.243 Net debt is calculated as gross debt minus financial assets corresponding to debt instruments.[66] Financial assets corresponding to debt instruments are:

- Monetary gold and Special Drawing Rights (SDRs)
- Currency and deposits
- Debt securities
- Loans
- Insurance, pension, and standardized guarantee schemes [GFS]
- Other accounts receivable.

7.244 Monetary gold, as defined in the *2008 SNA* and this *Manual*, includes elements of a debt instrument (unallocated gold accounts) and a nondebt instrument (gold bullion). In principle, the gold bullion element of monetary gold should be excluded from the calculation of net debt. However, in practice, the total amount for monetary gold may have to be used in the net debt calculation because compilers of public sector debt statistics may not be able to exclude the gold bullion element.

7.245 *Net debt* can be calculated at *market value* (6M36), *nominal value* (6M37), and *face value* (6M38).

Concessional loans

7.246 Loans with concessional interest rates could be seen as providing a benefit to the borrower in the form of a transfer equal to the difference between the actual interest payable and the amounts that would

[66] This category calculates net debt as total debt liabilities minus all financial assets corresponding to debt instruments. For some purposes, it may be useful to net individual debt instruments against their corresponding financial assets. For other purposes, it may be useful to calculate debt net of highly liquid assets. However, in most cases, a one-on-one netting of a debt instrument against its corresponding financial asset may not be analytically useful because, typically, specific types of assets are not earmarked to repay specific types of liabilities. Debt net of highly liquid assets is, in most cases, equal to gross debt minus financial assets in the form of currency and deposits. However, in some cases, debt securities held for debt management purposes could be included as highly liquid financial assets.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

be payable if market-equivalent interest prevailed. If such a transfer were recognized, it would usually be recorded as current transfer/grant (depending on the type of recipient), and the interest recorded would be adjusted by the same amount. However, the means of incorporating the impact of concessional rates within macroeconomic statistics have not fully evolved, although various alternatives have been advanced.[67] Accordingly, until the treatment is agreed, information on concessional debt should be provided through supplementary information in the form of two memorandum items. The first shows the stock of *concessional loans at nominal value* (6M391). The second shows an estimate of the value of the benefit transferred to the borrower—that is, the value of *implicit transfers resulting from loans at concessional interest rates* (6M392), calculated as described in footnote 67.

Arrears (6M5)

7.247 **Arrears** are defined as amounts that are both unpaid and past the due date for payment. In principle, amounts payable for any expense, acquisition of assets, or related to any liability may be in arrears.[68] For debt liabilities, arrears arise when principal or interest payments are not made when due. For expense and the acquisition of nonfinancial assets, amounts payable may be in arrears from inception. For example, when amounts payable for compensation of employees are not made when due, the other accounts payable for compensation of employees are in arrears. Also, when a contract stipulates payment on delivery for goods and services or nonfinancial assets and such amounts payable are not settled on delivery, other accounts payable for these goods and services or nonfinancial assets are in arrears from inception.

7.248 When arrears in an existing liability occur, they should continue to be shown in the same instrument until the liability is extinguished. However, if the contract provides for a change in the characteristics of a financial instrument when it goes into arrears, this change should be recorded as a reclassification through other changes in the volume of assets and liabilities (see paragraphs 3.97, 9.21, and 10.84).

7.249 If under a cash accounting system, arrears are not recorded separately, compilers will need to collect supplementary information to estimate arrears. Information on arrears is useful for various kinds of policy analyses and solvency assessments and should be shown as a memorandum item in the balance sheet where significant. Information on arrears should continue to be collected from their creation—that is, when payments are not made—until they are extinguished, such as when debt arrears are repaid, rescheduled, or forgiven by the creditor, or when (say) wages and salaries in arrears are paid.

7.250 The nominal value of arrears is equal to the value of the payments—interest and principal in the case of liabilities—missed, and any subsequent economic flows, such as the accrual of additional interest on a liability in arrears, or the settlement of arrears. (See also paragraphs 9.22–9.23.)

Explicit Contingent Liabilities (6M6)

Overview

7.251 Contingent liabilities create fiscal risks[69] and may arise from deliberate public policy or from unforeseen events, such as a financial crisis. **Contingent liabilities** are obligations that do not arise unless a particular, discrete event(s) occurs in the future. A key difference between contingent liabilities and liabilities[70] is that one or more conditions must be fulfilled before

[67] The one-off benefit at the point of loan origination can be calculated as being equal to the difference between the nominal value of the debt and its present value using a relevant market discount rate. This option has the advantage of considering all the possible sources of transfers in debt concessionality—maturity period, grace period, and frequency of payments, as well as the interest rate—and is consistent with nominal valuation of loans. Such an approach should be used for official lending involving an intention to convey a benefit and occurrence in a noncommercial setting (usually government-to-government). For example, in debt reorganization through the Paris Club, debt reduction in present value terms is calculated using a market-based discount rate, usually the OECD's Commercial Interest Reference Rate (CIRR). The difference between the nominal value of the applicable debt and its present value is the amount of capital transfer derived from the debt reorganization arrangements. For more details, see the *PSDS Guide*, paragraphs 4.83–4.86. For the treatment of concessional loans to employees, see paragraph 6.17.

[68] In some cases, arrears arise for operational reasons (such as minor administrative delays) rather than from a reluctance or inability to pay. Nonetheless, in principle, such arrears should be recorded as arrears when outstanding at the reference date.

[69] At the most general level, fiscal risks may be defined as any potential differences between actual and expected fiscal outcomes (e.g., fiscal balances and public sector debt). Contingent liabilities are a specific source of potential fiscal risk.

[70] Liabilities refer to those obligations recognized on a macroeconomic statistics balance sheet in the calculation of an institutional unit's net worth. Contingent liabilities are not included on the balance sheet (i.e., contingent liabilities are not taken into account in the calculation of a unit's net worth).

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

a contingent liability is recognized as a liability. With contingent liabilities, there is typically uncertainty over whether a payment will be required, and its potential size.[71]

7.252 A distinction is made between explicit and implicit contingent liabilities. **Explicit contingent liabilities** are defined as legal or contractual financial arrangements that give rise to conditional requirements to make payments of economic value. The requirements become effective if one or more stipulated conditions arise. By contrast, **implicit contingent liabilities** do not arise from a legal or contractual source but are recognized after a condition or event is realized. While the focus of GFS (and other macroeconomic statistical systems) is largely on explicit contingent liabilities, implicit contingent liabilities, such as the net implicit obligations for future social security benefits (see paragraph 7.261), are important factors in fiscal risk and vulnerability analyses. Other examples of implicit contingent liabilities include ensuring the solvency of the banking sector, covering the obligations of subnational governments (state and local governments) or the central bank in the event of a default, assuming unguaranteed debt of public sector units, and potential spending for natural disaster relief.[72]

7.253 Figure 7.2 provides an overview of liabilities and contingent liabilities in macroeconomic statistics. Explicit contingent liabilities can take a variety of forms, although guarantees are the most common. However, not all guarantees are contingent liabilities; as discussed earlier in this chapter, guarantees in the form of financial derivatives and provisions for calls under standardized guarantee schemes are liabilities on the balance sheet. On the other hand, one-off guarantees are contingent liabilities.

7.254 Explicit contingent liabilities comprise:

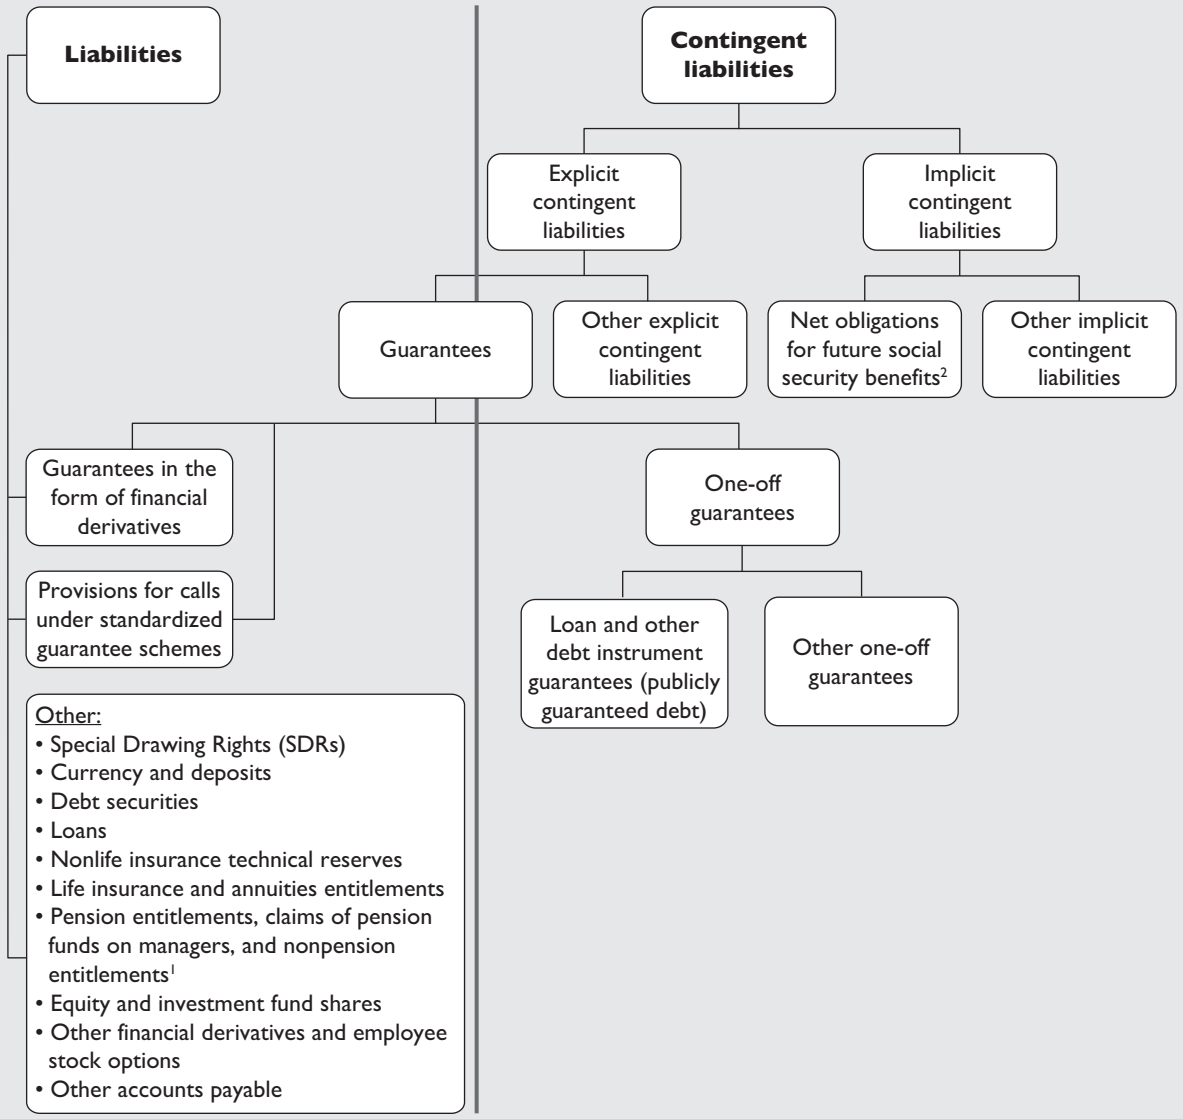
- *Publicly guaranteed debt* (6M61), which is one-off guarantees in the form of loan and other debt instrument guarantees (see paragraphs 7.259–7.260)
- *Other one-off guarantees* (6M62) for other than publicly guaranteed debt (see paragraphs 7.259–7.260)
- *Explicit contingent liabilities not elsewhere classified* (6M63), which are explicit contingent liabilities that are not in the form of guarantees—for example:
  - Potential legal claims, which are claims stemming from pending court cases[73]
  - Indemnities, which are commitments to accept the risk of loss or damage another party might suffer (e.g., indemnities against unforeseen tax liabilities arising in government contracts with other units)
  - Uncalled capital, which is an obligation to provide additional capital, on demand, to an entity of which it is a shareholder (e.g., an international financial institution)
  - Potential payments resulting from PPP arrangements.

7.255 Information on the stock positions of one-off guarantees is relevant for public financial policy and analysis—particularly the stock position of publicly guaranteed debt. It is recommended that *publicly guaranteed debt* (6M61) should be shown, at nominal value, as a memorandum item to the balance sheet. If significant, information on *other one-off guarantees* (6M62) and *explicit contingent liabilities not elsewhere classified* (6M63) should also be included as a memorandum item to the balance sheet, at nominal value.[74] One-off guarantees are discussed in paragraphs 7.256–7.260.

One-off guarantees

7.256 One-off guarantees comprise those types of guarantees where the debt instrument is so particular that it is not possible to calculate the degree of risk

[71] Uncertainty about the potential size of liabilities does not make them contingent liabilities.



[72] It is recommended in this *Manual* (and the *PSDS Guide*) to include as a separate memorandum item in the balance sheet the net obligations for future social security benefits—often the largest implicit contingency of government.

[73] A pending legal case may also be a contingent asset—for example, a case in which the government has claimed damages against another party.

[74] Limitations of this approach are that it offers no information on the likelihood of the contingency occurring and it may overstate the possible risk. For loan and other debt instrument guarantees, the maximum potential loss is likely to be less than their nominal value, because not all debts will default. There are several other approaches that address limitations to valuing explicit contingent liabilities; they are discussed in detail in Chapter 4 of the *PSDS Guide* and in Chapter 9 of the *EDS Guide*. The actual approach adopted will depend on the availability of information on the type of contingency. For this reason, it is particularly important to provide metadata on the method(s) used to value contingent liabilities.

Figure 7.2 Overview of Liabilities and Contingent Liabilities in Macroeconomic Statistics

[1] Includes liabilities for nonautonomous unfunded employer pension schemes.
[2] Excludes liabilities for nonautonomous unfunded employer pension schemes.

associated with the debt with any degree of accuracy. In contrast to standardized guarantees, one-off guarantees are individual, and guarantors are not able to make a reliable estimate of the risk of calls.

7.257 In most cases, a one-off guarantee is considered a contingent liability of the guarantor. Liabilities under one-off guarantees continue to be attributed to the debtor, not the guarantor, unless and until the guarantee is called.

7.258 In contrast, a one-off guarantee granted by government to a corporation in financial distress and with a very high likelihood to be called is treated as if the guarantee is called at inception.[75] The activation

[75] Such treatment should be undertaken with caution, not least to avoid double-counting of the debt and inconsistencies with other macroeconomic statistics (which still record the claim to the original debtor). Eurostat uses the following practical guidance with regards to publicly guaranteed debt: if government, as a guarantor, makes a payment on an existing guaranteed debt in three consecutive years,

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

of such a one-off guarantee is treated as debt assumption[76] and this liability is part of the public sector unit's balance sheet.

7.259 One-off guarantees may be grouped into loan and other debt instrument guarantees and other one-off guarantees:

- **Loan and other debt instrument guarantees**—or one-off guarantees of payment—are commitments by one party to bear the risk of nonpayment by another party. Guarantors are required to make a payment only if the debtor defaults. Loans and other debt instrument guarantees constitute publicly guaranteed debt that is defined as debt liabilities of public and private sector units, the servicing of which is contractually guaranteed by public sector units.
- **Other one-off guarantees** include credit guarantees (such as lines of credit and loan commitments), contingent credit availability guarantees, and contingent credit facilities. Lines of credit and loan commitments provide a guarantee that undrawn funds will be available in the future, but no financial liability/asset exists until such funds are actually provided. Undrawn lines of credit and undisbursed loan commitments are contingent liabilities of the issuing institutions—generally, banks. Letters of credit are promises to make payment upon the presentation of pre-specified documents. Underwritten note issuance facilities provide a guarantee that a borrower will be able to issue short-term notes and that the underwriting institution(s) will take up any unsold portion of the notes. Only when funds are advanced by the underwriting institution(s) will a liability/asset be created. The unutilized portion is a contingent liability. Other note guarantee facilities providing contingent credit or back-up purchase facilities are revolving underwriting facilities, multiple options facilities, and global note facilities. Bank and nonbank financial institutions provide back-up purchase facilities. Again, the unutilized amounts of these facilities are contingent liabilities.

7.260 Loan and other debt instrument guarantees (publicly guaranteed debt) differ from the other types of one-off guarantees. This is because the guarantor guarantees the servicing of an existing debt of other public and private sector units. With the other one-off guarantees, no financial liability/asset exists until funds are provided or advanced.

Net Implicit Obligations for Future Social Security Benefits (6M7)

7.261 As explained in paragraphs 7.194 and A2.39, no liability is recognized in macroeconomic statistical systems for social security benefits—such as retirement benefits (other than employment-related pensions) and health care benefits—payable in the future.[77] These implicit obligations to pay social security benefits in the future are not contractual obligations and are therefore not recorded on the balance sheet (see paragraph 7.252). The present value of social security benefits that have already been earned according to the existing laws and regulations but are payable in the future should be calculated in a manner similar to the liabilities of an employment-related pension scheme. This amount minus the present value of social security scheme contributions provides an indication of the net implicit obligations that a government unit has for social security benefits payable in the future.

Nonperforming Loan Assets at Fair Value (6M8)

7.262 Nonperforming loans are those for which (i) payments of principal and/or interest are past due by three months (90 days) or more; or (ii) interest payments equal to three months (90 days) interest or more have been capitalized (reinvested to the principal amount) or payment has been delayed by agreement; or (iii) evidence exists to reclassify a loan as nonperforming even in the absence of a 90-day past due payment, such as when the debtor files for bankruptcy. The amount of nonperforming debt outstanding remains a legal liability of the debtor and interest should continue to accrue, unless the liability has been extinguished (e.g., by repayment or as a result of a bilateral arrangement between debtor and creditor).

and this situation is expected to continue, then the debt is considered to be assumed, normally in its entirety (or for the proportion government is expected to repay, if there is evidence of that).

[76] Debt assumption is discussed in paragraphs A3.26–A3.31.

[77] In contrast, social security benefits due for payment but not yet paid are included as other accounts payable in a public sector unit's balance sheet. Also included in the balance sheet (and thus excluded from implicit contingent liabilities) are public sector units' liabilities for unfunded nonautonomous pension schemes for their employees.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

7.263 As mentioned earlier in this chapter, loans are recorded at nominal value (i.e., the amount advanced plus interest accrued and not paid minus any repayments). It is recognized that nominal value provides an incomplete view of the financial position of the creditor, particularly when the loans are nonperforming. In such cases, information on the *nominal value* (6M81), as well as the *fair value* (6M8),[78] of nonperforming loan assets should be included as a memorandum item to the balance sheet.

Classification of the Counterparty of Financial Assets and Liabilities by Institutional Sector

7.264 The preceding section discussed the classifications of financial assets and liabilities based on the characteristics of the instrument underlying the claim. For a fuller understanding of financial assets and liabilities of the general government or the public sector, the counterparties to these financial relationships should also be considered. For example, a classification of liabilities according to the economic sectors providing the financing (i.e., the sources of funding) complements the classification by type of financial instrument. Information on debtor-creditor relationships between sectors and subsectors is essential for proper consolidation of GFS. A classification of financial assets and liabilities according to whether the counterparty is a public or private nonfinancial or financial corporation, respectively, will be necessary to compile accurate consolidated general government or public sector balance sheets.

7.265 Two parties are associated with all financial claims. As a result, it is possible to cross-classify the financial instruments of financial claims with the sector of the counterparty, making a distinction between resident and nonresident units.[79] This supplemental classification is presented in Table 7.11, which should be compiled separately for financial assets and liabilities.[80]

[78] The concepts nominal value and fair value are described in paragraph 3.115.

[79] Although gold bullion has no counterparty, by convention, the counterparty to the stock position in gold bullion is shown as "other nonresidents" in Table 7.11.

[80] See Chapter 2 of this *Manual*, and the *2008 SNA*, Chapter 4, for a description of sector classification. Issues in the identification of counterparties of traded debt securities are discussed in the *PSDS Guide*, Chapter 7.

Classification of Debt Liabilities and Financial Assets Corresponding to Debt Instruments by Maturity

7.266 A supplementary classification of debt liabilities and financial assets corresponding to debt instruments by maturity and type of financial instrument provides information on the liquidity dimensions of debt. The **maturity of a debt instrument** refers to the time until the debt is extinguished according to the contract between the debtor and the creditor. A debt instrument's maturity can be either short-term or long-term:

- Short-term is defined as payable on demand or with a maturity of one year or less. This category includes arrears and interest on arrears.
- Long-term is defined as having a maturity of more than one year or no stated maturity (other than debt repayable on demand, which is considered short-term).

7.267 Maturity may relate to:

- Original maturity, which is the period from the issue date until the final contractually scheduled payment date, or
- Remaining maturity or residual maturity, which is the period from the reference date (balance sheet date) until the final contractually scheduled payment date.

7.268 This *Manual* recommends a three-way classification (see Table 7.12) that allows for deriving debt statistics on both original and remaining maturity bases:

- Short-term debt on an original maturity basis
- Long-term debt due for payment within one year or less
- Long-term debt due for payment in more than one year.

7.269 To derive short-term debt on a remaining maturity basis, the second bullet above can be combined with the first bullet above. To derive long-term debt on an original maturity basis, the second bullet above can be combined with the third bullet above. Other aggregates on an original or a remaining maturity basis can be derived directly from Table 7.12. The classification codes in Table 7.12 correspond to those in Table 7.9; only a suffix has been added to indicate the type of maturity.

7.270 Measuring the value of outstanding long-term public sector debt (original maturity) falling due in one year or less may raise practical difficulties, in which instance, one proxy measure that may be used is the undiscounted value of principal payments on long-term public sector debt liabilities (original maturity basis) due to mature in one year or less. This proxy measure is incomplete in its coverage of interest payments falling due in the coming year but can be compiled using the principles for projecting payments in a debt-service schedule.

7.271 Statistics on a remaining maturity basis permit an assessment of liquidity risk by indicating when public sector debt payments will fall due. Information on payments becoming due in the short- to near-term is particularly relevant for this analysis. Statistics on a remaining maturity basis are also used for debt management purposes. Statistics on an original maturity basis provide an indication of the borrower's credit-worthiness and the type of markets in which it is borrowing.

8 Transactions in Nonfinancial Assets

This chapter describes transactions in nonfinancial assets and their classification.

Introduction

8.1 Chapter 7 describes the balance sheet and the assets and liabilities recorded on it. As an integrated framework, GFS also includes the flows necessary to explain all changes between the balance sheet at the beginning of the period and the balance sheet at the end of the reporting period. As described in paragraphs 3.1–3.4, there are two types of flows—transactions and other economic flows—both of which can affect stock positions of assets and liabilities. This chapter describes the transactions that affect stock positions of nonfinancial assets. Chapter 9 describes the transactions that affect stock positions of financial assets and liabilities, and Chapter 10 describes other economic flows.

8.2 For each category of nonfinancial assets, there is an accounting identity linking successive balance sheets.[1] The identity states that:

The value of a category of nonfinancial assets on the balance sheet at the beginning of the reporting period

plus

The total value of that category of nonfinancial assets acquired in transactions during the reporting period

minus

The total value of that category of nonfinancial assets disposed of in transactions during the reporting

minus

The value of consumption of fixed capital for that category of nonfinancial assets during the reporting period

plus

The net value of other economic flows that affect that category of nonfinancial assets during the reporting period

equals

The value of the category of nonfinancial assets on the balance sheet at the end of the reporting period.

This identity requires that transactions, other economic flows, and stock positions be recorded consistently with regard to time of recording and valuation. The accounting rules governing these factors are described in Chapter 3.

8.3 Transactions can change stock positions of nonfinancial assets in different ways and all must be accounted for. The more important types of transactions follow:

- Existing assets of all types can be acquired from or disposed to other units by purchase/sale, barter, or transfer in kind.
- Newly produced fixed assets, inventories, and valuables can be sold or otherwise disposed of by their producers in the same manner as existing assets, or the producers can retain them for their own use.
- A government unit may produce goods and services for own use as fixed assets (i.e., own-account fixed capital formation). These transactions are classified as acquisitions of fixed assets (and shown as a memorandum item).
- Renovations, reconstructions, or enlargements that significantly increase the productive capacity or extend the service life of an existing fixed asset are classified as acquisitions of fixed assets even though physically they function as part of the existing asset. Land improvements are a separate category of fixed assets, distinct from the nonproduced land asset.

[1] With the exception of consumption of fixed capital, the same identity could be applied to financial assets and liabilities.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

- Consumption of fixed capital is an internal transaction that records the decrease in the value of fixed assets because they have been used repeatedly or continuously in production.
- Inventories can be acquired (additions) or disposed of (withdrawals) through internal transactions as well as transactions with other units. For example, withdrawals from inventories of materials and supplies for use in the production of general government services and transfers of completed production from work-in-progress inventories to inventories of finished goods are internal transactions. Recurrent losses and spoilage of goods held in inventories are also treated as internal transactions.

8.4 All transactions that increase a unit's holdings of nonfinancial assets are labeled acquisitions. With the exception of consumption of fixed capital, all transactions that decrease a unit's holdings of nonfinancial assets are labeled disposals. Thus, the results of transactions in a particular category of nonfinancial assets can be presented either as total acquisitions, total disposals, and consumption of fixed capital, or as *net investment in nonfinancial assets*.[2] The net investment in a nonfinancial asset is its acquisitions minus disposals minus consumption of fixed capital. The gross investment in a nonfinancial asset is its acquisitions minus disposals (i.e., consumption of fixed capital is not taken into account). On a cash basis, the purchases minus the sales of nonfinancial assets are referred to as the *net cash outflow from investment in nonfinancial assets*.

8.5 The remainder of this chapter first describes costs of ownership transfer, valuation, time of recording, consumption of fixed capital, and netting of transactions that affect nonfinancial assets and then provides details on the classification of transactions that affect specific categories of nonfinancial assets.

Costs of Ownership Transfer

8.6 Costs of ownership transfer are the costs associated with acquiring and disposing of nonfinancial assets (other than inventories[3]) and consist of:

- All professional charges or commissions incurred by both units acquiring or disposing of an asset, such as fees paid to lawyers, architects, surveyors, engineers, and valuers, and commissions paid to estate agents and auctioneers
- Any trade and transport costs separately invoiced to the purchaser
- All taxes payable by the unit acquiring the asset on the transfer of ownership of the asset
- Any tax payable on the disposal of an asset
- Any delivery and installation or disinstallation costs not included in the price of the asset being acquired or disposed of
- Any terminal costs[4] incurred at the end of an asset's life, such as those required to render the structure safe or to restore the environment in which it is situated.

8.7 The costs of ownership transfer on fixed assets, valuables, and nonproduced assets are treated as transactions in fixed assets. In particular, transactions in the:

- Costs of ownership transfer on fixed assets are recorded as transactions in the relevant fixed asset
- Costs of ownership transfer on valuables are recorded as transactions in *valuables* (312.1)
- Costs of ownership transfer on land are recorded, by convention, with *land improvements* (31114.1), a fixed asset
- Costs of ownership transfer on nonproduced assets other than land are recorded in fixed assets as transactions in *costs of ownership transfer on nonproduced assets other than land* (31133.1), as explained in paragraph 8.42; in the balance sheet, however, these costs of ownership transfer on nonproduced assets other than land are incorporated in the value of the asset to which they relate (see paragraph 3.111), even though the asset is nonproduced (i.e., there are no costs of ownership transfer on nonproduced assets other than land shown separately in the balance sheet).

[2] The net investment in inventories is referred to as "changes in inventories." Net investment in nonfinancial assets can be positive or negative.

[3] Usually, there are no costs of ownership transfer on inventories.

[4] In the case of some significantly large and important assets, such as oil rigs and nuclear power stations, there may also be major costs associated with the decommissioning of the asset at the end of its productive life. For some land sites, such as those used for landfill, there may be large costs associated with rehabilitation of the site. These are referred to collectively as terminal costs.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

8.8 Costs of ownership transfer are attributed to the purchaser or seller of the asset according to which unit bears the responsibility of meeting the costs. These costs of ownership transfer should be written off as consumption of fixed capital, as discussed in paragraph 6.60. Interest and other financing charges incurred in connection with a transaction are not costs of ownership transfer.

Valuation

8.9 General principles for valuation of transactions in assets and liabilities are discussed in paragraphs 3.108–3.112. Acquisitions and disposals of fixed assets and valuables are valued at market prices (i.e., exchange value plus costs of ownership transfer). Fixed assets acquired through barter or transfer in kind are valued at a market price-equivalent. Fixed assets produced for own-account capital formation or for transfers in kind are valued at their estimated market prices before adding any taxes less subsidies, transport, or distribution margins, or by their costs of production when satisfactory estimates of market prices cannot be made.[5]

8.10 Additions to and withdrawals from inventories are valued at market prices applicable at the time of the addition or withdrawal, which in the case of withdrawals may be quite different from their value when acquired.[6] No costs for installation or ownership transfer are added or subtracted for transactions in inventories.

8.11 Acquisitions and disposals of land are valued at their exchange value, and the costs of ownership transfer on land are included, by convention, with *land improvements* (311141.1). Acquisitions and disposals of nonproduced assets other than land are valued at their exchange value. The costs of ownership transfer on nonproduced assets other than land are recorded as a separate category of fixed assets, *costs of ownership transfer on nonproduced assets other than land* (31133.1), as explained in paragraph 8.42.

8.12 General government units may acquire or dispose of nonfinancial assets on a nonmarket basis as an element of their fiscal policy, either by purchasing an asset for more than its market value or by selling an asset for less than its market value. By their nature, such transactions involve a transfer component. If the asset's market value can be determined, then the transaction should be valued at that amount and a second transaction should be recorded as an expense to account for the transfer.[7] Usually, however, there is not an active market for the assets and it is difficult to estimate a market value. In this case, the value of the acquisition or disposal should be the amount of economic value exchanged, which could be in the form of ownership rights on physical objects (e.g., a dwelling) or intangible assets (e.g., a film original).

Time of Recording

8.13 As described in paragraph 3.62, on an accrual basis, transactions are recorded at the time economic value is created, transformed, exchanged, transferred, or extinguished. For transactions in nonfinancial assets, this time is when the economic ownership of the nonfinancial assets is obtained or relinquished. On a cash basis, transactions are recorded when cash payments are made.

8.14 Transactions (including by barter, payment in kind, or transfer in kind)[8] in nonfinancial assets are, in principle, recorded the moment when economic ownership changes, which often may depend on the provisions in the sales contract. When change of ownership is not obvious, the time of recording by the transaction partners[9] may be a good indication and, failing that, the moment when there is a change in physical possession or control.

8.15 The time of recording of the acquisition of a new nonfinancial asset depends on how the asset is acquired.

[5] In GFS, it is assumed that market prices of fixed assets constructed by general government units will not be known, and these values are calculated as the sum of expense on compensation of employees, use of goods and services, and the consumption of fixed capital used for own-account production of these assets. This treatment also applies to the production of valuables and major improvements to land when carried out on own account.

[6] Holding gains on inventories are discussed in paragraphs 10.16–10.17.

[7] The expense often will be a capital transfer to a market enterprise and classified as *capital transfers not elsewhere classified* (2822). It would be a capital grant if the recipient is a general government unit. For inventories, this type of transfer is a subsidy (see paragraph 6.91).

[8] These acquisitions and disposals are excluded from a pure cash basis of recording.

[9] To maintain symmetry in the macroeconomic system, the time of recording should be the same for both partners to the transaction.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

- If the asset is acquired from the producing unit as a finished good, then the timing is determined in the same manner as for the purchase of an existing asset—that is, when economic ownership changes hands. Typically, this time is not the time at which the asset was produced or the time at which it is put to use in production.
- When another unit produces buildings and structures under a contract of sale agreed in advance with the general government unit, and the production extends over more than one reporting period, then ownership of the structure is deemed to be transferred to the government unit as work proceeds; stage or progress payments may approximate the value of the transactions in fixed assets to be recorded.[10] In the absence of a contract of sale, the incomplete production each period is added to work in progress of the contractor (see also paragraph 7.37).
- When production is carried out on own account, there is no formal transfer of ownership. The producing unit effectively takes possession progressively as production proceeds, so that the asset is acquired as each transaction involved in its production is recorded. For example, if a government unit constructs a building using its own workforce, then each use of goods and services and work performed by employees is classified as an acquisition of the fixed asset as work takes place.

8.16 Consumption of fixed capital, in principle, should be recorded continuously throughout each reporting period. In practice, consumption of fixed capital can be computed only after the end of the reporting period because its value depends on the average price of the asset over the entire reporting period (see paragraphs 6.53–6.61).

8.17 Fixed assets acquired or disposed of by means of a financial lease are deemed to be acquired or disposed of when the lease is signed or economic control of the asset otherwise changes hands.

Consumption of Fixed Capital

8.18 Consumption of fixed capital is an internal transaction that reflects the fact that an institutional unit used up a portion of each of its fixed assets through its productive activities during the reporting period and the value of those assets declined correspondingly. As a result, *consumption of fixed capital* (23), which is recorded as an expense, is also recorded as a transaction that reduces the value of the respective category of fixed asset, so that there is no impact on expenditure nor net lending/net borrowing (see paragraph 4.20). The recording of consumption of fixed capital is discussed in detail in paragraphs 6.53–6.61 and Box 6.1.

Netting of Transactions

8.19 It is recommended that transactions in nonfinancial assets other than inventories be presented as acquisitions, disposals, and consumption of fixed capital, as indicated in Table 8.1. The net investment in a category of nonfinancial assets is computed as acquisitions minus disposals minus consumption of fixed capital.

8.20 Acquisitions of, use of, and disposals of inventories should be netted because the separate data for acquisitions and disposals are not economically meaningful. In addition, as a matter of practice, it is often impossible to estimate individual transactions in inventories (see paragraphs 8.44–8.47). Inventories are not subject to consumption of fixed capital.

Classification and Recording of Transactions in Nonfinancial Assets

8.21 The classification of transactions in nonfinancial assets is shown in Table 8.1. The table summarizes transactions in nonfinancial assets as acquisitions, disposals, and consumption of fixed capital.

8.22 The classification of transactions in nonfinancial assets is identical to the classification of stock positions in nonfinancial assets employed in Chapter 7 (Table 7.2). Chapter 7 also provides full definitions of the assets included in each category, and those definitions are not repeated here. This chapter provides guidance applicable to transactions affecting all or most categories of nonfinancial assets. The remainder of this section provides guidance only on those transactions for which the general guidance may not be sufficient.

8.23 In addition to the classification of transactions in nonfinancial assets described in this chapter, the Classification of the Functions of Government (COFOG) can also be applied to the acquisitions

[10] A transaction in other accounts receivable/payable is recorded if the value of the stage payment exceeds the value of the work put in place. As work proceeds, an acquisition of fixed assets is recorded by the final owner until the other accounts receivable/payable are exhausted.

Permits to use natural resources	314412.1	314412.2		314412
Permits to undertake specific activities	314413.1	314413.2		314413
Entitlement to future goods and services on an exclusive basis	314414.1	314414.2		314414
Goodwill and marketing assets	31442.1	31442.2		31442
Memorandum items				
Own-account capital formation				3M1
Compensation of employees				3M11
Use of goods and services				3M12
Consumption of fixed capital				3M13
Other taxes on production minus other subsidies on production				3M14

[1]Consumption of fixed capital is not recorded for inventories. It is recorded for nonproduced assets only to the extent of *costs of ownership transfer on nonproduced assets other than land* (a fixed asset). For land, the costs of ownership transfer are included, by convention, with *land improvements* (a fixed asset).

[2]In GFS, only the net changes in inventories resulting from transactions are recorded, but gross acquisitions and disposals may be recorded, if needed.

minus disposals of these assets. COFOG is described in the annex to Chapter 6.

Fixed Assets (311)[11]

8.24 The cost of acquisition of assets from third parties is determined by the market price of the transactions. Government or public sector units can also incur costs associated with the production or the maintenance of fixed assets. To determine the amount of these costs that should be recorded as the value of own-account production of fixed assets during the reporting period, a distinction between major improvements of assets and maintenance of assets is necessary. The section on Fixed Assets first describes how to distinguish transactions that should be recorded as acquisitions of fixed assets from transactions that should be recorded as expense related to maintenance. The recording of transactions in specific categories of assets follows.

Major improvements versus maintenance and repair

8.25 Major improvements (such as renovations, reconstructions, and enlargements) to existing assets that increase their productive capacity, extend their service lives, or both, are classified as acquisitions of fixed assets. On the other hand, maintenance and repair of fixed assets constitute an expense classified as the *use of goods and services* (22) (as mentioned in paragraph 6.45). By definition, however, major improvements do not lead to the creation of new assets that can be separately identified and valued. Instead, the value of such an improvement is added to the value of the existing underlying asset.

8.26 Although the distinction is not clear-cut, major improvements to assets are distinguished from maintenance and repairs by the following features:

- The decision to renovate, reconstruct, or enlarge an asset is a deliberate investment decision that may be undertaken at any time and is not dictated by the condition of the asset. Major renovations of ships, buildings, or other structures are frequently undertaken well before the end of their normal service lives.
- The major renovations, reconstructions, or enlargements increase the performance or capacity of existing assets or significantly extend their previously expected service lives. Enlarging or extending an existing road, building, or structure constitutes a major change in this sense, but a complete refitting or restructuring of the interior of a building also qualifies.

[11]The numbers in parentheses after each classification category are the GFS classification codes. Appendix 8 provides all classification codes used in GFS.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

8.27 Maintenance and repairs are distinguished by two features:

- They are activities that owners or users of assets are obliged to undertake periodically in order to be able to utilize such assets over their expected service lives. They are current costs that cannot be avoided if the fixed assets are to continue to be used. The owner or user cannot afford to neglect maintenance and repairs as the expected service life may be drastically shortened otherwise.
- They do not change the fixed asset or its performance, but simply maintain it in good working order or restore it to its previous condition in the event of a breakdown. Defective parts are replaced by new parts of the same kind without changing the basic nature of the fixed asset.

Buildings and structures (3111)

8.28 In addition to the transactions reflecting the acquisition of newly constructed buildings and structures, acquisitions of buildings and structures include all amounts payable for site clearance and preparation and the cost of all fixtures, facilities, and equipment that are integral parts of buildings and structures.

8.29 Certain structures, such as buildings, roads, and bridges, may be produced for communal use by groups of households. After the construction is completed, the ownership of such structures may then be transferred to a general government unit that will assume responsibility for their maintenance. When the transfer occurs, an acquisition of a structure is recorded together with the receipt of a capital transfer in kind.

8.30 The construction of new public monuments, as well as major improvements to existing public monuments, constitutes an acquisition of buildings and structures, either as *dwellings* (31111), *buildings other than dwellings* (31112), or *other structures* (31113), as explained in paragraphs 7.42–7.43.[12] However, when the special archaeological, historical, or cultural significance of a structure or site not already recorded in the balance sheet is first recognized, it is recorded as an other change in the volume of assets, as explained in paragraph 10.50.

8.31 The costs of *land improvements* (31114) are recorded as transactions and, in subsequent periods, transactions in *consumption of fixed capital* (23) are recorded, based on the service life of the improvement. Any excess in the increase in the value of the land over the value of land improvements or any increase in price levels due to adjacent capital activity is recorded as holding gains. Other changes in the volume of assets (economic appearance) of the nonproduced asset *land* (5141) should be recorded when adjacent activities bring land into the asset boundary (see paragraph 10.52).

8.32 Acquisitions of tunnels and other structures associated with the mining of mineral deposits are classified as acquisitions of structures and not as improvements to land. These assets are used separately from the land through which they are drilled or bored. The costs of ownership transfer on land are included, by convention, with land improvements, and these costs are written off over the period the owner expects to own the land.

Machinery and equipment (3112)

8.33 The determination of which goods should be classified as machinery and equipment is normally straightforward. However, as explained in paragraphs 6.43 and 7.40, some flexibility may be needed in the recording of small/hand tools.

Other fixed assets (3113)

Cultivated biological resources (31131)

8.34 As explained in paragraphs 7.59–7.63, cultivated biological resources comprise *animal resources yielding repeat products* (311311) and *tree, crop, and plant resources yielding repeat products* (311312). Acquisitions of cultivated biological resources include acquisitions from other units of plants and animals that are cultivated for the products they yield year after year and the value of similar plants and animals produced on own account.[13] Disposals consist of animals and plants sold or otherwise disposed of, including animals sold for slaughter or slaughtered by their owners and plants cut down before the end of their service lives. Disposals do not include exceptional losses of animals and plants due to major outbreaks of disease, contamination, drought, famine, or other natural disasters, which are recorded as

[12] Consumption of fixed capital on new public monuments as well as major improvements to existing public monuments should be calculated on the assumption of appropriately long service lives.

[13] Plants and animals grown for a single use, such as animals grown for slaughter and trees grown for timber, are treated as inventories rather than fixed assets (see paragraphs 7.60–7.61).

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

other changes in the volume of assets. Consumption of fixed capital on these resources includes incidental losses of animals and plants from natural causes, as well as the decline in an animal's or plant's value as it gets older.

8.35 The net investment in livestock that are cultivated for the products they yield year after year (e.g., dairy cattle) is equal to the total value of all mature animals and immature animals produced on own account or acquired by users of the livestock minus the value of their disposals minus consumption of fixed capital.

8.36 The net investment in plantations, orchards, etc. is equal to the value of the acquisitions of mature trees, shrubs, etc. (including immature trees, shrubs, etc. produced on own account) minus their disposals minus consumption of fixed capital. The value of immature trees, shrubs, etc. may be approximated, if necessary, by the value of accumulated costs incurred in their production.

Intellectual property products (31132)

8.37 As explained in paragraphs 7.64–7.73, intellectual property products comprise:

- *Research and development* (311321)
- *Mineral exploration and evaluation* (311322)
- *Computer software and databases* (311323)
- *Entertainment, literary, and artistic originals* (311324)
- *Other intellectual and property products* (311325).

8.38 The value of expenditure on *research and development* (311321) should be determined in terms of the economic benefits it is expected to provide in the future. It is treated as an asset except in cases where it is clear that the activity does not entail any economic benefits for its owner (see paragraphs 7.66–7.67).

8.39 As mentioned in paragraph 7.68, expenditure incurred on exploration is classified as the acquisition of *mineral exploration and evaluation* (311322). Mineral exploration expenditure includes the costs of actual test drillings and borings and all other costs incurred to make it possible to carry out the tests, such as prelicense, license, acquisition, and appraisal costs, the costs of aerial and other surveys, and transportation and other costs incurred to make the exploration possible. Consumption of fixed capital may be calculated for such assets by using average service lives similar to those used by mining or oil corporations in their own accounts.

8.40 *Computer software and databases* (311323) include acquisitions of computer software that comprise programs, program descriptions, and supporting materials for both systems and applications software that are expected to be used for more than one year. The net investment in nonfinancial assets in the form of computer software includes both the initial development and subsequent extensions of software, as well as acquisition of copies that are classified as assets. Software developed in-house is valued at its cost of production. This category also includes the purchase, development, or extension of large databases that the unit expects to use for more than one year. When a database is created, its value will generally have to be estimated by a sum-of-costs approach. These costs include the cost of preparing data in the appropriate format, staff time estimated on the basis of the amount of time spent in developing the database, and costs of items included as use of goods and services.[14] Not included are the cost of the database management system and the cost of acquiring or producing the data. Transactions in databases sold should be valued at their market price, which includes the value of the information content. If the value of a software component in a database that is sold is available separately, it should be recorded as the sale of software.

8.41 The production of new *entertainment, literary, and artistic originals* (311324) is recorded at their current market price when they are actually traded. However, this asset category is often undertaken on own account. Subsequently, they may be sold outright or by means of licenses. When produced on own account, it may be difficult to establish their market value, which depends on the present value of the future benefits the owner expects to derive from their use. In the absence of information, it may be necessary to value the acquisition of the original by its cost of production.

[14] If the database is created in-house, compensation of employees and use of goods and services related to this own-account capital formation are excluded from *compensation of employees* (21) and *use of goods and services* (22).

Costs of ownership transfer on nonproduced assets other than land (31133)

8.42 Transactions in the costs of ownership transfer on nonproduced assets[15] other than land are treated as transactions in fixed assets because these costs are considered a produced asset. The costs of ownership transfer on nonproduced assets other than land are subject to consumption of fixed capital, which is also included in this category. However, in the balance sheet, these costs of ownership transfer, as well as the consumption of fixed capital on these costs, are reflected in the value of the respective nonproduced assets. The additional entries necessary for this treatment are discussed in paragraph 10.83. The treatment of costs of ownership transfer on nonproduced assets is illustrated in Figure 8.1.

Weapons systems (3114)

8.43 The acquisitions and disposals of weapons systems that meet the general definition of assets include vehicles and other equipment such as warships, submarines, military aircraft, tanks, missile carriers and launchers, etc. The acquisitions of most single-use weapons they deliver, such as ammunition, missiles, rockets, bombs, etc., are classified as transactions in military inventories and their use as withdrawals from military inventories. However, some single-use items, such as certain types of ballistic missile with a highly destructive capability, may be classified as fixed assets (see paragraph 7.74).

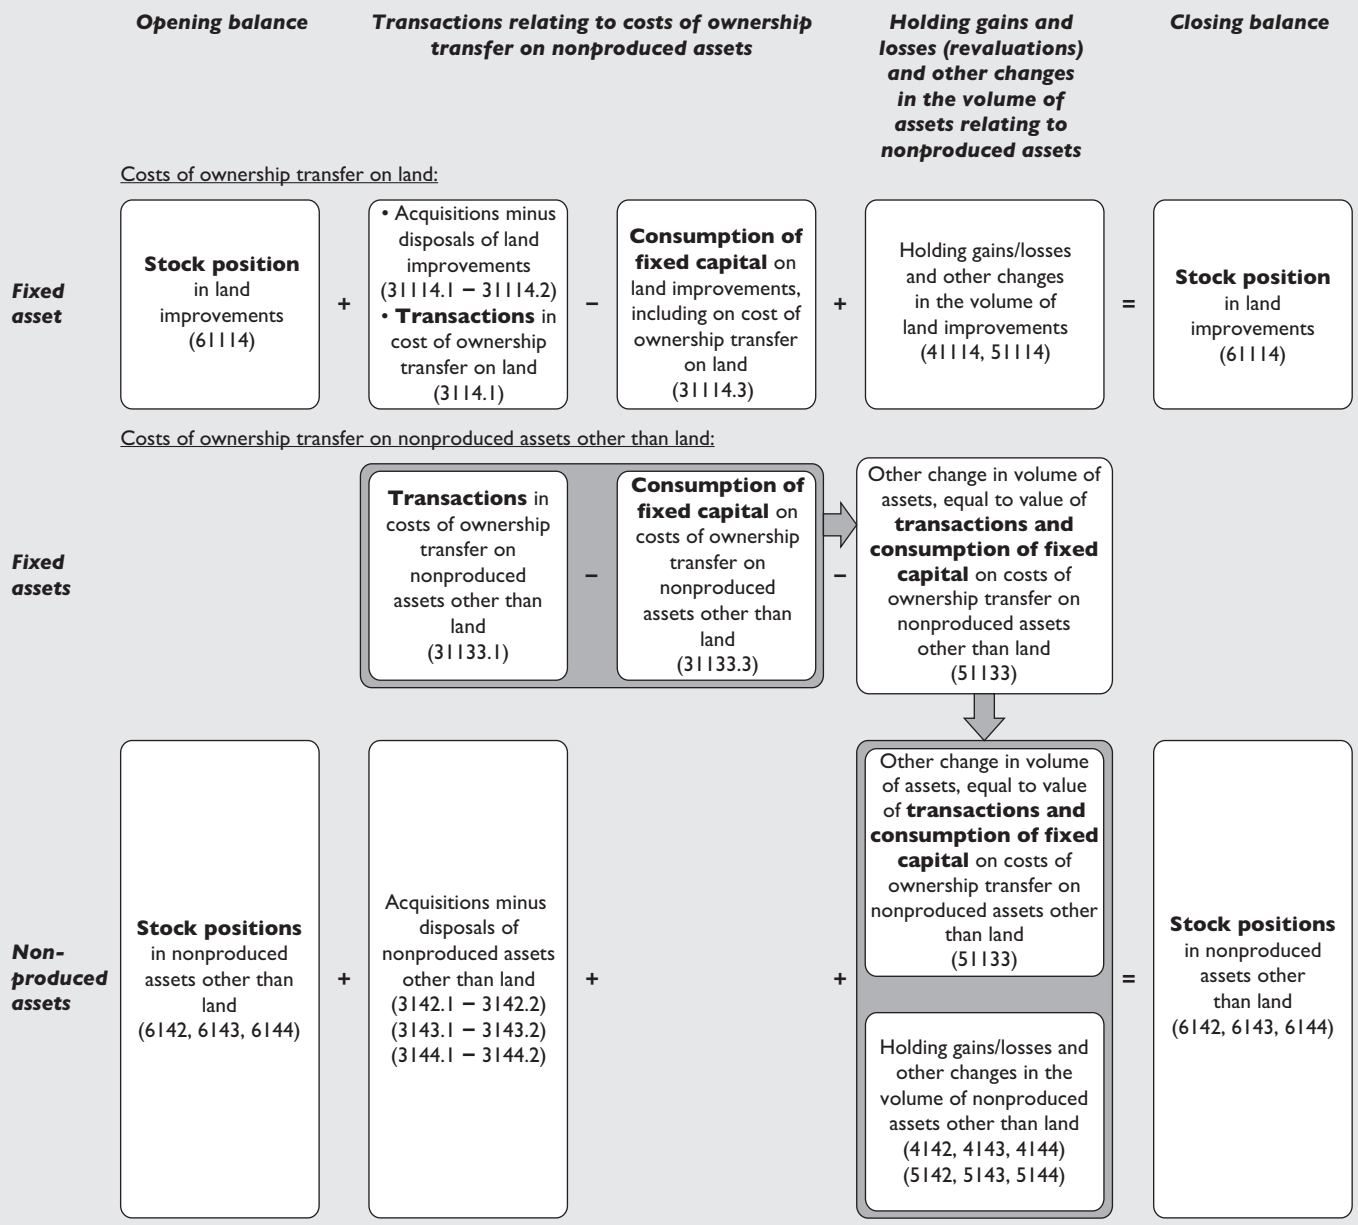
Inventories (312)

8.44 In principle, **net investment in inventories** (change in inventories) is measured by the value of the additions to inventories minus the value of withdrawals from inventories minus the value of any recurrent losses of goods held in inventories during the reporting period.[16] In general, additions to and withdrawals from inventories should be recorded according to the same principles used for recording transactions in other nonfinancial assets. Additions to inventories are recorded when products are purchased, produced, or otherwise acquired, and withdrawals from inventories are recorded when products are sold, used up in production, transferred to a different category of inventories, or otherwise relinquished.

8.45 In contrast to other nonfinancial assets, however, no costs of ownership transfer are included in the values of additions to or withdrawals from inventories, and no consumption of fixed capital is attributed to inventories, as indicated by the shaded area in Table 8.1. Further, only the net value of additions minus withdrawals of inventories is usually estimated rather than separate, gross values for additions and withdrawals, unlike for other nonfinancial assets. This estimate of the changes in inventories is used in the formula to determine an estimate of expense in the form of *use of goods and services* (22), as explained in paragraph 6.29.

8.46 To understand the various transactions in inventories, it is useful to distinguish between two functions performed by a unit: its function as a producer of goods and services and its function as an owner of assets. When a good is entered into inventories, it is acquired as an asset by the unit in its capacity as owner either by purchase (or barter) or by an internal transaction with itself as the producer. Conversely, a good leaving inventories represents the disposal of an asset by the owner either by sale or other use, by an internal transfer to the producer, or possibly as a result of recurrent losses (recurrent wastage, accidental damage, or pilfering).

8.47 Many transactions in inventories (i.e., additions to and withdrawals from) are purchases from or distributions to other units, but other acquisitions and disposals reflect internal transactions. All additions to and withdrawals from inventories, such as for use of goods or investment in fixed assets, should be valued at current market prices. Because of the continuous or frequent withdrawals from materials and supplies inventories and the additions to and withdrawals from work-in-progress inventories, information is usually not available to record these internal transactions accurately, and estimates may be necessary.



- When *materials and supplies* (31221) are transferred to a production process, a transaction is recorded for the withdrawal, which is balanced by an addition either to *work-in-progress inventories* (31222), *use of goods and services* (22), or, in the case of own-account capital formation, a

[15] Transactions in nonproduced assets are discussed in paragraphs 8.49–8.58.

[16] These changes in inventories are as a result of transactions. The value of the stock of inventories may also change due to other economic flows.

Figure 8.1 Illustrating the Treatment of Costs of Ownership Transfer on Nonproduced Assets

- Costs of ownership transfer on land are, by convention, included with land improvements. This applies to the transactions as well as the stock position of land improvements.
- There are no stock positions in costs of ownership transfer on nonproduced assets other than land shown separately in the balance sheet. These costs are included with the respective nonproduced assets in the balance sheet.
- Transactions in the costs of ownership transfer on nonproduced assets other than land are recorded as part of fixed assets.
- Costs of ownership transfer on nonproduced assets (and on produced assets other than inventories—which are not shown in this example) are subject to consumption of fixed capital over the period the owner expects to hold the asset.
- Costs of ownership transfer on nonproduced assets other than land and consumption of fixed capital on these costs are reclassified, through other changes in the volume of assets, to the respective nonproduced assets to maintain the integration of stock positions and flows. These reclassifications are considered to take place at the time of recording the transactions. The costs of ownership transfer on land, which are included with land improvements, are not reclassified to land and remain part of the stock of land improvements.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

specific fixed asset or possibly *valuables* (313). In other words, the balancing entry depends on the nature of the production process. The acquisition of gold, diamonds, etc. intended for use in production is recorded under *materials and supplies* (31221), but the acquisition of the same items to hold as a store of value is recorded under *valuables* (313).

- Transactions that add to *work-in-progress inventories* (31222) are, in principle, recorded continuously as production takes place. The counterpart transactions are reduction in other assets, such as *materials and supplies*, and the other costs incurred in production.[17] When production is completed, all work in progress is reclassified as *finished goods* (31223). This reclassification is recorded as other changes in the volume of assets under the respective subcategories of inventories. Withdrawals of *work-in-progress inventories* (31222) should be valued at their cost of production, where all inputs are valued at their current market prices at the time of withdrawal rather than the prices paid for them. The difference between the prices payable for the inputs and their current market prices is a holding gain or loss. The ownership of work-in-progress inventories is transferable, if necessary. For example, it may be sold under exceptional circumstances, such as the liquidation of a public corporation.
- Work-in-progress inventories should be recorded for single-use cultivated biological resources. Any cultivation of resources with repeat yields, other than on own account or under an agreed contract with another unit, is also included in work-in-progress inventories. However, repeat-yield resources, being cultivated on own account or under an agreed contract with another unit, are recorded as the acquisition of fixed assets.
- A good is finished when its producer has completed its intended production process and such inventories of *finished goods* (31223) may be held only by the units that produce them. When finished goods are sold or otherwise disposed of (e.g., as compensation of employees in kind or social benefits in kind), a transaction must be recorded to reduce inventories of *finished goods* (31223), which is balanced by an increase in *use of goods and services* (22). The distribution of finished goods as compensation of employees in kind or social benefits in kind is always recorded as *use of goods and services* (22) by the unit that produced these goods (see paragraph 6.39).
- Finished goods entering inventories are valued at the prices of those goods before adding any taxes, transport, or distribution margins, at the times the entries take place; finished goods withdrawn from inventories are valued at the prices before adding any taxes, transport, or distribution margins, at the time when their withdrawals take place. The difference between the "entering" and "withdrawal" values of finished goods is a holding gain or loss.
- When goods held as *goods for resale* (31224) are sold or otherwise disposed of, two transactions are recorded. First, reduce inventories of *goods for resale* (31224) and record a counterpart transaction in expense, recorded as *use of goods and services* (22) expense at the purchase price. Second, record (at the sale price) a *sales of goods and services* (142), which is balanced by either an increase in *currency and deposits* (3302) or *other accounts receivable* (3308). The difference between the value recorded as sales of goods and services and use of goods and services is reflected in the *net operating balance* (NOB). By convention, goods acquired by government for distribution as social transfers in kind or other transfers in kind but that have not yet been so delivered are also included in goods for resale. The distribution of such goods is recorded as a reduction in inventories of *goods for resale* (31224), and an increase in *subsidies* (25), *grants* (26), *social benefits* (27), or *current transfers not elsewhere classified* (2821).
- Goods for resale added to inventories are valued at their actual or estimated purchase prices, including any transportation charges paid to other units but not the costs of any transport services produced on own account by the unit taking delivery. In principle, goods acquired by barter are valued at their estimated purchasers' prices at the time of acquisition. However, because there are no taxes or margins on bartered goods, the purchaser's price is the same as the basic price.

[17] As explained in paragraph 6.27, an adjustment is made to *use of goods and services* (22) to account for those items used to produce nonfinancial assets, such as work-in-progress inventories.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Goods for resale withdrawn from inventories are valued similarly at the purchase prices at which they can be replaced when they are withdrawn, which may differ from the prices that were paid to acquire them and the prices for which they were sold.[18] Reductions in inventories are valued in this way whether the goods withdrawn are sold at a profit or at a loss, or even not sold at all as a result of physical deterioration, recurrent accidental damage, or pilfering.

- When *military inventories* (31225) are used or otherwise disposed of, their cost is recorded as *use of goods and services* (22) expense. A counterpart transaction is recorded as the withdrawal of *military inventories* (31225). Additions and withdrawals of military inventories are valued in a manner similar to finished goods or goods for resale, depending on how they were acquired.
- Recurrent losses of inventories resulting from physical deterioration, normal accidental damage, or pilfering should be treated as withdrawals in the same way as inventories withdrawn on purpose. In practice, determining the time of recording may be difficult because the time at which the inventories were stolen or spoiled may be unknown. Exceptional inventory losses are included as other changes in the volume of assets (see paragraph 10.70).

Valuables (313)

8.48 Acquisitions of valuables are valued at the prices payable plus any associated costs of ownership transfer incurred by the units acquiring the assets. Disposals are valued at the sales price minus any associated costs of ownership transfer incurred by the units disposing of the assets. Costs of ownership transfer may be significant for the services of appraisers, auctioneers, and dealers. Units fulfilling some functions of the monetary authority may have transactions in both monetary and nonmonetary gold, and care needs to be taken to classify them correctly and to record the other changes in the volume of assets needed to transfer gold from one category to the other.

Nonproduced Assets (314)

8.49 Transactions reflecting a change in the ownership of nonproduced assets should be recorded in the same manner as transactions in existing fixed assets. The recording of the costs of ownership transfer on nonproduced assets other than land and the consumption of fixed capital on these costs are discussed in paragraphs 8.42 and 10.83.

Land (3141)

8.50 Purchases and sales of land exclude the costs of ownership transfer on land for both buyers and sellers. These costs are, by convention, included in *land improvements* (31114). Actions that lead to major improvements in the quantity, quality, or productivity of land, or prevent its deterioration (such as land clearance,[19] land contouring, creation of wells and watering holes that are integral to the land in question, etc.), are also treated as resulting in *land improvements* (31114), not the acquisition of *land* (3141). When a government unit acquires land that is physically located in a foreign country (for use as an embassy, base, or other territorial enclave), the transaction converts the land into part of the economic territory of the country of the acquiring government and, therefore, it enters the balance sheet by means of a transaction (i.e., the acquisition of a nonfinancial asset).

8.51 Buildings, or other structures, and plantations are often purchased or sold together with the land on which they are situated, without separate valuations being placed on the structures and the land. Even if it is not feasible to obtain separate valuations, as may be the case for existing structures, it may be possible to determine whether the land or the structure accounts for most of their combined value and to classify the transaction as the purchase of land or of a structure, depending upon which has the greater value. If it is not possible to determine whether the land or the structure is the more valuable, by convention, the transaction should be classified as the purchase of a structure (i.e., as the acquisition of a fixed asset in the form of *buildings and structures* (3111)). A similar convention holds for plantations. In most

[18] The difference between the price at which goods for resale is added to inventories and the price at which it is withdrawn is a holding gain or loss.

[19] Costs relating to site clearance and preparation of land for purposes of construction are excluded; these are classified as the acquisition of buildings and other structures.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

cases, subsoil assets may be owned separately from the land and separate valuations should be estimated if possible. On the other hand, the law may stipulate that the ownership of the subsoil assets is inseparably linked to that of the land. For a financial lease of a building or plantation on the land when the assets are inseparable, see paragraph 7.95.

8.52 When governments acquire land (or other assets) under a compulsory sale by the owners, any difference between the market value of the assets acquired and any compensation provided is recorded as other changes in the volume of assets, in the form of an uncompensated seizure (see paragraph 10.62).

8.53 There is no consumption of fixed capital on land, but there are transactions in consumption of fixed capital on *land improvements* (31114) and costs of ownership transfer on land (which are included in land improvements).

Mineral and energy resources (3142)

8.54 Transactions *in mineral and energy resources* (3142) refer to acquisitions or disposals of deposits of mineral and energy resources in which the ownership of such assets passes from one institutional unit to another. Reductions in the value of known reserves of mineral and energy resources resulting from their depletion as a result of extracting the assets for purposes of production are not transactions but other changes in the volume of assets, as described in paragraph 10.52. Similarly, increases in the values resulting from discoveries are treated as other changes in the volume of assets. Decreases arising from reappraisals are also recorded as other changes in the volume of assets. The transactions in *mineral and energy resources* refer only to those mineral and energy resources over which ownership rights have been established.

Other naturally occurring assets (3143)

8.55 Transactions in noncultivated biological resources, water resources, and other natural resources relate to acquisitions or disposals of deposits of these resources in which the economic ownership of such assets passes from one institutional unit to another. Similar to mineral and energy resources, depletion of noncultivated biological resources, water resources, or other natural resources, because a portion of the asset has been extracted, is recorded as other changes in the volume of assets, as described in paragraph 10.52, and not as a transaction in nonfinancial assets.

Intangible nonproduced assets (3144)

8.56 As explained in paragraphs 7.104–7.117, intangible nonproduced assets consist of *contracts, leases, and licenses* (31441) and *goodwill and marketing assets* (31442).

8.57 Contracts, leases, and licenses may be marketable operating leases, licenses to use natural resources, permits to undertake specific activities and entitlement to future goods and services on an exclusive basis. The specific stocks and flows involved with contracts, leases, and licenses are discussed in Appendix 4.

8.58 As explained in paragraphs 7.113–7.117, goodwill is recorded in GFS only when its value is evidenced by a market transaction, usually the sale/purchase of the whole corporation. The amortization of goodwill and marketing assets or other intangible nonproduced assets is an other economic flow rather than a transaction (see paragraph 10.55).

9 Transactions in Financial Assets and Liabilities

This chapter describes transactions in financial assets and liabilities and their classification.

Introduction

9.1 Chapter 7 describes the balance sheet and the assets and liabilities recorded on it. As an integrated framework, GFS also include the flows necessary to explain all changes between the balance sheet at the beginning of the period and the balance sheet at the end of the reporting period. As described in Chapter 3, there are two types of flows—transactions and other economic flows—both of which can affect stock positions of assets and liabilities. This chapter describes the transactions that affect stock positions of financial assets and liabilities, and Chapter 10 describes other economic flows.

9.2 The accounting identity given in paragraph 8.2 for nonfinancial assets also holds for financial assets and liabilities.[1] The identity states that:

> The value of a category of financial assets (liabilities) on the balance sheet at the beginning of the reporting period
>
> *plus*
>
> The total value of that category of financial assets (liabilities) acquired (incurred) in transactions during the reporting period
>
> *minus*
>
> The total value of that category of financial assets (liabilities) disposed of (extinguished) in transactions during the reporting period
>
> *plus*
>
> The net value of other economic flows that affect that category of financial assets (liabilities)
>
> *equals*
>
> The value of the category of financial assets (liabilities) on the balance sheet at the end of the reporting period.

This identity requires that transactions, other economic flows, and stock positions be recorded consistently with regard to classification, time of recording, and valuation. The accounting rules governing these factors are described in Chapter 3.

9.3 Transactions can change stock positions of financial assets or liabilities in different ways and all must be accounted for. The more important types of transactions follow:

- Transactions involving revenue, expense, the transfer of economic ownership of a good or nonfinancial asset, or the provision of a service or labor almost always entail a counterpart entry in transactions in financial assets and liabilities for means of payment or claims on future means of payment. Even many transactions in kind, such as barter transactions and remuneration in kind, could conceptually lead to counterpart transactions in financial assets (*other accounts receivable*) and/or liabilities (*other accounts payable*) when the timing of the exchange does not coincide. The sale of a good, service, or asset may have as its counterpart a change in currency or transferable deposit. Alternatively, the counterpart may be reflected as another type of financial asset or liability, such as other accounts receivable or payable.
- New financial claims are often created by transactions in which a creditor advances funds to a debtor. The creditor then acquires a financial asset and the debtor incurs a liability.
- Some transactions in financial assets and liabilities are simply exchanges of financial instruments.

[1] For ease of expression, assets will often be used as a reference to both assets and liabilities.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

- Financial claims are normally terminated by transactions. In some cases, the debtor pays the creditor the funds stipulated by the financial instrument, thereby terminating the claim. In other cases, the debtor buys its own instrument in the market.
- Accrued interest is deemed to be reinvested in an additional quantity of the underlying financial instrument by means of a transaction.
- The trading and settlement of financial derivative contracts.

9.4 All transactions that increase a unit's holdings of assets are labeled acquisitions. All transactions that decrease a unit's holdings of assets are labeled disposals. Transactions that increase liabilities are referred to as the incurrence of a liability. Transactions that decrease liabilities are variously titled repayments, reductions, withdrawals, redemptions, liquidations, or extinguishments. Thus, the results of transactions in a particular category of financial assets can be presented either as total acquisitions and total disposals or as net acquisitions. Similarly, changes in liabilities can be presented as total incurrences and total reductions or as net incurrences. Transactions that change a category of financial assets are never combined with transactions that change the same category of liabilities. That is, in GFS, the net acquisition of loans is not presented as the increase in loans held as financial assets minus the increase of loans as liabilities (also see paragraph 9.17).

9.5 As explained in paragraph 4.17, the *net operating balance* minus the *net investment in nonfinancial assets* equals *net lending (+) / net borrowing (–)*. If the operating balance is not exhausted by the net investment in nonfinancial assets, the resulting surplus is called *net lending* (+). Alternatively, if the net operating balance is not sufficient to cover the net accumulation of nonfinancial assets, the resulting deficit is called *net borrowing* (–). Transactions in financial assets and liabilities explain how net lending/net borrowing is financed by means of changes in holdings of financial assets and liabilities—that is, total financing. In other words, the net acquisition of financial assets minus the net incurrence of liabilities is conceptually equal to net lending/net borrowing.

9.6 The remainder of this chapter describes first the valuation, time of recording, netting, and consolidation of transactions that affect financial assets and liabilities. It then provides details on transactions that affect specific categories of financial assets and liabilities. The classification of transactions in financial assets and liabilities by residence and sector of the counterparty is also discussed.

Valuation

9.7 The value of an acquisition or disposal of an existing financial asset or liability is its exchange value—that is, the current market price. The value of a newly created financial claim is generally the amount advanced by a creditor to a debtor.

9.8 All service charges, fees, commissions, and similar payments for services provided in carrying out transactions and any taxes payable on transactions are excluded from transactions in financial assets and liabilities. They are expense transactions classified as *use of goods and services* (22). In particular, when new securities are marketed by underwriters or other intermediaries as agents for the unit issuing the securities, the securities should be valued at the price payable by the purchasers. The difference between that price and the amount receivable by the issuing unit is a payment for the services of the underwriters. When dealers have a margin between their buying and selling prices, the buyer and seller record transactions in financial assets and liabilities at the same mid-price—that is, the midpoint between the buyer's price and the seller's price.

9.9 When a security is issued at a discount or premium relative to its contractual redemption value, the transaction should be valued at the amount actually payable for the asset and not the redemption value. Any interest that is prepaid jointly with the acquisition of a security should be treated as accrued interest that had been reinvested in an additional quantity of the security. In this case, the value of the acquisition is the sum of the amount paid for the security directly plus the amount prepaid for accrued interest. When issued at a premium, the difference between the redemption and issue price is amortized over the life of the instrument and reduces (rather than increases) the amount of interest accruing in each period.

9.10 In some cases, the value of a financial asset is determined by the value of the counterpart item to the transaction. For example, the initial value of a loan

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

resulting from a financial lease is usually the value of the nonfinancial asset leased (if no initial down payments or fees are involved). The value of other accounts payable resulting from the purchase of goods or services is the value of the goods acquired or services received.

9.11 As mentioned in paragraph 3.119, the value of a transaction expressed in a foreign currency is converted to the domestic currency using the midpoint of the buying and selling exchange rates at the time of the transaction.[2] If a transaction expressed in a foreign currency involves the creation of a financial asset or liability, such as other accounts receivable/payable, and is followed by a second transaction in the same foreign currency that extinguishes the financial asset or liability, then both transactions are valued at the exchange rates effective when each takes place.

9.12 Government units or public corporations may acquire or dispose of financial assets on a nonmarket basis as an element of their fiscal policy rather than as a part of their liquidity management. For example, they may lend money at a below-market interest rate or purchase shares of a corporation at an inflated price. It is generally accepted that concessional loans occur when units lend to other units and the contractual interest rate is intentionally set below the market interest rate that would otherwise apply. The degree of concessionality can also be enhanced with grace periods[3] and frequencies of payments and maturity periods favorable to the debtor. Since the terms of a concessional loan are more favorable to the debtor than market conditions would otherwise permit, concessional loans effectively include a transfer from the creditor to the debtor. However, the means of incorporating the transfer impact within the SNA and other macroeconomic statistics have not been fully developed, although various alternatives have been advanced. Accordingly, until the appropriate treatment of concessional debt is agreed, information on concessional debt should be provided in supplementary tables, and in the memorandum items *concessional loans at nominal value* (6M391) and *implicit transfers resulting from loans at concessional interest rates* (6M392), discussed in paragraph 7.246.

Time of Recording

9.13 On an accrual basis, transactions in financial assets and liabilities are recorded when economic ownership of the asset changes—that is, when the asset is created or liquidated—and when the addition or reduction in the amount of the financial instrument occurs, such as the accrual of interest and subsequent reduction when debt service payments are made.[4] This time is usually clear when the transaction involves an exchange of existing financial assets or the simultaneous creation or extinction of a financial asset and a liability. In most cases, it will be when the contract is signed or when money or some other financial asset is paid by the creditor to the debtor or repaid by the debtor to the creditor.

9.14 In some cases, the parties to a transaction may perceive economic ownership to change on different dates because they acquire the documents evidencing the transaction at different times. This variation usually is caused by the process of check clearing or the length of time checks are in the mail. The amounts involved in such "float" may be substantial in the case of transferable deposits and other accounts receivable or payable. If there is disagreement on a transaction between two general government units or a government unit and a public corporation, the date on which the creditor receives the payment is the date of record because a financial claim exists up to the point that the payment is cleared and the creditor has control of the funds.

9.15 When a transaction in a financial asset or liability involves a nonfinancial component, the time of recording is determined by the nonfinancial component. For example, when a sale of goods or services gives rise to a trade credit, the transaction should be recorded when economic ownership of the goods is transferred or when the service is provided. When a financial lease is created, the loan implicit in the transaction is recorded when control of the fixed asset changes.

[2] The difference between buying or selling prices and midpoint prices represents a service charge and should conceptually be reported as *sales of goods and services* (142) or *use of goods and services* (22). The service charge may be estimated from the average trade margin spread between the buying and selling rates. If not significant or not practical to identify, it is recommended to disregard any service charge in GFS.

[3] The treatment of grace periods is discussed in paragraphs 6.69.

[4] On the pure cash basis of recording, transactions are recorded when cash is paid or received. See Chapter 3 for more details on the cash basis of recording.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

9.16 Some transactions, such as the accrual of interest expense and its treatment as borrowing of an additional amount of the financial instrument, take place continuously. In this case, the transaction in the associated financial asset or liability also takes place continuously.

Netting and Consolidation of Flows

Netting

9.17 Transactions in financial assets and liabilities are presented in Table 9.1 as the net acquisition of each category of financial asset and the net incurrence of each category of liability. That is, in the GFS framework, only the net change in the holding of a type of asset is presented, not gross acquisitions and gross disposals, as with most nonfinancial assets. (Separate amounts for gross acquisitions and gross disposals may, of course, be presented if the underlying accounting records permit and the information is analytically meaningful.) When the same type of financial instrument is held both as a financial asset and a liability, transactions in financial assets are presented separately from transactions in liabilities rather than netting transactions in liabilities against transactions in financial assets.

Consolidation

9.18 As explained in paragraphs 3.152–3.168, **consolidation** is a method of presenting statistics for a set of units (or entities) as if they constituted a single unit. A consolidated set of accounts for a unit, or group of units, is produced by, first, an aggregation of all flows and stock positions within an agreed analytical framework, followed by the elimination, in principle, of all flows and stock positions that represent relationships among the units or entities being consolidated.

9.19 Transactions in financial assets are eliminated when the two parties to the transaction are units that are being consolidated. For example, if a local government unit purchases a security issued by the central government, both the acquisition of the financial asset and the incurrence of the liability would disappear in a presentation of statistics for the entire general government sector but not in a presentation of either the central or the local government subsector separately.

Arrears

9.20 As explained in paragraphs 7.247–7.250, **arrears** are defined as amounts that are both unpaid and past the due date for payment. In principle, amounts payable for any expense, for acquisition of nonfinancial assets, or related to any liability may become in arrears if the amounts are past due for payment (e.g., in the case of overdue debt service payments).

9.21 Some types of financial assets and liabilities, most notably debt securities, loans, financial derivatives, and other accounts receivable/payable, mature at scheduled dates, or series of dates, when the debtor is required to make specified payments to the creditor. If the payments are not made as scheduled, the debtor has effectively obtained additional financing by not making the scheduled payments. When arrears occur, no transactions should be imputed, but the arrears should continue to be shown in the same instrument until the liability is extinguished. However, if the contract provided for a change in the characteristics of a financial instrument when it goes into arrears, this change should be recorded as a reclassification in the form of other changes in the volume of the financial assets and liabilities (see paragraph 10.84). If the contract is renegotiated or the nature of the instrument changes from one instrument category to another (e.g., from bonds to equity), the resulting flow should be recorded as transactions in the repayment of the original liability and the creation of a new liability (see paragraph 3.97).

9.22 Nonetheless, interest accrues on liabilities in arrears (both principal and interest arrears) and is known as late interest. Late interest should accrue at the same interest rate as on the original debt instrument, unless the interest rate for arrears was stipulated in the original debt contract, in which case this stipulated interest rate should be used. The stipulated rate may include a penalty rate in addition to the interest rate on the original debt. For other liabilities in arrears, in the absence of other information, interest costs accrue on these arrears at the market rate of interest for overnight borrowing. Also, any additional charges relating to arrears (such as penalties) should be recorded as interest on arrears of the debtor at the time the charges accrue. If an item is purchased on credit and the debtor fails to pay within the period stated at the time the purchase was made, any extra charges incurred should be regarded as interest on arrears and accrue until the debt is extinguished.

3221–3228	*Same instrument breakdown as above*	3321–3328	*Same instrument breakdown as above*

9.23 When using the cash basis of recording, cash payments for the settlement of arrears should be recorded with a counterpart entry in the relevant categories of expense, net acquisition of nonfinancial assets, or net incurrence of liabilities. Recording arrears in this way recognizes the appropriate economic nature of these payments since they have not been recorded under the appropriate GFS categories in the past (see also paragraph 7.249).

Classification of Transactions in Financial Assets and Liabilities by Type of Financial Instrument and Residence

9.24 Table 9.1 presents the classification of transactions in financial assets by type of financial instrument and residence. This classification is consistent with the classification of the same financial assets and liabilities employed in Chapter 7 (Table 7.9). Chapter 7 also provides full definitions of the financial assets or liabilities included in each category, and those definitions are not repeated here. The remainder of this section provides guidance only on those transactions for which the general guidance may not be sufficient.

9.25 In principle, the classification of transactions in financial assets and liabilities by residence is based on the residence of the units that are a party to the transaction being recorded. The classification of stock positions in financial assets and liabilities in a unit's balance sheet (see paragraph 7.264) is based on the residence of the issuer of financial instruments (assets), and the residence of the holder of the financial instruments (liabilities). If a transaction in financial

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

assets or liabilities between a resident and a nonresident unit involves an instrument originally issued by a resident, an entry in other changes in the volume of assets (reclassification) should be recorded to maintain the integrated GFS framework of flows and stock positions (see also paragraphs 9.85–9.87 and 10.79). In practice, available information may not permit the identification of the two parties to the transaction. Therefore, transactions recorded in the source data for external transactions in financial assets and liabilities may include those that take place not only between residents and nonresidents but also between two residents in nonresident financial assets and liabilities.

9.26 In addition to transactions in interest and principal on debt liabilities, general government and public sector units may undertake a range of complex debt-related transactions, such as assuming debt of other units, making payments on behalf of other units, debt rescheduling, debt forgiveness, debt defeasance, and financial leasing. The special features of these types of transactions are described in Appendix 3.

9.27 The classification of financial instruments in GFS, described in this chapter, does not include functional categories used in the Balance of Payment and International Investment Position, such as direct investment, portfolio investment, or international reserves.[5]

Monetary Gold and Special Drawing Rights (SDRs) (3201, 3221, 3301, 3321)[6]

Monetary gold (32011, 32211)

9.28 Transactions in monetary gold are the exclusive responsibility of the monetary authorities, which will normally be the central bank (a public financial corporation). It is possible, however, for a unit of the general government sector to undertake some monetary functions, in which case it may have transactions in monetary gold. When transactions in financial assets are classified by residence of the counterparty, the counterpart liability to transactions in monetary gold is shown as external because monetary gold can be held only as part of foreign reserves.[7]

9.29 Transactions in monetary gold can take place only between two monetary authorities or between a monetary authority and an international financial organization. If the monetary authority adds to its holdings of monetary gold by acquiring newly mined gold or existing gold offered on the private market, then the gold so acquired is said to have been monetized. No transaction in financial assets should be recorded. Instead, the acquisition of the gold should first be recorded as a transaction in nonfinancial assets, and then the reclassification of the gold as monetary gold should be recorded as an other economic flow. Demonetization of gold is recorded symmetrically (see paragraph 10.84).

9.30 Transactions in nonmonetary gold (including gold not held as reserves by the monetary authorities and all gold held by financial institutions other than the monetary authorities) are treated as acquisitions minus disposals of valuables (if the sole purpose is to provide a store of wealth) and otherwise as changes in inventories. Deposits, loans, and securities denominated in gold are treated as financial assets (not as gold) denominated in foreign currencies.

Special Drawing Rights (SDRs) (32012, 32212, 33012, 33212)

9.31 SDRs are held exclusively by participants of the IMF's SDR Department and prescribed holders, and are transferable among them. The creation of SDRs (referred to as allocations of SDRs) and the extinction of SDRs (cancellations of SDRs) are recorded as transactions. Transactions in SDRs also take place when a holder exercises its right to obtain foreign exchange or other reserve assets from other participants and prescribed holders and when SDRs are sold, loaned, or used to settle financial obligations.

9.32 At the time of the SDR allocation, the amounts recorded as SDR allocations (liabilities) and holdings (financial assets) are identical and on the same public sector unit's balance sheet. This public sector unit—as official holder—may, subsequently, exchange some or all of its SDR holdings (financial asset) with other official holders for a freely usable currency(ies) or to

[5] For information on these categories, see the *BPM6*, Chapter 6. See also Appendix 7 for more information on the linkages between GFS and the Balance of Payments and International Investment Position.

[6] The numbers in parentheses after each classification category are the GFS classification codes. Appendix 8 provides all classification codes used in the GFS framework.

[7] See paragraphs 7.126–7.130 for more details on monetary gold.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

meet its liabilities. Consequently, the SDR allocations and holdings on the balance sheet of that public sector unit would no longer be identical; the SDR holdings would be less than the allocations because they have been exchanged. As a result, interest payable on the SDR allocation of that public sector unit will be larger than interest receivable on its SDR holdings. Interest receivable on the SDR holdings exchanged will accrue to the new holder. These transactions in SDRs (and resulting stock positions) are recorded at their gross amounts.

Currency and Deposits (3202, 3212, 3222, 3302, 3312, 3322)

9.33 Because the market price of domestic currency and deposits is fixed in nominal terms, the net acquisition of domestic currency and deposits is equal to the stock held at the end of the reporting period minus the stock held at the beginning of the period, adjusted for any currency that was lost, stolen, or destroyed. Calculation of the net acquisition of foreign currencies and deposits must exclude the effects of changes in exchange rates, which are recorded as holding gains or losses (as also mentioned in paragraph 10.23).

9.34 Currency is treated as a liability of the unit that issued the currency. Consequently, when a unit puts new currency into circulation, a transaction is recorded that increases its liability for currency. Usually, the counterpart to the increase in liabilities is an increase in the unit's financial assets, most likely deposits.[8] Transactions in gold and commemorative coins that do not circulate as legal tender are treated as transactions in inventories or valuables rather than currency (see paragraph 7.135). The cost of producing new currency is an expense transaction unrelated to the value of transactions in currency.

9.35 Transactions in unallocated accounts for precious metals (including gold) are classified under deposits (as explained in paragraph 7.15), except for transactions between two monetary authorities in unallocated gold accounts for reserves purposes. If a monetary authority acquires an unallocated gold account from a nonmonetary authority, the transaction is recorded as a transaction in currency and deposits and then reclassified as monetary gold (see paragraph 10.84).[9]

Debt Securities (3203, 3213, 3223, 3303, 3313, 3323)

9.36 Most transactions in bonds and other types of debt securities are covered by the general guidelines previously established. The accrual of interest on certain debt securities may deserve special attention and is summarized here (also see paragraphs 6.62–6.83). Interest is the amount debtors will have to pay their creditors over and above the repayment of the amounts advanced by the creditors. Interest accrues on a debt instrument for its entire life as determined by the conditions set at inception of the instrument. When payments are fixed in advance, accrued interest is determined using the original yield-to-maturity. A single, effective yield—established at the time of the security issuance—is used to calculate the amount of accrued interest in each period to maturity. This approach is known as the "debtor approach."

9.37 Most debt securities have a fixed or variable interest rate and may also be issued at a discount or, possibly, a premium. In such cases, the interest receivable by the holders of the debt securities has two components:

- The amount of money income receivable from coupon[10] payments each period, plus
- The amount of interest accruing each period attributable to the difference between the redemption price and the issue price.

9.38 On a cash basis, interest expense is recorded at the time it is paid in cash, with a reduction in currency and deposits as the counterpart.

Debt securities issued at par

9.39 For debt securities for which the issue and redemption prices are the same (i.e., issued at par), total interest accrued over the whole life of the debt

[8] Seigniorage profits (i.e., the difference between the face value of currency issued and its costs of production, including the costs of base metals) for the issuer of currency are implicitly included under currency and deposits and are not treated as revenue.

[9] See also *BPM6*, paragraph 9.20.

[10] A coupon payment is a contractually agreed cash amount paid by the issuer of the debt security to the holder, at each coupon date. It is calculated from the coupon rate, face value of the debt security, and the number of payments per year, and may differ from the accrued interest if debt securities are issued at a discount or a premium.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

securities is given by the periodic coupon payments. If coupon payments are fixed, accrued interest can be calculated by allocating the coupon payment to the relevant period using a daily compound formula.

Debt securities issued at a discount or premium

9.40 Debt securities issued at a discount (or premium), such as short-term bills of exchange and discounted and zero-coupon bonds, are recorded at the time of issue at the issue price.[11] The difference between the discounted issue price of such debt securities and their price at maturity (redemption price) is treated as interest accruing over the life of the debt security. For each reporting period, the holder of the debt security should record a transaction for the receipt of interest revenue arising from the difference between the issue and redemption prices and its reinvestment in an additional quantity of the debt security. The issuer of the debt security records the accrual of interest expense and an increase in its liability for debt securities. For debt securities issued at a premium, the difference between the issue price and the price at maturity should be amortized over the life of the instrument, reducing (rather than increasing) the amount of interest accruing in each period. On a cash basis, interest resulting from the discount should be recorded as an expense on redemption of the bond. Interest resulting from a premium should be recorded as a reduction in interest expense at the time of issue.

Index-linked debt securities

9.41 With an index-linked debt security,[12] an indexation mechanism links the amount to be paid at maturity or coupon payments (or both) to an indicator agreed by the parties. The values of the indicators are not known in advance. For debt securities with indexation of the amount to be paid at maturity, these amounts may be known only at the time of redemption. As a result, total interest flows before redemption cannot be determined with certainty. To estimate the change in the value of the debt security due to interest accrued before the values of the reference indicators are known, some proxy measures need to be used. In this regard, it is useful to distinguish the following three arrangements:

- Indexation of coupon payments only with no indexation of amount to be paid at maturity
- Indexation of the amount to be paid at maturity with no indexation of coupon payments
- Indexation of both the amount to be paid at maturity and coupon payments.

9.42 The principles describing the transactions for these index-linked debt securities revolve around determining the value of interest and are discussed in paragraphs 6.75–6.78.

Debt securities with embedded derivatives

9.43 For debt securities with embedded derivatives,[13] such as call, put, or equity conversion options, the recording of accrued interest is the same as for securities that do not have such features. For all periods leading up to the exercise of the option, the interest accrued is unaffected by the presence of the option. When the embedded option is exercised, the securities are redeemed and the accrual of interest ceases.

Loans (3204, 3214, 3224, 3304, 3314, 3324)

9.44 The terms of a loan contract frequently require periodic payments for all interest expense accrued since the previous periodic payment and a payment covering a portion of the original amount borrowed. On an accrual basis, interest accrues continuously over the reporting period and should be added to the principal; the payments of interest and principal are transactions in financial assets or liabilities (see paragraph 6.64). On a cash basis, periodic interest and principal payments are recorded as interest expense/revenue and transactions in financial assets or liabilities, respectively, when cash payments are made—no interest is accrued (see paragraph 6.65).

9.45 When goods are acquired under a financial lease, a change of economic ownership from the lessor to the lessee is deemed to take place, even though the leased goods remain legally the property of the lessor. This change in economic ownership is

[11] The issue price is the actual amount paid—that is, after the discount has been subtracted or premium added.

[12] It is possible for loans and other financial instruments to be index linked and the same transactions would be recorded.

[13] As explained in paragraph 7.148, securities with an embedded derivative are classified entirely as debt securities. A separate financial derivate component is not recorded.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

financed by a loan transaction: the lessor and lessee record a loan equal to the market value of the asset, this loan being gradually paid off over the period of the lease. The implication of treating a financial lease as a loan is that interest accrues on the loan. The rate of interest on the imputed loan equates the present value of the total amount payable in installments over the life of the lease (including any value to be repaid at maturity) with the market value of the asset at the time the lease is initiated. The installment covers interest accrued during the period as well as the component of the repayment of the principal.

9.46 As described in paragraphs 7.159 and 7.161, repurchase agreements and gold swaps are treated as loans with no change of economic ownership for the underlying assets that legally were sold. Similarly, the winding up of the repurchase agreement or swap according to the initial terms of the agreement is treated as a liquidation of a loan. The economic nature of an off-market swap is equivalent to a combination of borrowing (the lump sum) in the form of a loan transaction and an on-market swap transaction (financial derivative) (see paragraph 7.162).

Equity and Investment Fund Shares (3205, 3215, 3225, 3305, 3315, 3325)

Equity (32051, 32151, 32251, 33051, 33151, 33251)

9.47 The treatment of transactions in publicly traded shares is generally straightforward. Problems may be created, however, by the operations of quasi-corporations and public corporations.

9.48 Additions to the funds and other resources of a quasi-corporation, including in-kind transfers of nonfinancial assets, are treated as purchases of equity by the owner of the quasi-corporation. This includes new finance made available for use by the enterprise in purchasing fixed assets, accumulating inventories, acquiring financial assets, or redeeming liabilities. Similarly, receipt by the owner of proceeds from sales of any of the quasi-corporation's assets, transfers in kind from the quasi-corporation, and withdrawals by the owner of accumulated retained earnings of the quasi-corporation are treated as reductions in equity by the owner. Liquidating dividends payable to shareholders when an enterprise becomes bankrupt (or is otherwise wound up) should also be recorded as withdrawal of equity.

9.49 For government units, regular transfers to corporations or quasi-corporations to cover persistent operating deficits are *subsidies* (251), but if payments from government are irregular and are made to cover accumulated losses or exceptional losses due to factors outside the control of the enterprise, they are treated as a capital transfer under *capital transfers not elsewhere classified* (2822).[14] If government makes a transfer to a public corporation to finance all or part of the costs to finance its acquisition of nonfinancial assets, this also is recorded as equity unless there is no reasonable expectation of a sufficient rate of return on the investment, in which case the transfer is recorded as *capital transfers not elsewhere classified* (2822) (see Box 6.3). Regular withdrawals of the income from public corporations or quasi-corporations are property income under, respectively, *dividends* (1412) or *withdrawals of income from quasi-corporations* (1413). The exception occurs when dividends are disproportionately large relative to the recent level of dividends and earnings. Any dividends declared greatly in excess of the recent level of dividends and earnings should be treated as withdrawal of owners' *equity* (32051, 32151, 32251, 33051, 33151, 33251) from the public corporation. This will be the case for distributions by public corporations to shareholders of proceeds from privatization receipts and other sales of assets and large and exceptional one-off payments based on accumulated reserves or holding gains.

9.50 Government units may acquire equity in a public corporation or quasi-corporation as a result of legislation or an administrative change creating the corporation or quasi-corporation. In some cases, this event will amount to a reclassification of existing assets and liabilities, which is recorded as an other economic flow that results in an addition of equity to the government unit's balance sheet. An advance of funds to create the new enterprise is a transaction reflecting the purchase of equity. As explained in paragraph 6.121, retained earnings of a foreign direct investment enterprise are treated as if they were distributed and remitted to foreign direct investors in proportion to their ownership of the equity of the enterprise and then reinvested by them by means of additions to equity.

[14] See Box 6.3 for more details.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

9.51 From time to time, corporations restructure their shares and may offer shareholders a new number of shares for each share previously held. These bonus shares are not, however, treated as transactions, but as a form of redenomination. If a public corporation buys its own shares, the transaction is classified as being a reduction in the equity liability, rather than an acquisition of an asset. Because a corporation cannot have a claim on itself, the liability is deemed to be extinguished, even if the shares are not canceled.

9.52 Membership dues and subscription fees payable to international organizations are treated as the acquisition of equity in cases when there is a possibility—even if unlikely—of repayment of the full amount.[15] A capital contribution to an international organization or nonprofit institution is a capital transfer if it does not give rise to equity for the provider of the contribution (see paragraphs 6.94 and 6.124).

Privatization/Nationalization

9.53 Privatization generally is the disposal to private owners by a government unit of the controlling equity of a public corporation or quasi-corporation. Such a disposal is treated as a transaction in equity.[16] If a public corporation or quasi-corporation sells some of its assets and provides part or all of the proceeds to its parent government unit, then the provision of the proceeds would also be a disposal of equity of the government unit. Brokers' commissions and other privatization costs are expense transactions just as all other costs of ownership transfer related to the acquisition or disposal of a financial asset.

9.54 Government units also can be privatized. If the assets disposed of as a single transaction constitute a complete institutional unit, the transaction should be classified as a sale of equity. The government is assumed to have converted the unit to a quasi-corporation immediately prior to disposal by means of a reclassification of assets, which should be recorded as an other economic flow. If the assets disposed of do not constitute a complete institutional unit, then the transactions should be classified as a disposal of the individual nonfinancial and/or financial assets.

9.55 Nationalization is generally the acquisition from private owners by a government unit of the controlling equity of a private corporation or quasi-corporation. Such an acquisition is treated as a transaction in equity. In some exceptions, government units may acquire ownership of a private corporation or quasi-corporation by way of confiscation or appropriation. There is no payment to the owners (or the compensation is not commensurate with the fair value of the assets). This is not the result of a transaction by mutual agreement. The difference between the market value of the asset acquired and any compensation provided (a transaction) should be recorded as other changes in the volume of assets, in the form of an uncompensated seizure (see paragraph 10.62).[17]

Investment fund shares (32052, 32152, 32252, 33052, 33152, 33252)

9.56 Changes to the value of investment funds due to the issuance or repayment of shares or units are recorded as transactions. The increase (decrease) in the value of investment fund shares or units, other than from holding gains and losses, is recorded as distributed to the share- or unit holders and reinvested by the holders in the shares or units (see paragraph 5.121). This treatment is similar to the treatment of retained earnings of a foreign direct investment enterprise. Gains and losses arising from the value of an asset or fund to reflect its current market value are not recorded as transactions, but as holding gains or losses.

Insurance, Pension, and Standardized Guarantee Schemes [GFS] (3206, 3216, 3226, 3306, 3316, 3326)

9.57 General government units may incur liabilities for these reserves, entitlements, and provisions as operators of nonlife insurance and standardized guarantee schemes, nonautonomous pension funds, and unfunded pension schemes. General government units may acquire insurance technical reserves as financial assets in their capacity as holders of nonlife insurance policies. Public corporations can engage

[15] In most cases, these membership dues and subscription fees should be recorded as an expense in *use of goods and services* (22) if there is an exchange of a payment for some form of a service or, if no exchange, as a *current transfer not elsewhere classified* (2821).

[16] The public corporation is reclassified to a private corporation through an entry in other changes in the volume of assets and liabilities, as explained in Chapter 10.

[17] The same treatment would apply to the acquisition of land or any other nonfinancial asset under a compulsory sale.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

in all types of insurance activities.[18] When operating standardized guarantee schemes, such as student loan guarantees, deposit guarantees, and export credit guarantees, general government units record transactions in liabilities for *provision for calls under standardized guarantee schemes*. These transactions in liabilities comprise:

- Prepayments of net fees: fees prepaid in the reporting period less previously prepaid fees earned for the reporting period
- Provisions for outstanding calls: expected calls less any expected asset recoveries on the standardized guarantees provided in the recording period less any calls settled in the recording period (see paragraphs A4.78–A4.80).

Nonlife insurance technical reserves [GFS] (32061, 32161, 32261, 33061, 33161, 33261)

9.58 In general, nonlife insurance premiums are paid in advance of the period covered by the policy. On an accrual basis, all such prepaid premiums are transactions that increase the insurance unit's liability and the policyholder's asset for insurance technical reserves. As the period covered by the premium progresses, the insurance unit continuously earns the premium, which requires a transaction to decrease its liability and the policyholder's asset for nonlife insurance technical reserves.

9.59 When events occur giving rise to a valid claim, a transaction is recorded that increases reserves against outstanding claims as a liability of the insurance unit and an asset of the beneficiaries. If payment of the claim is delayed for a substantial length of time or consists of periodic payments over several reporting periods, the value of the transaction corresponds to the present value of the expected payments.

9.60 The change in unearned premiums and reserves against outstanding claims is shown as a transaction in liabilities of the insurer and a transaction in assets of the policyholders. The relevant transactions in revenue and expense are discussed in paragraphs 5.149–5.151 and 6.125.

9.61 On a cash basis, premiums received and claims paid are shown as a transaction in revenue and expense of the insurer and the policyholders when payments are made.

Life insurance and annuities entitlements (32062, 32162, 32262, 33062, 33162, 33262)

9.62 As noted in paragraph 7.179, it is unlikely for general government units to incur liabilities or hold assets with respect to life insurance and annuities, unless they provide such schemes to their employees. Changes in life insurance and annuities entitlements are transactions in liabilities for the insurer and transactions in financial assets for the policyholders. In the case of annuities, the transactions constitute a stream of ongoing payments, rather than a lump sum that reduces the liability. The treatment of life insurance and annuities is elaborated in paragraph A4.69.

Pension entitlements [GFS] (32063, 32163, 32263, 33063, 33163, 33263)

9.63 If a public sector unit operates a pension scheme, then it will have transactions in liabilities for pension entitlements.

9.64 For a defined-benefit scheme, actual and imputed social contributions receivable from employees, employers, or other institutional units on behalf of individuals or households with claims on the public sector unit for future pension benefits will increase the unit's liability for pension entitlements. The increase in the existing liability (because the future payments are discounted over fewer periods) is recorded as a transaction in pension entitlements with the corresponding entry being an expense in the form of imputed social contributions, as explained in paragraph 6.117. Payments to retired persons or their dependents and survivors in the form of periodic payments or lump sums reduce the liability, with a decrease in currency and deposits as the counterpart entry. On a cash basis, the benefits paid should be recorded as an expense in the form of *employer social benefits* (273).[19]

[18] It is assumed that general government units do not operate life insurance schemes and do not purchase life insurance policies. The treatment of insurance technical reserves created by life insurance activities of public corporations is similar to autonomous pension funds, but is not addressed separately here. Also see the *2008 SNA*, Chapter 17, and the *BPM6*, Appendix 6c.

[19] The cash treatment differs from the accrual treatment because there are no imputations for contributions and accumulated liabilities in a cash-based system. Furthermore, in a cash system, the benefits paid cannot be regarded as compensation of employees because they are paid to retired employees, not current employees—there is no exchange of labor involved at the time.

9.65 For a defined-contribution scheme, transactions in pension liabilities for the pension fund are actual contributions receivable from employers on behalf of employees, from employees, and possibly from other individuals (formerly participating in a scheme, self-employed and unemployed persons, and retirees) plus contribution adjustments (property expense for investment income disbursement[20]) minus benefits payable. The same transactions in financial assets are recorded for the participants in the scheme. On a cash basis, transactions in liabilities of the insurance corporation are equal to social contributions and investment income received in cash minus benefit payments in cash.

9.66 On occasion, large one-off transactions (lump sums) may occur between a government and another institutional unit, often a public corporation, linked to pension reforms or to privatizations of public corporations. The goal may be to make the public corporation competitive and financially more attractive by removing existing pension liabilities from the balance sheet of the corporation. This goal is achieved by government assuming the liability in question in exchange for an asset or assets from the public corporation. If the value of the assets receivable is equal to the value of the liability assumed, the transaction is recorded as an exchange of assets and liabilities. However, the value of the asset(s) may not be the same value as the liability.

- If the value of the asset(s) receivable is less than the value of the liability incurred, an expense in the form of a capital transfer from government to the public corporation should be recorded for the difference. The assumer (government) records an increase in liabilities for pension entitlements, an increase in the relevant financial and/or nonfinancial assets, and an expense in the form of capital transfer to the public corporation (see paragraph 6.124). The public corporation records a decrease in liabilities for pension entitlements, a decrease in financial and/or nonfinancial assets, and revenue in the form of a capital transfer from government.
- If the value of the asset(s) receivable is more than the value of the liability incurred, a capital transfer from the public corporation to the government is recorded for the difference (see paragraph 5.148). The public corporation records a decrease in liabilities for pension entitlements, a decrease in financial and/or nonfinancial assets, and an expense in the form of a capital transfer to government.

9.67 Where a government unit assumes pension liabilities, the pension obligations absorbed by the social security fund continue to be classified as pension entitlement liabilities. These obligations are gradually extinguished as the benefits are paid out. As noted in paragraph 7.261, net implicit obligations for future social security benefits are shown as a memorandum item to the balance sheet.

Claims of pension fund on pension manager (32064, 32164, 32264, 33064, 33164, 33264)

9.68 As explained in paragraph 7.199, an employer may contract with a third party to administer a pension fund for its employees. When the funding of a deficit of the pension fund is the responsibility of the employer or other sponsor (pension manager), then a claim of the pension fund on the manager accrues. Similarly, if the employer or sponsor (pension manager) has a right to claim surpluses of the pension fund, then a claim of the manager to the pension fund may accrue.

Provision for calls under standardized guarantee schemes (32065, 32165, 32265, 33065, 33165, 33265)

9.69 As explained in paragraphs 7.201–7.202, standardized guarantee schemes have much in common with nonlife insurance and are thus recorded in similar ways. The treatment of standardized guarantee schemes is elaborated in paragraphs A4.78–A4.80.

Financial Derivatives and Employee Stock Options (3207, 3217, 3227, 3307, 3317, 3327)

Financial derivatives (32071, 32171, 32271, 33071, 33171, 33271)

9.70 Transactions involving financial derivatives may arise at inception, on secondary markets, with ongoing servicing (such as for margin payments), and at settlement. Transactions in derivatives preferably

[20] Holding gains and losses generated by the investment of cumulated pension entitlements are not included in investment income.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

should be shown separately for assets and liabilities, whenever possible, but net settlements are acceptable when gross reporting is impractical. Any commission payable to brokers or other intermediaries for arranging a financial derivatives contract is treated as a payment for a service. In many cases, however, financial derivatives transactions involve implicit service charges, and it is usually not possible to estimate the service element. In such cases, the entire value of the transaction should be treated as a transaction in financial derivatives.

9.71 At inception:

- The creation of a forward-type contract (see paragraphs 7.212–7.214) does not generally require the recording of a transaction in a financial derivative because risk exposures of equal value are usually being exchanged. That is, there is usually zero exposure and zero value for both sides. In some cases, however, there may be a nonzero transaction value at issue, such as with off-market swaps. (In addition, there may be a service charge for the issue.)
- The purchaser of an option (see paragraph 7.209) pays a premium to the seller, which is the acquisition price of the instrument. Sometimes a premium is paid after the inception of the contract. In that case, the value of the premium is recorded at the inception of the contract in the same manner as if it had been paid then, but is shown as being financed by other accounts receivable/payable between the writer and the purchaser.

9.72 Subsequent changes in the prices of derivatives are recorded as holding gains or losses, not as transactions, as explained in paragraph 10.42.

9.73 Sales of options in secondary markets—whether exchanges or over the counter—are valued at market prices and recorded as transactions in financial derivatives.

9.74 When a contract requires ongoing servicing (such as an interest rate swap) and a cash payment is received, there is a decrease (increase) in a financial derivative asset (liability) if, at the time of the payment, the contract is in an asset (liability) position. If compilers are unable to implement this approach because of market practice, all cash receipts should be recorded as reductions in financial assets, and all cash payments should be recorded as decreases in liabilities.

9.75 Margins are payments of cash or deposits of collateral that cover actual or potential obligations incurred through financial derivatives—especially futures or exchange-traded options. As discussed in paragraph 7.219, repayable margins in cash are classified as transactions in deposits or other accounts receivable/payable, and nonrepayable margins are classified as transactions in financial derivatives.

9.76 At settlement, either a cash payment is made or an underlying item is delivered.

- When a financial derivative is settled in cash, a transaction equal to the cash value of the settlement is recorded for the derivative. In most instances, when a cash settlement payment is received, a reduction in a financial derivative asset is recorded. When a cash settlement payment is made, a reduction of a financial derivative liability is recorded.
- When an underlying item is delivered, two transactions are recorded:
  - The transaction involving the underlying item is valued at the market price at the time. The entry for the underlying item is recorded under the relevant heading (goods, financial instrument, etc.).
  - The transaction involving the derivative is valued as the difference, multiplied by the quantity, between the market price for the underlying item and the strike price specified in the derivative contract.
- When more than one contract is settled—in cash, at the same time, and with the same counterparty—some of the contracts being settled are in asset positions and some are in liability positions. In this situation, transactions involving assets should be recorded separately from those involving liabilities, wherever possible, but net settlements are acceptable when gross reporting is impractical.

Employee stock options (32072, 32172, 32272, 33072, 33172, 33272)

9.77 General government units are very unlikely to issue stock options. Only entities with issued share capital can create employee stock options, so they may arise for public corporations in unusual cases. An employee stock option is created on a given date

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

(the "grant" date), providing that an employee may purchase a given number of shares of the employer's stock at a stated price (the "strike" price) either at a stated time (the "vesting" date) or within a period of time (the "exercise" period) immediately following the vesting date.

9.78 At the grant date, a transaction in *employee stock options* should be recorded as the corresponding entry to *compensation of employees in kind* (2112). The value of the employee stock options recorded as compensation of employees should be spread over the period between the grant and vesting dates, if possible. Similarly, any increase in the value of the employee stock options between the grant and vesting date should be classified as compensation of employees. If this is not possible, for a pragmatic solution see paragraph 9.80.

9.79 When the option is exercised, the transaction in the employee stock option is recorded at a value that reflects the difference between the market price of the equity and the price paid by the buyer for the equity. Any change in the value between vesting date and exercise date is not treated as compensation of employees but as a holding gain or loss (see paragraph 10.43).

9.80 In practice, it is most unlikely that estimates of the costs of employee stock options to the employers are revised between the grant date and the exercise date. For pragmatic reasons, therefore, the whole of the increase between grant date and exercise date is treated as a holding gain or loss (see paragraph 10.43). Cancellation of employee stock options is recorded as other changes in the volume of assets (see paragraph 10.57).

9.81 Employee stock options do not generally raise separate issues to those for financial derivatives, but one special case occurs when an employee of a subsidiary is issued options for stock in the parent company. Because the parent is not the employer, the subsidiary records a transaction acquiring the option from the parent before granting the stock option to the employee. See also paragraph 7.222 regarding stock options provided to suppliers of goods and services to an enterprise.

Other Accounts Receivable/Payable (3208, 3218, 3228, 3308, 3318, 3328)

9.82 Other accounts receivable/payable consist of trade credits and advances and miscellaneous other items due to be paid or received. Transactions in trade credits occur when credit is extended directly to purchasers of goods and services. Advances are recorded for amounts paid in advance of work being performed, or for prepayments of goods and services (see paragraph 7.225).

9.83 Miscellaneous other accounts receivable/payable occur with respect to accrued but unpaid taxes, dividends, purchases and sales of securities, rent, wages and salaries, social contributions, social benefits, and similar transactions. Prepayments of taxes are also included in this category. Accrued but unpaid interest should be added to the principal of the underlying asset rather than included in this category.

9.84 This category is used to bridge the timing difference between the occurrence of economic events and the time the actual cash flows take place. It should not be used to record statistical discrepancies.

Classification of Transactions in Financial Assets and Liabilities by Sector and Residence

9.85 For a full understanding of financial flows and the role they play in government finance, it is often important to know not just what types of liabilities a general government unit uses to finance its activities and what types of financial assets it holds as investments. It is also important to know which sectors are providing the financing and what types of financial assets are held. In addition, it is often necessary to analyze financial flows between subsectors of the general government sector or the public sector. These flows of funds may be analyzed in a from-whom-to-whom framework.[21] Table 9.2 presents a classification of transactions in financial assets and liabilities based on the sector and residence of the two parties involved in the transactions.

9.86 An issuer of securities is usually not a party involved in a secondary market transaction in that security. However, when a transaction changes the residence or sector of the creditor, an entry in other

[21] See the *PSDS Guide*, Chapter 7, and *Handbook on Securities Statistics*, Part 2, for a detailed discussion of the from-whom-to-whom approach.

changes in the volume of assets (reclassification) should be recorded to maintain the integrated GFS framework of stock positions and flows (see paragraphs 9.25 and 10.79).

9.87 The composition of the sectors listed in Table 9.2 is described in Chapter 2. All nonresident units are referred to collectively as the external sector ("rest of the world" sector in the *2008 SNA*). In the GFS framework, it is important to know not only the total amount of financing receivable from nonresident units, but also the types of nonresident units supplying the financing.[22] In GFS, therefore, the sector classification principles could also be applied to nonresident units. In particular, all foreign governments and international organizations are treated as separate sectors in Table 9.2.

Classification of Debt Liabilities and Financial Assets Corresponding to Debt Instruments by Maturity

9.88 A supplementary classification of the stock positions of debt liabilities and financial assets corresponding to debt instruments by maturity and type of financial instrument is of particular interest and is shown in Table 7.12. If analytically useful, the same classification structure could be applied for transactions in these debt liabilities and financial assets corresponding to debt instruments.

[22] Often, in cases of traded debt securities, this will show only the initial holders.

10 Other Economic Flows

This chapter describes the other economic flows that are recorded in the government finance statistics framework. The two major categories are holding gains and losses and other changes in the volume of assets.

Introduction

10.1 Other economic flows are changes in the volume or value of assets or liabilities that do not result from transactions. This chapter describes the two major categories of other economic flows that change net worth:

- A **holding gain or loss**[1] is a change in the monetary value of an asset or liability resulting from changes in the level and structure of prices, excluding qualitative or quantitative changes in the asset or liability. Holding gains and losses can apply to almost all assets and liabilities and, in the case of assets and liabilities expressed in a foreign currency, include gains and losses resulting from changes in exchange rates.[2]
- **Other changes in the volume of assets** are any changes in the value of an asset or liability that do not result from a transaction or a holding gain. Other changes in the volume of assets result from events that change the quantity or quality of an existing asset, events that add a new asset to the balance sheet or delete an existing asset from the balance sheet, and events that require a reclassification of existing assets.

[1] Revaluation may also be used with the same meaning as holding gain or loss.

[2] A holding gain or loss always affects net worth. The words gain and loss are used in reference to the direction of the change in net worth. A flow that increases the value of an asset or decreases the value of a liability will increase net worth and is referred to as a holding gain. A flow that decreases the value of an asset or increases the value of a liability will decrease net worth and is a holding loss. References to financial assets can be assumed to refer also to liabilities.

10.2 Other economic flows are recorded in a *Statement of Other Economic Flows*; an abbreviated version is shown in Table 10.1. The balancing item to this statement is described as the ***change in net worth due to other economic flows***, which is defined as the sum of the change in net worth due to holding gains or losses and the change in net worth due to other changes in the volume of assets.

- The balancing item ***change in net worth due to holding gains*** (or revaluations) is defined as the sum of the positive or negative holding gains on all assets and liabilities.
- The balancing item ***change in net worth due to other changes in the volume of assets*** is defined as the sum of the positive and negative other changes in the volume of assets and liabilities.

10.3 Many other economic flows change both the value of an asset or a liability and the value of net worth by the same amount. For example, holding gains that lead to an increase in the value of assets

Table 10.1 Statement of Other Economic Flows (Abbreviated)

9	Change in net worth due to other economic flows
91	Nonfinancial assets
92	Financial assets
93	Liabilities

increase net worth. In contrast, other economic flows related to reclassifications do not affect total net worth. These reclassifications change the value of two assets or two liabilities by the same amount but with opposite signs, or they change one asset and one liability by the same amount—for example, the reclassification of a loan when it becomes negotiable (see paragraph 7.149).

10.4 Other economic flows are classified by the type of asset or liability affected. The classification of assets and liabilities given in Chapter 7 is used for this purpose. In Table 10.2, total other economic flows are classified as being either holding gains and losses or other changes in the volume of assets. In addition, other economic flows can be classified by the type of event that caused the flow in as much detail as needed for fiscal analysis. The types of holding gains or specific types of other changes in the volume of assets could be introduced as an expansion of the table, if considered useful. For example, subcategories of other changes in volume of assets could identify whether the changes are due to the appearance, disappearance, or change in classification of assets and liabilities.

Holding Gains

Holding Gains in General

10.5 Holding gains result from price changes and can accrue on almost all economic assets held for any length of time during a reporting period. It does not matter whether an asset is held the entire period, acquired during the period and held until the end of the period, held at the beginning of the period and disposed of during the period, or acquired and disposed of within the same period. In each case, a holding gain is possible and must be recorded for the entire difference between the opening balance sheet date (or at time of acquisition) and closing balance sheet date (or time of disposal).

10.6 Holding gains may be unrealized or realized:

- An **unrealized holding gain** is one accruing on an asset that is still owned or a liability that is still outstanding at the end of the reporting period. The values of the assets and liabilities in the closing balance sheet incorporate the unrealized holding gains or losses.
- A **holding gain is realized** when an asset is sold, redeemed, used or otherwise disposed of, or a liability incorporating a holding gain or loss is repaid. The value of transactions includes the value of realized holding gains or losses. In other words, unrealized holding gains are realized when transactions take place.

10.7 The holding gain is recorded when the price change occurs, which may be at a different time from when the holding gain is realized. Thus, to capture the full value of the holding gains and losses that arose during the reporting period, both realized and unrealized gains and losses need to be covered.

10.8 Holding gains do not include a change in the value of an asset resulting from a change in the quantity or quality of the asset (which are other changes in the volume of assets)—in particular:

- The decline in the value of the fixed assets due to physical deterioration, normal rates of obsolescence, and normal accidental damage should be recorded as *consumption of fixed capital* (23) and not as a holding loss.
- Debt securities issued at a discount may increase in value progressively prior to redemption because of the accrual of interest. The increase in the market value of a bill or bond due to the accrual of interest should be recorded as a transaction in the asset and is not a holding gain.

10.9 It is not possible to calculate total holding gains using only balance sheet data since the stock positions do not reflect each of the economic events that may have occurred during a reporting period (see paragraphs 3.1–3.4). To measure holding gains directly, therefore, the calculation requires records to be maintained of all individual transactions and individual other changes in the volume of assets plus the price of each asset at the time of the opening and closing balance sheets. Observable market prices for nonfinancial assets are generally not as readily available as for financial assets and liabilities. If, in practice, not all of the requisite data are available, alternative estimation techniques must be employed to calculate holding gains.

10.10 A commonly used alternative method to estimate holding gains and losses is based on the identity that the ending balance sheet value for a

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Same instrument breakdown as above	4321–4328	5321–5328	9321–9328

category of assets must equal the opening balance sheet value plus the net value of transactions, other changes in the volume of assets, and holding gains that affect that category of assets or liabilities. If the information available on balance sheets, transactions, and other changes in the volume of assets is complete and accurate, then the net value of holding gains can be calculated to complete the identity. This formulation does not imply that the value of holding gains is a residual item—even if estimated this way, the results should always be carefully examined and evaluated.

10.11 For some analytic purposes, it may be desirable to divide the total value of holding gains accruing on a category of assets or liabilities into neutral and real holding gains.

- **Neutral holding gains and losses** over a period are the increase (decrease) in the value of an asset that would be required, in the absence of transactions and other changes in the volume of assets, to maintain command over the same amount of goods and services as at the beginning of the period. It is the value needed to preserve the real value of the asset.
- A **real holding gain** is defined as the value accruing to an asset as a result of a change in its price relative to the prices of goods and services in general. An increase in the relative price of an

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

asset leads to a positive real holding gain, and a decrease in the relative price of an asset leads to a negative real gain.[3]

10.12 In concept, holding gains and losses occur continuously because prices change continuously. As a practical matter, holding gains for the entire reporting period are normally estimated at the end of the period.

Holding Gains for Particular Types of Assets

Fixed assets (411)[4]

10.13 Estimating the holding gains on fixed assets is complicated by the fact that the value of a fixed asset changes as a result of consumption of fixed capital as well as price changes. Consumption of fixed capital, however, is valued in terms of the average prices prevailing during a reporting period. Thus, estimating the change in the price of a given fixed asset of a given age and condition is critical for estimating both consumption of fixed capital and holding gains.

10.14 Holding gains may occur on existing fixed assets because the market price of the asset itself changes over time. If market prices are not readily available, market-value equivalent prices should be used (see paragraph 7.31). When assets of the same kind are still being produced and sold on the market, an existing asset should be valued in the opening or closing balance sheet at the current acquisition price of a newly produced asset minus the accumulated consumption of fixed capital (i.e., at written-down replacement cost) up to that time.

10.15 When new assets of the same type are no longer being produced, the valuation of existing assets may pose difficult conceptual and practical problems. If broadly similar kinds of assets are still being produced, it may be reasonable to assume that the prices of the existing assets would have moved in the same way as those of new assets if they were still being produced. Such an assumption becomes questionable, however, when the characteristics of new assets are much improved by technical progress.[5]

Inventories (412)

10.16 The estimation of holding gains on inventories is needed for the calculation of *use of goods and services* (22) using the indirect method, as illustrated in Table 6.3. However, estimation may be difficult because of a lack of data on transactions or other changes in the volume of inventories:

- Many transactions in inventories are internal transactions, and the prices prevailing at the time they occur may not be adequately recorded.
- Withdrawals from inventories include an allowance for recurrent losses that are part of the normal operations of a production process.
- Other changes in the volume of assets are likely to consist of goods destroyed by natural disasters, major fires, and other exceptional events. Estimating the prices and quantities involved in these events may be difficult.

10.17 Thus, holding gains on inventories exclude both exceptional and recurrent losses on inventories. Certain types of inventories (e.g., stationery) have stable prices and are held over reasonably short periods of time, in which case the holding gains or losses are normally minimal. In other cases, such as strategic stocks, more sophisticated methods have to be applied. As records on transactions and other changes in the volume of assets may not be available, it becomes necessary to try to deduce the value of changes in inventories from the value and quantities of the opening and closing inventories using methods that attempt to partition the difference between the values of the opening and closing stock positions of assets into transactions and holding gains. Such methods are only as good as the assumptions on which they are based.[6] In general, if assumptions are made, they should cover as short a period as possible. When there are high rates of inflation, estimating holding gains accurately in this way becomes more important.

[3] Information on the calculation and interpretation of neutral and real holding gains is in the *2008 SNA*, paragraphs 12.87–12.93.
[4] The numbers in parentheses after each classification category are the GFS classification codes. Appendix 8 provides all classification codes used in GFS.
[5] See Organisation for Economic Co-operation and Development, *Measuring Capital—OECD Manual: Measurement of Capital Stocks, Consumption of Fixed Capital and Capital Services* (Paris, 2009), for more details.
[6] Also see the *2008 SNA*, paragraph 12.99.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Valuables (413)

10.18 The nature of valuables is that they are held as a store of value in the expectation that their value will increase over time. Any increase/decrease in value of an individual valuable is treated as a holding gain/loss.

Nonfinancial assets disposed of during the reporting period

10.19 There are no remaining costs of ownership transfer included in the value of the asset when it is sold to a new owner, as the amount the old owner receives is equal to the amount the new owner pays except for any costs of ownership transfer incurred by the new owner. This is because consumption of fixed capital is calculated on the value of the asset excluding the costs of ownership transfer over the whole of its life, and the consumption of fixed capital in respect of the costs of ownership transfer is calculated only over the period that the owner expects to hold the asset (see paragraph 6.60).

10.20 When a nonfinancial asset is disposed of in a market-related transaction[7] at a value that is different from the balance sheet value of the asset immediately prior to disposal, a revaluation should be recorded to reflect the current market value of the asset in the balance sheet. This applies to all nonfinancial assets but not to scrap.[8]

Monetary gold and Special Drawing Rights (SDRs) (4201, 4221, 4301, 4321)

10.21 The price of gold is usually quoted in dollars; therefore, monetary gold (including unallocated gold accounts) is subject to holding gains and losses because of changes in the exchange rate as well as in the price of gold itself.

10.22 The value of the SDR is based on a basket of key currencies; therefore, the value of SDRs is always subject to holding gains and losses. From time to time, new allocations of SDRs may be made; when this occurs, the allocation is recorded as a transaction.

[7] If there is a transfer element to the transaction, the economic value of the transfer should be recorded as a separate transaction (see paragraph 3.122).

[8] In cases where the scrap value does not coincide with the residual balance sheet value of the asset immediately before disposal, an adjustment is to be made to the value of the asset via the other changes in the volume of assets account.

Financial assets and liabilities with fixed monetary values

10.23 Not all financial assets and liabilities have market prices. Currency, deposits, most loans, and other accounts receivable/payable, such as trade credit and advances, are recorded at nominal value. As a result, holding gains resulting from market price changes on these assets are always zero in terms of the currency in which they are denominated. When these financial assets are denominated in a foreign currency or held as unallocated gold accounts (or similar accounts in other precious metals), their value in domestic currency terms can change because of a change in the exchange rate or a change in the value of the precious metal.

Debt securities (4203, 4213, 4223, 4303, 4313, 4323)

10.24 Debt securities typically have market prices that change over time. Changes in the value of the stock of debt securities between balance sheet dates arise from transactions in debt securities (i.e., acquisitions, disposals, and the accrual of interest), other changes in the volume of assets (such as write-offs), and revaluations (e.g., changes in the market rate of interest, exchange rate, expectation of creditworthiness, etc.).

10.25 When debt securities, especially deep-discount and zero-coupon bonds, are issued at a discount, then, in the absence of other changes, the price will gradually rise over the life of the bond until it reaches the maturity value. This gradual increase in the market price of a bond that is attributable to the accumulation of accrued interest is a transaction, not a holding gain. The converse treatment applies to bonds issued at a premium.

10.26 The values of debt securities may change when the market rates of interest and/or exchange rates change. With the exception of broad-based index-linked securities (see paragraph 6.77), changes in the values of debt securities that are attributable to changes in market rates of interest and exchange rates (for debt securities denominated in another currency) are holding gains. An increase in interest rates causes a decrease in the market value of the fixed-rate debt securities, which is a holding gain for the debtor and a holding loss for the creditor, and conversely for a decrease in interest rates.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

10.27 Prices of bonds may also change because of a change in the creditworthiness of the issuer or guarantor. Such changes give rise to holding gains.

10.28 As explained in paragraphs 6.76–6.77, when the amount to be paid at maturity or when the coupon payments and the amount to be paid at maturity are indexed to a narrow index (e.g., a gold index) that includes a holding gain motive, any deviation of the underlying index from the originally expected path leads to holding gains or losses.

10.29 Holding gains or losses may accrue on bills in the same way as for bonds. However, because bills are short-term debt securities with much shorter times to maturity, the holding gains generated by interest rate changes are often much smaller than on bonds with the same face values.

Equity and investment fund shares (4205, 4215, 4225, 4305, 4315, 4325)

10.30 General government units may have financial assets or liabilities in the form of equity and investment fund shares. For example, a general government unit may own all or part of the equity of a public corporation or the equity of a quasi-corporation. As with any other asset, a change in the monetary value of these financial assets resulting from price changes is a holding gain or loss.

10.31 Several events can affect the valuation of shares and other equity. For purposes of explanation, a distinction is made between:

- Shares issued by incorporated corporations that are listed (publicly traded) and unlisted shares whose value can be otherwise independently determined
- Unlisted shares issued by incorporated corporations whose value cannot be independently determined and other equity of unincorporated enterprises, such as quasi-corporations.

10.32 If the shares of a public corporation are publicly traded or their value can be independently determined, then the holding gains or losses of the government unit or other public corporation that owns the shares are determined by reference to the market price per share or the independently determined price per share. Several factors may affect the market price per share, such as market perceptions on the profitability of the corporation and when shares go ex-dividend. Valuation changes in shares are recorded as holding gains and losses.

10.33 As explained in paragraph 7.229, net worth is zero for quasi-corporations[9] and for public corporations for which the value of shares cannot be independently determined (most likely because the controlling government unit owns all of the shares). In these cases, the total value of the implicit equity of the quasi-corporation or shares of the corporation is equal to the total value of its assets minus the total value of its liabilities other than equity. As a result, a holding gain equal to the change in the total value of this measure of the equity needs to be recorded, taking into account all retained earnings, and other additions to and withdrawals from equity that may have occurred.

10.34 As mentioned in paragraphs 5.121 and 6.119, reinvested earnings on investment fund shares or of a foreign direct investment enterprise are treated as a type of property income and not holding gains.

Insurance, pension, and standardized guarantee schemes (4206, 4216, 4226, 4306, 4316, 4326)

10.35 When the reserves for nonlife insurance and standardized guarantee schemes are denominated in domestic currency, there are generally no holding gains and losses, just as there are none for currency or deposits and loans. In some exceptions, if an amount for a claim outstanding has been agreed upon and it has been agreed that it will be indexed pending payment, then there may be a holding gain or loss recorded for it.

10.36 Liabilities for pension entitlements include liabilities for the future payment of pensions and other retirement benefits of defined-benefit schemes. The value of these liabilities can change for several reasons, one of which is the passage of time. The liability is computed as the present value of the future benefits, and it will increase each period because there is one fewer period over which it is discounted. In GFS, this increase is treated as a *property expense for investment income disbursements* (2813) (see paragraphs 6.113–6.118).

10.37 In GFS, a holding gain is recorded with respect to the liability for a defined-benefit pension

[9]Because quasi-corporations do not issue shares, market prices do not apply to them.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

scheme when there is a change in the value of the liability because of a change in the interest rate used to discount the future benefits. The liability should be reviewed periodically and revalued as necessary for changes in market interest rates.

10.38 At first sight, it would seem that there are no other economic flows involved for a defined-benefit pension scheme since the two components recorded as the pension contributions and property expense for investment income disbursements are matched by equal-value increases in entitlements. However, because the nature of a defined-benefit pension scheme is that the level of benefit entitlements is determined by a formula, there are other factors that may intervene to affect changes in the level of entitlements. These factors include a price escalation clause, changes in the formula used to determine benefits, and demographic assumptions about lifespan.

10.39 The factors that change the level of entitlements (i.e., changes in the formula used to determine the benefits and demographic assumptions) should be recorded as other changes in the volume of assets (see paragraph 10.73); the adjustments from changes in the price escalation formula are recorded as holding gains or losses.

10.40 The impact of promotions, merit increases, and other real salary increases on entitlements is a special case.[10] Many defined-benefit pension schemes use a formula to set benefits based on either the final salary or average salary as a key determinant. Therefore, this implies that any promotion or other real increase in salaries means that the total pension entitlements accrued to date are increased to take account of the new salary level. This is a significant benefit for the individual and has consequences for the employer's pension liabilities. It is recommended that a simple and adequate solution would be to treat the impact of promotions for the unit as a whole as a price change and record this change as a holding gain. If the projected benefit obligation method is used to value pension entitlements, an adjustment in the form of other changes in the volume of assets is needed if the enterprise makes a structural change in the way promotions and merit increases are awarded (see paragraph 10.72).

[10] Also see the *2008 SNA*, paragraphs 17.180–17.186.

10.41 An equal-valued holding gain should be recorded with respect to the liability for a defined-contribution pension scheme whenever a holding gain is recorded with respect to the assets of the fund. The investment of accumulated pension entitlements of a defined-contribution pension scheme leads to holding gains (and possibly losses). These come about through the management of investment in assets held by the fund. The holding gains appear under entries for the relevant assets for the pension fund, with a matching entry for the increase in the liability of the pension fund toward the policyholders (households).

Financial derivatives and employee stock options (4207, 4217, 4227, 4307, 4317, 4327)

10.42 Financial derivatives have quoted prices or have prices that can be derived from the underlying item that is the subject of the derivative. Thus, financial derivatives register holding gains and losses.

10.43 Employee stock options can also register holding gains and losses. In principle, any change in value between the grant date and vesting date should be recorded as compensation of employees, while any change in the value between vesting date and exercise date is treated as a holding gain or loss. In practice, and for pragmatic reasons, the whole of the increase between grant date and exercise date is treated as a holding gain or loss (see paragraph 9.80). An increase in value of the share price above the strike price is a holding loss for the employer.

Financial assets denominated in foreign currencies

10.44 The value of a financial asset denominated in a foreign currency is its current value in the foreign currency converted into the domestic currency at the current exchange rate. Therefore, holding gains may occur not only because the price of the asset in the foreign currency changes but also because exchange rates change.

Debt instruments that do not accrue interest

10.45 There may be an unusually long time[11] before payment is due on an outstanding debt liability

[11] What constitutes an unusually long time in this context will depend on the circumstances. For example, for any given time period, the higher the level of interest rates or the longer the delay in payment, the greater is the opportunity cost of delayed payment.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

(or the corresponding financial asset in the form of a debt instrument) on which no interest accrues (see paragraph 7.30). If so, the value of the principal should be reduced by an amount that reflects the time to maturity and an appropriate existing contractual rate, such as for similar debt instruments. Once the value of the principal is reduced through a revaluation, interest should accrue until actual payment is made, at the rate used to discount the principal.

Other Changes in the Volume of Assets

10.46 Other changes in the volume of assets cover a wide variety of events. For the purpose of description, these events are divided into three groups:[12]

- Events that involve the appearance or disappearance of existing resources as economic assets. In other words, certain assets enter and leave the GFS balance sheet through events other than by transactions
- The effects of external events—exceptional and unexpected—on the economic benefits derivable from assets (and corresponding liabilities)
- Changes in classification.

10.47 Many other volume changes occur at specific times and should be recorded when the event occurs. Some other volume changes occur continuously or at frequent intervals, such as the depletion of subsoil and other naturally occurring assets or environmental damage to assets. These changes should be recorded in the same manner as holding gains.

Appearance or Disappearance of Existing Economic Assets

10.48 For a resource to be an economic asset, ownership rights over it must be enforced and it must be capable of providing economic benefits. If a resource that is known to exist but is not classified as an economic asset becomes an economic asset because of a change in relative prices, technology, or some other event, an entry in other changes in the volume of assets should be recorded to recognize the asset's value and add it to the balance sheet. Conversely, an economic asset may need to be removed from the balance sheet because it is no longer capable of supplying economic benefits or because the owner is no longer willing or capable of exercising ownership rights over the asset.

10.49 The recording of events relating to the appearance and disappearance of assets can be grouped according to the main type of asset under consideration based on whether they relate to:

- The economic recognition of produced assets
- Entry and exit from the asset boundary of natural resources
- Contracts, leases, and licenses
- Changes in goodwill and marketing assets, or
- Financial assets (and liabilities).

10.50 Usually, two types of assets can appear under the economic recognition of produced assets: public monuments and valuables. These are existing goods that may not already have been recorded in the balance sheets as public monuments or valuables for any of several reasons; they may date from a time before the reporting period covered by the accounts, they may have been originally recorded as expense for use of goods, or they may be structures that have already been written off.

- Public monuments are included with dwellings, buildings other than dwellings, or other structures, as appropriate, in the classification of fixed assets (see paragraphs 7.42–7.43). When the special archaeological, historical, or cultural significance of a structure or site not already recorded in the balance sheet is first recognized, it is classified as an economic appearance and recorded as other changes in the volume of assets. For example, such recognition might be accorded to an existing structure or site that is fully written off and thus no longer recorded in the balance sheet. Alternatively, a structure or site that is already within the asset boundary, but is new or only partially written off, may be assessed as having the status of a public monument. If the monument was previously written off, then its recognition as a public monument is recorded as an economic appearance of an asset. If it was previously classified as another type of asset, it is recorded as a reclassification of an asset (see paragraphs 10.80–10.84) and if at the same time a new valuation is placed on the monument, this increase in value is recorded as an economic appearance.

[12]The distinctions made here are only for purposes of description; the GFS classifications do not specify this breakdown.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

- Valuables, such as precious stones, antiques, and other art objects, for which the high value or artistic significance has not already been recorded in the balance sheet, should be recognized as an economic appearance. Hitherto, the object may have been of little value and not considered an asset. For example, the item might have been considered an ordinary good whose purchase was recorded as an expense, classified in *use of goods and services* (22). Recognition of its worth as a store of value leads to its entrance into the balance sheet as a valuable. The recognition of the value of a previously unvalued item is often necessitated by a sale (e.g., at auction). The sale is recorded as a transaction under the disposal of nonfinancial assets only after the asset first entered into the balance sheet of the seller through an entry in other changes in the volume of assets.

10.51 Conversely, a nonfinancial asset that no longer has economic value because of a change in technology, relative prices, or other event must be removed from the balance sheet. For example, the commercial exploitation of mineral reserves, land, forests, fish stocks, aquifers, and other naturally occurring assets may become unfeasible. If so, then a negative entry in other changes in the volume of assets would be recorded to remove the asset from the balance sheet.

10.52 It may be difficult to determine the exact time at which a natural asset should be added to the balance sheet, and to determine the value that should be attributed to it at that time. Often, the date at which the first substantial commercial exploitation begins or the signing of a contract to permit commercial exploitation is used to establish the time of recording. Several events may result in natural resources to enter or exit the asset boundary:

- Discoveries/extractions and upward/downward reappraisals of subsoil resources—The value of these resources may increase in the balance sheet by the discovery of new exploitable deposits, whether as a result of systematic scientific explorations or surveys, or by chance. Economic appearance may also occur because a deposit of subsoil minerals has become economically exploitable as a result of technological progress or relative price changes.
- Conversely, the value of these resources may decrease in the balance sheet by the depletion of deposits of subsoil assets as a result of the physical extraction and use of the assets, or from downward reappraisals that reduce their exploitability because of changes in technology or relative prices.
- Natural growth/harvesting of noncultivated biological resources—The natural growth of noncultivated biological resources, such as natural forests and fish stocks, may take various forms: a stand of natural timber may grow taller, or fish in the estuaries may become more numerous. Although these resources are economic assets, growth of this kind is not under the direct control, responsibility, and management of an institutional unit and thus is not treated as a transaction in net investment in fixed assets. In principle, natural growth should be recorded gross, and the depletion of these resources should be recorded as economic disappearance, as described in the next bullet. This recording would be consistent with the gross recording of transactions in acquisitions and disposals described under the net investment in nonfinancial assets. In practice, however, many countries will record natural growth net because only the net physical measures are likely to be available. The net physical measure multiplied by the market price for a unit of the asset may be used in estimating the value of the volume change to be recorded.
- The depletion of natural forests, fish stocks in the open seas, and other noncultivated biological resources included in the asset boundary of general government or public sector units as a result of harvesting, forest clearance, or other use beyond sustainable levels of extraction constitutes an economic disappearance of assets and should be recorded as negative other changes in the volume of assets.
- Transfers of other natural resources to/out of economic activity—Not all land included in the geographic surface area of a country is necessarily within the asset boundary of GFS. Land may make its economic appearance when, for example, general economic development in nearby areas transforms the land from a wild or waste state to a state in which ownership rights can be enforced and the land can be put to economic use.[13] Land may also make its economic

[13] For the treatment of land improvements, including land reclamation, see paragraphs 7.49–7.51.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

appearance (or enter the asset boundary) because of activity in the vicinity—for example, land that becomes more desirable because a new development is established nearby or an access road built. Any excess in the value of the land over the value of land improvements or any increase due to adjacent capital activity is recorded as economic appearance. For virgin forests, gathering firewood is not commercial exploitation, but large-scale harvesting of a virgin forest for timber is and brings the forest into the asset boundary. Similarly, drawing water from a natural spring does not bring an aquifer into the asset boundary of GFS, but a significant diversion of groundwater does. A move to charge for regular extraction from a body of surface water may also bring a water resource into the balance sheet.

- A government unit can create an economic asset by exerting ownership rights over a naturally occurring asset that had not previously been recognized as an asset, such as the electromagnetic spectrum or fish stocks in exclusive economic zones. When this occurs, the asset enters the balance sheet through other changes in the volume of assets.
- It is possible that some natural resources cease to be exploited because of changed technology or reduced demand for the resulting product, or for legislative reasons, such as the suspension of fishing to ensure the survival of fish stocks. When this change in use occurs, the asset is removed from the balance sheet through other changes in the volume of assets.
- Quality changes in natural resources due to changes in economic uses—In this case, the asset is already within the asset boundary. The change in quality of the asset due to changes in its economic use is regarded as the appearance of additional amounts of the asset. For example, the use of bare rural land changes when it becomes land underlying buildings and may result in a change in the balance sheet value that is effected through an other change in the volume of the asset.
- All degradation of land, water resources, and other natural assets caused by economic activity should be recorded as negative other changes in the volume of assets. The degradation may be the anticipated result from regular economic activity or less predictable erosion and other damage to land from deforestation or improper agricultural practices.
- The difference between a quality change and a price change is a matter of degree, and it may not always be clear whether other changes in the volume of assets or a holding gain is most appropriate. For example, activities adjacent to land may bring land into the asset boundary (recorded as another volume change), while the value of land in the vicinity may also increase due to a rise in general price levels of land (recorded as holding gains).

10.53 It is recommended to recognize assets in the form of contracts, leases, and licenses in the balance sheet of the holder only when the value of the asset can be realized (see paragraph 7.106). In this case, they are first recorded as other changes in the volume of assets and, subsequently, form the basis of a transaction (or series of transactions). The value of the contract, lease, or license that is treated as an asset is equal to the present value of the excess of the prevailing price over the contract price. The value will decline as the remaining contract period shortens. Changes in the value of the contract, lease, or license due to changes in the prevailing price are recorded as holding gains or losses (revaluations); changes due to the expiration of the time over which the contract, lease, or license is valid are recorded as other changes in volume of assets (i.e., to write off the cost of the asset). The rate at which the value is written down should be in accordance with internationally accepted accounting standards. The treatment of contracts, leases, and licenses is discussed more extensively in Appendix 4.

10.54 When an enterprise—whether a corporation, quasi-corporation, or unincorporated enterprise—is sold, the price payable may not equal the sum of all the assets minus the liabilities of the enterprise. The difference between the price payable and the sum of all the assets minus liabilities is called the purchased goodwill and marketing assets of the buyer. The value may be positive or negative (or zero). When the buyer includes this asset in the calculation of the net worth of the enterprise at the moment it is bought, net worth is exactly zero.

10.55 The value of purchased goodwill and marketing assets is calculated at the time of the sale, and entered in the books of the seller as an other

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

change in the volume of assets. Subsequently, it is then exchanged as a transaction with the purchaser. Thereafter, the value of the purchased goodwill and marketing asset must be written down in the books of the purchaser via entries under other changes in the volume of assets. The rate at which it is written down should be in accordance with internationally accepted accounting standards. These standards are typically conservative in the amount that may appear on the balance sheet of an enterprise and should be subject to an "impairment test" whereby accountants can satisfy themselves that the remaining value is likely to be realizable in case of a further sale of the enterprise.

10.56 Goodwill that is not evidenced by a sale or purchase is not considered an economic asset in GFS. In some exceptions, a marketing asset may be subject to sale. When this is the case, entries should be made for the buyer and the seller along the lines of those made for purchased goodwill and marketing assets when the entire enterprise is sold.

10.57 Financial assets and liabilities may appear on or disappear from the balance sheet in several ways—for example:

- A creditor may determine that a financial claim can no longer be collected because of the debtor's bankruptcy or other factors. If so, the creditor writes off the debt and removes the claim from its balance sheet by means of an entry in other changes in the volume of assets.[14]
- Cancellations of employee stock options are recorded as other changes in the volume of assets.

10.58 The creation of SDRs (referred to as allocations of SDRs) and the extinction of SDRs (cancellations of SDRs) are treated as transactions, not other changes in the volume of assets.[15]

The Effect of External Events on the Value of Assets

10.59 There are three principal causes of the reduction in the value of an asset, or even its disappearance, that are not related to the nature of the asset but to conditions prevailing in the economy that impact either the value or ownership of assets. These are catastrophic losses, uncompensated seizures, and other changes in the volume of assets not elsewhere classified. Each is discussed in the remainder of this section.

Catastrophic losses

10.60 A **catastrophic loss** is the partial or complete destruction of a significantly large number of assets within any of the asset categories resulting from a large-scale, discrete, and recognizable event. Such events will generally be easy to identify. They are usually sudden or one-time events of large proportions. They include major earthquakes, volcanic eruptions, tidal waves, exceptionally severe hurricanes, droughts, and other natural disasters; acts of war, riots, and other political events; and technological accidents, such as major toxic spills or release of radioactive particles into the air. Included here are such major losses as deterioration in the quality of land caused by abnormal flooding or wind damage; destruction of cultivated assets by drought or outbreaks of disease; and destruction of buildings, equipment, or valuables in fires or earthquakes. An entry in other changes in the volume of assets is recorded to reduce or eliminate the value of any asset damaged or destroyed.

10.61 Although produced assets are the most likely candidates to be damaged or destroyed by a catastrophic loss, nonproduced assets and financial assets are also subject to damage or destruction. For example, major decreases in the value of land and other natural assets caused by abnormal flooding or wind damage and the accidental destruction of currency or bearer securities as a result of natural catastrophes or abnormal political events would be included.

[14] Usually, debt is written off as uncollectible because of the bankruptcy or liquidation of the debtor; however, it may sometimes be written off for other reasons, such as a court order. The write-off may be full or partial; partial write-offs may arise, for example, under a court order, or if the liquidation of the debtor's assets allows some of the debt to be settled. Recognition that the debt is uncollectible should be distinguished from internal accounting provisions of the creditor for the possibility of default (such as adjustments to fair value of nonperforming loans). Although such provisions may be useful for analysis, they do not mean that the debt should no longer be recognized as existing and should therefore not be considered as written off. In contrast, as described in paragraphs 6.124 and A3.7–A3.9, a reduction in a financial claim by mutual agreement between the creditor and debtor is a transaction rather than an other change in the volume of assets.

[15] See paragraphs 7.131–7.134 and 9.31.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Uncompensated seizures

10.62 Government units may take possession of the assets of other institutional units without full compensation for reasons other than the failure to pay taxes, fines, or similar levies. Such seizures of assets, legal or illegal, are not capital transfers because they do not take place by mutual agreement of the units involved. The difference between the market value of the assets seized and any compensation provided is recorded as an other change in the volume of assets, in the form of an uncompensated seizure. Foreclosures and repossessions of assets by creditors are transactions when the contractual agreement between debtor and creditor provides this avenue of recourse.

Other volume changes not elsewhere classified

10.63 The value of a fixed asset is continuously reduced by consumption of fixed capital until the asset is disposed of or has no remaining value. It is possible for the assumptions underlying the calculation of consumption of fixed capital to be inaccurate, in which case corrections to the value of the asset need to be made through other changes in the volume of assets. Similarly, if the assumption about the rate of shrinkage of inventories was inaccurate, this should also be corrected through an entry in other changes in the volume of assets. Financial assets and liabilities, such as those related to insurance, pension, and standardized guarantee schemes, can also be affected by volume changes.[16]

Fixed assets (511)

10.64 The calculation of the consumption of fixed capital reflects an assumption about normal rates of physical deterioration, obsolescence, and accidental damage. Each of these assumptions may prove to be faulty. In that case, an adjustment in the form of other changes in the volume of assets must be made.

10.65 Physical deterioration may include the effect of unforeseen environmental degradation on fixed assets. Entries must, therefore, be made through other changes in the volume of assets for the decline in the value of the fixed assets from, for example, the unforeseen effects of acidity in the air and acid rain on building surfaces or vehicle bodies.

10.66 The introduction of improved technology can render an asset obsolete or accelerate the rate of obsolescence. For example, improved models of the asset or of a new production process that no longer requires the asset may lead to unforeseen obsolescence. In consequence, the amount included in consumption of fixed assets for their expected obsolescence may have been underestimated, so an entry in other changes in the volume of assets should be recorded.

10.67 The amount included for normally expected damage—as included in the calculation of consumption of fixed capital—may fall short of the actual damage. Adjustments must therefore be made through other changes in the volume of assets for the decline in the value of the fixed assets due to these events. While these losses may be larger than normal, they are not on a scale sufficiently large to be considered catastrophic—they are therefore included in other volume changes not elsewhere classified.

10.68 As explained in paragraph 6.60, costs of ownership transfer should, in principle, be written off over the expected time the asset will be in the possession of the purchaser. If the asset is disposed of before the costs of ownership transfer are completely written off, the remainder should be recorded as an other change in the volume of assets.

10.69 Production facilities with long construction periods may cease to have an economic use before they are completed or are put into service. For example, a nuclear power plant or industrial site may never be put into service. When the decision to abandon is made, the value of the fixed asset (or in some cases, work-in-progress inventories) as recorded in the balance sheet should be written off through an other change in the volume of assets.

Exceptional losses in inventories (512)

10.70 Exceptional inventory losses from fire, robbery, insect and vermin infestation of grain stores, and unusually high levels of disease in livestock, etc. are included as other changes in the volume of assets. In this context, exceptional losses indicate that the losses are not only large in value but also irregular in occurrence. Even very large losses that occur regularly should be taken into account when calculating the net change in inventories, as explained in paragraph 8.47. The adjustment for unforeseen damage could be an

[16] See paragraphs 10.39–10.40 and A2.54.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

increase in assets if the actual damage falls short of the amount covered by the allowance for losses.

Life insurance and annuities entitlements (52062, 52162, 52262, 53062, 53162, 53262)

10.71 For an annuity, the relationship between the expected net premiums and benefits is usually determined when the contract is entered into, taking account of mortality data available at that time. Any subsequent changes will affect the liability of the annuity provider toward the beneficiary, and the consequences should be recorded as other changes in the volume of assets.

Pension entitlements (52063, 52163, 52263, 53063, 53163, 53263)

10.72 In defined-benefit pension schemes, the level of benefits promised to participating employees is determined by a formula that is usually based on the participants' length of service and salary. Changes in pension entitlements that are imposed without negotiation are recorded as other changes in the volume of assets.[17] That is because such changes are assumed to be imposed unilaterally by the employer and do not constitute a capital transfer negotiated by mutual agreement.

10.73 As explained in paragraph 10.38, for a defined-benefit pension scheme, any changes in the value of the liability due to changes in the formula used to determine benefits and due to changes in demographic assumptions about the lifespan should be recorded as other changes in the volume of assets. If the projected benefit obligation method is used to value pension entitlements, an adjustment in the form of other changes in the volume of assets is needed if the enterprise makes a structural change in the way promotion and merit increases are awarded (see paragraph 10.40).

10.74 No such adjustments are needed for defined-contribution schemes where the benefits are determined solely in terms of the contributions and investment earnings of the scheme.[18]

[17] The cases where changes in pension entitlements are recorded as transactions are discussed in paragraphs 9.63–9.67. The distinction between transactions and other changes in the volume of assets remains theoretical, as it is recognized that the distinction between what is negotiated and what is imposed without negotiation will be difficult to determine in practice, with different situations prevailing in different countries.

[18] Also see the *2008 SNA*, Chapter 17, Part 2.

Provisions for calls under standardized guarantee schemes (52065, 52165, 52265, 53065, 53165, 53265)

10.75 Changes to provisions for calls under standardized guarantee schemes not resulting from transactions and holding gains and losses are shown as other changes in volume of assets. For example, such other changes in volume of assets occur whenever a significant change to the expected level of calls is recognized beyond any asset recovery (see paragraph A4.79).

Changes in Classification

10.76 The composition of the general government or public sector's balance sheet may change because there has been a reclassification of an entire institutional unit, the structure of a unit, or a group of assets and liabilities. A reclassification rearranges assets and liabilities without adding to or subtracting from total net worth.

Changes in sector classification and structure

10.77 An entire unit may be reclassified from the general government sector to another sector or to the general government sector from another sector without a change of ownership or control, normally because the unit either begins or ceases to sell its output for economically significant prices. When a unit is reclassified out of the general government sector, all of the unit's assets and liabilities are removed from the general government sector's balance sheet and the net value of those assets and liabilities is replaced by a financial asset, *equity and investment fund shares*, to reflect the continued ownership or control of the unit by a general government unit. The reverse will be true when a unit is reclassified into the general government sector. By contrast, when a public corporation is privatized, all of the unit's assets, liabilities, and net worth are reclassified from being that of a public corporation to a private corporation.[19]

10.78 A change in the structure of units is also recorded as an other change in the volume of assets—for example, when two general government units merge into a single unit, or a single unit splits into two units.

[19] In the balance sheet of the shareholder (such as government), the privatization transaction will lead to a reduction in the financial asset *equity and investment fund shares.*

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

When two units are merged, all financial claims and liabilities that existed between them are eliminated. Symmetrically, when a unit splits into two or more units, new financial claims and liabilities may appear between the new units.

10.79 In cases where general government units issue negotiable securities that sell in secondary markets, the holders of the securities may change during the life of the security. In debt data classified by counterparties, this change in the debtor/creditor relationship should be recorded as a reclassification under other changes in the volume of assets (see also paragraphs 9.25 and 9.86). For example, a central government debt security may be sold originally to a bank and then subsequently sold by the bank to a local government unit. To show on the central government's balance sheet that the new holder of the security on the reporting date is the local government, entries in other changes in the volume of assets are recorded in the central government accounts, reducing the security liability to the bank and increasing the liability to the local government.[20] No transactions between the central government, bank, and the local government should be imputed to reclassify the holder of the securities.

Changes in classification of assets and liabilities

10.80 Depending on the degree of detail of the classifications of assets, there may be reclassifications of existing assets and liabilities from one category to another, usually when there is a change in the purpose for which an asset is used. The change in classification is recorded as other changes in the volume of assets with the same value for both entries. If the change in the use also means a change in its value, then a second entry in other changes in the volume of assets is recorded for the entrance into the asset boundary of the asset with the higher value. It is not recorded as a revaluation since the value increase is due to the change in use and is not due to price changes.

10.81 The use of a structure may be changed from a dwelling to a government office building or vice versa. If these types of structures are classified separately, then an entry in other changes in the volume of assets is recorded. The positive change in one asset category is balanced by a negative change in the other asset category. A conversion resulting solely from new investment in a building is not an other change in the volume of the asset but a transaction in fixed assets (see paragraph 8.28).

10.82 In all instances, work in progress needs to be reclassified to finished goods prior to sale, through an entry in other changes in the volume of assets. In principle, reclassification from one type of inventory to another or from fixed assets to inventories should not involve a change in value. If at the time of conversion, the previous value is different from the appropriate new value, an entry in other changes in the volume of assets should be recorded under economic appearance or disappearance as appropriate. If this is found to be happening systematically, the valuation techniques for inventories should be re-examined.

10.83 As explained in paragraph 8.42, transactions in the costs of ownership transfer of nonproduced assets other than land are classified as fixed assets and these costs are subject to consumption of fixed capital. To maintain the integration of stock positions and flows, the costs of ownership transfer of nonproduced assets other than land and the consumption of fixed capital relating to these costs are reclassified to the respective nonproduced assets through an entry in other changes in the volume of assets.[21] This reclassification is considered to take place at the time of recording the transactions in cost of ownership transfer and consumption of fixed capital, respectively.

10.84 Some examples of changes in the classification of financial assets and liabilities are:

- When monetary gold held in the form of gold bullion becomes a reserve asset, it enters the financial assets in the balance sheet as a reclassification via other changes in the volume of assets from valuables to monetary gold. At the time it is acquired by a monetary authority, it is first classified as inventory or a valuable.[22] The same

[20] Because the local government has a claim on central government, without the central government being involved in the transaction, the same other volume change would be recorded on the local government's balance sheet to show that the central government is the creditor.

[21] Two entries are recorded in other changes in the volume of assets: a reduction in the fixed asset *costs of ownership transfer on nonproduced assets other than land* (31133) and an increase in the value(s) of the respective nonproduced assets.

[22] Gold is reclassified to inventories if not primarily held as a store of value.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

recording is followed for allocated gold accounts that become part of monetary gold. When unallocated gold accounts become reserve assets, they are reclassified from currency and deposits to monetary gold, also through other changes in the volume of assets. Monetary gold may be sold to another monetary authority, but otherwise, any reduction in holdings follows a similar declassification path; the monetary gold is reclassified to be either a valuable or inventories (in the case of gold bullion) or currency and deposits (in the case of unallocated gold accounts). Subsequent transactions are recorded in terms of inventories or valuables or currency and deposits and not in terms of monetary gold.

- In cases when benefits under a defined-contribution pension scheme are converted to annuities, a reclassification should be recorded from pension entitlements to annuities entitlements.
- When loans become tradable in the conditions stated in paragraph 7.149, a reclassification should be recorded from loans to debt securities.
- If arrears arise and the contract provides for a change in the characteristics of a financial instrument when it goes into arrears, this change should be recorded as a reclassification in the other changes in the financial assets and liabilities account. The reclassification applies to situations where the original contract remains, but the terms within it changes (e.g., interest rates or repayment periods).
- If the amount payable under a derivative remains due for payment after the derivative matures, the amount due no longer represents a derivative because the value is fixed. It is therefore reclassified under other accounts receivable or payable.[23]
- Bonds that are convertible into equity are reclassified as *equity and investment fund shares* when the option is exercised.
- In cases where government units acquire equity in a public corporation or quasi-corporation as a result of legislation or an administrative change creating the corporation or quasi-corporation, this event will amount to a reclassification of the corporation's existing assets and liabilities that results in an addition of *equity and investment fund shares* to the balance sheets of government and the corporation (see paragraph 9.50).

[23]The creation and exhaustion of financial derivatives are transactions in financial assets (and liabilities), not other changes in the volume of assets.

APPENDIX

1 Changes from the *GFSM 2001* and *GFSM 1986*

This appendix describes the changes in the Government Finance Statistics Manual 2014 (GFSM 2014) from the *Government Finance Statistics Manual 2001 (GFSM 2001), and describes the differences with the traditional approach to fiscal reporting as depicted in* A Government Finance Statistics Manual 1986 (GFSM 1986).

Introduction

A1.1 In the *GFSM 2014*, the guidelines in the *GFSM 2001* have been revised to harmonize with the updates in other macroeconomic statistical manuals and guides, such as the overarching *System of National Accounts 2008* (*2008 SNA*), the sixth edition of the *Balance of Payments and International Investment Position Manual* (*BPM6*), and the *Public Sector Debt Statistics: Guide for Compilers and Users* (*PSDS Guide*).

A1.2 The *GFSM 2014* addresses important international economic developments in recent years and takes into account improved recording and methodological treatments of various events. The changes incorporated can broadly be summarized as methodological changes agreed to in the update of the *2008 SNA*, clarifications on existing methodological guidelines, presentational changes, and editorial changes.

A1.3 The remainder of this appendix first describes the changes in the *GFSM 2014*, compared to the *GFSM 2001*. Since many countries are still in various stages of migrating from presenting fiscal statistics in a traditional way, based on the *GFSM 1986*, the second part of this appendix also provides a description of the difference between the guidelines in this *Manual* and the *GFSM 1986*.

Changes from the *GFSM 2001*

A1.4 The *GFSM 2014* retains the basic conceptual framework of its predecessor, the *GFSM 2001*. However, this *Manual* introduces improved treatments for recent developments and specific events, elaborates on aspects of reporting that have proved to be complex, and takes into consideration new needs of compilers and users of GFS. The remainder of this section describes the main changes, grouped according to the chapters of the *GFSM 2014*, before describing changes in terminology introduced in this *Manual*. The discussion of the changes includes cross-references to the relevant paragraphs in the chapters.

Chapter 1

A1.5 A definition for *fiscal policy*, *general government sector*, and *public sector* is introduced in paragraph 1.2.

A1.6 A section to describe the evolution of international statistical guidelines on government finance statistics, starting in the early 1970s, is presented in paragraphs 1.6–1.9. This section also broadly outlines the reasons for the update of the *GFSM 2001*.

A1.7 The section on the structure and features of the GFS framework introduces two supplementary statements—namely, the *Statement of Total Changes in Net Worth* and the *Summary Statement of Explicit Contingent Liabilities and Net Obligations for Future Social Security Benefits* (see paragraphs 1.18–1.19). These supplementary statements are added to the GFS framework due to their analytical usefulness for users of fiscal data.

A1.8 The valuation principle described in paragraph 1.29 indicates that *current market prices* are used to value economic flows and stock positions. This principle is clarified by indicating that market-value equivalents are used for assets and liabilities that are not traded in markets, or are traded infrequently.

A1.9 The important linkages between GFS and other macroeconomic datasets are introduced in

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

paragraph 1.35, also recognizing the close relationship with accounting standards. Paragraph 1.39 highlights the importance of good dissemination practices as spelled out in the General Data Dissemination System, Special Data Dissemination Standard, and the Special Data Dissemination Standard Plus.

Chapter 2

A1.10 The delineation of general government and public sector institutional units is clarified. The chapter is reorganized to first delineate the domestic economy, and then it describes institutional units and the types of units that exist in macroeconomic statistics, before defining institutional sectors. These principles are then applied to delineate the general government and public sectors, and the practical application of the sector classification principles to selected cases is described.

A1.11 The concept of *residence* is elaborated on to align with guidance of *2008 SNA* and *BPM6* (see paragraph 2.6). The additional guidance includes defining and describing the treatment of *notional resident units* (see paragraph 2.13) and *nonresident special purpose entities* (see paragraph 2.15). Additional guidance on identifying *international and regional organizations* is presented in paragraphs 2.16–2.19. The treatment of multiterritory *regional enterprises* (see paragraph 2.20) and *currency union central banks* (see paragraph 2.21) is explained.

A1.12 The rationale for working with the institutional unit in macroeconomic statistics is explained in paragraph 2.23. In addition, the concepts *establishment* and *enterprise* are defined and explained in paragraphs 2.24 and 2.25, respectively.

A1.13 The description of the types of institutional units is organized to make a distinction between persons or groups of persons in the form of *households* and *legal or social entities* (see paragraph 2.27). Households are defined and described in paragraphs 2.28–2.29, while legal or social entities are defined, and the types of legal or social entities described in more detail (see paragraphs 2.30–2.38).

A1.14 The section on applying the definition of institutional unit to government introduces a discussion on *artificial subsidiaries* and *ancillary activities*, and applies these concepts to *resident SPEs* and a *government central borrowing authority* (see paragraphs 2.42–2.45).

A1.15 The definition and identification of *nonfinancial and financial corporations sectors* are presented in detail (see paragraphs 2.52–2.57). The additional guidance is provided to clarify the distinction between these corporations and government units. This includes the introduction of three broad classes of financial corporations—namely, financial intermediaries, financial auxiliaries, and other financial corporations—and specifically explains *financial intermediation*.

A1.16 The delineation of general government and public corporations is clarified using the concept of *market and nonmarket producers*. The application of the concept *economically significant prices* to determine whether a unit is a market or nonmarket producer is elaborated on (see paragraphs 2.65–2.75).

A1.17 Guidance is provided on how to determine whether a nonprofit institution is under control of government. *Indicators of control* and how to apply these to establish control of government are provided in Box 2.1.

A1.18 An extensive discussion on the *public corporations subsector* is introduced in paragraph 2.104. The rationale for the extension of GFS to include data for public corporations is described in paragraph 2.105, and the types of public corporations are presented in paragraphs 2.113–2.121. Guidance is provided on how to determine whether a corporation is under control of government (see paragraphs 2.107–2.112). *Indicators of control* and how to apply them to establish control of government over corporations are provided in Box 2.2.

A1.19 Using the concepts of residence, institutional units, control, and market versus nonmarket producers, a *decision tree* for sector classification of the public sector is introduced in paragraph 2.124 and Figure 2.4.

A1.20 A separate section describes the practical application of the sector classification principles to selected cases—these cases are the topics of frequently asked questions. Included are: the identification of *quasi-corporations* (see paragraph 2.125); distinguishing *head offices and holding companies* (see paragraph 2.128); *restructuring agencies* (see paragraph 2.129); *financial protection schemes* (see paragraph 2.132); *special purpose entities* (see paragraph 2.136); *joint ventures* (see paragraph 2.140); *sinking funds* (see paragraph 2.144); *pension schemes* (see paragraph 2.147);

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

provident funds (see paragraph 2.148); *sovereign wealth funds* (see paragraph 2.152); *market regulatory agencies* (see paragraph 2.156); and *development funds and/or infrastructure companies or entities* (see paragraph 2.160).

A1.21 The annex to Chapter 2 of the *GFSM 2001*, describing *social protection*, is subsumed in Appendix 2 of the *GFSM 2014*. This appendix presents guidance on the identification and sectorization of entities involved in social protection, as well as guidance on the recording of the flows and stock positions related to their economic activities.

Chapter 3

A1.22 A distinction between *monetary* and *nonmonetary* transactions is introduced in paragraphs 3.8 and 3.19, respectively. This distinction also forms the basis for the distinction between transfers (capital and current transfers), exchanges, in-kind transactions, and internal transactions.

A1.23 A definition of stock positions is provided in paragraph 3.36. The concepts *economic benefits* and *ownership* are used to define economic assets, before a distinction is drawn between *legal* and *economic ownership* in paragraphs 3.38–3.39. These concepts are used to determine the *asset boundary* and define *assets* and *liabilities* (see paragraphs 3.42–3.50).

A1.24 The *GFSM 2014* reinstates a more balanced approach between having *both accrual and cash* information in an integrated statistical framework. Therefore, starting in paragraph 3.61, alternative recording bases are discussed with a reference to using the accrual basis of recording in the *Statement of Operations* (see paragraph 3.69) and using the cash basis of recording in the *Statement of Sources and Uses of Cash* (see paragraphs 3.67 and 3.103).

A1.25 Additional guidance on the application of the accrual basis of recording principles is described from paragraph 3.76 onward. Guidance on the time of recording and measurement of *taxes* and *other compulsory transfers* is presented in paragraph 3.77.

A1.26 The time of recording dividends when using an accrual basis of recording is defined as when the equity or shares go *ex-dividend* (see paragraphs 3.87 and 5.112).

A1.27 When using an accrual basis of recording, the time of recording transactions in goods and services, nonfinancial assets, and many financial assets and liabilities is defined as the moment when *economic ownership changes*. Recognition is given to cases where change of ownership is not obvious and additional guidance for those cases is provided (see paragraphs 3.88–3.97).

A1.28 Guidance on the time of recording other economic flows is described in paragraphs 3.98–3.102.

A1.29 Guidance on using the cash basis of recording in the *Statement of Sources and Uses of Cash* is elaborated in paragraphs 3.103–3.106.

A1.30 Guidance on valuation is elaborated on and the section is structured to present descriptions of the *general valuation rule* (see paragraph 3.107), *valuation of transactions* (see paragraphs 3.108–3.112), *valuation of stock positions* including *alternatives valuation methods* (see paragraphs 3.113–3.117), *valuation adjustments* in special cases (see paragraphs 3.118–3.125), and *valuation of other economic flows* (see paragraphs 3.126–3.129).

A1.31 The *GFSM 2014* introduces a discussion on *currency*, starting with a discussion on the *unit of account* for the compilation of GFS in paragraph 3.130. Guidance is provided on *currency conversions* for transactions and stock positions (see paragraphs 3.132–3.133) and the distinction between *domestic and foreign currency* (see paragraphs 3.134–3.136) and *currency of denomination* and *currency of settlement* (see paragraphs 3.137–3.139).

A1.32 Starting in paragraph 3.152, the *GFSM 2014* presents a detailed discussion of *consolidation*. The concept is defined (see paragraphs 3.153–3.154), a distinction is made between *intrasectoral* and *intersectoral consolidation* (see paragraphs 3.155–3.157), and *reasons* for consolidation are discussed (see paragraphs 3.158–3.160), before *conceptual guidelines* for the process of consolidation are presented (see paragraphs 3.161–3.164). Paragraphs 3.165–3.166 present practical guidelines on *implementing consolidation*, while paragraphs 3.167–3.168 describe consolidation principles used in other datasets.

Chapter 4

A1.33 The analytic objectives of the GFS framework were expanded to include the ability to assess management and policy decisions, as well as sustainability and liquidity decisions (see paragraphs 4.3–4.5).

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

A1.34 Paragraph 4.7 elaborates on the coverage of GFS, emphasizing that data should cover the nonmarket activities of the general government sector, as well as the market activities of the public sector.

A1.35 Two additional statements are included in the GFS framework, to further enhance the analytical usefulness of GFS (see paragraphs 4.13–4.15 and 4.46–4.49):

- Statement of Total Changes in Net Worth
- Summary Statement of Explicit Contingent Liabilities and Net Implicit Obligations for Future Social Security Benefits.

A1.36 The concept *expenditure* is reinstated as an aggregate in both the *Statement of Operations* and in the *Statement of Sources and Uses of Cash* (see paragraph 4.21, Table 4.1, and Table 4.2).

A1.37 The definition and identification of *policy lending* are elaborated on in Box 4.1.

A1.38 The composition of the item *net change in the stock of cash*, as presented in the *Statement of Sources and Uses of Cash*, is clarified—the item refers to the financial asset *currency and deposits* (3202), and should not include other financial instruments or overdrafts (see paragraph 4.33).

A1.39 The description of the *Balance Sheet* is expanded with a discussion on the use of the net worth concept in the case of public corporations (see paragraph 4.40).

A1.40 Box 4.1 in the *GFSM 2001* is replaced with an annex to Chapter 4 of the *GFSM 2014*, *Using GFS for Fiscal Analysis*. The annex offers an overview of how analysts can use the data in GFS to build well-defined and internationally comparable *fiscal indicators*. Some of the indicators can be observed or derived directly from the GFS framework, while others can be derived using GFS together with additional data.

Chapter 5

A1.41 The rationale for defining *revenue* as an increase in net worth resulting from a transaction is added in paragraph 5.1.

A1.42 The definition of *grants* (13) is revised to no longer refer to grants as *noncompulsory* transfers. The change accommodates cases where compulsory revenue sharing occurs between government units. The definition is also expanded to indicate that grants are transfers that do not meet the definition of a tax, subsidy, or social contribution (see paragraphs 5.5 and 5.101).

A1.43 Definitions of the respective categories of *other revenue* (14) are replaced by a definition of the main category *other revenue* (14), with only references to the subcategories it comprises (see paragraph 5.6).

A1.44 The section on defining revenue is enhanced with the inclusion of a discussion on the treatment of refunds and corrections, and with an explanation of the delineation between revenue and transactions in assets and liabilities (see paragraphs 5.7–5.8).

A1.45 The section on the time of recording and measurement of revenue is expanded to clearly indicate the time of recording when using the accrual basis of recording, as well as the cash basis of recording (see paragraphs 5.10–5.11). Further clarification is provided on applying an accrual basis of recording to revenue transactions (see paragraphs 5.12–5.17), as well as on the treatment of amounts assessed, but discovered to be uncollectable (see paragraph 5.20).

A1.46 The basis on which the classification of revenue should be made is presented in paragraph 5.21, while paragraph 5.22 describes the rationale for standardized summary classifications and the usefulness of adding subitems according to analytical use and need.

A1.47 Paragraphs 5.27–5.32 describe the treatment of *tax refunds and tax relief*. In this regard, the *GFSM 2014* adopted the gross recording of *payable tax credits*, while *nonpayable tax credits* continue to be treated on a net basis.

A1.48 The tax category *unallocable* (1113), in the *GFSM 2001*, is renamed *other taxes on income, profits, and capital gains* (1113) in the *GFSM 2014*, and a breakdown of the category is introduced to separately identify these taxes receivable from *general government units* (11131) and *unallocable taxes on income, profits, and capital gains* (11132) (see paragraph 5.42 and Tables 5.1 and 5.2). This change allows the identification of those taxes receivable from other general government units that are subject to consolidation.

A1.49 The tax attribution rules are described in paragraphs 5.33–5.38. The tax attribution rules applicable to cases where the activities of the *religious organizations* are funded from earmarked taxes

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

collected by general government are clarified in paragraph 5.39.

A1.50 The *GFSM 2001* tax category for *taxes on financial and capital transactions* (1134) is moved from *property taxes* (113) to *general taxes on goods and services* (1141). In the *GFSM 2014*, this tax category retains its name, but with a different classification code—namely, *taxes on financial and capital transactions* (11414) (see paragraphs 5.52 and 5.61). This change aligns the *GFSM 2014* with the *2008 SNA*, which regards this tax as a tax on the sale rather than on the property itself. To maintain consistency with codes used in the *GFSM 2001*, the codes in taxes on property do not follow directly.

A1.51 A new definition for *excises* is introduced in paragraph 5.62.

A1.52 The concept *profits on fiscal monopolies* (1143) is clarified, and its application to public enterprises, lotteries, and other gambling activities is elaborated on (see paragraphs 5.63–5.68).

A1.53 The coverage of *taxes on specific services* is extended to include the *implicit taxes* that result from the central bank imposing a rate of interest other than the market rates (see paragraphs 5.70 and 6.89, Box 6.2).

A1.54 The coverage of *taxes on use of goods and on permission to use goods or perform activities* (1145) is clarified (see paragraph 5.72). Boundaries of this tax with *administrative fees* (paragraph 5.73), *taxes on business activities* (see paragraph 5.76), *other tax categories* (see paragraph 5.77), and *the acquisition or use of an asset* (see paragraph 5.78) are explained.

A1.55 *Taxes on use of goods and on permission to use goods or perform activities* (1145) are subdivided into *motor vehicle taxes* (11451) and *other taxes on the use of goods and on the permission to use goods or perform activities* (11452). For the latter, the *GFSM 2014* introduces several subcategories of taxes to clarify their classification (see paragraph 5.81 and Table 5.4). Furthermore, the accrual recording of business licenses and taxes on pollution (such as emission trading schemes) is elaborated on (see paragraph 5.81).

A1.56 The *implicit taxes* or *subsidies* created by multiple exchange rate regimes are introduced in paragraph 5.89. Furthermore, it is clarified that lumpsum payments receivable by government from monetary authorities should be disaggregated according to the economic nature of the components of the payment (see paragraph 5.90).

A1.57 The concept *social contributions* (12) is clarified (see paragraph 5.94), specifically making a distinction between voluntary and compulsory contributions, describing the flexibility arrangement for the recording of social contributions used in the *2008 SNA* (see paragraph 5.95), and presenting the boundary between social contributions and other categories of taxes (see paragraph 5.96).

A1.58 The treatment of *grants* is elaborated on, specifically describing the distinction between current and capital grants, grants in kind, and the time of recording in an accrual and cash basis of recording (see paragraph 5.103–5.105).

A1.59 The time of recording *dividends* when using an accrual basis of recording is clarified to be when the equity or shares go *ex-dividend* (see paragraphs 3.87, 5.112, and 6.109). In addition, it is clarified that legally constituted corporations, reclassified to be a general government unit, could also distribute dividends (see paragraph 5.113). The treatment of disproportionately large dividends is clarified (see paragraphs 5.115–5.116).

A1.60 The coverage of *property income from investment income disbursements* (1414) is expanded to include distributions to holders of investment fund shares or units (see paragraph 5.120).

A1.61 The concept *rent* (1415) is elaborated on to explain the distinction between a resource lease, the creation of an asset, *contracts, leases, and licenses* (31441), or the sale of the resource. Two types of resource rent, for land and subsoil assets, are described in detail and the boundary with the rental of produced assets is explained (see paragraphs 5.124–5.133).

A1.62 The *GFSM 2014* assumes the *2008 SNA* and *BPM6* treatment of *reinvested earnings on foreign direct investment* (1416) (see paragraphs 5.134–5.135 and 6.121).

A1.63 The classification of *administrative fees* (1422) is clarified to include fees payable for voluntary participation in deposit insurance or other guarantee schemes that do not qualify to be a standardized guarantee scheme. For it to be administrative fees, the amount payable should be in proportion to the cost of producing the service (see paragraph 5.138).

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

A1.64 The treatment of fines and penalties imposed for evasion of taxes and bails set by courts is clarified in *fines, penalties, and forfeits* (143) (see paragraph 5.143).

A1.65 The *GFSM 2001* revenue categories for *voluntary transfers other than grants* (144) and *miscellaneous and unidentified revenue* (145) are subsumed in two new categories—namely, *transfers not elsewhere classified* (144) and *premiums, fees, and claims receivable related to nonlife insurance and standardized guarantee schemes* (145) (see paragraphs 5.145 and 5.149). Revenue from *subsidies* (14411) receivable is introduced as a separate category of transfer not elsewhere classified (see paragraph 5.146), while the other transfers are distinguished as *other current transfers not elsewhere classified* (14412) (see paragraph 5.147) and *capital transfers not elsewhere classified* (1442) (see paragraph 5.148).

A1.66 The revenue category *premiums, fees, and claims related to nonlife insurance and standardized guarantee schemes* (145) (see paragraph 5.149) is introduced to allow for the appropriate recording of the revenue related to nonlife insurance and standardized guarantees. Subcategories provide for the identification of *premiums receivable* (14511), *fees for standardized guarantees receivable* (14512), *current claims receivable* (14513), and *capital claims receivable* (1452) (see paragraphs 5.150–5.151).

Chapter 6

A1.67 The rationale for defining *expense* as a decrease in net worth resulting from a transaction is added in paragraph 6.1.

A1.68 The distinction between economic classification of expense and functional classification of expense is clarified in paragraphs 6.2 and 6.3, respectively.

A1.69 The section on defining expense is enhanced with the inclusion of a discussion on the *treatment of refunds and corrections* and the delineation between expense and transactions in assets and liabilities (see paragraphs 6.4–6.5).

A1.70 The section on the *time of recording* expense is expanded to clearly indicate the time of recording when using the accrual basis of recording, as well as the cash basis of recording. Furthermore, the time of recording of the acquisition and *use of goods and services* (22) is clarified (see paragraphs 6.6–6.7).

A1.71 The definition of *compensation of employees* is clarified to emphasize the individual employer-employee relationship, and the exchange of manual and intellectual labor services (see paragraph 6.9). Furthermore, the nature of wages and salaries in cash (see paragraph 6.13) and in kind (see paragraph 6.17) is elaborated on.

A1.72 Guidance on estimating *imputed employers' social contributions* (2122) is elaborated on. A clear distinction between nonpension and employment-related pension benefits is introduced (see paragraphs 6.23–6.26).

A1.73 The section on the *use of goods and services* (22) is reorganized to: define the concept (see paragraph 6.27); make a distinction between the time of recording use of goods and services when using an accrual and cash basis of recording (see paragraphs 6.28–6.31); describe the boundary between use of goods and services and compensation of employees (see paragraph 6.33); describe the boundary between use of goods and services and transfers (see paragraph 6.37); describe the boundary between use of goods and services and transactions in the acquisition of nonfinancial assets (see paragraph 6.43); and describe other boundaries related to use of goods and services (see paragraph 6.50).

A1.74 Conceptually, the coverage of *use of goods and services* (22) in the *GFSM 2001* is changed to exclude *weapons and weapons systems* in the *GFSM 2014* (see paragraphs 6.49). These are recognized as the acquisition of a specific category of *nonfinancial assets* in the *GFSM 2014* (see paragraph 8.43).

A1.75 The relationship between *inventory* (612) and *use of goods and services* (22) is clarified in Table 6.3.

A1.76 The treatment in GFS of the *implicit fees for financial services* is explained (see paragraphs 6.52 and 6.81). These implicit fees include items such as financial intermediation services indirectly measured (FISIM), service fees implied by nonlife insurance premiums, and the implicit fees payable by governments to central banks for nonmarket services.

A1.77 The concept *consumption of fixed capital* (23) is elaborated on. The relation between consumption of fixed capital as recorded in the *2008 SNA* and in GFS is explained (see paragraph 6.53). The relation

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

between consumption of fixed capital and depreciation as used in government financial records is also explained (see paragraph 6.54). The calculation of consumption of fixed capital is described in Box 6.1. Furthermore, the treatment of *costs of ownership transfer* as a component of consumption of fixed capital is explained in paragraphs 6.60 and 8.42.

A1.78 The description of *interest* (24) is clarified to show the relationship between interest as recorded in the *2008 SNA* and interest as recorded in the *GFSM 2014*. It is suggested to identify the counterpart for interest transactions to allow for consolidation (see paragraph 6.62). A discussion on recording interest, when using a cash basis of recording, is introduced in paragraph 6.65. Recording interest in the case of grace periods and step-up interest arrangements is explained in paragraphs 6.69–6.70. The recording of interest related to index-linked securities is explained in paragraphs 6.75–6.78. Furthermore, clarification is provided on the treatment of interest on debt securities with embedded derivatives, nonperforming loans, and arrears (see paragraphs 6.79–6.82).

A1.79 Recording *subsidies* (25) is clarified. The treatment of subsidies in cases when an institutional unit acts on behalf of another unit to redistribute the subsidies is explained in paragraph 6.84. It is also clarified that subsidies are receivable by all resident and nonresident producers, and that units such as general government units, nonprofits institutions serving households, and households can receive subsidies in their capacity as producers (see paragraph 6.86). The coverage of subsidies is extended to include the *implicit subsidy* that results from the central bank imposing a rate of interest other than the market rates (see paragraphs 5.70 and 6.89, Box 6.2). The discussion on subsidies also introduced the distinction between subsidies on products and subsidies on production to better align with this distinction in the *2008 SNA* (see paragraphs 6.89–6.90).

A1.80 To further delineate subsidies, a list of items that do not constitute subsidies is included (see paragraph 6.91), and Box 6.3 elaborates on transactions with public corporations with specific reference to the classification of "*capital injections*" into public corporations.

A1.81 The definition of *grants* (26) is revised to no longer refer to grants as *noncompulsory* transfers. This change accommodates cases where compulsory revenue sharing occurs between government units. The definition is also expanded to indicate that grants are transfers that do not meet the definition of a tax, subsidy, or social contribution (see paragraph 6.92).

A1.82 The treatment of *grants in kind* is elaborated on, specifically describing the distinction between current and capital grants, and the time of recording in, respectively, an accrual and cash basis of recording (see paragraph 6.93–6.95).

A1.83 The circumstances under which *social assistance benefits* (272) become payable are clarified to include contributions payable to social insurance schemes on behalf of households who cannot otherwise afford to participate in the scheme (see paragraph 6.101).

A1.84 The distinction between imputations for *employment-related nonpension social benefits* and *employment-related pensions and other retirement benefits* is clarified in paragraph 6.105.

A1.85 The time of recording *dividends* (2811) when using an accrual basis of recording is clarified to be when the equity or shares go *ex-dividend* (see paragraphs 3.87, 5.112, and 6.109). The treatment of disproportionately large dividends is clarified (see paragraphs 5.116 and 6.110).

A1.86 The coverage of *property expense for investment income disbursements* (2813) is expanded to include distributions to holders of investment fund shares or units (see paragraph 6.113).

A1.87 It is clarified that *rent* (2814) includes amounts payable under resource leases on land, subsoil resources, and on other natural resources. The measurement of such amounts payable is clarified in the context of the corresponding revenue item (see paragraph 6.120).

A1.88 The *GFSM 2014* assumes the *2008 SNA* and *BPM6* treatment of *reinvested earnings on foreign direct investment* (2815) (see paragraph 6.121).

A1.89 The *GFSM 2001* expense categories for *miscellaneous other expense* (282) are subsumed in two new categories in the *GFSM 2014*—namely, *transfers not elsewhere classified* (282) and *premiums, fees, and claims payable related to nonlife insurance and standardized guarantee schemes* (283) (see paragraphs 6.122 and 6.125, respectively). The transfers are

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

distinguished as *current transfers not elsewhere classified* (2821) (see paragraph 6.123) and *capital transfers not elsewhere classified* (2822) (see paragraph 6.124).

A1.90 The expense category *premiums, fees, and claims related to nonlife insurance and standardized guarantee schemes* (283) is introduced to allow for the appropriate recording of the expense related to nonlife insurance and standardized guarantee schemes. Subcategories provide for the identification of *premiums payable* (28311), *fees for standardized guarantees* (28312), *current claims payable* (28313), and *capital claims payable* (2832) (see paragraph 6.125).

A1.91 The discussion on the Classification of Functions of Government (COFOG) in Chapter 6 of *GFSM 2001* is moved to the annex to Chapter 6 in *GFSM 2014*.

A1.92 *COFOG* in GFS is limited to the expenditure of government, which differs from its application to all outlays of government as used in the OECD/UN classification (see paragraph 6.127 in the annex).

A1.93 The annex is reorganized to separately present: the structure of *COFOG* classifications (see paragraph 6.128); uses of *COFOG* (see paragraph 6.130); distinction between *individual and collective goods and services* (see paragraph 6.133); units of classification (see paragraph 6.140); problems in identifying functions of government (see paragraph 6.143); and the cross-classification of expenditure (see paragraph 6.148). No changes occurred in the functions themselves.

Chapter 7

A1.94 The usefulness of a set of balance sheets integrated with economic flows is elaborated on in paragraph 7.2.

A1.95 A distinction is drawn between *legal and economic ownership* in paragraphs 3.38–3.41 and 7.5–7.13. These concepts are used to determine the *asset boundary* and to provide an overview of assets and liabilities (see paragraphs 7.14–7.19).

A1.96 The asset boundary is clarified to not include *contingent assets and liabilities* (see paragraph 7.13), and financial claims are clarified to include: debt instruments; financial derivatives and employee stock options; equity and investment fund shares; and monetary gold in the form of unallocated gold accounts (see paragraph 7.15).

A1.97 The *GFSM 2001* treatment of *monetary gold and SDRs* (6201/6301) as financial assets without a corresponding financial claim is revised. In the *GFSM 2014,* only monetary gold in the form of *gold bullion* is regarded as a financial asset without a corresponding financial claim. Also, recognizing that transactions in SDR holdings may be entered into by two domestic units, the exclusion of SDRs from domestic financial asset flows is eliminated (see paragraphs 7.15 and 7.125–7.134, respectively).

A1.98 The concept of *produced versus nonproduced nonfinancial assets* is introduced in paragraph 7.17–7.19.

A1.99 The valuation of assets and liabilities is elaborated on in paragraphs 7.20–7.25. The usefulness of nominal value of financial instruments is presented in paragraph 7.21, while the treatment of *cost of ownership transfer* is described in paragraph 7.22. Possible methods of estimating current market prices are described in paragraphs 7.25–7.33.

A1.100 The time of recording *change in ownership* in fixed assets that are produced over two or more accounting periods, and those built under a public-private partnership, is elaborated on (see paragraphs 7.37 and 7.39, respectively).

A1.101 The creation of *notional units* to own fixed assets in territories where they are not residents is explained in paragraphs 2.13 and 7.91.

A1.102 Identifying *public monuments* and guidance on their recording are clarified in paragraph 7.42.

A1.103 The definition and identification of *dwellings* (61111) are clarified and guidance on the valuation of dwellings is provided in paragraphs 7.44–7.45.

A1.104 Within buildings and structures, a category of fixed assets for *land improvements* (61114) is added. The cost of ownership transfer on all land is included with land improvements (see paragraphs 7.49–7.51).

A1.105 Subcategories are introduced for *machinery and equipment other than transport equipment* (61122) to separately identify *information, computer, and telecommunications (ICT) equipment* (see paragraphs 7.56–7.57) and *machinery and equipment not elsewhere classified* (see paragraph 7.57).

A1.106 The definition and identification of *cultivated biological resources* (61131) are clarified, and

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

the time of recording when the production of these fixed assets takes a long time to complete is elaborated on. Subcategories are introduced to further clarify the composition of this item (see paragraphs 7.59–7.63 and Table 7.5).

A1.107 The definition and identification of *intellectual property products* (61132) are elaborated on. Subcategories separately identify *research and development* (611321), *mineral exploration and evaluation* (611322), *computer software and databases* (611323), *entertainment, literary, and artistic originals* (611324), and *other intellectual property products* (611325). The coverage of this item is expanded to include research and development products so that patented resources no longer appear as nonproduced assets. Furthermore, the coverage of computer software is expanded to include databases (see paragraphs 7.64–7.73).

A1.108 *Weapons systems* are introduced as a separate fixed asset category (see paragraph 7.74).

A1.109 In the *GFSM 2014*, categories of *inventory* (612) are aligned with the categories used in *2008 SNA*. The category s*trategic stocks* (6121) is eliminated as a separate category of inventory and is subsumed in *goods for resale* (61224), and a category for military inventories is added (see paragraphs 7.75–7.86).

A1.110 The definition of *land* (6141) is clarified and guidance is provided on the valuation of land (see paragraphs 7.92–7.96).

A1.111 The *GFSM 2001* category *subsoil assets* is replaced by *mineral and energy resources* (6142). The ownership and recording of this category of asset are elaborated on in paragraphs 7.97–7.99.

A1.112 The classification of *other naturally occurring assets* (6143) is elaborated on. Subcategories for specific classes of *other naturally occurring assets* are introduced, and their definitions are clarified (see paragraphs 7.100–7.103 and Table 7.7).

A1.113 The category *intangible nonproduced assets* (6144) is clarified, and subcategories are introduced for *contracts, leases, and licenses* (61441) and *goodwill and marketing assets* (61442) (see paragraphs 7.104–7.117).

A1.114 Negotiability is introduced as a distinguishable feature of securities (see paragraph 7.119).

A1.115 *Market value* for valuing debt instruments is elaborated on by providing practical guidance on valuation (see paragraph 7.122).

A1.116 *Monetary gold and Special Drawing Rights* (6201, 6221, 6301, 6321) as financial instruments are elaborated on (see paragraphs 7.125–7.134).

A1.117 The coverage of *currency and deposits* (6202/6302) is clarified and the valuation of this instrument explained (see paragraphs 7.135–7.142).

A1.118 A description of various types of *debt securities* (6203/6303) and their recording is introduced in paragraphs 7.143–7.156.

A1.119 The description of *loans* (6204/6304) is expanded to clarify *financial leases* (see paragraph 7.158), *gold swaps* (see paragraph 7.161), and *off-market swaps* (see paragraph 7.162). The treatment of securities repurchase agreements is clarified as a collateralized loan (see paragraph 7.159). The valuation of loans and treatment of nonperforming loans are presented in paragraph 7.163.

A1.120 The category *equity and investment fund shares* (6205/6305) is elaborated on to distinguish various types of financial instruments (see paragraphs 7.164–7.177). *Investment fund shares* (62052/63053) have a specialized role in financial intermediation and are introduced as a separate category (see paragraphs 7.174–7.177).

A1.121 The category for the reserves of *insurance, pension and standardized guarantee schemes* (6206/6306) is clarified by introducing subcategories for: *nonlife insurance technical reserves* (see paragraphs 7.183–7.186); *life insurance and annuities entitlements* (see paragraphs 7.187–7.188); *pension entitlements* (see paragraphs 7.189–7.198); *claims of pension funds on pension managers* (see paragraphs 7.199–7.200); and *provisions for calls under standardized guarantee schemes* (see paragraphs 7.201–7.202).

A1.122 The coverage of *insurance, pension, and standardized guarantee schemes* (6206/6306) is expanded following recognition of *standardized guarantees* in a way similar to nonlife insurance and the recognition of *claims of pension funds on pension managers* (see paragraphs 7.201–7.202 and 7.199–7.200, respectively).

A1.123 The category *financial derivatives and employee stock options* (6207/6307) is clarified by defining

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

the two concepts (see paragraphs 7.204 and 7.221, respectively), describing the types of financial derivatives (see paragraphs 7.209–7.218), and explaining the use of margins (see paragraphs 7.219–7.220).

A1.124 The main balancing item on the balance sheet, *net worth* (6), is clarified and the relationship with equity for public corporations explained (see paragraphs 7.228–7.233).

A1.125 The items recorded as memorandum items to the balance sheet are expanded to include: *net financial worth* (see paragraph 7.235), *various valuations of gross and net debt* (see paragraphs 7.236–7.245), *concessional loans* and the *implicit transfers resulting from loans at concessional interest rates* (see paragraph 7.246), *arrears* (see paragraphs 7.247–7.250), *explicit contingent liabilities* (see paragraphs 7.251–7.260), *net implicit obligations for future social security benefits* (see paragraph 7.261), and *nonperforming loans* (see paragraph 7.262).

A1.126 The classification of the counterparty of financial assets and liabilities by institutional sector is introduced in paragraphs 7.264–7.265 and Table 7.11.

A1.127 The classification of *debt liabilities* and their corresponding financial assets by *maturity* is introduced in paragraphs 7.266–7.271 and Table 7.12.

Chapter 8

A1.128 The concept of *net investment in nonfinancial assets* is introduced in paragraph 8.4, and a distinction drawn with *gross investment in nonfinancial assets* (i.e., consumption of fixed capital is not taken into account).

A1.129 The treatment of *costs of ownership transfer* associated with acquiring and disposing of nonfinancial assets (other than inventory) is clarified (see paragraphs 8.6–8.8).

A1.130 The *valuation* of transactions in nonfinancial assets is elaborated to make a clear distinction between valuation of acquisitions and disposals of: *fixed assets* (see paragraph 8.9); *inventories* (see paragraph 8.10); *land* (see paragraph 8.11); and *nonproduced assets other than land* (see paragraph 8.11).

A1.131 Time of recording transactions in nonfinancial assets is clarified to be when *economic ownership changes*. Guidelines for alternatives to use when change of ownership is not obvious are provided (see paragraphs 8.13–8.17).

A1.132 The classification of transactions in nonfinancial assets is identical to the classifications of the same stock positions introduced in Chapter 7 (see paragraph 8.22 and Table 8.1).

A1.33 The treatment of public monuments as *buildings and structures* (3111) is clarified in paragraph 8.30.

A1.134 Transactions related to *land improvements* (31114) are introduced as a separate category of transactions in paragraph 8.31.

A1.135 Transactions related to *cultivated biological resources* (31131) are clarified to include net investment in livestock that are cultivated for the products they yield, and net investment in plantations, orchards, etc. Guidance is provided on the valuation of these transactions (see paragraphs 8.34–8.36).

A1.136 Guidance on the transactions in *intellectual property products* (31132) is expanded to clarify the valuation of transactions related to *research and development* (311321) (see paragraph 8.38), *mineral exploration and evaluation* (311322) (see paragraph 8.39), *computer software and databases* (311323) (see paragraph 8.40), and *entertainment, literary, and artistic originals* (311324) (see paragraph 8.41).

A1.137 The treatment of *costs of ownership transfer on nonproduced assets other than land* (31133) is introduced in paragraph 8.42. Figure 8.1 is included to illustrate the treatment of these costs in the GFS framework.

A1.138 The recording of transactions related to the acquisition and disposals of *weapons systems* (3114) is introduced in paragraph 8.43.

A1.139 Transactions related to the additions and withdrawals of *inventory* (312) are elaborated on. A distinction is made between the owner of inventory acting as a producer of goods and services and acting as an owner of assets (see paragraphs 8.44–8.47).

A1.140 The nature and treatment of transactions in all the categories of *nonproduced assets* are elaborated on (see paragraphs 8.49–8.58).

Chapter 9

A1.141 An explanation of the relationship between *transactions* and the impact of these on financial assets/liabilities is introduced in paragraph 9.3. Similarly, the impact of *net lending/net borrowing* on the economy is explained in paragraph 9.5.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

A1.142 *Concessional loans* and their treatment in macroeconomic statistics are clarified in paragraph 9.12.

A1.143 *Arrears* are defined in paragraph 9.20, and the recording of transactions related to arrears is described in paragraphs 9.21–9.23.

A1.144 The classification of transactions in financial assets and liabilities by instrument and residence of the counterparty is described in paragraphs 9.24–9.27. The classification by instrument that follows is the same as those described in the balance sheet (Chapter 7).

A1.145 Transactions related to *monetary gold and special drawing rights* (3201/3301) are clarified in paragraphs 9.28–9.32.

A1.146 For *debt securities* (3203/3303), transactions related to interest and amortization are elaborated on (see paragraphs 9.36 – 9.43).

A1.147 The impact of recording transactions between the owners of enterprises and the enterprise is clarified. Transactions such as dividends, transfers, membership dues and subscription fees payable to international organizations, and other operations, such as privatization and nationalization, are clarified in the description of transactions in *equity* (32051/33051) (see paragraphs 9.47–9.55).

A1.148 The recording of the change in value of *investment fund shares or units*, other than from holding gains and losses, is described in paragraph 9.56.

A1.149 For *insurance, pension, and standardized guarantee schemes* (3206/3306), the transactions influencing these reserves are elaborated on for each subcategory of the reserves (see paragraphs 9.57–9.69).

A1.150 The coverage of *financial derivatives and employee stock options* (3207/3307) is expanded to separately identify employee stock options. Transactions related to *financial derivatives* (32071/33071) are clarified. A distinction is introduced between transactions at inception, on secondary markets, with ongoing servicing, and at settlement (see paragraphs 9.71–9.76). Transactions related to *employee stock options* (32072/33072) are introduced in paragraph 9.77.

A1.151 The classification of transactions in financial assets and liabilities by sector and residence is introduced in paragraphs 9.85–9.87 and Table 9.2.

A1.152 The classification of transactions in debt liabilities and their corresponding financial assets by maturity is introduced in paragraph 9.88. If analytically useful, the same classification structure could be applied for transactions as what is depicted for stock positions in Table 7.12.

Chapter 10

A1.153 Other economic flows are described and the two components of other economic flows—namely, holding gains and losses and other changes in the volume of assets—are defined in paragraph 10.1.

A1.154 The section on holding gains for particular types of nonfinancial assets is elaborated on. Specific guidance is added on: the difference between *unrealized* and *realized holding gains* (see paragraph 10.6); *neutral* and *real holding gains* (see paragraph 10.11); estimating the holding gains on *fixed assets* (see paragraphs 10.13–10.15) and *inventories* (see paragraphs 10.16–10.17); *valuables* (see paragraph 10.18); and *nonfinancial assets* disposed of during the reporting period (see paragraphs 10.19–10.20).

A1.155 The impact of various events on the valuation of financial instruments is elaborated on. Specific guidance is added on: *monetary gold and SDRs* (see paragraphs 10.21–10.22); financial assets and liabilities with fixed monetary values (see paragraph 10.23); *debt securities* (paragraphs 10.24–10.29); *equity and investment fund shares* (see paragraphs 10.30–10.34); *insurance, pension, and standardized guarantee schemes* (see paragraphs 10.35–10.41); and *financial derivatives and employee stock options* (see paragraphs 10.42–10.43).

A1.156 Paragraph 10.44 introduces holding gains and losses related to financial instruments denominated in foreign currencies, and debt instruments that do not accrue interest over an unusually long time are discussed in paragraph 10.45.

A1.157 Paragraph 10.46 introduces three events that result in other changes in the volume of assets—namely, the *appearance or disappearance* of existing resources as economic assets, the effects of *external events*, and *changes in classifications*.

A1.158 The appearance or disappearance of financial assets and liabilities from the balance sheet is elaborated on with specific reference to the appearance of public monuments and valuables (see paragraph 10.50). Circumstances under which natural

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

assets, such as subsoil assets, noncultivated biological resources, other natural resources, or land, appear on the balance sheet are explained in paragraph 10.52.

A1.159 The effects of external events on the value of assets and liabilities are described in paragraph 10.59. Details on the recording of these events are provided and include *catastrophic losses* (see paragraph 10.60), *uncompensated seizures* (see paragraph 10.62), and *other volume changes not elsewhere classified* (see paragraph 10.63).

A1.160 Paragraph 10.68 introduces the reclassification of *costs of ownership transfer* on nonproduced assets other than land, and the *consumption of fixed capital* relating to these costs. The reclassification is necessary to maintain the integration of stock positions and flows.

A1.161 Paragraph 10.79 elaborates on the reclassifications of negotiable securities necessary due to secondary transactions.

A1.162 The reclassification of monetary gold held in the form of *gold bullion* when it becomes a reserve asset is introduced as an example of changes in the classification of financial assets and liabilities (see paragraph 10.84).

Cross-Cutting Changes in Terminology

A1.163 The following changes in terminology were made to further clarify the text of the *Manual*.

- References to GFS *system* are replaced with GFS *framework*—this allows a clear distinction with the *2008 SNA*.
- In the context of GFS, references to *accounting* principles and periods are replaced by references to *statistical guidelines* and *reporting periods*—this allows a clear distinction with the use of the term accounting in source data compilation in the context of public sector accounting.
- References to *flows* are replaced by references to *economic flows*, while it is acknowledged that flows will often be used as a short form for economic flows.
- References to the balances of assets and liabilities as *stocks* are replaced by references to *stock positions*—this allows a clear distinction with the use of the word "stocks" referring to a specific type of financial instrument.
- References to *net acquisition of nonfinancial assets* are replaced with references to *net investment in nonfinancial assets*—the former term is often misinterpreted as including only the acquisition minus disposals of nonfinancial assets, while consumption of fixed capital should also be included in this concept. Similar to what is customary in the case of operating balances, references to net/gross investment in nonfinancial assets can now be used to make a distinction for the including/excluding of consumption of fixed capital.
- References to *net lending/borrowing* are replaced with references to *net lending/net borrowing*, to enhance the precision in terminology.
- References to the Statement of Government Operations are replaced with references to Statement of Operations—this allows the use of this statement for government units as well as public sector units.
- References to *other nonrecurrent taxes on property* (1135) in the *GFSM 2001* are replaced with references to *capital levies* (1135)—this allows the terminology in GFS to align with *2008 SNA* terminology.
- References to *property income attributed to insurance policyholders* are replaced with references to *property income from investment income disbursements*—this allows the terminology in GFS to align with *2008 SNA* terminology.
- References to the expense for *social contributions* (212) are replaced by references to *employers' social contributions* (212)—this clarifies the economic nature of this item. Similarly, *actual social contributions* (2121) and *imputed social contributions* (2122) are replaced with *actual employers' social contributions* (2121) and *imputed employers' social contributions* (2122), respectively.
- References to the *outlays* of government are replaced with references to *expenditure*—this eliminates confusion with the use of outlays in the OECD/UN classification, which include expense, acquisition of nonfinancial assets, and transactions in financial assets and liabilities.
- References to *nonresidential buildings* (61112) are replaced with references to *buildings other than dwellings* (61112)—this allows the terminology in GFS to align with *2008 SNA* terminology.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

- References to *other machinery and equipment* (61122) are replaced with references to *machinery and equipment other than transport equipment* (61122)—this allows the revised GFS category to align with historic data and to subsume the *2008 SNA* categories of *information, computer, and telecommunications equipment* and *other machinery and equipment*.
- References to *cultivated assets* (61131) are replaced with references to *cultivated biological resources* (61131)—this allows the terminology in GFS to align with *2008 SNA* terminology.
- References to *subsoil assets* (6142) are replaced with references to *mineral and energy resources* (6142)—this allows the terminology in GFS to align with *2008 SNA* terminology.
- References to *intangible fixed assets* (61132) are replaced with references to *intellectual property products* (61132)—this allows the terminology in GFS to align with *2008 SNA* terminology. The word "products" is included to make clear that it does not include third-party rights, which are nonproduced assets.
- References to *securities other than shares* (6203/6303) are replaced with *debt securities* (6203/6303)—this allows the terminology in GFS to align with *2008 SNA* terminology.
- References to *shares and other equity* (6205/6305) are replaced with *equity and investment fund shares* (6205/6305)—this allows the terminology in GFS to align with *2008 SNA* terminology.
- References to *insurance technical reserves* (6206/6306) are replaced with *insurance, pension, and standardized guarantee schemes* (6206/6306)—this allows the terminology in GFS to align with *2008 SNA* terminology.
- References to *financial derivatives* (6207/6307) are replaced with *financial derivatives and employee stock options* (6207/6307)—this allows the terminology in GFS to align with *2008 SNA* terminology.
- References to *entity* when meaning a good, service, nonfinancial asset, etc. are replaced with references to *resource*—this eliminates the confusion with entities referred to in the context of institutional units.

Changes from the *GFSM 1986*

Introduction

A1.164 The integrated GFS framework described in the *GFSM 2014* represents a substantial modernization and expansion of the framework described in *A Manual on Government Finance Statistics, 1986* (*GFSM 1986*). Major changes have been made to definitions, classifications, balancing items, the coverage of units and economic events to be recorded in the GFS framework, and the timing at which economic events are to be recorded. The GFS framework is also more harmonized with other macroeconomic statistical frameworks than is the *GFSM 1986*. There are numerous detailed changes within each major topic, but an exhaustive listing of all such changes is beyond the scope of this appendix.

Coverage of Units

A1.165 The focus of the coverage of units in the GFS framework is the general government sector as defined in the *2008 SNA*. Its definition is based on the concept of an institutional unit, which is described in Chapter 2. The general government sector consists of all resident government units and all resident nonprofit institutions that are controlled by government. The coverage of the *GFSM 1986* is defined on a functional basis rather than a unit basis. It includes all units carrying out a function of government, but, in principle, only those transactions that are directly related to the functions of government are included. By implication, the transactions that do not represent the fulfillment of a fiscal policy are excluded. In particular, all transactions related to the functions of the monetary authority and other depository financial institutions are excluded.

A1.166 Supranational authorities are international organizations that have been endowed with the authority to raise taxes or other compulsory transfers within the territories of the countries that are members of the authority. Despite the fact that supranational authorities fulfill some of the functions of government within each member country, they are always considered nonresident institutional units. As a result, they are not included in the GFS framework for any country. In the *GFSM 1986*, transactions resulting from governmental functions carried out within a country by supranational organizations are included

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

in the statistics for that country. It is possible, however, to compile statistics for supranational authorities using the GFS framework as if they constituted a separate country and to classify relevant categories of transactions by country.

Time of Recording Economic Events

A1.167 The time at which transactions and other economic flows are recorded is determined by the principles of accrual accounting in the GFS framework. That is, flows are recorded when economic value is created, transformed, exchanged, transferred, or extinguished. In the *GFSM 1986*, transactions are recorded when cash is received or paid. In general, flows are recorded at an earlier time under the accrual basis than under the cash basis.

A1.168 Recording flows on the accrual basis will automatically capture past-due obligations, such as arrears of debt principal, interest payments, or payments for goods and services. In the *GFSM 1986*, use of the cash basis means that arrears and changes in the level of arrears are not recorded.

A1.169 The accrual basis of recording permits the difference between the redemption value of a bond or similar security and its issue price to be recorded as interest as it is earned or incurred rather than when the security matures. In the *GFSM 1986*, the entire difference between the issue and redemption prices is recorded as interest when the security is redeemed.

Coverage of Events

A1.170 The coverage of events in the GFS framework is broader than in the *GFSM 1986* because the revised framework includes all economic events that affect assets, liabilities, revenue, or expense, rather than just those represented by a cash transaction. For example, barter and grants of goods and services are included. The *GFSM 1986* incorporates in-kind transactions only selectively and as memorandum items.

A1.171 The GFS framework includes other economic flows, which are all flows other than transactions that affect a unit's stock position of assets, liabilities, and net worth. Other economic flows must be included to fully reconcile the balance sheet at the beginning of an accounting period with the balance sheet at the end of the period. Examples of other economic flows are price changes and the destruction of assets. By definition, other economic flows are noncash events, which means that they are not part of the *GFSM 1986*.

Valuation

A1.172 Assets and liabilities are valued at current market prices in the GFS framework, including debt securities that may have a different nominal value. Several assets/liabilities are valued at nominal value as proxy for market value—for example, loans generally are not traded and therefore do not have market values. They are recorded at their nominal values. In the *GFSM 1986*, debt securities are always valued at the amount the government is obligated to pay when the debt matures, which may differ from both the nominal value and the current market value. The GFS framework includes a provision for recording the nominal value of debt securities as a memorandum item.

Gross and Net Recording of Flows

A1.173 The presentation of flows on a gross or net basis is, for the most part, the same in the GFS framework and the *GFSM 1986*. The major exception pertains to the sales and expenses of market establishments. Generally speaking, a market establishment is a part of a general government unit that is situated in a single location and whose primary activity is to produce and sell goods and services at economically significant prices. In concept, it is possible to compile complete accounting records with respect to an establishment's productive activity, including sales and the costs of production. In the GFS framework, the sales and costs of production of market establishments are presented on a gross basis as revenue and expense, respectively. In the *GFSM 1986*, the net value of sales less the costs of production is recorded as revenue if positive and as expenditure if negative.

Integration of Flows and Stocks

A1.174 The GFS framework is fully integrated—that is, the stock position at the end of a reporting period can be derived from the stock position at the beginning of the reporting period and the flows occurring during the period. As a result of this integration, all events that affect the financial performance, financial position, or liquidity situation of the general government sector are included. In the *GFSM 1986*, the stock positions included are limited to debt

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

liabilities. The changes in the stock position of debt liabilities cannot be reconciled with the flows recorded. Flows in the *GFSM 1986* represent only cash flows and will not account for changes in stocks related to flows other than cash, such as discounts allowed, debt assumption, debt forgiveness, etc. Supplementary tables are included that indicate the additional data that would be needed to complete the reconciliation.

Definitions and Classifications

A1.175 Revenue in the GFS framework is an increase in net worth resulting from a transaction. Thus, revenue includes grants but excludes proceeds from disposals of nonfinancial assets. In the *GFSM 1986*, revenue is defined as the set of all nonrepayable receipts other than grants. Thus, revenue includes proceeds from disposals of nonfinancial assets.

A1.176 Similarly, expense in the GFS framework is a decrease in net worth resulting from a transaction. Purchases of nonfinancial assets do not affect net worth and are not considered expense transactions. The term "expense" replaces "expenditure" from the *GFSM 1986* because it is more closely associated with the accrual basis of recording and indicates that transactions in nonfinancial assets are excluded. Expenditure is defined in the *GFSM 1986* as the set of all nonrepayable payments and includes purchases of nonfinancial assets.

A1.177 The classifications of revenue are substantially different in the two manuals. Revenue in the *GFSM 1986* is classified as tax, nontax, or capital revenue. Grants form a separate, nonrevenue category of receipts. In the GFS framework, revenue is subdivided into taxes, social contributions, grants, and other revenue. In more detail:

- Taxes exclude social contributions in the revised GFS framework, but include them in the *GFSM 1986*.
- Social contributions in the GFS framework include social security contributions, which are classified as taxes in the *GFSM 1986*, and other social contributions to social insurance schemes operated for the benefit of government employees, which are classified as nontax revenue in the *GFSM 1986*.
- Other revenue in the GFS framework includes most of the category of nontax revenue in the *GFSM 1986* plus capital transfers, which are classified as capital revenue in the *GFSM 1986*.
- Capital revenue in the *GFSM 1986* consists of sales of nonfinancial assets and receipts of capital transfers. Sales of assets are not revenue in the GFS framework, but capital transfers are classified as revenue.

A1.178 Expense/expenditure is classified in two ways—by function and by economic type of transaction—in both the GFS framework and the *GFSM 1986*. The classification by function in both manuals is the *Classification of Functions of Government* (*COFOG*) published by the United Nations. The GFS framework incorporates the 2000 edition of *COFOG*.

A1.179 The classification of expense by economic type in the GFS framework is broadly similar to the corresponding classification in the *GFSM 1986*. The primary exception is that acquisitions of nonfinancial assets are not considered an expense in the GFS framework. Other changes include the following:

- Consumption of fixed capital is an expense in the GFS framework. As a noncash expense, it is excluded from the *GFSM 1986*.
- Transfer payments are classified by type of payment in the GFS framework. In the *GFSM 1986*, they are classified by the sector receiving the payment. The major types of transfer payments are subsidies, grants, social benefits, transfers not elsewhere classified, and premiums, fees, and claims related to nonlife insurance and standardized guarantee schemes.

A1.180 A new classification is dedicated to net investment in nonfinancial assets resulting from transactions because they are not classified as revenue or expense in the GFS framework. The classification follows the parallel classification in the *2008 SNA*, which is based on the type of asset involved in the transaction. This classification includes consumption of fixed capital because it represents a decline in the value of fixed assets.

A1.181 "Lending minus repayments" is a category of transactions in the *GFSM 1986* representing the net acquisition of financial assets for policy purposes, and is classified together with expenditure for the calculation of the overall deficit/surplus. In the GFS framework, these transactions are classified together with other transactions in financial assets. However,

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

if supplementary information is available on policy lending, both the overall balance and policy lending can be calculated from GFS source data, as a fiscal indicator (see annex to Chapter 4, Table 4A.2).

Balancing Items

A1.182 Several new balancing items are introduced in the GFS framework, a consequence of the view that fiscal analysis must include a variety of considerations and that no single measure is sufficient for all purposes. In the *GFSM 1986*, the analytic framework is focused on a single balancing item, the overall deficit/surplus, although provision is made for other balancing items.

A1.183 The analytic framework of the integrated GFS features several balancing items. The *Statement of Operations* includes the following:

- The net operating balance, which is defined as revenue minus expense and represents the change in net worth resulting from transactions
- Net lending/net borrowing, which is defined as the net acquisition of financial assets minus the net incurrence of liabilities, or, alternatively, as the net operating balance minus the net investment in nonfinancial assets; it is also equal to the gross operating balance minus gross investment in nonfinancial assets.

A1.184 The *Statement of Sources and Uses of Cash* includes the cash surplus/deficit to indicate the balance of cash flows from government operations and the gross investment in nonfinancial assets. It is similar to the overall deficit/surplus of the *GFSM 1986* except that net cash outflows from policy lending (lending minus repayment of policy-related transactions in financial assets or liabilities) are not subtracted.

A1.185 Another balancing item in the GFS framework is the overall balance, defined as net lending/net borrowing adjusted through the rearrangement of transactions in assets and liabilities that are deemed to be for public policy purposes. Notably, policy lending is added to expense while privatization proceeds (including fixed asset sales) are included as transactions in financial items in calculating the overall fiscal balance. It is the equivalent of the overall deficit/surplus in the *GFSM 1986*, but determined using the accrual basis of recording.

A1.186 Other balancing items in the GFS framework include net worth, net financial worth, the change in net worth, the change in net financial worth (all related to the balance sheet), the change in net worth from other economic flows, the primary balance, and savings. There are no similar balancing items in the *GFSM 1986*.

Harmonization with Other Statistical Systems

A1.187 The GFS framework is harmonized with other international macroeconomic statistical systems. That is, the basic concepts, definitions, and conventions are the same to the extent possible, given the objective of the GFS framework to provide data that support fiscal analysis. The other statistical manuals with which the GFS framework has been harmonized are the *2008 SNA*, the sixth edition of the IMF's *Balance of Payments and International Investment Position Manual*, and the IMF's *Monetary and Financial Statistics Manual* (in the process of being updated). In contrast, the *GFSM 1986* follows the 1968 version of the *SNA* where possible, but the degree of harmonization is much less, primarily because of the use of the cash basis of recording in the *GFSM 1986*. Appendix 7 of this *Manual* provides additional information on linkages of the GFS framework with other macroeconomic statistics.

APPENDIX

2 Social Protection

This appendix describes the various organizational structures used to provide social protection and the associated government finance statistics compiled for the general government or public sectors.

Introduction

A2.1 Social protection is the systematic intervention intended to relieve households and individuals of the burden of a defined set of social risks.[1] **Social risks** are defined as events or circumstances that may adversely affect the welfare of households either by imposing additional demands on their resources or by reducing their income. Needs may occur due to sickness, unemployment, retirement, housing, education, or family circumstances. Many governments devote considerable economic resources to protect citizens and their employees against these risks.

A2.2 This appendix describes the nature of social protection, the boundary between social protection and private insurance, and the criteria used in the classification of social protection arrangements. A typology of social protection arrangements is presented. The typology has the purpose of identifying the type and sector attribution of social protection arrangements, in order to assist the compiler in the recording of flow and stock positions. Examples of the recording of specific flows related to various types of social protection arrangements are presented in tabular form.[2]

[1] The Classification of Functions of Government (COFOG) (see Annex to Chapter 6) has a category labeled social protection, but its scope differs from social protection described here, notably by excluding health care.

[2] A discussion of the issues involved in the organization and treatment of social protection schemes can also be found in the European Commission, *European System of Integrated Social Protection Statistics* (*ESSPROS) Manual 2008* (Luxembourg, 2008).

The Nature of Social Protection

A2.3 Households benefit from social protection in different ways:

- Households could receive benefits when they meet certain eligibility criteria that originated from a social risk without making any contributions. These benefits are classified as an expense that leads to a redistribution of income through transfers.
- Households could make contributions and receive benefits as transfers receivable in the event of the occurrence of the specified social risks. Neither the contributions nor the benefits constitute an exchange as no direct exchange of economic value occurs. The payment of the social contribution entitles the contributor to some contingent future benefits. The finances of these arrangements function similarly to nonlife insurance schemes (see paragraph A4.70). Such social protection arrangements are essentially a process of redistribution across a wide section of the population, with many individuals contributing resources so that those in need may benefit.[3] These social benefits are classified as an expense.
- Households (including employees, self-employed, and unemployed) could make contributions (actual and imputed) to a scheme to accumulate assets. They can withdraw from these accumulated assets in the event of the occurrence of the specified social risk. Examples are employment-related pensions and other retirement benefits, compulsory saving schemes, and other types of annuities. The finances of these arrangements function similarly to life insurance schemes (see paragraph A4.69). There is relatively little redistribution among the various households holding

[3] As described in paragraph 6.97, the category *social benefits* [GFS] differs from social benefits as defined in the *2008 SNA*.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

similar policies, and members of households are able to predict with a reasonable degree of certainty what they will receive and when. Therefore, contributions and payments of these benefits are transactions in financial assets and liabilities.

A2.4 Depending on the nature of the social protection arrangement, the unit that administers the arrangement could earn revenue (social contributions) and/or incur expense (social benefits) related to the social protection arrangement. ***Social contributions*** *[GFS]* (12) are actual or imputed revenue receivable by social insurance schemes to make provision for social insurance benefits payable (see paragraphs 5.94–5.100). As an expense, ***social benefits*** [GFS] (27) are current transfers receivable by households intended to provide for the needs that arise from social risks (see paragraphs 6.96–6.106). Alternatively, the unit that administers the arrangement could be involved in transactions in financial assets and liabilities, classified as *insurance, pensions, and standardized guarantee schemes* (see paragraphs 7.178–7.202).

A2.5 The social risks covered by social protection vary from country to country and from scheme to scheme. Generally, social protection may be divided into two classes—namely:

- Pensions and other retirement benefits
- All other social benefits, collectively described as nonpension social benefits.

A2.6 Pensions and other retirement benefits are payable when individuals cease employment upon retirement. Pensions may also be payable to other individuals—for example, a bereaved spouse or other dependents, or to someone suffering from a permanent disability. As indicated in Figure A2.1, pensions and other retirement benefits are provided to individuals via social assistance, social security, employment-related pension schemes, or private insurance.

A2.7 Nonpension social benefits include payments made to individuals when they are temporarily unemployed, suffering from a medical condition, or suffering from an event that prevents them from working for a period. The following list of typical nonpension social benefits illustrates their general nature:

- The beneficiaries, or their dependents, require medical, dental, and other treatments, or hospital, convalescent, or long-term care as a result of sickness, injuries, maternity needs, chronic invalidity, old age, etc. These social benefits are provided in kind in the form of treatment or care provided free or at prices that are not economically significant, or by reimbursing expense incurred by households or individuals.
- The beneficiaries have to support dependents of various kinds: spouses, children, elderly relatives, physically or mentally disabled persons, etc. These social benefits are usually payable in cash in the form of regular dependents' or family allowances.
- The beneficiaries suffer a reduction in income as a result of not being able to work full-time. These social benefits are usually payable regularly in cash for the duration of the condition or for a maximum period. In some instances, a lump sum may be provided additionally or instead of the regular payment. People may be prevented from working for various reasons, including involuntary unemployment, temporary layoffs, short-time working, sickness, accidental injury, the birth of a child, etc.
- The beneficiaries suffer a reduction in income because of the death of the main income earner. These social benefits are usually payable in cash, often in the form of regular allowances or, in some instances, a lump sum.
- The beneficiaries are provided with housing either free or at prices that are not economically significant, or by reimbursing some of the expense they incur.
- The beneficiaries are provided with allowances to cover education expenses incurred on behalf of themselves or their dependents; education services may occasionally be provided in kind (i.e., education services provided free or at prices that are not economically significant[4] to those subject to social risks).

A2.8 Social benefits can be provided in cash or in kind. If provided in kind, the goods or services could be produced by the unit providing the benefits, they could be purchased by the unit providing

[4] In this case, the social benefit will cover only the difference between the normal price of such services and the price payable.

[1] Including defined-contribution schemes, treated similar to life insurance.

the benefits from a market producer before distributing them to the household, or the households could purchase the goods and services and be reimbursed. Some benefits are provided indirectly, such as through tax allowances, exemptions, and deductions; benefits provided in this manner are not considered social benefits in GFS. However, if social benefits are made available via the tax system in the form of payable tax credits, these payable tax credits should be recorded on a gross basis and recorded as a social benefit payable by government (see paragraphs 5.29–5.32).

A2.9 In GFS, a social benefit expense is always a transfer payment because the benefits are provided without the recipients being required to provide something of equivalent value in return. Allowances provided as compensation of employees or loans provided by employers to employees are not social benefits. Transfers are defined and explained in more detail in paragraph 3.10.

A2.10 Social benefits do not include transfers payable in response to events or circumstances that are not normally covered by social insurance schemes. Therefore, transfers made in response to unusual events, such as natural disasters or destruction during wars, should be recorded as *transfers not elsewhere classified* (282) in GFS (see paragraphs 6.122–6.126).

Boundary between Social Protection and Private Insurance

A2.11 Social benefits are provided by general government employers to their employees and their dependents, or other units, such as trade unions and nonprofit institutions serving households. Social benefits are always provided in collective arrangements. Consequently, individual insurance policies taken out on the private initiative of individuals or households solely in their own interest are excluded from social protection arrangements. When individuals take out insurance policies in their own names, on their own initiative, and independently of their employers or government, the claims receivable are not treated as social benefits, even if the policies are taken out against the same kinds of social risks as those listed in paragraphs A2.6–A2.7—these private initiatives are treated as private insurance.

A2.12 Individual saving arrangements that maintain the integrity of the participants' contributions and are restricted to protecting against social risks are private insurance schemes. Under such arrangements,

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

the contributions of the participants and/or their employers are kept in a separate account and may be withdrawn under specified circumstances, such as retirement, unemployment, invalidity, and death.

A2.13 Social protection arrangements (covering social assistance and social insurance) must be organized collectively for groups of workers or be available by law to all workers or designated categories of workers, possibly including unemployed persons as well as employed. Social insurance includes private social insurance schemes arranged for selected groups of workers employed by a single employer, and social security schemes (see paragraph 2.101).[5]

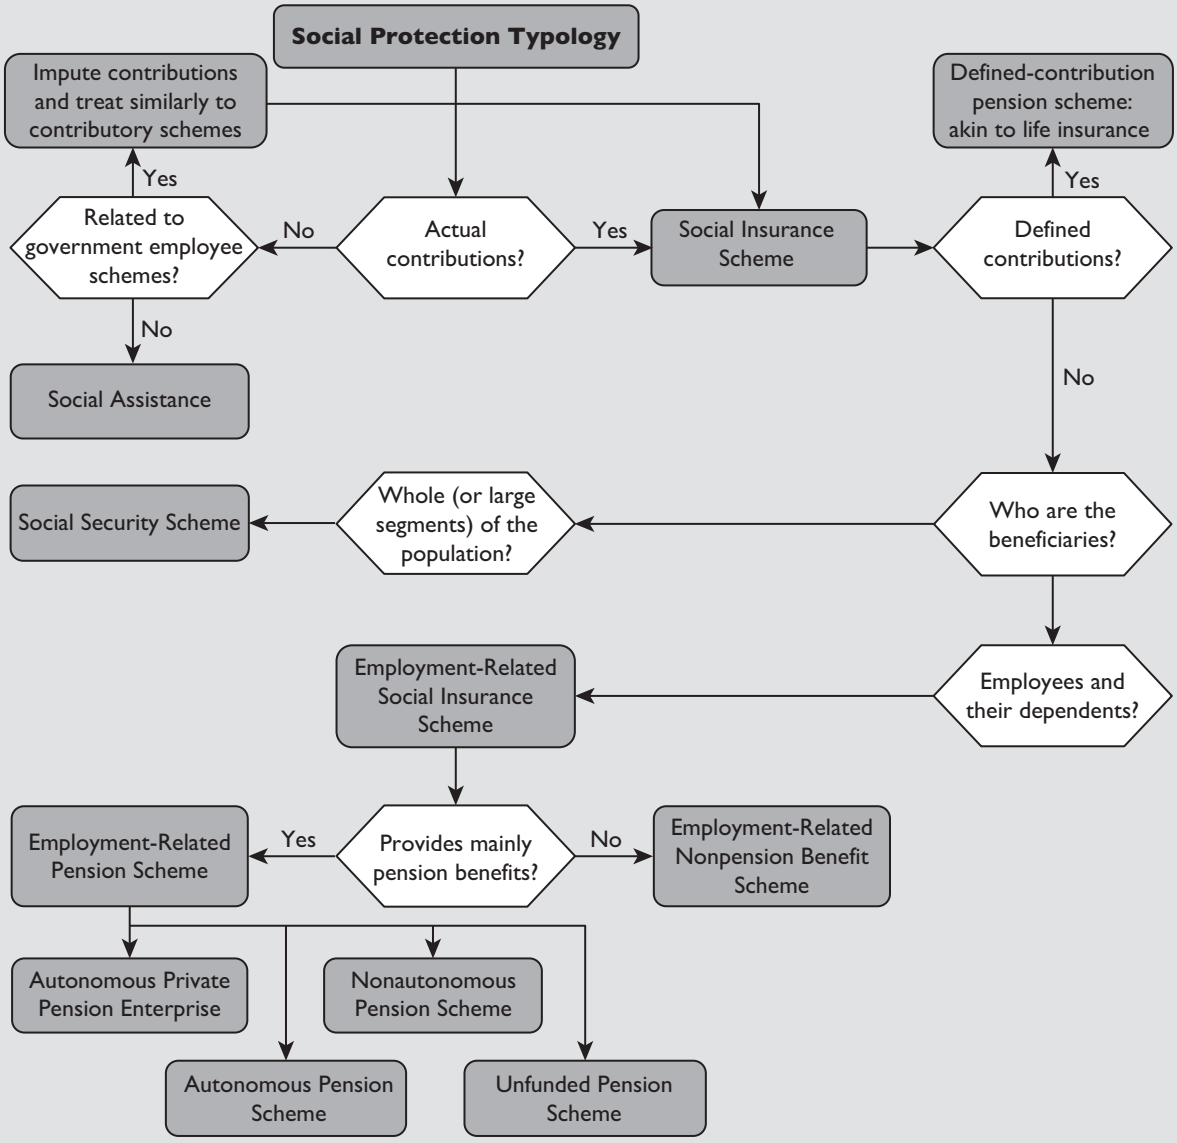
A2.14 Many social insurance schemes (covering social security schemes and employment-related insurance schemes) are organized collectively for groups of workers so that those participating do not have to take out individual insurance policies in their own names. In such cases, there is no difficulty about distinguishing social insurance from private insurance taken out on an individual basis. However, some social insurance schemes may permit, or even require, participants to take out policies in their own names. In order for an individual policy to be treated as part of a social insurance scheme, the eventualities or circumstances against which the participants are insured must be of the kind listed in paragraphs A2.5–A2.7, and, in addition, one or more of the following conditions must be satisfied:

- Participation in the scheme is obligatory either by law for a specified category of persons, whether employed or unemployed, or under the terms and conditions of employment of an employee, or group of employees.
- The scheme is a collective one operated for the benefit of a designated group of persons, whether employees or unemployed, participation being restricted to members of that group.
- An employer makes a contribution (actual or imputed) to the scheme on behalf of an employee, regardless of whether the employee also makes a contribution.

A2.15 The premiums payable, and claims receivable, under individual policies taken out under a social insurance scheme are recorded as social contributions and social benefits. Most individual policies that qualify as social insurance schemes are likely to be for pension provision, but it is possible that they may cover other eventualities—for example, to provide income if the policyholder is unable to work for a prolonged period because of ill health.

A2.16 Participation in insurance schemes, public or private, may be voluntary for the workers concerned, but it is more common for it to be obligatory. For example, participation in schemes organized by individual employers may be required by the terms and conditions of employment collectively agreed between employers and their employees. Participation in nationwide social security schemes organized by government units may be compulsory by law for the entire labor force, except perhaps for persons who are already covered by private schemes. Making a distinction in underlying source data between compulsory and voluntary social contributions is required when the total fiscal burden is calculated (see Table 4A.1). In contrast, social assistance is provided without any insurance involved (see paragraph A2.25).

Classification Criteria for Social Protection Arrangements



A2.17 As indicated in Figure A2.2, the following criteria are used in macroeconomic statistics to classify social protection arrangements:

- Contributory versus noncontributory—Contributory schemes require actual or imputed social contributions by the protected persons or by other parties on their behalf to obtain entitlement to the benefits. Noncontributory arrangements do not require the payment of contributions, but other eligibility requirements may apply.
- Compulsory versus voluntary—Compulsory schemes may be established by law and/or regulation or by agreement between employer and employees. In some cases, a scheme may be mixed, where some people are required to participate and others are allowed a choice. Participation in voluntary schemes is at free will.
- Cover the whole (or large segments of the) population or just government employees—Social protection is provided collectively to the general population (or a large segment of the general

[5] Social insurance schemes are a subset of social protection arrangements, and social security schemes are a subset of social insurance schemes.

Figure A2.2 Typology of Social Protection

population), although possibly limited by eligibility criteria, while employment-related schemes provide benefits as part of the conditions of employment.[6]

- Provide pension and other retirement benefits, or other types of social benefits—Social protection arrangements distinguish between those that provide pensions and other retirement benefits, and those that provide other types of nonpension benefits, such as medical, unemployment, disability, etc. This distinction determines the transactions recorded for the arrangement; for example, employment-related pension schemes are considered to give rise to liabilities in the form of pension entitlements recorded under the debt instrument insurance, pension, and standardized guarantee schemes.
- Autonomous versus nonautonomous—A social protection scheme is autonomous when a

[6] As indicated in paragraph A2.12, individual insurance or saving arrangements that maintain the integrity of the participant's contributions are not considered social insurance.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

separate institutional unit exists[7] that is directly held responsible, and accountable, for the decisions and actions the unit takes. Where a separate institutional unit does not exist, the arrangement would be considered nonautonomous and be classified with the unit that controls it.

- Defined-contribution versus defined-benefit schemes—A defined-contribution scheme is one where the benefits are determined by the actual contributions made to the scheme, and the investment income and holding gains and losses earned on these and previous contributions. Under a defined-benefit scheme, the ultimate benefit is calculated by means of a formula embodied in the terms of the social insurance scheme. These benefits are usually determined in terms of the undertakings made by the employer or operator of the scheme.
- Funded versus unfunded schemes—A social insurance scheme is funded if contributions are held in a segregated fund (reserve), from which future benefits will be payable. If a segregated fund is sufficient to finance the present value of the future benefits payable, the scheme is fully funded. If the segregated fund is insufficient to finance the net present value of the future benefits payable, it is underfunded. If the reserve is more than sufficient to finance the net present value of the future benefits payable, it is overfunded. For an unfunded scheme, contributions are not held in a segregated fund (reserve). By definition, unfunded schemes have no separate pool of reserves and cannot be a separate institutional unit.

Typology of Social Protection Arrangements

A2.18 The classification of social protection is based on the type of social protection arrangement governing the payment of the benefits. Social protection can be organized as social assistance or social insurance schemes, with the latter organized as social security schemes or employment-related social insurance schemes. The units involved in the organization and operation of social protection can be general government units, public corporations, nonprofit institutions serving households, or private corporations.

[7] The definition of an institutional unit and the criteria that an entity must fulfill to be an institutional unit are described in paragraph 2.22.

A2.19 Using the various aspects of the classification criteria for social protection, as described earlier, Figure A2.2 provides a typology designed to assist compilers in identifying and classifying various social protection arrangements. Identifying the type of unit involved in social protection arrangements is an important step in determining the recording of flows and stock positions, which differs depending on the type of arrangement.

A2.20 The first level in the typology of social protection is based on whether payments of contributions are required to obtain entitlement to benefits. Where no contributions are required, social protection is provided as a social assistance arrangement (see paragraphs A2.25–A2.29). The requirement to make payments of social contributions by the protected persons or by other parties on their behalf to obtain entitlement to the benefits indicates the existence of a social insurance scheme (see paragraphs A2.30–A2.31). However, noncontributory employment-related social protection schemes provided by employers for the benefit of their employees are treated as if they were contributory schemes because contributions are imputed. The amounts necessary to obtain coverage against the specified social risks are imputed as social contributions, and another transaction imputes the employees' payment of the same amounts to the employer as social contributions (see paragraph A2.40).

A2.21 The next level in the typology of social protection is determined by whether the social insurance is arranged as a defined-contribution or defined-benefit scheme. Defined-contribution schemes will constitute either a compulsory savings arrangement or an employment-related pension scheme, and, as described in paragraph A2.12, these arrangements are treated similarly to life insurance. Paragraphs A2.55–A2.59 describe the treatment of defined-contribution schemes.

A2.22 Within social insurance, the types of beneficiaries covered by the scheme determine the next level in the typology. When the beneficiaries are the general population, or a large segment of the general population, the scheme would be a social security scheme, as discussed in paragraphs A2.33–A2.39. If individuals or households are eligible to receive social benefits as a group of employees, it is an employment-related social insurance scheme, as discussed in paragraph A2.40.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

A2.23 The typology of employment-related social insurance schemes further distinguishes based on the types of benefits provided by the scheme: Employment-related pension schemes provide pension and other retirement benefits and are discussed in paragraphs A2.41–A2.59; employment-related nonpension social insurance schemes provide nonpension benefits and are discussed in paragraphs A2.64–A2.66. These benefits may be provided in cash or in kind, similar to the benefits as described in paragraph A2.27.

A2.24 Employment-related pension and other retirement benefit schemes can further be distinguished by whether they are funded or unfunded (see paragraph A2.17). While unfunded schemes are always considered nonautonomous, for funded schemes a further distinction is made between those that are nonautonomous (see paragraph A2.44) or autonomous (see paragraph A2.47).

Social Assistance

A2.25 Social assistance provides social protection benefits to all persons who are in need without any formal requirement to participate as evidenced by the payment of contributions. The eligibility to receive social benefits is not conditional on the payment of contributions by the protected persons or by other parties on their behalf. There may, however, be specific eligibility criteria, such as a "means test," where the expression indicates a maximum qualifying level of income or assets. The benefits payable by such an arrangement are social assistance benefits. ***Social assistance benefits*** (272) are transfers payable in cash or in kind to households to meet the same needs as social insurance benefits but are not made under a social insurance scheme (see paragraph A2.30).

A2.26 All social assistance is organized and operated by government units and NPISHs. The benefits are payable to households, out of the unit's general resources, according to the specified criteria. Eligibility is purely related to the criteria stipulated in the social protection arrangement.

A2.27 Social assistance benefits may be provided in cash or in kind. The classification of this expense is further discussed in paragraphs 6.101–6.102, and Table A2.1 illustrates the recording of flows related to social assistance. Social assistance benefits in kind are recorded when:

Table A2.1 Illustrative Recording of Flows Related to Social Assistance

Description	Debit		Credit	
1.1 Government provides benefits payable to qualifying persons who have met the eligibility criteria of a social assistance arrangement				
Assistance to households in cash	2721	Social assistance benefits in cash	3212 / 3318	Currency and deposits / Other accounts payable[1]
1.2 Government provides goods purchased from market producers to persons who have met the eligibility criteria of a social assistance arrangement				
Government acquires the goods	31224	Inventories (goods for resale)[2]	3212 / 3318	Currency and deposits / Other accounts payable[1]
Government provides goods	2722	Social assistance benefits in kind	31224	Inventories (goods for resale)[2]
1.3 Government reimburses market providers or households for goods and services acquired from market entities in accordance with the conditions of a social assistance arrangement				
Government reimburses providers or households	2722	Social assistance benefits in kind	3212 / 3318	Currency and deposits / Other accounts payable[1]
1.4 Government produces and provides goods or services to the population in accordance with the condition of a social assistance arrangement				
The operational costs incurred in the production of the goods and services are recorded as relevant	21, 22, 23	Compensation of employees, use of goods and services, and consumption of fixed capital	3212 / 3318	Currency and deposits / Other accounts payable[1]

[1]In a cash reporting environment, the expense will be recorded at the time of the cash flow. In an accrual reporting environment, an other account payable should be recorded in cases where the payment is not made when the eligibility criteria have been met.

[2]The flow of inventories will be recorded only in an inventory accounting system.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

- Government provides directly to the households goods and services purchased from market producers.
- Market entities provide goods and services directly to households, with the government providing reimbursement either directly to the provider or to the household for expenses incurred. Although households are reimbursed in cash for eligible purchases of goods and services, the transaction should be recorded as social assistance benefits in kind.[8]

A2.28 A distinction should be made between social assistance benefits and certain other expense categories incurred by government—notably:

- When a government unit produces the goods and services provided to households as social assistance benefits, they are not recorded as social benefits but rather by type of expense incurred in producing these goods and services: *compensation of employees* (21), *use of goods and services* (22), and *consumption of fixed capital* (23).[9]
- If a government unit reimburses corporations for the cost of goods and services provided to targeted social assistance beneficiaries, the transfers are recorded as social assistance benefits in kind. These transfers to corporations should be distinguished from *subsidies* (25), which are transfers to enterprises intended to reduce prices or increase the provision of goods and services for the general population.
- Social assistance benefits do not include transfers payable in response to events or circumstances that are not normally covered by social insurance schemes (see paragraph A2.10).

A2.29 Typically, social assistance benefits will be recorded on an accrual basis as an expense when all eligibility criteria have been met and the benefits become payable. Although some benefits, such as disability or maternity payments, may be payable over several reporting periods, no liability for the future payments of social assistance benefits should be recorded on the balance sheet of government. Other accounts payable will be recognized only in cases where a benefit accrued but remained unpaid at the end of a reporting period.[10] However, to increase transparency and allow an analysis of the sustainability of social assistance policies, an estimate of the present value of social assistance benefits that have already been earned, according to the existing laws and regulations, but are payable in the future, could be calculated in a manner similar to the liabilities of an employment-related insurance scheme.

Social Insurance Schemes

A2.30 Social insurance schemes provide social protection and require formal participation by the beneficiaries, evidenced by the payment of contributions (actual or imputed). These schemes are organized in such a way that a third party, usually an employer or the government, encourages or obliges individuals to participate in a scheme that provides benefits for a number of identified circumstances, including pensions in retirement. Social insurance schemes have much in common with direct insurance (see paragraph A4.68) and may be run by insurance corporations. The payment of contributions (corresponding to premiums in the case of direct insurance) and benefits (corresponding to claims in the case of direct insurance) is recorded according to the nature of the scheme. Participation is usually linked to employment, and contributions are payable either by the participants, an employer, or both. Therefore, a social insurance scheme is an insurance scheme for which the following two conditions are satisfied:

- The benefits receivable are conditional on participation in the scheme and constitute social benefits.

[8] The economic substance of the transactions is recorded as if the government purchased the goods and distributed them to the beneficiaries. The intermediate step of acquisition and disposal of inventories of goods is netted out in the calculation of change in inventories.

[9] This treatment differs from the treatment in the *2008 SNA*. See Appendix 7, Box A7.1, for an explanation of the difference in the treatment of goods produced by government and transferred in kind.

[10] For example, assume person A has met the eligibility criteria for unemployment payments in period t1, and is entitled to receive benefits for six periods. Because of administrative delays, no benefit payment was made in the first period—therefore, an *other account payable* at the end of that period, equal to the value of payment for one period only, should be recorded. Similarly, if another payment is not made in the second period, the account payable will increase with the value of benefits for another one month. The full amount of benefits to be receivable over the six periods should not be recognized as an upfront payable, but rather be accrued continuously over the period of eligibility.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

- At least one of the following three conditions is met:
  - Participation in the scheme is obligatory either by law or under the terms and conditions of employment of an employee, or group of employees.
  - The scheme is a collective one operated for the benefit of a designated group of workers, whether employed or unemployed, participation being restricted to members of that group.
  - An employer makes a contribution (actual or imputed) to the scheme on behalf of an employee, regardless of whether the employee also makes a contribution.

A2.31 A **social insurance contribution** is the amount payable to a social insurance scheme in order for a designated beneficiary to be entitled to receive the social benefits covered by the scheme. A social insurance benefit is a social benefit payable because the beneficiary participates in a social insurance scheme and the identified circumstances have occurred.

A2.32 As indicated in paragraph A2.22, the types of beneficiaries covered by the social insurance scheme determine the next level in the typology of this scheme (see Figure A2.2). The individuals or households eligible to receive social insurance benefits are either a group of employees, the general population, or a large segment of the general population. Social security schemes are social insurance schemes that cover the community as a whole, or large sections of the community, and are imposed and controlled by government units. In contrast, as indicated in paragraph A2.40, social insurance schemes in which employers provide social insurance benefits only to their employees, former employees, or their beneficiaries are referred to as other employment-related social insurance schemes. Where the same scheme covers the general population and government employees, the scheme is treated as a social security scheme. However, if the conditions for participation and benefits payable, as determined by the employment contract, differ from those of the social security scheme for nongovernment employee participants, an employment-related scheme exists and the flows and stock positions of the two schemes should be distinguished within the social security fund (see paragraph 2.102).

Social security schemes

A2.33 Social security schemes are social insurance schemes covering the community as a whole, or large sections of the community, and are imposed and controlled by government units. These schemes cover a wide variety of programs, providing benefits in cash or in kind for old age, invalidity or death, survivors, sickness and maternity, work injury, unemployment, family allowance, health care, etc. There is not necessarily a direct link between the amount of the contribution payable by an individual and the benefits receivable.

A2.34 Social security schemes that are organized separately from the other activities of government units, hold their assets and liabilities separately from the latter, and engage in financial transactions on their own account qualify as institutional units. These institutional units are described as social security funds. A **social security fund** is a particular kind of government unit that is devoted to the operation of one or more social security schemes. These special types of government units are identified separately in a subsector to allow for the alternative methods of constructing subsectors of the general government sector (see paragraph 2.78). The existence of a social security fund depends on its organization as a separate institutional unit, not on other characteristics of the scheme, such as types of benefits provided or sources of finance.

A2.35 Not all social security schemes are operated by social security funds. Where a separate social security fund does not exist, the transactions of the social security scheme would be reported as an integral part of the transactions of the government unit that controls operations of the social security scheme. Social security schemes can therefore be operated by government units that are not social security funds. Consequently, statistics for the social security funds subsector may not include all social security schemes. If a social security scheme is not a separate institutional unit, however, there may be separate accounts to manage the scheme's finances, which would permit compiling supplementary statistics on social security activities with broader coverage than that of the social security subsector.

A2.36 By definition, social security schemes are contributory—participants in the scheme are required to make regular contributions to be eligible to

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

receive benefits for themselves or their dependents. The primary receipts of social security schemes are social security contributions. As shown in Table 5.1 in Chapter 5, social security contributions are classified according to their source, which may be employers or households. Participation in social security schemes can be compulsory or voluntary. Further breakdown in the classification of these social contributions would allow a distinction between contributions receivable in cash and in kind, and between compulsory and voluntary contributions. In addition to social contributions, social security schemes may receive grants from general government resources and may earn property income from the investment of their assets.

A2.37 *Social security benefits [GFS]* (271) payable are current transfers and are classified as one of the social benefits categories. These can further be classified as being payable in cash or in kind (see Table 6.1). Social security benefits in kind can be provided to beneficiaries in the same ways as social assistance benefits in kind (see paragraphs A2.27–A2.28). Table A2.2 illustrates the recording of some of the flows related to social security schemes.

A2.38 Social security schemes are characterized by a degree of contingent reciprocity. Social security contributions secure entitlements to benefits that are contingent on the event underlying the social risk occurring. Nonetheless, the amount and timing of receipts of benefits by beneficiaries (if any) are subject to various eligibility criteria without necessarily a direct relationship between the amount of the contribution payable by an individual and the benefits receivable. Therefore, the link between benefits and contributions is not considered sufficiently strong to give rise to a financial claim on the part of contributors. The potential individual claims of contributors (and therefore the corresponding government obligations) are regarded as contingent. Also, because social security benefits can be changed at will by the government or legislature as part of its overall economic policy, there is uncertainty about the eventual payment or level of payment of these social benefits.[11] As a result, in GFS, no liabilities are associated with the potential future claims on social security schemes. An expense is recorded only when payment of the benefits is due.

A2.39 However, a high expectation exists that social security benefits earned according to the existing laws will be payable in the future. Therefore, an estimate equal to the net implicit obligations for future social security benefits should be presented as a memorandum item to the Balance Sheet, and details of it presented as a supplementary statement, the *Summary Statement of Explicit Contingent Liabilities and Net Implicit Obligations for Future Social Security Benefits* (see paragraphs 4.47 and 7.261).

Other employment-related social insurance schemes

A2.40 Other employment-related social insurance schemes derive from an employer-employee relationship in the provision of pension entitlement and other social benefit to employees as part of the conditions of employment. By definition, these schemes are contributory and, for government or public sector units, protect only their own employees and dependents. The provision of social insurance benefits by government to its own employees is considered to be part of an actual or implicit contract between the government, as employer, and the employees, to compensate them for the provision of their labor services. Therefore, employment-related social insurance schemes give rise to requited expense transactions for government when the social contributions became payable. To accurately reflect the accrued costs of employment, the actual and imputed social insurance contributions should be recorded as *employers' social contributions* (212) in the expense category for *compensation of employees* (21) (see Table 6.1).

Employment-related pensions and other retirement benefit schemes

A2.41 Employment-related social insurance schemes that provide pensions and other retirement benefits can be organized as a funded or unfunded social insurance scheme. Table A2.3 illustrates the recording of some of the flows of employment-related pensions.

A2.42 There are three types of employment-related pension schemes:

- A nonautonomous pension scheme that is therefore regarded as an integral part of the employer

[11] The amounts of social security contributions receivable and benefits payable may be deliberately changed in order to achieve objectives of government policy. The change may have no direct connection with the functions of social security. For example, the contributions and benefits may be raised or lowered in order to influence the level of aggregate demand in the economy, or to ensure fiscal sustainability.

Table A2.2 Illustrative Recording of Flows Related to Social Security Schemes

Description	Debit		Credit	
2.1 The government social security scheme receives contributions from various contributors				
Social security contributions receivable from employees, self-employed, and unemployed	3212 / 3218	Currency and deposits / Other accounts receivable[1]	1211 / 1213	Social security contributions: Employee contributions/self-employed, and unemployed
Social security contributions receivable from employers	3212 / 3218	Currency and deposits / Other accounts receivable[1]	1212	Social security contributions: Employer contributions
2.2 The government as employer makes contributions to social security schemes on behalf of its employees				
Government contributions as employer become payable	2121	Actual employers' social contributions	3212 / 3318	Currency and deposits / Other accounts payable[1]
2.3 The government social security scheme provides social security benefits to the eligible beneficiaries in accordance with the conditions of the scheme				
Social security scheme benefits become payable	2711	Social security benefits in cash	3212 / 3318	Currency and deposits / Other accounts payable[1]
2.4 The government social security scheme provides goods purchased from market producers to qualifying beneficiaries				
Social security scheme acquires the goods	31224	Inventories (goods for resale)[2]	3212 / 3318	Currency and deposits / Other accounts payable[1]
Social security scheme provides goods to households	2712	Social security benefits in kind	31224	Inventories (goods for resale)[2]
2.5 The government social security scheme reimburses market providers or households for goods and services provided by market entities to eligible beneficiaries in accordance with the conditions of the scheme				
Social security scheme reimburses providers or households	2712	Social security benefits in kind	3212 / 3318	Currency and deposits / Other accounts payable[1]
2.6 The government social security scheme produces and provides goods or services to the population in accordance with the conditions of the scheme				
No social security benefits are recorded in GFS—the operational costs incurred in the production of the goods and services are recorded as relevant	21, 22, 23	Compensation of employees, use of goods and services, and consumption of fixed capital	3212 / 3318	Currency and deposits / Other accounts payable[1]

Note: The net implicit obligation for future social security benefits should be recorded as a memorandum item (see paragraph 7.261).

[1]In a cash reporting environment, the revenue/expense will be recorded at the time of the cash flow. In an accrual reporting environment, an other account receivable/payable should be recorded in cases where the payment is not made when the eligibility criteria have been met.

[2]The flow of inventories will be recorded only in an inventory accounting system. In a cash reporting environment, social benefits in kind will not be recorded. The purchases of goods and services distributed as social benefits in kind will be included in purchases of goods and services (22).

- A separate institutional unit that operates a pension scheme that is therefore regarded as an autonomous pension fund
- A scheme managed by an insurance enterprise on behalf of the employer regarded as a financial corporation.

A2.43 The manner in which the employment-related pension scheme is organized determines the recording of the associated transactions. Insurance enterprises and autonomous pension funds are units of the financial corporations sector, while nonautonomous pension funds and unfunded employment-related social insurance schemes are units of the general government sector.

Nonautonomous employment-related pension schemes

A2.44 Nonautonomous social insurance schemes are operated by the employer, and these schemes are usually unfunded schemes because they are organized by the employer without assigning specific accounts or otherwise creating special reserves for the payment of benefits. Instead, the benefits are payable from the employer's general resources.

A2.45 A nonautonomous pension fund for public sector employees does not meet the criteria to be considered an institutional unit, and is therefore deemed to be included in the unit that operates the scheme. This is also the case when the employer has established

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Table A2.3 Illustrative Recording of Flows Related to Employment-Related Pension Schemes

Description	Debit		Credit	
3.1 The government makes pension contributions on behalf of its employees to an autonomous pension fund maintained by an insurance company (i.e., it is part of the private financial corporation sector)				
Government pays social contributions as component of compensation of employees	2121	Actual employers' social contributions	3212 / 3318	Currency and deposits / Other accounts payable[1]
3.2 The government makes pension contributions on behalf of its employees to an autonomous pension fund set up by government as a separate institutional unit (i.e., it is part of the public financial corporation sector)				
Government pays social contributions as component of compensation of employees	2121	Actual employers' social contributions	3212 / 3318	Currency and deposits / Other accounts payable[1]
3.3 The government operates a funded nonautonomous pension fund for its employees (i.e., a separate reserve is maintained in the government account but it is not an institutional unit)				
Government pays social contributions as component of compensation of employees	2121	Actual employers' social contributions	3212 / 3318	Currency and deposits / Other accounts payable[1]
Receipts of social contributions by the pension fund account giving rise to a liability	3212 / 3218	Currency and deposits / Other accounts receivable[1]	3316	Insurance, pension, and standardized guarantee schemes
Government, as owner of the pension fund account, receives property income on the investments of the pension fund	3212 / 3218	Currency and deposits / Other accounts receivable[1]	1411 / 1412	Interest Dividends
Government attributes the property income to the policy holders[2]	2813	Property expense for investment income disbursements	3316	Insurance, pension, and standardized guarantee schemes
Government provides pension benefit payments to eligible beneficiaries	3316	Insurance, pension, and standardized guarantee schemes	3212 / 3318	Currency and deposits / Other accounts payable[1]
3.4 Government operates an unfunded nonautonomous pension fund for its employees (i.e., there are no actual contributions and no separate reserve is maintained in the government account)				
Government provides pension benefit payments to eligible beneficiaries: cash basis of recording	2731	Employment-related social benefits in cash	3212	Currency and deposits
Imputed social contributions as component of compensation of employees: accrual basis of recording	2122	Imputed employers' social contributions	3316	Insurance, pension, and standardized guarantee schemes
Government provides pension benefit payments to eligible beneficiaries: accrual basis of recording	3316	Insurance, pension, and standardized guarantee schemes	3212 /	Currency and deposits
Government recognizes the increase in liability for benefit entitlements due to time passing	2813	Property expense for investment income disbursements	3316	Insurance, pension, and standardized guarantee schemes
3.5 All defined-benefit schemes can also be subject to other economic flows				
Pension liabilities increase due to unilateral changes in conditions of the scheme	5	Other changes in the volume of assets and liabilities	5316	Insurance, pension, and standardized guarantee schemes
Pension liabilities increase due to changes in interest rates used to calculate the present value of the liability	4	Holding gains/losses	4316	Insurance, pension, and standardized guarantee schemes

[1]In a cash reporting environment, the revenue/expense will be recorded at the time of the cash flow. In an accrual reporting environment, an other account receivable/payable should be recorded in cases where the payment is not made when the eligibility criteria have been met.

[2]These disbursements will primarily be reinvested in the fund as social contributions, while the portion that will meet the cost of operating the fund should be recorded as the purchases of a financial service from the pension fund.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

segregated reserves, but the organization and operations of the scheme do not meet the criteria to be an institutional unit (see paragraph 2.22). The economic flows and stock positions of nonautonomous employment-related pension funds are integrated with those of the controlling employer. All of the assets, liabilities, transactions, and other economic events of the pension fund are combined with the corresponding items of the employer operating the scheme, which may be a general government unit or a public corporation. The treatment of the assets, liabilities, transactions, and other economic events related to the nonautonomous pension fund is similar to that of an autonomous pension fund. However, in this case, the contributions payable as a component of compensation of employees, the receipt of the contributions by the pension scheme, and the associated liabilities are recorded by the same level of government. These flows are not eliminated in consolidation because households are regarded as, respectively, the recipient and payer. These flows should be rerouted as described in paragraph 3.28.

A2.46 In accordance with the accrual basis of recording, the amount that would be required to cover the accrual of the social benefits must be imputed. This will also ensure that the full cost of employment is accounted for by recording the imputed social contributions, with a counterpart entry that creates the associated liability for these pension benefits. This imputation recognizes the economic flows during the period in which the underlying economic event takes place. It also improves transparency because it records the cost of providing the social benefits to its employees and flags the risks associated with the future demands on resources. When these pension benefits are paid, the payment is recorded as a reduction in liabilities.[12]

Autonomous employment-related pension schemes

A2.47 To be regarded as autonomous, the entity responsible for the employment-related pension scheme must have the characteristics of an institutional unit (see paragraph 2.22). These institutional units are considered to provide financial services (i.e., insurance/pensions) to the household sector, and are therefore classified in the financial corporations sector. They are classified as either private or public financial corporations, depending on whether they are controlled by the private or public sectors (see Box 2.2).

A2.48 An employer may contract with a third party to administer the pension funds for its employees. The employment-related pension scheme is then managed through an insurance enterprise or an autonomous pension fund. The employer's primary responsibility with respect to the scheme is to pay the social contributions on behalf of its employees. The government unit records the payment as part of compensation of employees, under actual social contributions (see Table 6.1 and paragraph 6.21). No other transactions are recorded by the government unit as employer, as it has no direct liability for future provision of social benefits.

A2.49 However, in cases where the employer continues to determine the terms of the pension schemes and retains the responsibility for any deficit in funding, as well as the right to retain any excess funding, the employer is described as the pension manager and the unit working under the direction of the pension manager is described as the pension administrator. If the agreement between the employer and the third party is such that the employer passes the risks and responsibilities for any deficit in funding to the third party in return for the right of the third party to retain any excess, the third party becomes the pension manager as well as the administrator.

A2.50 When the pension manager is a unit different from the administrator, and the responsibility for any deficit, or claims on any excess, rests with the pension manager, the claim of the pension fund on the pension manager should be shown under the liability, *claims of pension funds on pension managers* (63064). By contrast, if the pension fund makes more investment income from the pension entitlements it holds than necessary to cover the increase in entitlements, the difference is payable to the pension manager of the scheme. The pension manager records this claim on the pension administrator as a financial asset, *claims of pension funds on pension managers* (62064).[13]

[12] When using the cash basis of recording, the only flow recorded for these unfunded pension schemes is the *employment-related social benefits* expense, with a counterpart entry as a decrease in *currency and deposits*. The expense is recorded when cash payments are made.

[13] Although this financial asset effectively represents a claim of the pension manager on the pension fund, the same line item title is used for both the asset and liability accounts.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

A2.51 If government controls the financial corporation that manages the employment-related pension scheme for government employees, the corporation will be part of the public financial sector, and the relevant flows and stock positions would be recorded when compiling GFS for the public sector. The receipt of social contributions by this insurance enterprise or pension fund gives rise to a liability, classified in the financial instrument *insurance, pensions, and standardized guarantee schemes* (6306), and more specifically in *pension entitlements* (63063). The liability originates from the obligation to pay future pension benefits—any subsequent payment of the benefits will be recorded as a reduction in this liability. Although the social contributions are payable directly by the employer to the financial corporation, they are recorded in GFS as if payable by the employer to households as compensation of employees: households in turn pay the contributions to the financial corporation. Because of this rerouting, these transactions should not be eliminated in consolidation of the public sector (see paragraph 3.28).

A2.52 For the financial corporation, revenue from the investment of the financial reserves should be classified as the relevant category of property income. However, since these resources are considered to give rise to an asset of the policyholders, such income should be attributed to policyholders. An expense is recorded, classified as *property expense for investment income disbursements* (2813), with a counterpart entry that increases the liability to reflect the policyholders' increase in claims for pension entitlements.

A2.53 Autonomous employment-related pension schemes can be organized as a defined-benefit pension scheme or a defined-contribution pension scheme.

Defined-benefit pension schemes

A2.54 A **defined-benefit pension scheme** is one where the benefits payable to an employee on retirement are determined by the use of a formula, either alone or as a minimum amount payable. The level of benefits promised to participating employees is determined by a formula embodied in the terms of the social insurance scheme. These terms are usually based on factors such as the participants' length of service and salary.[14] The calculation of imputed contributions and net present value of future benefits requires advanced actuarial techniques, beyond the responsibility of GFS compilers. The present value of future benefit entitlements increases each period because there is one fewer period over which it is discounted. This increase should be a transaction in property expense for *investment income disbursements* (2813) (see paragraph 6.113). Furthermore, a holding gain should be recorded with respect to the liability in order to reflect any change in the value of the liability because of a change in the interest rate used to discount the future benefits. A change in the liability resulting from a change in the benefit structure should always be treated as an other volume change, because it does not constitute a transaction but represents a unilateral change brought about by the employer.

Defined-contribution pension schemes

A2.55 A **defined-contribution pension scheme** is one where the benefits payable to an employee on retirement are defined exclusively in terms of the level of the funds built up from the contributions made over the employee's working life and the increases in value that result from the investment of these funds by the manager of the scheme. The risk of the scheme to provide an adequate retirement income is thus borne by the employee, and the benefits that will be payable depend on the assets of the fund.[15] For a defined-contribution pension scheme, a pension fund is always deemed to exist.

A2.56 Contributions to a defined-contribution pension scheme are invested on behalf of the employees as future beneficiaries. The investment income on the cumulated assets of the pension fund is recorded as revenue for the fund, classified according to the nature of the respective property income revenue (usually including *interest* (1411), *dividends* (1412), or

[14] There are four sources of changes in pension entitlements in a defined-benefit pension scheme: (i) the current service increase—it is the increase in entitlement associated with the wages and salaries earned in the current period; (ii) the past service increase—it is the increase in the value of the entitlement due to the fact that for all participants in the scheme, retirement (and death) is one year nearer; (iii) a decrease due to the payment of benefits to retirees of the scheme; and (iv) other factors—that is, factors that are related to other changes in the volume of assets.

[15] Defined-contribution schemes are also referred to as money-purchase schemes.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

rent (1415)). The investment income is also recorded as being distributed to the beneficiaries (classified as *property expense for investment income disbursements* (2813)), who are deemed to reinvest the income in the pension fund as contributions. Therefore, the investment income payable on defined-contribution entitlements is equal to the investment income on the financial investments plus any net operating surplus earned by renting land or buildings owned by the fund.

A2.57 The value of the pension entitlement liability of a defined-contribution pension scheme is the market value of the financial assets held by the pension fund on behalf of the future beneficiaries. Any changes in the market value of these investments of the pension fund would include holding gains and losses. These holding gains and losses should be recorded as changes in the value of the relevant assets of the institutional unit administering the pension fund. In addition, these holding gains or losses should also be attributed to the policyholders. Therefore, a matching entry for the holding gain or losses in the liability of the pension fund toward households should be recorded.

A2.58 For a defined-contribution pension scheme, the risks and costs associated with the scheme are borne by the beneficiaries. There are no imputed contributions for defined-contribution pension schemes, unless the employer operates the scheme directly. In that case, the value of the costs of operating the scheme is treated as an imputed contribution payable to the employee as part of compensation of employees. This amount is recorded by the employer as the sale of a financial service to the employees, classified as *imputed sales of goods and services* (1424) (see paragraph 5.140). When the fund is operated by a unit other than the employer, the operating costs are financed from investment income retained by the fund to meet its costs and generate a profit. Therefore, in keeping with the recording of insurance, the investment income generated is treated as being attributed in full to the beneficiaries in the household sector who use part of the income to purchase a financial service from the fund, and reinvest the remainder with the fund.

A2.59 As indicated in paragraphs A2.3 and A2.21, defined-contribution schemes are similar to life insurance schemes.[16] However, a scheme that may be defined in terms similar to a defined-contribution scheme, but with a guaranteed minimum benefit specified, or other hybrid schemes, should be treated as defined-benefit pension schemes in macroeconomic statistics.

Government assumption of employment-related pension obligations of other institutional units

A2.60 On occasion, large one-off transactions (lump-sum transactions) may occur between a government and another institutional unit, often a public corporation, linked to pension reforms or to privatization of the public corporations. The goal may be to make the corporation competitive, or financially more attractive, by removing existing pension liabilities from its balance sheet. This goal is achieved by government assuming the liability in exchange for an asset or assets from the other institutional unit. When the value of the asset(s) receivable is the same as the value of the liability assumed, the transaction is recorded as a transaction in financial assets and liabilities for both units involved.

A2.61 However, if the value of the asset(s) receivable by government is less than the value of the liability assumed, an expense in the form of a capital transfer from government to the corporation is recorded for the difference. The assumer (government) records an increase in liabilities for pension entitlements, an increase in the relevant financial and/or nonfinancial assets, and an expense in the form of capital transfer to the corporation (see paragraph 6.91). The corporation records a decrease in liabilities for pension entitlements, a decrease in financial and/or nonfinancial assets, and revenue in the form of a capital transfer from government.

A2.62 If the value of the asset(s) receivable is more than the value of the liability incurred, a capital transfer receivable from the corporation to the government is recorded for the difference (see paragraph 5.148). The corporation records a decrease in liabilities for pension entitlements, a decrease in financial and/or nonfinancial assets, and an expense in the form of a capital transfer to government.

[16] The treatment of the flows and stock positions of these schemes is similar to the treatment of compulsory savings schemes.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

A2.63 Even if the arrangement transforms the pension liability, so that it is to be administered as part of a social security fund, the initial assumption of the pension obligation should be recorded as in the foregoing paragraphs. The pension obligations absorbed by the social security fund continue to be classified as pension entitlement liabilities. These obligations are gradually extinguished as the benefits are paid out.

Employment-related nonpension social insurance schemes

A2.64 Employment-related nonpension social insurance schemes can be operated by the government or by autonomous nongovernment entities. In either case, the actual or imputed employers' contributions are included as an expense in the compensation of employees, under social contributions. For funded schemes, the actual contributions made to the scheme are classified under actual employers' social contributions. For unfunded schemes, the amount that would be required to purchase equivalent social benefits must be imputed by the employer, and should be classified under imputed employers' social contributions. Where a scheme is operated by the government, a simultaneous transaction equal to the actual or imputed social contributions is recorded as revenue from the household sector back to government, and classified under actual social security contributions or imputed social contributions. The social benefits provided by the government are classified as an expense under employment-related social benefits. Table A2.4 illustrates the recording of some of these flows of employment-related nonpension social insurance schemes.

A2.65 Some employers provide nonpension social benefits directly to their employees, former employees, or dependents without involving an insurance enterprise or autonomous pension fund, and without creating a special fund or segregated reserve for the purpose. Employees may be considered as being protected against various specified social risks, even though no reserves are built up to provide for future entitlement to social security benefits. An expense for employers' social contributions should therefore be imputed for such employees (see paragraph 6.22), equal in value to the amount of social contributions revenue needed to obtain the de facto entitlements to the accrued social benefits. These amounts take into account any actual contributions made by the employer or employee. The amounts depend not only on the levels of the benefits currently payable but also on the impact on future employer's liabilities of demographic and actuarial factors, such as expected changes in the numbers, age distribution, and life expectancies of their present and previous employees. Therefore, the values that should be imputed for the contributions ought, in principle, to be based on the same kind of actuarial considerations that determine the levels of premiums charged by insurance enterprises.

A2.66 In practice, however, it may be difficult to estimate such imputed contributions. The government unit may make estimates itself, perhaps on the basis of the contributions payable into similar funded schemes, in order to calculate its likely liabilities in the future. Otherwise, the only practical alternative may be to use the unfunded nonpension benefits payable by government during the same reporting period as an estimate of the imputed remuneration that would be needed to cover the imputed contributions. This is a second best option as the value of the imputed contributions may diverge from the unfunded nonpension benefits actually paid in the same period, due to factors such as the changing composition and age structure of the government labor force.

Table A2.4 Illustrative Recording of Flows Related to Employment-Related Nonpension Social Insurance Schemes

Description	Debit		Credit	
4.1 Social insurance contributions receivable from employers and employees				
Social insurance contributions receivable from employees	3212 / 3218	Currency and deposits / Other accounts receivable[1]	1221	Other social contributions: Employee contributions
Social insurance contributions receivable from employers	3212 / 3218	Currency and deposits / Other accounts receivable[1]	1222	Other social contributions: Employer contributions
4.2 The government as employer makes contributions to social insurance schemes on behalf of its employees				
Government contributions as employer becomes payable	2121	Actual employers' social contributions	3212 / 3318	Currency and deposits / Other accounts payable[1]
4.3 Government as employer imputes contributions to the social insurance scheme where no or insufficient contributions to obtain entitlement to benefits were made				
Imputed contributions	2122	Imputed employers' social contributions	1223	Imputed contributions
4.4 Employer social insurance scheme provides benefits to government employees				
Employer social insurance scheme pays benefits in cash	2731	Employment-related social benefits in cash	3212 / 3318	Currency and deposits / Other accounts payable[1]
4.5 Employer social insurance scheme provides goods purchased from market producers to employees in accordance with the conditions of the scheme				
Employer social insurance scheme acquires the goods	31224	Inventories (goods for resale)[2]	3212 / 3318	Currency and deposits / Other accounts payable[1]
Employer social insurance scheme provides goods to households	2732	Employment-related social benefits in kind	31224	Inventories (goods for resale)[2]
4.6 Employer social insurance scheme reimburses market providers or households for goods and services provided by market entities in accordance with the conditions of the scheme				
Employer social insurance scheme reimburses providers or households	2732	Employment-related social benefits in kind	3212 / 3318	Currency and deposits / Other accounts payable[1]
4.7 Government produces and provides goods or services to their employees in accordance with an employer's social insurance scheme				
No employer social insurance benefits are recorded in GFS—the operational costs incurred in the production of the goods and services are recorded as relevant	21, 22, 23	Compensation of employees, use of goods and services, and consumption of fixed capital	3212 / 3318	Currency and deposits / Other accounts payable[1]

Note: The net implicit obligation for future social security benefits should be recorded as a memorandum item (see paragraph 7.261).

[1]In a cash reporting environment, the revenue/expense will be recorded at the time of the cash flow. In an accrual reporting environment, an other account receivable/payable should be recorded in cases where the payment is not made when the eligibility criteria have been met.

[2]The flow of inventories will be recorded only in an inventory accounting system.

APPENDIX

3 Debt and Related Operations

This appendix provides guidance on selected issues that may arise in the recording of flows and stock positions related to public sector debt.

Introduction

A3.1 In the recording of debt[1] of the general government or public sectors, complex methodological issues can arise with regard to flows (i.e., transactions and other economic flows) and stock positions associated with the debt liabilities. Some of the most common issues are discussed in detail, with examples of their treatment, in Chapter 4 of the *PSDS Guide*. This appendix provides a summary of the same issues and their treatment.

Debt Reorganization

A3.2 Debt reorganization (also referred to as debt restructuring) is defined as an arrangement involving both the creditor and the debtor (and sometimes third parties) that alters the terms established for servicing an existing debt. Governments are often involved in debt reorganization, as debtor, creditor, or guarantor.

A3.3 Debt reorganization usually involves relief for the debtor from the original terms and conditions of debt obligations. This may be in response to liquidity constraints, where the debtor does not have the cash to meet debt service payments due, or sustainability issues, where the debtor is unlikely to be able to meet its debt obligations in the medium term.

A3.4 A failure by a debtor to honor its debt obligations (e.g., default) does not constitute debt reorganization because it does not involve an arrangement between the creditor and the debtor. Similarly, a creditor can reduce the value of its debt claims on the debtor in its own accounts through debt write-offs—unilateral actions that arise, for example, when the creditor regards a claim as unrecoverable, perhaps because of bankruptcy of the debtor, and, as a result, no longer carries the claim on its balance sheet. Again, this is not considered debt reorganization.

A3.5 The four main types of debt reorganization are:

- *Debt forgiveness*, which is a reduction in the amount of, or the extinguishing of, a debt obligation by the creditor via a contractual arrangement with the debtor.
- *Debt rescheduling or refinancing* (or debt exchange), which is a change in the terms and conditions of the amount owed, which may result in a reduction in debt burden in present value terms.
- *Debt conversion and debt prepayment* (or debt buybacks for cash), where the creditor exchanges the debt claim for something of economic value, other than another debt claim, on the same debtor; examples of debt conversion are debt-for-equity swaps, debt-for-real-estate swaps, debt-for-development swaps, and debt-for-nature swaps.[2]
- *Debt assumption* when a third party is also involved.

A3.6 A debt reorganization package may involve more than one of the types just mentioned; for example, most debt reorganization packages involving debt forgiveness also result in a rescheduling of the part of the debt that is not forgiven or cancelled.

Debt Forgiveness

A3.7 Debt forgiveness (or debt cancellation) is defined as the voluntary cancellation of all or part of a

[1] Gross debt and net debt are defined in paragraphs 7.236–7.245.

[2] Some agreements described as debt swaps are equivalent to debt forgiveness from the creditor together with a commitment from the debtor country to undertake a number of development, environmental, etc., expenses. These transactions should be considered under debt forgiveness, as counterpart funds are not provided to the creditor.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

debt obligation within a contractual arrangement between a creditor and a debtor. With debt forgiveness, there is a mutual agreement between the parties involved and an intention to convey a benefit. In contrast, with debt write-off, there is no such agreement or intention—it is a unilateral recognition by the creditor that the amount is unlikely to be collected (see paragraphs A3.32–A3.34).[3] Debt forgiven may include all or part of the principal outstanding, inclusive of any accrued interest arrears (interest that fell due for payment in the past) and any other interest costs that have accrued. Debt forgiveness includes forgiveness of some, or all, of the principal amount of a credit-linked note arising from an event affecting the entity on which the embedded credit derivative was written. Also included is forgiveness of principal that arises when the debt contract stipulates that the debt will be forgiven if a specified event occurs, such as forgiveness in the case of a type of catastrophe. Debt forgiveness does not arise from the cancellation of future interest payments that have not yet fallen due and have not yet accrued.

A3.8 Debt forgiveness is always recorded as a capital grant or transfer from the creditor to the debtor, which extinguishes the financial claim and the corresponding debt liability. A government or public sector unit may be involved in debt forgiveness as a creditor or a debtor. Market prices are the basis for valuing debt forgiveness, except for loans, where nominal value is used.

A3.9 Although no transactions are recorded for debt forgiveness under the cash basis of recording, the stock positions relating to the debt liability and the corresponding financial asset would reflect the debt forgiveness.

Debt Rescheduling and Refinancing

A3.10 Debt rescheduling and refinancing involve a change in an existing debt contract and its replacement by a new debt contract, generally with extended debt service payments.[4] Debt rescheduling involves rearrangements on the same type of instrument, with the same principal value and the same creditor as with the old debt. Debt refinancing entails a different debt instrument, generally at a different value, and possibly with a different creditor.[5] For example, a creditor may choose to apply the terms of a Paris Club (see *PSDSG*, paragraphs 10.125–10.134) agreement either through a debt rescheduling option (changing the terms and conditions of its existing claims on the debtor) or through refinancing (making a new loan to the debtor that is used to repay the existing debt).

Debt rescheduling

A3.11 Debt rescheduling is a bilateral arrangement between the debtor and the creditor that constitutes a formal postponement of debt service payments and the application of new and generally extended maturities. The new terms normally include one or more of the following elements: extending repayment periods, reductions in the contracted interest rate, adding or extending grace periods for the payment of interest and principal, fixing the exchange rate at favorable levels for foreign currency debt, and rescheduling the payment of arrears, if any. In the specific case of zero-coupon securities, a reduction in the principal amount to be paid at redemption to an amount that still exceeds the principal amount outstanding at the time the arrangement becomes effective could be classified as either an effective change in the contractual rate of interest or a reduction in principal with the contractual rate unchanged. Such a reduction in the principal payment to be made at maturity should be recorded as debt forgiveness, or debt rescheduling if the bilateral agreement explicitly acknowledges a change in the contractual rate of interest. Paris Club creditors provide debt relief to debtor countries in the form of rescheduling, which is debt relief by postponement or, in the case of concessional rescheduling, reduction in debt service obligations during a defined period (flow treatment) or as of a set date (stock treatment).

[3] Debt forgiveness is unlikely to arise between commercial entities.

[4] If the original terms of the contract provide that the maturity or interest rate terms, or both, change as a result of, for example, a default or decline in credit rating, then this involves a reclassification. In practice, these reclassification entries cancel out within the same instrument category unless the original and new terms have a different principal, different instrument classification, or different maturity classification. In contrast, if the original terms of a debt (typically a loan or debt security, but also other debt instruments) are changed through renegotiation by the parties, this is treated as transactions in the repayment of the original debt and the creation of a new debt liability.

[5] From the debtor perspective, debt refinancing may involve borrowing from a third party to repay a creditor. The definition of debt refinancing used here is a narrower concept reflecting transactions between the debtor and same creditor only.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

A3.12 With debt rescheduling, the applicable existing debt is recorded as being repaid and a new debt instrument (or instruments) created with new terms and conditions. This treatment does not apply, however, to interest arrears that are rescheduled when the conditions in the existing debt contract remain unchanged. In such a case, the existing debt contract is not considered as rescheduled, only the interest arrears. A new debt instrument is recorded for the rescheduled interest arrears.

A3.13 The debt rescheduling transaction is recorded at the time agreed to by both parties (the contractually agreed time), and at the value of the new debt (which, under a debt rescheduling, is the same value as that of the old debt). If no date is set, the time at which the creditor records the change of terms is decisive. If the rescheduling of obligations due beyond the current period is linked to the fulfillment of certain conditions, when the obligations fall due (such as multiyear Paris Club rescheduling), entries are recorded only in the period when the specified conditions are met.

Debt refinancing

A3.14 Debt refinancing involves the replacement of an existing debt instrument or instruments, including any arrears, with a new debt instrument or instruments. It can involve the exchange of the same type of debt instrument (such as a loan for a loan) or different types of debt instruments (such as a loan for a bond). For example, a public sector unit may convert various export credit debts into a single loan, or exchange existing bonds for new bonds through exchange offers given by its creditor (rather than a change in terms and conditions).

A3.15 The treatment of debt refinancing transactions is similar to debt rescheduling. The debt being refinanced is extinguished and replaced with a new financial instrument, or instruments. The old debt is extinguished at the value of the new debt instrument, except for nonmarketable debt (e.g., a loan) owed to official creditors.

A3.16 If the refinancing involves a direct debt exchange, such as a loan-for-bond swap, the debtor records a reduction in liabilities under the appropriate debt instrument and an increase in liabilities to show the creation of the new obligation. The transaction is recorded at the value of the new debt (reflecting the current market value of the debt), and the difference between the value of the old and new debt instruments is recorded as a holding gain or loss. However, if the debt is owed to official creditors and is nonmarketable, the old debt is extinguished at its original value with the difference in value with the new instrument recorded as debt forgiveness (see paragraphs A3.7–A3.9). Where there is no established market price for the new bond, an appropriate proxy is used. For example, if the bond is similar to other bonds being traded, the market price of a traded bond would be an appropriate proxy for the value of the new bond. If the debt being swapped was recently acquired by the creditor, the acquisition price would be an appropriate proxy. Alternatively, if the interest rate on the new bond is below the prevailing interest rate, the discounted value of the bond, using the prevailing interest rate, could serve as a proxy. If such information is not available, the face value of the bond being issued may be used as a proxy. See also debt-for-equity conversion in paragraph A3.21).

A3.17 The balance sheet reflects the changes in the stock positions as a result of the transactions extinguishing the old debt instrument and creating the new debt instrument along with any valuation changes. For example, a loan-for-bond exchange will generally result in a reduction in the liabilities of the debtor (reduction in the claim of the creditor on the debtor) because the loan is recorded at nominal value, while the bond is recorded at market value, which may be lower.

A3.18 If the proceeds from the new debt are used to partially pay off the old (existing) debt, the remaining old debt is recorded being extinguished and a new debt instrument is created (equal to the value of the remaining old debt extinguished), unless the old debt is paid off through a separate transaction.

A3.19 If the terms of any new borrowings are concessional, the creditor could be seen as providing a transfer to the debtor. Debt concessionality is discussed in paragraphs A3.39–A3.41.

Debt Conversion and Debt Prepayment

Debt conversion

A3.20 Debt conversion (swap) is an exchange of debt—typically at a discount—for a nondebt claim (such as equity), or for counterpart funds that can be used to finance a particular project or policy. In essence, public sector debt is extinguished and a nondebt liability created in a debt conversion.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

A3.21 A common example of debt conversion is debt-for-equity swaps.[6] Determining the value of the equity may be difficult if the equity is not actively traded on a market, as is likely to be the case if the unit that issued the equity is a controlled public corporation. If the equity is not traded, its valuation should be based on one of the methods set out in paragraph 7.173.

A3.22 Further examples of debt conversions are other types of debt swaps (such as external debt obligations for exports or "debt-for-exports") or debt obligations for counterpart assets that are provided by the debtor to the creditor for the creditor to use for a specified purpose, such as wildlife protection, health, education, and environmental conservation (debt-for-sustainable-development).

A3.23 Direct and indirect debt conversions should be distinguished. A direct swap leads directly to the acquisition of a nondebt claim on the debtor (such as a debt-for-equity swap). An indirect debt conversion involves another claim on the economy, such as a deposit, that is subsequently used to purchase equity.

Debt prepayment

A3.24 Debt prepayment consists of a repurchase, or early payment, of debt at conditions that are agreed between the debtor and the creditor. The debt is extinguished in return for a cash payment agreed between the debtor and the creditor. The transaction is recorded at the value of the debt prepaid. Debt prepayment could be driven by the debtor's need to reduce the cost of its debt portfolio by taking advantage of favorable economic performance or market conditions to repurchase debt.

A3.25 If the debt is owed to official creditors and is nonmarketable (e.g., a loan), an element of debt forgiveness could be involved (i.e., if the prepayment occurs within an agreement between the parties with an intention to convey a benefit). As explained in the section on debt forgiveness (see paragraph A3.8), a capital transfer or capital grant from the creditor to the debtor is recorded for debt forgiveness, which reduces the value of the outstanding liability/claim.

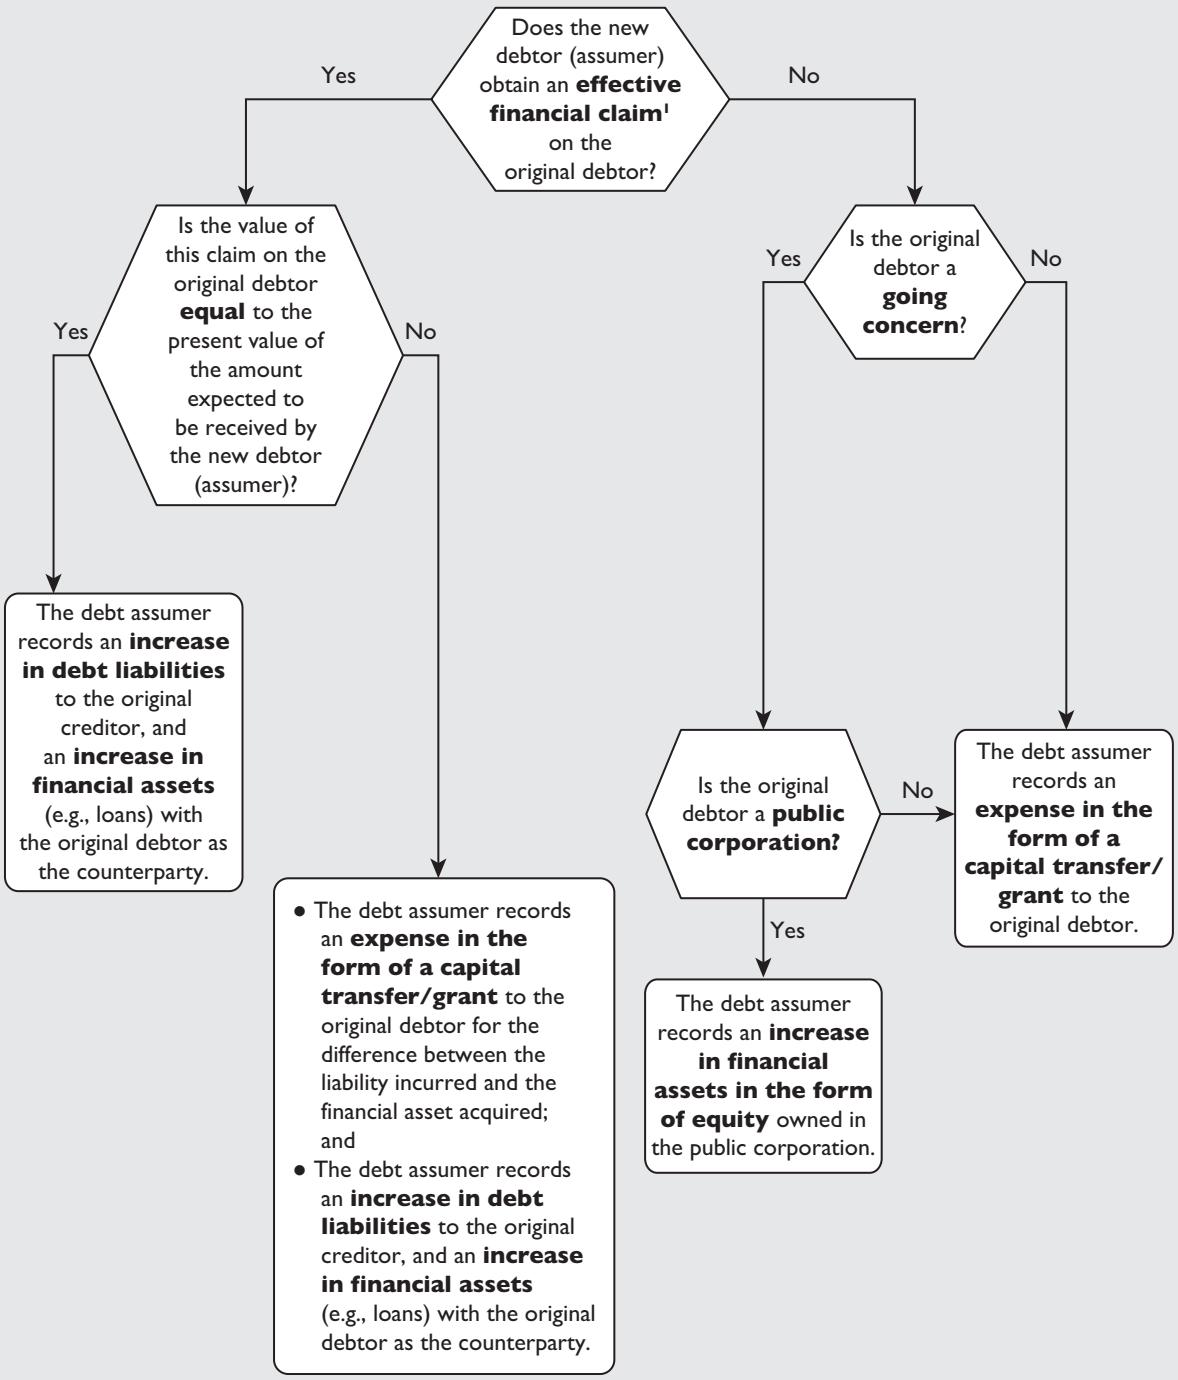
[6] Often, a third party is involved in a debt-for-equity swap, buying the claims from the creditor and receiving equity in a public corporation (the debtor).

Debt Assumption and Debt Payments on Behalf of Others

Debt assumption

A3.26 Debt assumption is a trilateral agreement between a creditor, a former debtor, and a new debtor (typically a government unit), under which the new debtor assumes the former debtor's outstanding liability to the creditor, and is liable for repayment of debt. Calling a guarantee is an example of debt assumption. If the original debtor defaults on its debt obligations, the creditor may invoke the contract conditions permitting the guarantee from the guarantor to be called. The guarantor unit must either repay the debt or assume responsibility for the debt as the primary debtor (i.e., the liability of the original debtor is extinguished). A public sector unit can be the debtor that is defaulting or the guarantor. A government can also, through agreement, offer to provide funds to pay off the debt obligation of another government unit owed to a third party.[7]

A3.27 The statistical treatment of debt assumption depends on (i) whether the new debtor acquires an effective financial claim on the original debtor, and (ii) if there is no effective financial claim, the relationship between the new debtor and the original debtor and whether the original debtor is bankrupt or no longer a going concern.[8] This implies three possibilities (see Figure A3.1):



- The debt assumer (new debtor) acquires an effective financial claim on the original debtor. The debt assumer records an increase in debt liabilities to the original creditor, and an increase in financial assets, such as in the form of loans, with the original debtor as the counterparty. The original debtor records a decrease in the original debt liability to the creditor and an increase in liabilities, such as in the form of a loan, to the debt assumer. The value of the debt assumer's claim on the original debtor is the present value

[7] For example, a central government unit offering to provide funds to pay off the debt of a local government unit owed to a bank.

[8] An "effective financial claim" is understood to be a claim that is supported by a contract between the new debtor and the original debtor, or (especially in the case of governments) an agreement, with a reasonable expectation to be honored, that the original debtor will reimburse the new debtor. A "going concern" is understood to be an entity in business, or operating for the foreseeable future.

Figure A3.1 Decision Tree for the Statistical Treatment of Debt Assumption

[1]An "effective financial claim" is understood to be a claim that is supported by a contract between the new debtor and the original debtor, or (especially in the case of governments) an agreement, with a reasonable expectation to be honored, that the original debtor will reimburse the new debtor.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

of the amount expected to be received by the assumer. If this amount is equal to the liability assumed, no further entries are required.

If the amount expected to be recovered is less than the liability assumed, the debt assumer records an expense in the form of capital transfer/grant to the original debtor for the difference between the liability incurred and the financial asset acquired in the form of loans. For the debt assumer, gross debt increases by the amount of debt assumed.

- The debt assumer (new debtor) does not acquire an effective financial claim on the original debtor. This may be the case when the original debtor is bankrupt or no longer a going concern, or when the debt assumer seeks to convey a benefit to the original debtor. The debt assumer records an expense in the form of a capital transfer/grant to the original debtor, and an increase in debt liabilities to the original creditor. The original debtor records revenue in the form of a capital transfer/grant, which extinguishes the debt liability on its balance sheet.

  The exception to this case is when the original debtor is a public corporation that continues to be a going concern, which is discussed next.

- The debt assumer (new debtor) does not acquire an effective financial claim and the original debtor is a public corporation that continues to be a going concern. The debt assumption amounts to an increase in the equity owned by the debt assumer in the public corporation (original debtor). The debt assumer records an increase in debt liabilities to the original creditor, and an increase in financial assets in the form of equity and investment fund shares. The public corporation records a decrease in the debt liability to the original creditor, and an increase in nondebt liabilities in the form of equity and investment funds shares.

A3.28 A special case is where debt assumption involves the transfer of nonfinancial assets (such as fixed assets or land) from, for example, a public corporation (original debtor) to the debt assumer (new debtor). In this case, the debt assumer records an increase in debt liabilities to the original creditor and the acquisition of a nonfinancial asset(s). If the market value of the nonfinancial asset(s) is equal to the value of the liability assumed, no further entries are required. A capital transfer/grant between the debt assumer and original debtor is recorded for any difference between the value of the liability assumed and the market value of the nonfinancial assets.

A3.29 Although no transactions are recorded for debt assumption under the cash basis of recording, the stock positions would change due to the debt assumption. Any subsequent payments in cash relating to the assumed debt would be recorded as interest, and/or transactions in financial assets other than cash and liabilities, as relevant.

Debt payments on behalf of others

A3.30 Rather than assuming a debt, a public sector unit may decide to repay that debt or make a specific payment on behalf of another institutional unit (original debtor), without a guarantee being called or the debt being taken over. In this case, the debt stays recorded solely on the balance sheet of the other institutional unit, the only legal debtor. While this activity is similar to debt assumption, as the existing debt remains with unaltered terms, debt payment on behalf of others is not considered debt reorganization. Such a situation may occur where a debtor is experiencing temporary liquidity difficulties rather than permanent solvency problems.[9]

A3.31 The treatment of debt payments on behalf of others depends on whether the public sector unit paying the debt acquires an effective financial claim on the debtor.

- If the paying unit obtains an effective financial claim on the original debtor, the paying unit records an increase in financial assets (e.g., loans) and a decrease in currency and deposits. The recipient (debtor) records a decrease in the original debt liability and an increase in another liability—which may be debt or nondebt—to the paying unit. If the claim of the paying unit on the debtor is in the form of a debt instrument, gross debt and net debt of the paying unit and recipient (debtor) do not change. However, if the claim of the paying unit on the debtor is in the form of a nondebt instrument—for example, equity:
  - For the paying unit, gross debt remains unchanged, but net debt increases (due to the

[9] Debt payments on behalf of others are different from the case where debt may be considered to be assumed at inception when a guarantee has a very high likelihood to be called, as described in paragraph 7.258.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

reduction in its financial assets in the form of currency and deposits).

- For the recipient (debtor), gross debt and net debt decrease (due to the reduction in the debt liability).

- If the paying unit does not obtain an effective financial claim on the original debtor, the paying unit records an expense in the form of a capital transfer—classified according to the nature of the recipient—and a decrease in financial assets in the form of currency and deposits. The receiving unit (debtor) records a revenue in the form of a capital transfer—classified according to the nature of the paying unit—and a decrease in the original debt liability.

Other Debt-Related Issues

Debt Write-Offs and Write-Downs

A3.32 Debt write-offs or write-downs refer to unilateral reductions by a creditor of the amount owed to it. This usually occurs when a creditor concludes that a debt obligation has no value or a reduced value because part or all of the debt is not going to be repaid (frequently because the debtor is insolvent). For example, a public corporation that borrowed from the general government unit may be insolvent. As a result, the general government unit's claim loses some, or all, of its value and is written down or written off on the balance sheet of the government unit (creditor).[10] In contrast, a unilateral write-off by a debtor, or debt repudiation, is not recognized in the macroeconomic statistical systems.

A3.33 Unlike debt forgiveness (see paragraphs A3.7–A3.9), which is a mutual agreement and, therefore, a transaction, a debt write-off or write-down is a unilateral action and, therefore, recorded as other changes in the volume of assets. The financial asset is removed from the balance sheet of the creditor and the corresponding liability should be removed from the balance sheet of the debtor, also through other changes in the volume of assets, to maintain consistency in the macroeconomic statistics.[11]

[10] If a bankruptcy still allows some of the debt to be settled, it is possible that the creditor writes off only a part of the claim.
[11] Provisions by the creditor for bad debts or expected losses (sometimes referred to as "write-down") are not recorded in macroeconomic statistics.

A3.34 Although no transactions are recorded for a debt write-off or write-down under the cash basis of recording, the stock positions relating to these operations would be reduced, reflecting the debt write-off or write-down.

New Money Facilities

A3.35 In some arrangements that assist the debtor to overcome temporary financing difficulties, new money facilities are agreed with the creditor to repay maturing debt obligations. The two debt instruments involved—the maturing debt obligation and the new money facility—are treated separately.

A3.36 The creditor records a reduction in the original claim on the debtor and an increase in a new claim on the debtor. Similarly, the debtor records a reduction in the original liability to the creditor and an increase in a new liability to the creditor. If the terms of the new borrowings are concessional, the creditor could be seen as providing a transfer to the debtor. (Debt concessionality is discussed in paragraphs A3.39–A3.41.)

Debt Defeasance

A3.37 With **defeasance**, a debtor unit removes liabilities from its balance sheet by pairing them with financial assets, the income and value of which are sufficient to ensure that all debt-service payments are met. Defeasance may be carried out by placing the assets and liabilities in a separate account within the institutional unit concerned or by transferring them to another unit. In either case, the macroeconomic statistical systems do not recognize defeasance as affecting the outstanding debt of the debtor. Thus, no transactions with respect to defeasance are recorded in the GFS framework, as long as there has been no change in the legal obligations of the debtor. When the assets and liabilities are transferred to a separate account within the unit, both assets and liabilities should be reported on a gross basis. If a separate entity resident in the same economy is created to hold the assets and liabilities, that new unit should be treated as an ancillary entity and consolidated with the defeasing unit.

A3.38 The sectorization of restructuring agencies (also referred to as "defeasance structures") is discussed in paragraphs 2.129–2.131.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Debt Concessionality

A3.39 There is no consistent definition or measure of debt concessionality in macroeconomic statistics. However, it is generally accepted that concessional loans occur when units lend to other units and the contractual interest rate is intentionally set below the market interest rate that would otherwise apply. The degree of concessionality can be enhanced with grace periods,[12] and frequencies of payments and maturity periods favorable to the debtor.

A3.40 Since the terms of a concessional loan are more favorable to the debtor than market conditions would otherwise permit, concessional loans effectively include a transfer from the creditor to the debtor. However, the means of incorporating the transfer impact within macroeconomic statistics have not been fully developed, although various alternatives have been advanced. Accordingly, until the appropriate treatment of concessional debt is agreed, information on concessional debt should be provided in a memorandum item to the balance sheet (see paragraph 7.246) and/or in supplementary tables.

A3.41 The case of Paris Club debt concessionality is discussed in Chapter 4 of the *PSDS Guide*.

Debt Arising from Bailout Operations

A3.42 A bailout refers to a rescue from financial distress. It is often used when a government unit provides either short-term financial assistance to a corporation to help it survive a period of financial difficulty, or a more permanent injection of financial resources to help recapitalize the corporation. A bailout may, in effect, constitute nationalization if the government acquires control of the corporation it is bailing out. Bailouts of financial institutions are a case in point. They are likely to involve highly publicized, one-time transactions often involving large amounts and are, therefore, easy to identify.

A3.43 Analysts generally refer to "capital injections" made by government into corporations when some significant financial support is provided to capitalize or recapitalize the corporation in financial distress. The *2008 SNA* uses "capital injections" to mean a direct intervention that is recorded in macroeconomic statistics either as a capital transfer, a loan, an acquisition of equity, or a combination of these. Direct intervention by general government units may take various forms—for example:

- Providing recapitalization through an injection of financial resources ("capital injection") or the assumption of a failed corporation's liabilities.
- Providing loans and/or acquiring equity in the corporations in distress (i.e., "requited recapitalization") on favorable terms, or not.
- Purchasing assets from the financially distressed corporation at prices greater than their true market value.

A3.44 Indirectly, general government may intervene by extending the range of guarantees it is prepared to offer.

A3.45 Broadly, two main issues arise with bailout operations:

- The first issue is the sectorization of the entity or unit created to finance or manage the sales of assets and/or liabilities of the distressed corporation. The sectorization is important, in particular, for determining whether its transactions, other economic flows, and stock positions (debt liabilities and other assets and liabilities) are within the general government sector or public corporations sector.
- The second issue is the appropriate statistical treatment of "capital injections."

The sectorization issue

A3.46 A government might create a restructuring agency (or "defeasance structure") in the form of a special purpose entity (SPE), or other type of public body, to finance or to manage the defeasance of impaired assets or repayment of liabilities of the distressed corporation.[13] As is the case with all entities in macroeconomic statistics, the sectorization of a restructuring agency should reflect the underlying economic nature of the entity. Thus, the sectorization rules, as outlined in Chapter 2, should be applied to

[12] The grace period is the period from the disbursement of the loan until the first payment due by the debtor.

[13] In the case of banks with impaired assets, such entities are commonly referred to as "bad banks."

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

determine whether such an entity or unit should be treated as part of the general government sector or public financial corporations sector:

- If a public institutional unit is created by government solely to assume management of the assets or liabilities of the distressed corporation, and is not a market producer, the unit should be classified in the general government sector because it is not involved in financial intermediation.
- If the new unit has other functions and the management of the assets or liabilities of the distressed corporation is a temporary task, its classification as a government unit or a public financial corporation is made according to the rules described in the section on restructuring agencies in paragraphs 2.129–2.131.

Statistical treatment of "capital injections"

A3.47 The assistance provided by government (or another public sector unit) to the unit suffering financial distress is usually recorded as a loan, a capital transfer, or an equity injection. Figure A3.2 provides a decision tree for the statistical treatment of "capital injections."

A3.48 When a public sector unit (investor unit), such as a government unit, intervenes by means of a capital injection that is legally in the form of a loan to the corporation in distress, the statistical treatment depends on whether the investor unit obtains an effective financial claim on the corporation, as described in paragraph A3.27.

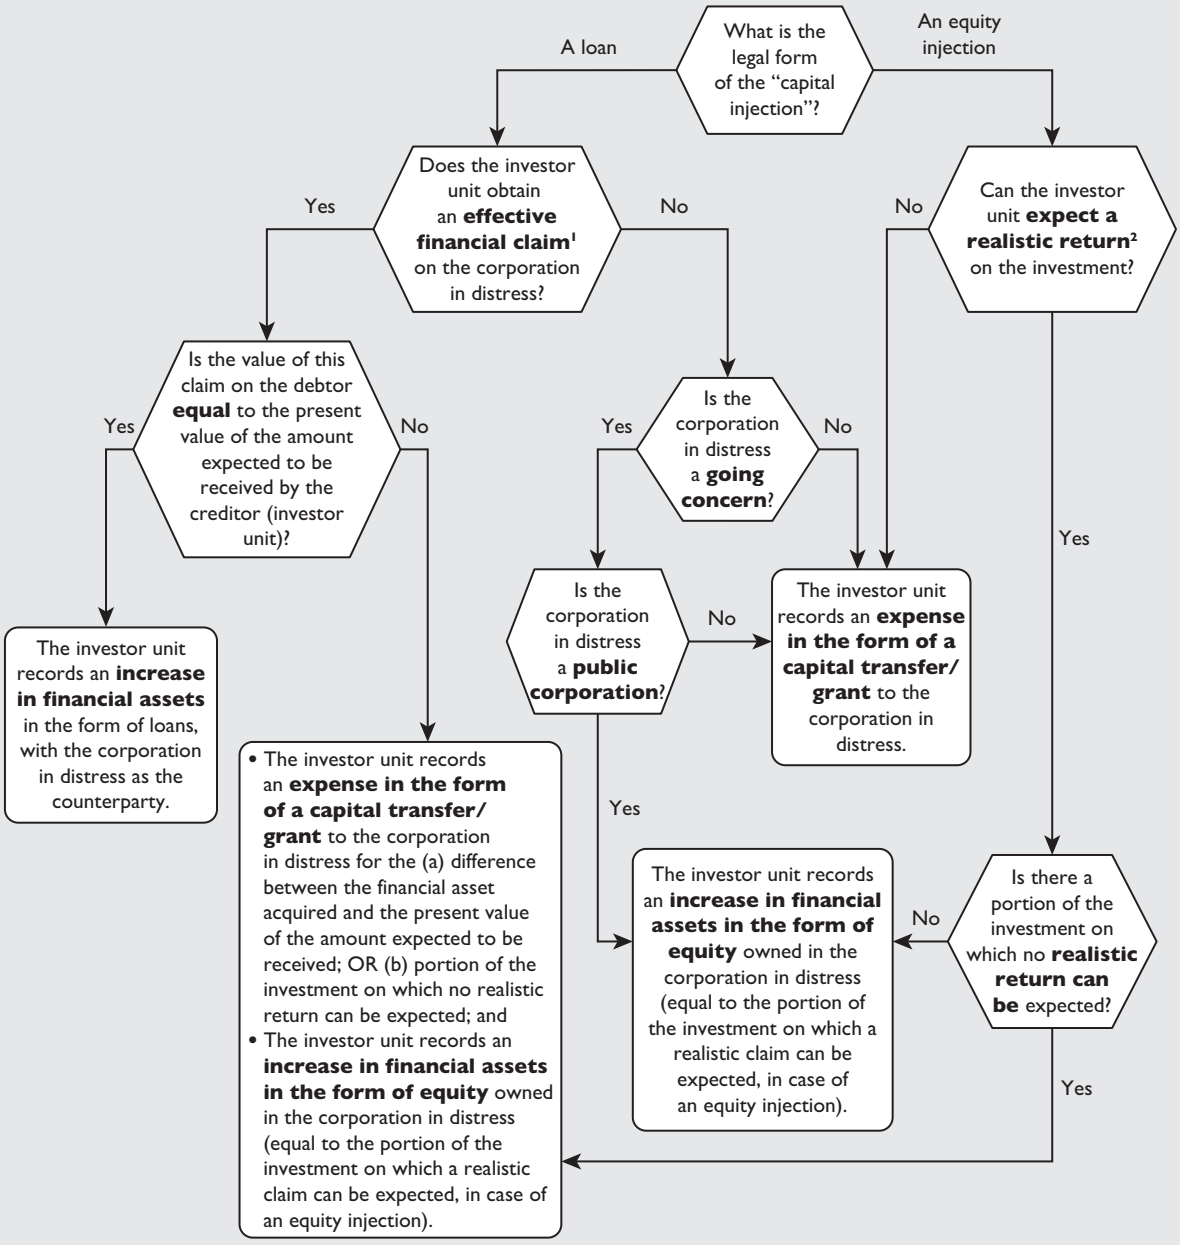
A3.49 When a public sector unit, such as government, intervenes by means of a capital injection other than a loan to the corporation in distress, the statistical treatment depends on whether a realistic return[14] can be expected on this investment:

- If the public sector unit (investor unit) can expect a realistic return on the investment, the investor unit records an increase in financial assets in the form of equity and investment fund shares, and a decrease in financial assets (e.g., currency and deposits) or an increase in liabilities, depending on how the acquisition of equity is financed. The corporation in financial distress records an increase in financial assets (e.g., currency and deposits), and an increase in nondebt liabilities in the form of equity and investment fund shares.
- The portion of the investment on which no realistic return can be expected—which may be the entire investment—is treated as a capital transfer.

A3.50 A capital injection in the form of a capital transfer (full or partial) is recorded when the funds are provided:

- Without receiving anything of equal value in exchange
- Without a reasonable expectation of a realistic rate of return
- To compensate for the impairment of assets or capital as a result of large operating deficits accumulated over two or more years, and exceptional losses due to factors outside the control of the enterprise.

A3.51 The unit providing the assistance records expense in the form of a capital transfer and a decrease in financial assets (e.g., currency and deposits) or an increase in liabilities, depending how this capital transfer is financed. The recipient records revenue in the form of a capital transfer and an increase in financial assets in the form of currency and deposits.



A3.52 In determining the magnitude of the capital transfers, the following points need to be taken into account:

- If the government buys assets from the corporation to be assisted, the amount paid may be more than the true market price of the assets.
- The purchase of assets should be recorded at the current market price, and, except for loans, a capital transfer should be recorded for the difference between the market price and the actual amount paid.
- Governments often buy loans from financial institutions during a bailout. Unless a loan becomes tradable and is traded at an established market value, it is always recorded in balance sheets at nominal value. Only if a market for the loans develops and the loans are regularly traded, they are reclassified as securities (see paragraphs 7.157 and 7.163) and also recorded at market value.

[14] A realistic rate of return on funds is indicated by the intention to earn a rate of return that is sufficient to generate dividends or holding gains at a later date, and that is a claim on the residual value of the corporation.

- When government buys a loan that has a fair value much less than its nominal value, no capital transfer for the difference in value is recorded as loans are recorded at nominal value on the balance sheet. Any difference between the price paid and the nominal value is recorded as a valuation change (see *BPM6* paragraph 9.33). However, if there is reliable information that some loans are irrecoverable, their value is reduced to zero in the balance sheet (with an "other volume change") and a capital transfer is recorded equal to the value paid by the government to the corporation. If some or all of these loans subsequently become recoverable, this is shown as a revaluation in the government's balance sheet.
- If government extends a guarantee as part of a bailout, the guarantees should be recorded according to whether this is a one-off guarantee or part of a standardized guarantee scheme (see paragraphs 7.254–7.260 for details on the statistical treatment of guarantees).

A3.53 Additional factors should be taken into account for borderline cases, such as the following:

- If the capital injection is covering large operating deficits accumulated over two or more years or exceptional losses due to factors outside the control of the enterprise, the capital injection is, by definition, a capital transfer.
- If capital injection is made to a quasi-corporation that has negative equity (see paragraph 6.91), the capital injection is always a capital transfer.
- If the capital injection is undertaken for specific purposes relating to public policy in order to compensate a bank in financial distress for anticipated defaults/bad assets/losses within its balance sheet, the capital injection is a capital transfer, unless a realistic return can be expected, in which instance an equity investment is recorded.
- If there are private shareholders providing a significant share (in proportion to their existing shareholding) of equity during the injection, then the capital injection is an equity investment since the assumption is that private investors would be seeking a return on their investment.

Debt of Special Purpose Entities

A3.54 Special purpose entities (SPEs) are described in paragraphs 2.136–2.139. For GFS, the appropriate units and institutional sectorization of the SPE must be determined. If the SPE is part of the public sector, its debt should be part of the debt of the public sector or relevant subsector.

A3.55 As noted in paragraphs 2.41–2.45, governments may establish public corporations that sell goods or services exclusively to government, without tendering for a government contract in competition with the private sector. Such a public corporation is called an artificial subsidiary and should be classified as part of the general government sector (its parent unit). Often, such government artificial subsidiaries are set up as SPEs. These units, which are legally corporations, should be classified as part of the general government sector and their debt liabilities are thus part of general government debt.

A3.56 A government may conduct fiscal activities through an entity that is resident abroad. For example, a government may fund its outlays by issuing securities abroad through an SPE. This SPE is not part of the general government sector in either home or host economy. Such entities are not treated in the same way as embassies and other territorial enclaves because they operate under the laws of the host economy. Governments may be direct investors in these units/entities. However, special imputations of transactions and stock positions between the government and the SPE abroad must be used to ensure that any fiscal operations undertaken through nonresident entities are reflected in the transactions and stock positions of the home government concerned.[15] As a result, the government will show an actual, or imputed, debt to its SPE arising from any debts the SPE incurs on behalf of the government.

A3.57 When an SPE entity resident in one economy borrows on behalf of the government of another economy, and the borrowing is for fiscal purposes, the statistical treatment in the accounts of that government is as follows:

[15] The reason for having a special approach for government entities is that, unlike in the private sector, the nonresident entity undertakes functions at the behest of general government for public policy, not commercial purposes. Without this approach, a misleading picture of government expenditure and debt could arise.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

- At the time of borrowing—A transaction creating a debt liability of the government to the borrowing entity is imputed equal to the amount borrowed. The counterpart entry is an increase in the government's equity in the borrowing entity.
- At the time funds or assets acquired with the funds (as applicable) are transferred to the government—A transaction for the flow of funds or assets is recorded, matched by a reduction of the government's equity in the borrowing entity by the same amount.
- At the time expenses are incurred, or assets are transferred by the borrowing entity to a third party (i.e., are not transferred to the government), where applicable—A current or capital transfer between the government and the entity is imputed, with the matching entry of a reduction in the value of the government's equity.

A3.58 These entries are made symmetrically for both the government and the borrowing entity. The entries do not affect the transactions or stock positions between the borrowing entity and its creditors or other third parties, which are recorded as they occur, with no imputations.

Debt Arising from Securitization

A3.59 Securitization occurs when a unit, named the originator, conveys the ownership rights over financial or nonfinancial assets, or the right to receive specific future flows, to another unit, named the securitization unit. In return, the securitization unit pays an amount to the originator from its own source of financing. The securitization unit obtains its own financing by issuing debt securities using the assets or rights to future flows transferred by the originator as collateral.[16] When asset-backed securities are issued by a public sector unit, they form part of public sector debt.

A3.60 Securitization results in debt securities for which coupon or principal payments (or both) are backed by specific financial or nonfinancial assets or future revenue streams. A variety of assets or future revenue streams may be used for securitization, including residential and commercial mortgage loans, consumer loans, government loans, and credit derivatives. A general government unit may issue debt securities backed by specific earmarked revenue. In macroeconomic statistical systems, the ability to raise taxes or other government revenue is not recognized as a government asset that could be used for securitization.[17] Nevertheless, the earmarking of future revenue, such as receipts from toll roads, to service debt securities issued by a general government (or public sector) unit may resemble securitization (see paragraphs A3.64 and A3.66).

A3.61 Securitization schemes vary within and across debt securities markets. At the broadest level, a distinction is made about whether a securitization unit is involved. In securitization schemes where debt securities are issued by a securitization unit, the issuing institutional unit is a financial intermediary in the financial corporations sector. The securitization unit is often an SPE. However, as described in paragraph 2.137, resident SPEs functioning in only a passive manner relative to general government and carrying out fiscal activities are not treated as separate institutional units in the macroeconomic statistical systems. Such SPEs are treated as part of the general government sector regardless of their legal status—therefore:

- If a securitization unit is involved, four types of schemes may be distinguished from a macroeconomic statistics perspective:
  - True-sale securitization,[18] which is schemes involving a true transfer (sale) of assets—from a macroeconomic statistics perspective[19]—from the original asset owner's balance sheet to that of the securitization unit

[16] For a detailed discussion of securitization, see *Handbook on Securities Statistics*, Bank for International Settlements, European Central Bank, and International Monetary Fund, May 2009, as well as the *2008 SNA*, paragraphs 22.131–22.133. The *Handbook* also considers that securitization can occur when there is no securitization unit or transfer of assets.

[17] For example, future tax revenue has not yet accrued, presumably because the event that leads to the tax liability has not yet taken place, and consequently no asset exists on the government balance sheet.

[18] "Type 2" schemes in the *Handbook on Securities Statistics* and the "first case" of securitization in the *2008 SNA*.

[19] To be treated as a sale, the asset must already appear on the balance sheet of the public sector unit (e.g., central government) and there must be a full change of ownership to the securitization unit, as evidenced by the transfer of the risks and rewards linked to the asset. The following must be considered: (i) The purchase price should equal the current market price, otherwise it is not a sale; and (ii) if the originator (e.g., central government) guarantees repayment of any debt related to the asset acquired by the securitization unit, it is unlikely that all of the risks associated with the asset have been transferred and there is, therefore, no sale.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

- No true-sale securitization,[20] which is schemes that do not involve a true transfer of assets—from a macroeconomic statistics perspective—from the original asset owner's balance sheet to that of the securitization unit (see footnote 19)
- No asset securitization,[21] which is schemes involving securitization of future revenue streams that are not recognized as assets in macroeconomic statistics
- Synthetic securitization with a securitization unit,[22] which is schemes involving the transfer of credit risk only (but not the transfer of assets), through a securitization unit.

- If no securitization unit is involved, two types of securitization are possible:
  - On-balance sheet securitization,[23] which is schemes in which the original asset owner issues new debt securities and there is no transfer of assets
  - Synthetic securitization without a securitization unit,[24] which is schemes involving the transfer of credit risk only (but not the transfer of assets), through the direct issue of debt securities by the original asset owner.

A3.62 True-sale securitization involves debt securities issued by a securitization unit where the underlying assets have been transferred from the original asset owner's (i.e., the originator's) balance sheet to that of the securitization unit. The securitization unit uses the proceeds from selling the debt securities to investors to finance the acquisition of the assets. The revenue stream from the pool of assets (typically, interest payments and principal repayments on the loans) is used to make the coupon payments and principal repayments on the debt securities issued. In case of a true-sale securitization by a public sector unit, the original asset owner's gross debt remains unchanged. The gross debt of the securitization unit increases as a result of the securities issued. If this unit is a public financial corporation, its debt is part of public sector debt. A resident securitization "unit" controlled by a government unit that is an SPE but does not meet the requirements of an institutional unit is treated as part of general government regardless of its legal status. Such an SPE's debt is part of general government's debt (see also paragraph A3.61).

A3.63 If no true sale had taken place from a macroeconomic statistics perspective (see footnote 19), the amount received from the securitization unit by the public sector unit as the originator is treated as borrowing, usually in the form of a loan.[25] The debt securities issued by the securitization unit are part of public sector debt, if the securitization unit is part of the public sector.

A3.64 No asset securitization involves securitization of future revenue streams. As mentioned in paragraph A3.60, the ability to raise taxes or other government revenue is not recognized as a government asset that could be used for true-sale securitization. In most cases, it is not the rights to the future revenue that are used as collateral, but the obligation of the public sector unit to use a sufficient amount of the future income to repay the borrowing in full. If more income is earned than is needed to repay the borrowing, the excess is retained by the public sector unit. So, if "rights" to future government revenue are transferred to a securitization unit, the amount received from the securitization unit by the public sector unit, arising from the proceeds of the debt securities issue, is treated as borrowing, usually in the form of a loan.[26] The revenue stream continues to accrue to government and government uses these proceeds to repay the loan from the securitization unit. The debt securities issued by the securitization unit are part of public sector debt if the securitization unit is part of the public sector.

A3.65 Synthetic securitization involves transfer of the credit risk related to a pool of assets without transfer of the assets themselves, either through a securitization unit or through the direct issuing of debt securities by the original asset owner.

- Synthetic securitization with a securitization unit: The owner of a pool of assets buys credit default

[20] Derived from the "first case" of securitization in the *2008 SNA*.
[21] The "second case" of securitization in the *2008 SNA*.
[22] "Type 3" schemes in the *Handbook on Securities Statistics*.
[23] "Type 1" schemes in the *Handbook on Securities Statistics*.
[24] "Type 3" schemes in the *Handbook on Securities Statistics*.

[25] When both the originator and the securitization unit are in the public sector, this loan will be eliminated from public sector debt through consolidation.
[26] When both the originator and the securitization unit are in the public sector, this loan will be eliminated from public sector debt through consolidation.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

swaps (CDS) (protection buyer) from the securitization unit (protection seller) for a premium to obtain protection against possible default losses on the pool of assets.[27] The protection seller issues a debt instrument. The proceeds from the issue of debt securities by the securitization unit are invested in low-risk, low-return financial assets (such as deposits), and the income accrued on this investment, together with the premium from the CDS, finances coupon payments on the debt securities due by the securitization unit to the investors. On maturity, the holders of the debt securities are reimbursed, provided there has been no default on the pool of assets. If there is a default, the protection buyer is compensated by the protection seller for the default losses related to the pool of assets, while the holders of the debt securities (investors) suffer losses for the same value, a realized holding gain for the protection seller.

The debt securities issued by the securitization unit are part of public sector debt if the securitization unit is part of the public sector.

- Synthetic securitization without a securitization unit: The owner of the asset issues credit-linked notes (CLN). CLN are debt securities that are backed by reference assets (such as loans and bonds), with an embedded CDS allowing credit risk to be transferred from the issuer to investors. There is usually a higher interest rate to compensate the investors for taking on higher risks. Credit protection for the pool of assets is sold by the investors to the protection buyer (or issuer of the CLN) by buying the CLN. Repayment of principal and interest on the notes is conditional on performance of the pool of assets. If no default occurs during the life of the note, the full redemption value of the note is paid to investors at maturity. If a default occurs, investors receive the redemption value of the note minus the value of the default losses.

  With synthetic securitization without a securitization unit, the debt securities (CLN) issued by a public sector unit are part of that unit's debt.

A3.66 On-balance sheet securitization involves debt securities backed by a future revenue stream generated by the assets. The assets remain on the balance sheet of the debt securities issuer (the original asset owner), typically as a separate portfolio. There is no securitization unit involved. The issue of debt securities provides the original asset owner with funds and the debt securities form part of the original asset owner's debt.

[27] A credit default swap is a financial derivative whose primary purpose is to trade credit default risk.

Debt Arising from Off-Market Swaps

A3.67 In macroeconomic statistics, swaps give rise to financial derivatives, which are nondebt instruments (see paragraph 7.215). However, off-market swaps have a debt component.

A3.68 An **off-market swap** is a swap contract that has a nonzero value at inception as a result of having reference rates priced differently from current market values—that is, "off-the-market." Such a swap results in a lump sum being paid, usually at inception, by one party to the other. The economic nature of an off-market swap is a combination of borrowing (i.e., the lump sum), in the form of a loan, and an on-market swap (financial derivative). The loan component of an off-market swap is debt and, if a public sector unit receives the lump-sum payment, this will be part of public sector debt. Examples of swaps contracts that may involve off-market reference rates include interest rate and currency swaps.

A3.69 Because the economic nature of an off-market swap is equivalent to a combination of a loan and a financial derivative, two stock positions are recorded in the balance sheet:

- A loan—a debt instrument—which is equal to the nonzero value of the swap at inception and with a maturity date equivalent to the expiration date of the swap
- A financial derivative (swap) component—a nondebt instrument—that has a market value of zero at inception.

A3.70 The loan position is a liability of the party that receives the lump sum, while the derivative position may appear either on the financial asset or liability side, depending on market prices on the balance sheet date.

A3.71 Future streams of flows relating to these stock positions are also partitioned between those relating to the loan and financial derivative component, respectively.

On-Lending of Borrowed Funds

A3.72 On-lending of borrowed funds refers to a resident institutional unit, A (usually central government), borrowing from another institutional unit(s), B (usually a nonresident unit), and then on-lending the proceeds from this borrowing to a third institutional unit(s), C (usually state or local governments, or public corporation (s)), where it is understood that unit A obtains an effective financial claim on unit C. On-lending of borrowed funds is motivated by several factors—for example:

- Institutional unit A may be able to borrow from unit B at more favorable terms than unit C could borrow from unit B
- Institutional unit C's borrowing powers are limited by factors such as foreign exchange regulations; only unit A can borrow from nonresidents.

A3.73 On-lending results in (at least) two separate financial claims. These claims should not be offset against each other in government finance and public sector debt statistics; institutional unit B has a debt claim on unit(s) A, and unit(s) A has a debt claim on unit C, which may be consolidated (see paragraph A3.76). Depending on the residence of institutional unit(s) B and C, respectively, these debt liabilities (and the corresponding financial claims) are classified as domestic or external.

A3.74 The statistical treatment of the two claims to be recorded if the resident institutional unit (A), which on-lends the borrowed funds to unit(s) C, obtains an effective financial claim on unit(s) C, depends on:

- The residence of the creditor(s) from which unit A is borrowing (i.e., unit(s) B)
- The residence of unit(s) C to which unit A is on-lending the borrowed funds (see Table A3.1).

A3.75 The classification of the debt liability of institutional unit A to unit(s) B depends on the type of instrument(s) involved: typically, such borrowing is in the form of loans and/or debt securities. In such cases, institutional unit A's debt liabilities in the form of loans and/or debt securities increase (credit) as a result of the borrowing from unit(s) B, with a corresponding increase (debit) in unit A's financial assets in the form of currency and deposits. These events result in an increase in the gross debt position of unit A, but no change in its net debt position.

Table A3.1 Summary of the Statistical Treatment of On-Lending of Borrowed Funds by Institutional Unit A

1. Unit A borrows from unit(s) B	Depending on the residence of institutional unit(s) B, unit A has a domestic/external debt liability to unit(s) B. (Institutional unit(s) B has a domestic/external financial claim on unit A.)
2. Unit A on-lends to unit(s) C	Depending on the residence of institutional unit(s) C, unit A has a domestic/external financial claim on unit(s) C. (Institutional unit(s) C has a domestic/ external liability to unit A.)

A3.76 The debt liability of institutional unit(s) C to unit A, as a result of the on-lending of the borrowed funds, is typically in the form of a loan. In other words, institutional unit C's debt liabilities increase (credit) as a result of the borrowing from unit A, with a corresponding increase (debit) in unit C's financial assets in the form of currency and deposits. Institutional unit A's financial assets (e.g., loans) will increase (debit) as a result of the on-lending to unit C and its financial assets in the form of currency and deposits will decrease (credit). If institutional unit(s) C is classified to the same sector, subsector, or group of units as unit A, this debt liability (and corresponding financial claim) is eliminated in consolidation.

A3.77 The amortization of each of the debt liabilities (and corresponding financial assets) is recorded in the books of the unit in whose balance sheet the debt liability appears. Thus, if institutional unit A has a debt liability to unit B, the amortization of this (usually external) liability (debit) is recorded in the books of unit A, even if these borrowed funds were on-lent to unit C.

A3.78 Similarly, the amortization of institutional unit C's (usually domestic) debt liability (debit) to unit A is recorded in the books of unit C. Unit A would record a decrease (credit) in its (domestic) financial claims on unit C. The amortization of institutional unit C's debt liability to unit A improves unit C's gross debt position, while its net debt position remains the same.

Stock Positions and Related Flows with the IMF

A3.79 This section briefly describes the stock positions and flows in countries' financial assets and liabilities arising from membership in the International Monetary Fund (IMF), as they relate to public sector debt statistics. Debt data compilers first have to determine in which public sector unit(s) to record the stock positions and related flows with the IMF. Stock positions and flows in financial assets and liabilities of member countries with the IMF are usually recorded in the accounts of the public sector unit as determined by the legal and institutional arrangements in the member country.

A3.80 The IMF conducts its dealings with a member through the fiscal agency and the depository:

- Each member country designates a fiscal agency to conduct financial transactions with the IMF on behalf of the member.[28]
- Each member is also required to designate its central bank as a depository for the IMF's holdings of the member's currency.[29] In most member countries, the central bank is both the fiscal agency and the depository.

A3.81 The next sections discuss member countries' quotas in the IMF, their reserve positions in the IMF, remuneration (interest) receivable from the IMF, the account that is used for administrative payments (the "No. 2 Account"), and their Special Drawing Rights (SDRs) allocations and holdings.

Quotas

A3.82 Member countries are assigned a quota on joining the IMF. A quota is the capital subscription, expressed in SDRs, that each member must pay the IMF on joining and consists of two components:

- Reserve asset component—A member is required to pay 25 percent of its quota in SDRs or in currencies specified by the IMF. This 25 percent portion is a component of the member's reserve assets and is known as the "reserve tranche." In the public sector unit's accounts, subscribing this portion is shown as a transaction involving an increase in external financial assets in the form of currency and deposits—that is, the reserve tranche position, which is a liquid claim on the IMF (debit), offset by an equal reduction in existing external financial assets[30] (credit).
- Domestic currency component—The remaining 75 percent of the quota is payable in the member's own currency at the designated depository. The payment is made either in domestic currency (IMF No. 1 Account) or if the member country so chooses, by issuance of a promissory note (in the IMF Securities Account). The No. 1 Account is used for the IMF's operational transactions (e.g., purchases and repurchases), and small transfers may be made from this account to the No. 2 Account, which is used for the payment of local administrative expenses incurred by the IMF in the member's currency.[31] The promissory notes are encashable by the IMF on demand. The domestic portion of the quota payment is not recorded in the public sector unit's accounts, because it is considered in economic terms to be of a contingent nature. No interest is payable on either the deposit account or the note.

A3.83 There are periodic reviews of the size of member quotas. Recording transactions that reflect a change in a member's quota is the same as the recording that takes place when the quota is initially paid.

Reserve position in the IMF

A3.84 A member country's reserve position in the IMF equals the sum of the reserve tranche plus any indebtedness of the IMF (under bilateral loan agreements, notes, or participation in standing borrowing agreements such as the General Agreements to Borrow and New Agreements to Borrow) in the General Resources Account that is readily available to the member country (for further details, see *BMP6*, paragraph 6.85). The reserve tranche represents the member's unconditional drawing right on the IMF, created by the foreign exchange portion of the quota subscription, plus increases (decreases) through the

[28] The fiscal agency may be the member's treasury (ministry of finance), central bank, official monetary agency, stabilization fund, or other similar agency. The IMF can deal only with, or through, the designated fiscal agency.
[29] If the member has no central bank, it shall designate such other institution as may be acceptable to the IMF.
[30] The type of instrument varies.
[31] When the IMF uses funds from the No. 2 Account to pay for the acquisition of goods and services, the member country shows a reduction in this account and an offset transaction in the use of goods and services.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

IMF's sale (repurchase) of the member's currency to meet the demand for use of IMF resources by other members in need of balance of payments financing. A member's reserve position in the IMF constitutes part of its reserve assets (external financial assets).

A3.85 To utilize its reserve tranche in the IMF, a member must present a declaration of a balance of payments need and purchase foreign exchange from the IMF with its own currency. The domestic currency, equal to the value of the foreign exchange, is paid into the IMF's No. 1 Account with the member's depository or through the issuance to the IMF of a noninterest-bearing promissory note recorded in the IMF's Securities Account. The transaction is recorded in the public sector unit's accounts as a reduction in the member's external financial assets in the form of currency and deposits (i.e., the reserve tranche position in the IMF), which is offset by an increase in the member's external financial assets (i.e., foreign exchange).

Credit and loans from the IMF

A3.86 A member may make use of IMF credit or concessional loans under the trusts administered by the IMF (for financing for low-income countries) to acquire additional foreign exchange from the IMF. The use of IMF credit and concessional loans results in the same outcome—that is, the member entering into these agreements has access to foreign exchange in return for agreeing to meet a set of conditions. Both IMF credit and concessional loans are classified in the public sector unit's accounts as external liabilities in the form of loans, although the two types of arrangements are executed in different ways:

- When a member country uses IMF credit, it "purchases" foreign exchange from the IMF in return for its domestic currency deposited in the IMF No. 1 Account (or backed by the issuance of a promissory note). Use of IMF credit is shown as the member's loan liability (denominated in SDRs) in the accounts of the public sector unit, reflecting the economic nature of the transaction. Liabilities under IMF credit arrangements are extinguished when the member uses foreign exchange to "repurchase" its domestic currency.
- The concessional loans, also denominated in SDRs, result in the member borrowing foreign exchange with a commitment to repay. Such loans do not affect the IMF No. 1 Account. Repayments must be made in SDRs or freely useable currencies.

A3.87 If the value of the member's domestic currency changes in relation to the SDR, "maintenance of value payments" are made once a year in the No. 1, No. 2, and Securities Accounts in domestic currency to maintain a constant SDR liability. Because the liability is denominated in SDRs, the maintenance of value payments are not entered as transactions in the central bank's accounts, but as holding gains/losses (revaluations) when the domestic currency is used as the unit of account.

A3.88 When the central bank passes on proceeds from IMF borrowing to a general government unit:

- The central bank has a domestic financial claim (loan) on the general government unit and the general government unit has a domestic debt liability to repay (principal and interest).
- The central bank has an external debt liability to repay, and may use the debt service payments received from the general government unit to do so.

Remuneration

A3.89 The IMF pays its members "remuneration" quarterly (in SDRs) on the basis of their reserve tranche position, except for a small portion related to prior quota payments in gold that are interest-free resources to the IMF. This remuneration should be recorded on an accrual basis as interest income (revenue) of the public sector unit, which is realized as an increase in its external financial assets in the form of currency and deposits.

IMF No. 2 Account

A3.90 As discussed in paragraph A3.82, the IMF No. 2 Account is used by the IMF for administrative payments and is reflected as a liability in the public sector unit's accounts. Transactions involving the No. 2 Account are recorded as increases or decreases in this liability and are offset by the source of funds (in the case of an increase) or the use of funds (in the case of a decrease). When the IMF transfers funds from the No. 1 Account to the No. 2 Account, the public sector unit's accounts will show an increase in its reserve tranche (i.e., currency and deposits). The

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

increase reflects the reduction in IMF holdings of the member's currency in the No. 1 Account and is offset by an increase in the member's liabilities relating to currency and deposits.

Special Drawing Rights (SDRs)

A3.91 The SDR is an international reserve asset created by the IMF in 1969. The SDR is administered by the IMF's SDR Department, which is required by the IMF's *Articles of Agreement* to keep its accounts strictly separate from those of the General Department. Members participating in the SDR Department incur the financial asset or liability position unto itself. Given that financial claims on and liabilities to members in the SDR system are attributed on a cooperative basis, a residual partner category—other nonresidents—is used as the counterparty to SDR holdings and allocations.[32]

A3.92 SDR allocations received by a country are recorded as a liability in the form of SDRs (part of gross debt of the public sector unit) with a corresponding entry for SDR holdings as a financial asset. The calculation of a public sector unit's net debt takes into account SDR holdings and SDR allocations. Interest income on SDR holdings (revenue) and interest expense on SDR allocations are accrued on a gross basis to the outstanding financial asset and liability, respectively.

A3.93 The SDR allocation is debt of the recipient (i.e., the participant in the SDR Department), and forms part of public sector debt. The SDR holdings are part of the public sector's financial assets. However, the international statistical systems do not specify on which balance sheet SDR holdings and allocations should be recorded (e.g., the central bank or a general government entity such as the ministry of finance or treasury). This is because SDR allocations are made to IMF members that are participants in the SDR Department of the IMF, and it is for those members to follow domestic legal and institutional arrangements to determine the ownership and recording of SDR allocations and SDR holdings in the public sector.

A3.94 For GFS and public sector debt statistics, it is particularly relevant in which public sector unit's accounts the SDR holdings and allocations are recorded. If the SDR allocation is recorded on the government's balance sheet, the allocation is part of general government debt. If the SDR allocation is on the central bank's balance sheet, the allocation is not part of general government debt but still part of public sector debt.

A3.95 SDRs are held exclusively by participants, the IMF, through the General Resources Account, and prescribed holders,[33] and are transferable among them. At the time of the SDR allocation, the amounts recorded as SDR allocations (liabilities) and holdings (financial assets) are identical and on the same public sector unit's balance sheet. This public sector unit—as official holder—may, subsequently, exchange some or all of its SDR holdings (financial asset) with other official holders for freely usable currency(ies). In this case, the SDR allocations and holdings on the balance sheet of the public sector unit are no longer identical; the SDR holdings are less than the allocations because they have been converted into freely usable currencies (i.e., currency and deposits). As a result, interest payable on the SDR allocation of public sector unit will be larger than interest receivable on its SDR holdings. Interest receivable on the SDR holdings exchanged will accrue to the new holder.

[32] See paragraph 7.264 for a discussion of the classification of the counterparty by institutional sector.

[33] The IMF has prescribed a limited number of international financial institutions as holders of SDRs.

APPENDIX

4 Some Cross-Cutting Issues

This appendix applies government finance statistics principles to illustrate the recording of: leases, licenses, permits, and contracts; public-private partnerships; and insurance and standardized guarantee schemes.

Introduction

A4.1 Some cross-cutting issues relate to the recording of the impact of specific events on revenue, expense, and flows and stock positions of assets and liabilities. Aspects of recording these events are described in various chapters of this *Manual.* However, bringing all of these together enhances the clarity of recording these events. This appendix deals with three such issues:[1]

- Leases, licenses, permits, and contracts
- Public-private partnerships (PPPs)
- Insurance and standardized guarantee schemes.

Leases, Licenses, Permits, and Other Contracts

Introduction

A4.2 Many transactions are specified in terms of a contract between two institutional units. The majority of contracts are such that one unit provides a good, service, or asset to the other unit for an agreed payment at an agreed time (possibly immediately after agreeing on the price). Such contracts may be written and legally binding or may be informal or even only implicit. However, these contracts are simply agreements about the terms under which goods, services, and assets are provided to the recipient along with the ownership of the item. In particular, these contracts can help to determine the point at which the transactions should be recorded in GFS in accordance with the accrual principles described in paragraphs 3.69–3.75.

A4.3 For certain types of contracts and legal agreements, variously described as leases and licenses (or permits), the terms of the agreement may affect not only the time of recording of transactions but also the classification of transactions and the ownership of the item subject to the agreement. The purpose of this section is to provide guidance on how transactions entered into under these more complex arrangements should be recorded in GFS.

Leases

A4.4 Three types of leases are recognized in macroeconomic statistics: operating leases, financial leases, and resource leases. Each of these leases relates to the use of a nonfinancial asset. Fundamental to the distinction between the different types of leases is the difference between legal and economic ownership. The legal owner of resources is the institutional unit entitled by law and sustainable under the law to claim the benefits associated with the asset. By contrast, the economic owner of resources is entitled to claim the benefits associated with the use of the asset in the course of an economic activity by virtue of accepting the associated risks. This distinction between legal and economic ownership is elaborated upon in paragraphs 3.37–3.41 and 7.5. The legal owner is often the economic owner as well. When they are different, the legal owner has divested itself of the majority of risks in return for agreed payments from the economic owner. Thus:

- In the case of operating leases and resource leases, there is no change of economic ownership: the legal owner continues to be the economic owner. Resource leases are agreements for the use of natural resources, such as land and radio spectrum. Operating leases are agreements for the use of all other nonfinancial assets.
- In the case of financial leases, there is a difference between economic ownership and legal

[1] While social protection and debt operations can also be regarded as cross-cutting issues, these issues are described separately in Appendixes 2 and 3.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

ownership of the asset. Financial leases can apply to all nonfinancial assets, including natural resources under some circumstances.

A4.5 The following paragraphs discuss the treatment of operating leases, financial leases, and resource leases in detail.

Operating leases

A4.6 Operating leasing is the activity of renting out produced assets under arrangements that provide use of a tangible asset to the lessee, but do not involve the transfer of the bulk of risks and rewards of ownership to the lessee. The legal and economic owner is called the lessor. One indication that an operating lease exists is that the responsibility for repair and maintenance of the asset lies with the legal owner. Under an operating lease, the asset remains on the balance sheet of the lessor.

A4.7 Amounts payable under an operating lease for the use of the asset are referred to as rentals and are recorded as payments for a service. In principle, any fixed asset may be subject to an operating lease. The character of operating leases may most easily be described in relation to fixed assets since operating leases often concern vehicles, office equipment (e.g., photocopiers), construction equipment, buildings, etc. The service provided by the lessor to the lessee goes beyond the mere provision of the asset. It includes other elements, such as the convenience for the lessee that the lessor takes responsibility for the maintenance and security of the asset—an important point from the user's view. In the case of equipment, the lessor, or owner, normally maintains a stock of equipment in good working order that can be hired on demand or at short notice. The lessor is normally a specialist in the operation of the equipment, a factor that may be important in the case of highly specialized equipment, where the lessee may not have the necessary expertise or facilities to maintain the equipment properly. The lessor may also undertake to replace the equipment in the event of a serious or prolonged breakdown. In the case of a building, the lessor is responsible for the structural integrity of the building, and would usually be responsible in the case of damage—for example, due to a natural disaster. The lessor is usually also responsible for ensuring that elevators, heating, and ventilation systems function adequately.

A4.8 Operating leases often aim at meeting the needs of users who require certain types of equipment only intermittently. Many operating leases are for short periods, although the lessee may renew the rental when the period expires and the same user may hire the same piece of equipment on several occasions. Because of the evolution of increasingly complicated types of machinery, especially in the electronics field, the servicing and backup facilities provided by a lessor are important factors that may influence a user to rent. Other factors that may persuade users to rent over long periods rather than purchase are considerations regarding the lessor's balance sheet, cash flow, or tax liability.

A4.9 The service provided under an operating lease should be recorded as *use of goods and services* (22) for the lessee and *sales of goods and services* (142) for the lessor. *Consumption of fixed capital* (23) on the fixed asset involved is recorded in the accounts of the lessor.

Financial leases

A4.10 A **financial lease** is a contract under which the lessor, as legal owner of an asset, conveys substantially all risks and rewards of ownership of the asset to the lessee. The economic nature of the arrangement is such that the lessor is deemed to provide a loan to allow the lessee to acquire the majority of risk and rewards of ownership, but the lessor retains legal title (ownership) as collateral for the loan. In other words, the lessee becomes the economic owner of the asset. Under a financial lease, the lessor records a loan to the lessee with which the lessee acquires the asset. Thereafter, the leased asset is shown on the balance sheet of the lessee and not of the lessor; the corresponding loan is shown as an asset of the lessor and a liability of the lessee.

A4.11 Financial leases are distinguished from other types of leases because substantially all risks and rewards of ownership are transferred from the legal owner of the nonfinancial asset (the lessor) to the user of the nonfinancial asset (the lessee). The following provisions in the lease contract would normally lead to a lease being classified as a financial lease:

- The lease contract transfers legal ownership of the asset to the lessee at the end of the lease term, or
- The lease contract gives the lessee the option to acquire legal ownership of the asset at the end of

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

the lease term at a price that is sufficiently low that the exercise of the option is reasonably certain, or

- The lease term is for the major part of the economic life of the asset, or
- At inception, the present value of the lease payment amounts to substantially all of the value of the asset, or
- If the lessee can cancel the lease, the losses of the lessor are borne by the lessee, or
- Gains or losses in the residual value of the asset accrue to the lessee, or
- The lessee has the ability to continue the lease for a secondary period for a payment substantially lower than market value.

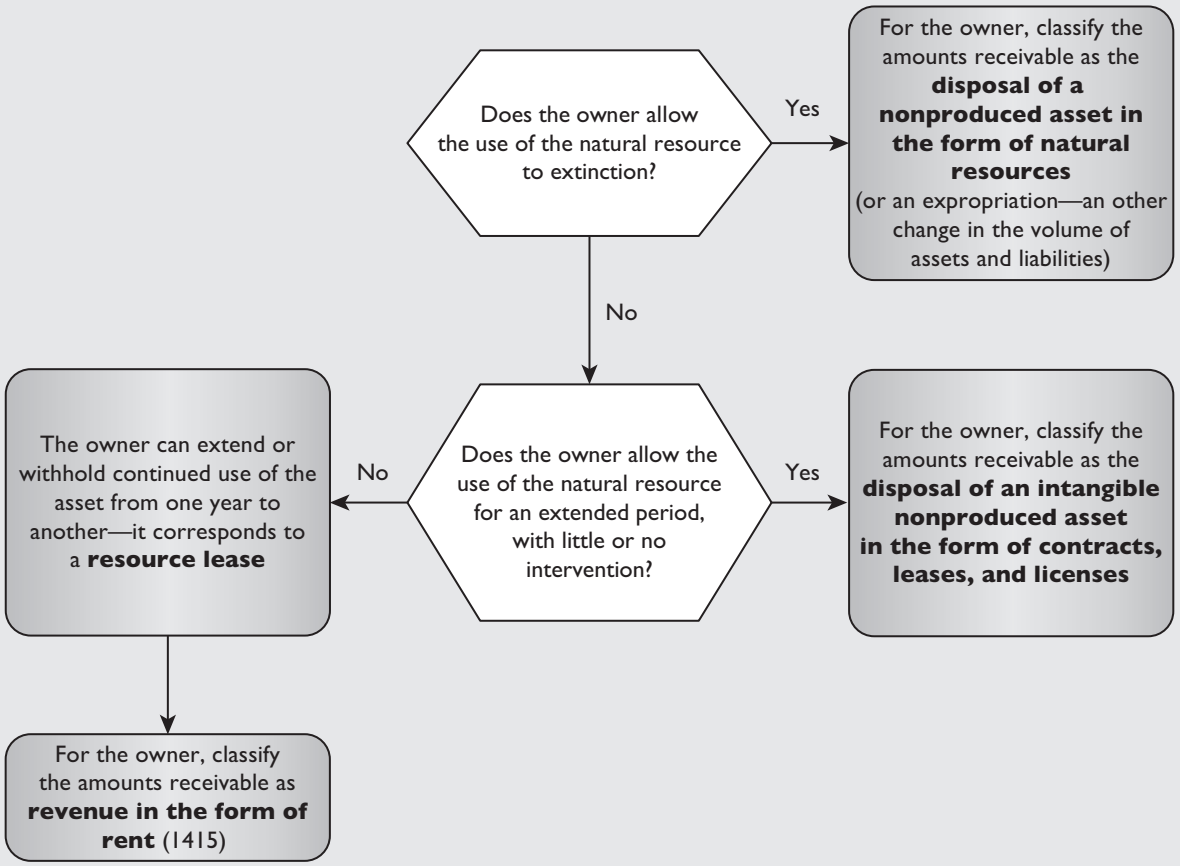
A4.12 These provisions in the lease contract may not be conclusive that substantially all of the risks have been conveyed. For example, if the asset is conveyed to the lessee at the end of the lease at its fair value at that time, the lessor holds substantial risks of ownership. The lease is then considered to be an operating lease. Financial leases are also called "finance leases" or "capital leases," highlighting that the motivation (paragraphs A4.10–A4.11) is to finance the acquisition of a nonfinancial asset. Internationally accepted accounting practices generally recognize financial leases in the same manner as in GFS.[2] A treatment akin to financial leases is also adopted for some public-private partnerships[3] (PPPs) (see paragraphs A4.58–A4.65 and the *2008 SNA*, paragraphs 22.154–22.163).

A4.13 The statistical treatment of financial leases is designed to capture the economic reality of such arrangements, by treating assets under a financial lease as if they were purchased and owned by the user. The lessee (economic owner) records the acquisition of the asset that is financed by an imputed loan. The loan is redeemed through payments during the contract (consisting of interest and original principal elements) and any residual payment at the end of the contract (or alternatively, by the return of the good to the lessor). If the lessor is a financial intermediary, part of the payment is also treated as a service charge (see paragraph 6.81).

A4.14 It is common, but not necessary, for a financial lease to cover the whole economic life of the asset. Regardless of whether the lease is for the whole economic life of the asset or for less, the value of the imputed loan, at inception, corresponds to the market value of the asset, and is valued at nominal value throughout its life, in the same way as other loans. The value of the loan consists of the present value of the future payments due to the legal owner plus the value of the asset at the end of the lease, as specified in the lease agreement.

A4.15 At the inception of the lease, the value of the asset appearing on the balance sheet of the lessee should be equal to the value of the loan owed to the lessor at that time. At the end of the lease term, the asset may be returned to the lessor to cancel the loan, or a new arrangement, including the outright purchase of the asset, may be reached between the lessor and lessee. If the lease is for less than the expected economic life of the asset, the lease usually specifies the value to the lessor at the end of the lease or the terms under which the lease can be renewed. Any variation in the price of the asset from the value specified in the lease agreement is borne by the lessee.

Resource leases



A4.16 A **resource lease** is an agreement whereby the legal owner of a natural resource that macroeconomic statistics treat as having an infinite life makes it available to a lessee in return for a regular payment recorded as property income and described as rent. In the case of resource leases, there is no change of economic ownership and, therefore, the resource continues to be recorded on the balance sheet of the lessor, even though it is used by the lessee. Payments due under a resource lease are recorded as revenue or expense in the form of *rent* (1415 or 2814). By convention, no consumption of fixed capital is applied to natural resources. Depletion of a natural resource is instead recorded as an other change in the volume of assets (see paragraph 10.52).

[2] At the time of publication of this *Manual*, the treatment of financial and operating leases is under review by international accounting standard setters.

[3] For example, a build, own, operate, transfer scheme could be established to assign the risks and rewards of ownership to the government, and the private partner would be treated as the provider of a financial lease.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Figure A4.1 Illustrating the Treatment of Licenses and Permits to Use a Natural Resource

A4.17 Land is the classic case of an asset subject to a resource lease, but all other natural resources are also treated this way. An exception, when a long-term lease of land may be recorded as the sale of land, is described in paragraph A4.26.[4]

Licenses and Permits to Use a Natural Resource

A4.18 In many countries, licenses and permits to use natural resources are issued by government because government claims ownership of the resources on behalf of the community. However, government could also issue these licenses and permits if the resources are privately owned.

A4.19 As illustrated in Figure A4.1, there are three different sets of conditions that may apply to the use of a natural resource:

- The owner may permit the resource to be used to extinction. This option results in the sale (or possibly an expropriation) of the nonproduced resource asset itself.
- The owner may permit the resource to be used for an extended period of time in such a way that, in effect, the user controls the use of the resource during this time with little if any intervention from the legal owner. This permit leads to the creation of an intangible nonproduced asset classified as *contracts, leases, and licenses*

[4] Further discussions of natural resources in the next section also indicate other cases where the use of a resource should be taken as the sale of the resource.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

(31441) for the user, distinct from the resource itself; however, the value of the resource and the value of the nonproduced asset in the form of *contracts, leases, and licenses* are linked. An inverse relationship will exist between the value of the resource itself and the value of the intangible asset.[5]

- The owner can extend or withhold permission to continued use of the asset from one year to the next. This option corresponds to a resource lease on which *rent* is payable/receivable (see paragraphs A4.16–A4.17).

A4.20 The differences in treatment between the various options are not clear-cut.[6] There is no single, universal, and clear-cut criterion to distinguish between rent and asset sales, so a range of criteria should be considered in making the decision (see Box A4.1).

A4.21 The considerations listed in Box A4.1 can be seen as a more specific parallel to the distinction of economic ownership from legal ownership used in distinguishing between operating and financial leases described earlier. The conditions for treatment of the payment as the acquisition of an asset or rent are indicative rather than prescriptive. A decision on the appropriate treatment when some of the conditions are not met will necessitate consideration of how to record those transactions. For example, if, on balance, the decision is to treat the payment as rent, but a large upfront payment was made, this should be treated as a prepayment, recorded on an accrual basis. However, if the recipient is not willing to consider a refund if the contract is suspended, this is indicative of the sale of an intangible nonproduced asset rather than the payment of rent.

A4.22 The application of these principles to the main types of natural resources is described in the following text.

Radio spectrum

A4.23 Payment for a mobile phone license constitutes the sale of an asset rather than a payment for rent when the licensee acquires effective economic ownership rights over the use of the spectrum.[7]

A4.24 If the sale of such a license constitutes the sale of an asset, two possible treatments may apply: the sale of the spectrum itself or the sale of a permit to use the spectrum.

- When the life spans of the license and of the spectrum coincide, the payment for a license is treated as the sale of the spectrum itself (*other natural resources: radio spectrum* (314331)). The latter situation applies always when licenses are granted indefinitely.
- When the life span of the license is different from the life span of the spectrum, the payment for a license is treated as the sale of an intangible nonproduced asset classified as *permits to use natural resources* (314412) by the legal owner (licensor) to the economic owner (licensee).

A4.25 When the license agreement is treated as the sale of an intangible asset, in its own right, its value is established at the time of its sale. The value of the license declines with the remaining period of validity to a value of zero when the license expires. Symmetrically, the value of the spectrum to the lessor falls when the license acquires a value and progressively increases as the license expires. This reflects the potential for a further sale of the right to use the spectrum for another period.[8]

Land

A4.26 Land may be sold outright (i.e., when the legal ownership is transferred from one institutional unit to another)[9] or may be subject to a resource lease (e.g., tenant farmers usually pay regular rent to their landlord). A resource lease on land may instead be considered as a sale of the *land* (3141) if the

[5] The encumbered value of the resource is based on the present value of future rental payments taking the existence of the lease into account. The value of the resource increases as the contract winds down, while the value of the contract decreases over the same period. Also see Box A4.3.

[6] Also see this issue articulated in the context of the case of mobile phone licenses in *SNA News and Notes,* Volume 14, United Nations, 2002.

[7] To decide whether ownership is effectively transferred, the six criteria presented in Box A4.1 are to be considered.

[8] This recording ensures a neutral effect on the net worth of the overall economy during the life of the license.

[9] As described in paragraph 2.13, land may not be recorded as being sold to a nonresident unit. In such cases, a notional resident unit is created that holds title to the land; the nonresident unit then owns the equity in the notional resident unit.

Box A4.1 Criteria to Determine Whether a License Represents an Asset Sale or Rent

Several criteria need to be considered:

- Costs and benefits assumed by licensee—The greater the extent of the risks and benefits associated with the right to use an asset incurred by the licensee, the more likely the classification of a transaction as the sale of an asset as opposed to rent. Pre-agreement on the value of payments (whether by lump sum or by installments) effectively transfers all economic risks and benefits to the licensee and points, therefore, to the sale of an asset. If, on the other hand, the value of payment is contingent on the results from using the license, risks and benefits are only partially transferred to the licensee and the situation is more readily characterized as payment of rent. In the case of mobile phone licenses, the total amount payable is often pre-agreed. An additional indication of the degree to which commercial risks have been passed to the licensee is to examine the hypothetical case where a licensee goes bankrupt. If, in such a case, the licensor reimburses none of the upfront payment made by the licensee, this would constitute a strong case against a characterization of the transaction as rent, as apparently the licensee has incurred all the risks involved.
- Upfront payment or installment—As with other indicators, the mode of payment is in itself not conclusive for a characterization as a transaction in assets or rent payment. Generally, the means of paying for a license is a financial issue and not a relevant factor in determining whether it is an asset. However, business practice shows that upfront payments of rent for long periods (15–25 years in the case of mobile phone licenses) are unusual and this favors an interpretation as sale of an asset.
- Length of the license—Licenses granted for long periods suggest the transaction should be treated as the sale of an asset, and for shorter periods treated as payments for rent. The timeframe involved in mobile phone licensing (15–25 years) is considered rather unusual as a period for which to conclude a fixed payment of rent and therefore a further indication favoring an interpretation as sale of an asset.
- Actual or de facto transferability— The possibility to sell the license is a strong indication of ownership and if transferability exists, this is considered a strong condition to characterize the licensing act as the sale of third-party property rights. In practice, mobile phone licenses are often transferable either directly (by the corporation selling the license to another corporation) or indirectly (through the corporation being acquired through a takeover).
- Cancellation possibility— The stronger the restrictions on the issuer's capacity to cancel the license at its discretion, the stronger the case for treatment as a sale of an asset. Conversely, when licenses can easily be cancelled at the discretion of the issuer, ownership over benefits and risks has not been fully transferred to the licensee and the transaction qualifies more readily as rent.
- Conception in the business world and international accounting standards— Businesses, in accordance with international accounting standards, often treat a license to use the spectrum as an asset. Again, in itself this does not lead to treatment as an asset in the national accounts, and there are other areas where companies choose to present figures in their accounts in ways that are not consistent with the national accounts. But the treatment of the acquisition of mobile phone licenses as capital investment in company accounts provides an added incentive to treat them in a similar way in the national accounts.

Not all or a majority of these considerations have to be satisfied to characterize the license as a sale of an asset. However, to qualify as *rent* (1415 or 2814) of a natural resource asset (rather than the sale of an asset), at least some of the following conditions should hold:

- The contract is of short-term duration, or renegotiable at short-term intervals. Such contracts do not provide the lessee with a benefit when market prices for the leased asset go up in the way that a fixed, long-term contract would. Such benefits are holding gains that typically accrue to owners of assets.
- The contract is nontransferable. Nontransferability is a strong but not a sufficient criterion for the treatment of license payments as rent, because, although it precludes the lessee from cashing in on holding gains, it does not preclude the lessee from reaping comparable economic benefits (e.g., using the license in a business).
- The contract contains detailed stipulations on how the lessee should make use of the asset. Such stipulations are often seen in cases of rent of land, in which the owner wishes to retain control over the usage of the land. In the case of licenses, examples of such stipulations would be that the contract states what regions or types of customers should be served, or that it sets limits on the prices that the lessee may charge.
- The contract includes conditions that give the lessor the unilateral right to terminate the lease without compensation—for instance, for underuse of the underlying asset by the lessee.
- The contract requires payments over the duration of the contract, rather than a large, upfront payment. Although this condition is essentially financial in character and thus cannot be decisive on the type of the lease, it may indicate a degree of control for the lessor to direct the use of the nonproduced asset. The case for a treatment as rent is further supported if the payments are related to the revenue the lessee derives from the license.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

lease satisfies most or all of the criteria to be considered a sale of an asset in Box A4.1. When the land is leased in other circumstances, the payments are recorded as *rent* (1415 or 2814) under a resource lease agreement.

A4.27 In some jurisdictions, the land under buildings remains in the legal ownership of a landlord other than the owner of the buildings. If regular payments are made to the landlord, these are recorded as *rent* (1415 or 2814). However, it is sometimes the case that, even though the land legally belongs to another unit, the right to occupy it for an extended period is payable in a single upfront payment often when the building is acquired. In such a case the payment is recorded as the acquisition of a nonproduced asset, classified as *land* (3141) if the value of the land can be established separately from that of the building. If not, the composite asset should be classified in the category representing the greater part of the value (see paragraphs 7.94 and 8.51). In such a case, when the building changes ownership, the purchase price includes an element representing the present value of future rent payments. Therefore, the land is recorded as if the ownership is transferred along with the building above the land. If, at the end of the land lease, a further payment is liable for extension of the lease for another long-term period, this should be recorded as an acquisition of another nonproduced asset, as described earlier.

Timber

A4.28 For timber, four possibilities are distinguished: the sale of a natural resource asset, the sale of a permit, rent of a natural resource asset, or sale of forests that are produced assets.

- Sale of a natural resource asset—If government gives a unit permission to clear an area of natural forest, or to fell at its discretion without any restriction in perpetuity, the payments made to government (the owner) constitute the sale of the natural resource asset, classified as *noncultivated biological resources* (31431).[10]
- Sale of a permit—When licenses or permits issued to use the natural resource, such as timber, satisfy the criteria to be a separate asset, the assets are classified as *contracts, leases, and licenses* (31441).
- Rent of a natural resource asset—It is common for timber felling to be allowed, subject to strict limits with a fee payable per unit volume of timber felled (stumpage). The limits are usually such that the harvest of timber is sustainable and so the payments are recorded as *rent* (1415 or 2814) in the case of a natural forest. The option to have a lease permitting felling at the lessee's discretion but subject to the restoration of the land, in an acceptable forested state, at some time in the future is improbable.
- Sale of goods and services—When cultivated forests are produced assets in the form of inventories, the extraction of timber is treated as the *sale of goods and services* (142).

A4.29 Illegal logging is prevalent in some countries. In such cases, the quantity of timber extracted should be recorded as other changes in the volume of assets (i.e., uncompensated seizure).

Fish

A4.30 Natural stocks of fish with an economic value are an asset, and the same considerations apply to them as to other natural resources.[11] Two possibilities exist for commercial fishing:

- Fishing quotas are permits that may be allocated in perpetuity or for extended periods to particular institutional units—for example, where fishing is an established way of life and there may be little alternative economic employment. In such circumstances, the quotas may be transferable and, if so, there may be a well-developed market for them. Fishing quotas may, therefore, be considered as transferable permits to use a natural resource. Such permits are assets in macroeconomic statistics and classified as *permits to use natural resources* (614412) in the balance sheet.

[10] The sale of forested land may be recorded as the sale of the timber and the land separately, depending on the intended use of each.

[11] It is not realistic to consider that permission would be given to exhaust fish stocks, but illegal fishing may either reduce the stock position below the point of sustainability or exhaust it altogether. In these cases, an other volume change in the stock position should be recorded.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

- An alternative regime is to issue a permit for a strictly limited period of time, less than a year, to a nominated institutional unit, often a nonresident. This is a common practice in some islands in the South Pacific, for example. In these cases, the revenue from the licenses should be recorded as *rent* (1415) because it is a resource lease.

A4.31 A license for recreational fishing has long been considered, by convention, as payment of a tax under *other taxes on the use of goods and on permission to use goods or perform activities* (11452). This treatment is not changed by the wider considerations for commercial fishing.

Water

A4.32 A natural body of water with an economic value can be sold in its entirety either as part of the land that surrounds it or as a separate entity.

A4.33 As is the case for fish, it is unlikely that economic ownership would be ceded under a long lease with no preconditions on the quantity and state in which a similar amount of water should be returned to the owner. However, it is possible that surface water could be leased under a long lease for recreational purposes, for example. The treatment of such leases should be the same as for land (see paragraphs A4.26–A4.27).

A4.34 Regular payments for the extraction of water from natural water bodies (as opposed to the delivery of it) should be treated as *rent* (1415 or 2814). However, extraction of water as a produced commodity (e.g., purchases from a reservoir) should be recorded as the sale of goods and services.

Mineral and energy resources

A4.35 Mineral and energy resources differ from land, timber, and fish in that, although they also constitute a natural resource, they cannot be used sustainably. All extraction necessarily reduces the amount of the resource available for the future. This consideration necessitates a different set of recommendations for how transactions relating to their use should be recorded.

- When a unit, such as government, owning a mineral or energy resource cedes all rights over it to another unit, this constitutes the sale of the resource classified as *mineral and energy resources* (3142). Like land, mineral resources can be owned only by resident units; if necessary, a notional resident unit must be established to preserve this convention.
- When a unit extracts a mineral or energy resource under an agreement where the payments made each year are dependent on the amount extracted, the payments (sometimes described as royalties) are recorded as *rent* (1415 or 2814). The depletion of the resource itself is recorded as other changes in the volume of assets.[12]

Sharing Assets

A4.36 There are two ways in which assets may be shared, and the two cases require different treatments:

- The asset may be wholly legally owned by two or more units, each at different points in time.
- Alternatively, the risks of and benefits from the asset may be shared by two or more units at a single point in time.

A4.37 In macroeconomic statistics, even though the asset may be owned by different units at different times, when a balance sheet is drawn up, the whole of the value of the asset is attributed to one unit.

- For an asset subject to an operating lease, there is no ambiguity. The legal owner is also the economic owner and is the unit that shows the asset on its balance sheet.
- An asset subject to a financial lease is shown on the balance sheet of the economic owner. This is consistent with the views that the value of the asset represents the stream of future benefits coming from the asset and the economic owner is the unit entitled to receive these benefits in return for accepting the risks associated with using the asset in production.
- For an asset subject to a resource lease, the value is shown on the balance sheet of the legal owner.

[12] The reasons for recommending the simple recording of payments each year from the extractor to the owner as rent and changes in the size and value of the resource as other changes in the volume of assets of the legal owner are given in the *2008 SNA*, paragraph 17.343.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

A4.38 When licenses to use natural resources such as radio spectrum, land, timber, and fish satisfy the criteria to be classified as intangible assets under *permits to use natural resources* (314412), they are part of the subclass of nonfinancial assets in the form of *contracts, leases, and licenses* (31441) and are shown on the balance sheet of the licensee.

A4.39 Sharing the risks and rewards of an asset between different units at a point in time is unusual. The most common occurrence is that a single unit undertakes the activity in which the asset is used and that unit shares the returns among the owners in the form of distributed property income. However, occasionally it is possible that such a single unit does not exist and it is not meaningful to try to create it statistically. This is most common when the participating units are resident in different economies, as may be the case with an airline, or in the case of some unincorporated joint ventures. The terms under which unincorporated joint ventures are established are diverse, but one form allows that all members share the assets equally. In such cases, macroeconomic statistics record the assets shared between the owners in proportion to their ownership shares.

A4.40 In some joint ventures that are recognized as institutional units, one party may contribute an asset as its share of the costs. If this happens, an injection of equity equal to the value of the asset should be recorded along with the acquisition of the asset in question by the joint venture.

Permits to Undertake a Specific Activity

A4.41 In addition to leases and licenses to use an asset as described in the previous sections, permission may be granted by government to engage in a particular activity, independently of any assets involved in the activity. Permission to extract minerals in return for the payment of rent, for example, is not covered by this type of permit because the permit derives from the government's ownership of the assets. The permits that give permission to engage in a particular activity are designed to limit the number of individual units entitled to engage in the activity. Such permits may be issued by government or by private institutional units and different treatments apply to the two cases. This section deals only with permits issued by government. Permits issued by units other than government are not discussed here because their treatment does not affect the government accounts.[13]

Permits issued by government

A4.42 When governments restrict, for example, the number of cars entitled to operate as taxis or limit the number of casinos permitted by issuing licenses, they are, in effect, creating monopoly profits for the approved operators and recovering some of these profits as the "permission fee." Such fees are recorded as *other taxes on the use of goods and on permission to use goods or perform activities* (11452). This principle applies to all cases where government issues licenses to limit the number of units operating in a particular field where the limit is fixed arbitrarily and is not dependent only on qualifying criteria.

A4.43 In principle, if the license is valid for several reporting periods, the payment should be recorded on an accrual basis with an entry in *other accounts receivable* (3208) or *other accounts payable* (3308) for the amount of the license fee covering future reporting periods. However, if government does not recognize a liability to repay the licensee in the case of a cancellation, the whole of the fee payable should be recorded as a single tax payment at the time it is paid.

A4.44 The incentive to acquire such a license is the licensees' expectation that they acquire the right to make monopoly profits at least equal to the amount payable for the license. For the license holder, this stream of future income is treated as an asset if the licensee can realize this by on-selling the asset. The asset first appears in the accounts of the licensee as an other change in the volume of assets. Subsequent increases and decreases in its value are recorded as holding gains or losses. These types of assets are described as *permits to undertake a specific activity* (614413). The value of the asset is determined by the value at which it can be sold or, if no such information is available, is estimated at the present value of the future stream of monopoly profits.

A4.45 If the payment for the license is being recorded on an accrual basis, the licensee has in the

[13] See the *2008 SNA*, paragraphs 17.360–17.362. Similarly, contracts for time share arrangements are not discussed in this *Manual* (see the *2008 SNA*, paragraphs 17.344–17.348).

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

balance sheet an asset under *other accounts receivable* equal to the value of the license fee covering future reporting periods and an asset recorded as *permits to undertake specific activities* (614413) for the value of the license covering the excess of the monopoly profits over the cost. If the license is on-sold, the price paid by the new owner reflects both the value of the right to receive a refund from the government if the license is cancelled and the present value of the future stream of monopoly profits. If the license was recorded as a single reporting period tax payment, the value of the asset for the licensee is the value at which it can be sold or, if no such information is available, is estimated as the present value of the future stream of monopoly profits. Box A4.2 outlines the statistical treatment of permits issued by government using four examples.

Conditions for government permits recognized as assets

A4.46 A permit issued by government to undertake a specific activity may be treated as an asset (*permits to undertake specific activities* (614413)) only when all the following conditions are satisfied:

- The activity concerned does not utilize an asset belonging to government; if it does, the permission to use the asset is treated as an operating lease, a financial lease, a resource lease, or possibly the acquisition of an asset representing permission to use the asset at the discretion of the licensee over an extended period.
- The permit holder must be legally and practically able to sell the permit to a third party.
- The number of permits is limited, thereby allowing the holder to make monopoly profits when undertaking the activity concerned.
- The permit is not issued subject to a qualifying criterion. Revenue raised from the issuance of permits that are subject to qualifying criteria are treated as either *taxes on the use of goods and on permission to use goods, or perform activities* (11452) or payments for services under *administrative fees* (1422).

A4.47 Even if all these conditions are satisfied, if in practice the permits are not on-sold, it is not relevant to record the permits as assets. If any of the conditions is not satisfied, the payments are treated as *taxes on the use of goods and on permission to use goods or perform activities* (11452)—that is, without the creation of an asset in the form of *permits to undertake specific activities* (614413). (There may be an account payable in cases when the permit holders make payments that will accrue over more than one reporting period.)

Permits to use natural resources as sinks

A4.48 Governments may issue emission permits as a means of controlling total emissions. These permits do not involve the use of a natural asset (there is no economic value placed on the atmosphere so it cannot be considered an economic asset). However, it is inherent in the concept that these permits will be tradable and that there will be an active market for them.

A4.49 The payments for emission permits issued by government are treated as *taxes on the use of goods and on permission to use goods or perform activities* (11452), at the time the emissions occur. The timing difference between the payments received by government for the permits and the time the emission occurs gives rise to a transaction in financial liabilities classified as *other accounts payable* (3308) for government and a financial asset classified as *other accounts receivable* (3208) for the holder. The difference between the prepaid tax value of the permit and the market value of the permit represents a marketable contract (nonproduced nonfinancial asset) for the holder. The creation and disappearance of the nonproduced nonfinancial asset are recorded as an other change in volume of assets.

A4.50 The case of payments for discharging water may be considered as an example of the different possible ways of treating the payments:

- If a payment to discharge water is a fine imposed by government intended to inhibit discharge, the fine should be treated as revenue for government classified as *fines, penalties, and forfeits* (143). If such a fine is imposed on government or public sector units by another institutional unit, the fine is included in expense, classified as *current transfers not elsewhere classified* (2821).

Box A4.2 Statistical Treatment of Permits Issued by Government: Examples

Suppose unit A contracts with government to buy a permit to operate a casino for three years at a total cost of 12. A expects to make monopoly profits of 7 per year because the permit excludes other casinos from operating. The government may or may not be prepared to make a refund if A relinquishes the permit. A may utilize the permit for the three years for which it is valid or may sell it to unit B at the end of year 1. The recordings under these four possibilities are examined as follows.

Case 1: Government does not offer a refund and A keeps the permit for three years

At the start of year 1, A pays tax of 12 and through an other change in the volume of assets recognizes an asset worth 21 initially. Government records only tax revenue of 12. Assuming no market price changes or discount factor, by the end of the year the value of the asset has reduced by 7 as an other volume change, because one of the three years for which the permit was initially valid has expired. At this point the asset is contributing 14 to A's net worth. By the end of the second year A writes off an additional 7 as an other volume change, leaving a contribution to net worth of 7. By the end of the third year the asset is worth zero.

Case 2: Government does not offer a refund and A sells the permit to B after one year

At the start of year 1, A pays tax of 12 and through an other change in the volume of assets recognizes an asset worth 21 initially. Government records only tax revenue of 12. Assuming no market price changes or discount factor, by the end of the year the value of the asset has reduced by 7 as an other volume change, because one of the three years for which the permit was initially valid has expired. At this point, the value of the asset is 14. However, B is prepared to pay only 13 for the asset and A accepts this offer. A therefore reduces the value of the asset by 1 through a holding loss (revaluation change), before selling it for 13. B acquires the asset for 13 and, assuming no further market price changes, its value reduces by 6.5 in the other change in volume of assets account in each of the two following years.

Case 3: Government offers a possibility to refund and A keeps the permit for three years

At the start of year 1, A makes a payment of 12 to government, which is recorded as a payment of tax of 4 for the year. The remainder of the amount is a prepayment of a tax and, therefore, at the end of the year government has an other account payable to A of 8. The value of the permit to A is only the excess of the monopoly profit over the total amount that A will have to pay to government. At the start of year 1, A recognizes an asset with a value of 9 (the difference between 7 and 4 for three years) through an other change in the volume of assets. Assuming no market price changes or discount factor, by the end of year 1 this permit asset is worth only 6. At the end of that year, A's net worth includes an other account receivable from government of 8 and the remaining value of the permit of 6. The total value of A's assets is 14 as in case 1. During the second year, A's other account receivable from government reduces by 4 which is used to pay the accrued tax in year 2. In that year, the value of the permit also reduces by 3 from 6 to 3. At the end of the second year, A's net worth includes an other account payable from government of 4 and, assuming no further market price changes, a permit worth 3, bringing total assets to 7 as in case 1. At the end of year 3, both the other account payable and the value of the permit are reduced to zero.

Case 4: Government offers a possibility to refund and A sells the permit to B after one year

At the start of year 1, A makes a payment of 12 to government which is recorded as a payment of tax of 4 for the year. The remainder of the amount is a prepayment of a tax and, therefore, at the end of the year government has an other account payable to A of 8. The value of the permit to A is only the excess of the monopoly profit over the other account payable. At the start of year 1, A recognizes an asset with a value of 9 (the difference between 7 and 4 for three years) through an other change in the volume of assets. Assuming no market price changes or discount factor, by the end of the year, this permit asset is worth only 6. At the end of the year, A's net worth includes an other account receivable from government of 8 and the remaining value of the permit of 6. The total value of A's assets is 14, as in case 1. However, B is prepared to pay only 13 for the asset and A accepts this offer. As in case 2, A has to reduce the value of the permit by 1 through a holding loss (revaluation change) before selling the asset to B for 13. The other account payable from government of 8 is transferred to B and the asset (permit) is sold for 5. B's net worth is unchanged because B has paid A 13 but received the other account payable of 8 and an asset (permit) valued at 5 in return. In year 2, the other account payable is reduced by 4 and a tax payment of 4 is recorded and, assuming no further market price changes, the permit declines in value from 5 to 2.5. At the end of year 3, both the other account payable and the value of the permit are reduced to zero.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

- If a limited number of permits are issued with the intent to restrict discharges, the payment should be treated as *taxes on the use of goods and on permission to use goods or perform activities* (11452) if the medium into which the water is discharged is not regarded as an asset in macroeconomic statistics.
- If the medium into which the water is discharged is an asset and the necessary conditions are met concerning the terms on which the discharge is permitted, then the payment for the permit should be treated in the same way as the payment for a license to use the radio spectrum for mobile phones. If the payment is linked to remedial action, the payment is a payment for a service, unless the amount levied is out of proportion to the costs involved in subsequent water treatment, in which case the payment should be treated as *other taxes on the use of goods and on permission to use goods or perform activities* (11452).

Contracts for future production

A4.51 Although human capital is not recognized as an economic asset, there are cases where a contract that entitles the holder to limit the ability of a named individual to work for others may be regarded as an asset. Prolific and lucrative contracts may be for sports players where, for example, one football club can "sell" a player to another. In fact, the club is not selling the person, but rather the exclusive rights to have that person working for it. Similar contracts exist for the rights to publish literary works or musical performances. Such contracts are treated as assets, classified as *entitlement to future goods and services on an exclusive basis* (614414) within the asset class of contracts, leases, and licenses.

A4.52 Similar contracts may exist for the production of nonfinancial assets in future. An examination of the practice of purchasing the options of future aircraft production revealed, however, that in this case there is no transferable asset and a change of mind on the part of the potential purchaser or failure to deliver on the part of the supplier is settled by a change in the arrangements between the two parties and does not lead to the sale of the option to a third party. If an instance arises where the option to purchase nonfinancial assets is treated in the same way as a contract for a named individual's performance, the same classification would apply.

Leases as Assets

A4.53 As stated in paragraph A4.2, contracts underlie many transactions recorded in macroeconomic statistics and it is important to understand what the implications are for the time of recording and classification of transactions arising from a contract. Permits or licenses to use natural resources may constitute an asset, as may permits to undertake specific activities and contracts for future production.

A4.54 As indicated in paragraphs 7.105–7.106, a contract may be considered an asset when it is transferable to a third party (i.e., a unit other than the two specified in the original contract)—for example, a marketable operating lease acquiring a value as an asset. An example is given in Box A4.3. Assets reflecting such third-party property rights are always transitory: they exist only for the length of the lease and where there is a difference between the encumbered and unencumbered values.

A4.55 Permits to use natural resources and contracts for future production may also give rise to these types of third-party property rights assets. Similarly, permits to undertake specific activities may give rise to these types of assets even though the original payment, if payable to government, was treated as a tax. Financial leases do not give rise to these types of assets. If the value of the asset being leased increases by more than the payments due under the financial lease, the lessee may have the option of selling the asset, repaying the loan, and keeping the difference.

A4.56 In the case of marketable operating leases, the lease may be treated as an asset only when the two following conditions are satisfied:

- The lease specifies a predetermined price for the use of an asset that differs from the price the asset could be leased for at the current time.
- The lessee is able legally and practically to realize this price difference by subcontracting the lease to a third party.

A4.57 In practice, it is recommended that such assets should be recorded only when the value of the asset is significant and the lessee can actually exercise the right to realize the price difference.

Box A4.3 Practical Example of Leases as Assets

Suppose a lease on an apartment agreed some time ago specifies the rental at 100 per month but its current market rent is 120 per month. From the lessor's point of view, the apartment is "encumbered" by the existing lease; that is, it carries a penalty (in this case of 20 per month) because of the existence of the lease. The encumbered value of the apartment is based on the present value of future rental payments taking the existence of the lease into account; that is, the future income stream is 100 for the remaining period of the lease and 120 thereafter (ignoring any allowance for inflation). The unencumbered value of the apartment is a present value based on an income stream of 120 per month from the current period forward. The value to be entered in the landlord's balance sheet is the encumbered value, which is also all the landlord (lessor) can hope to realize if he sold the apartment while the tenant has the right to maintain the lease. To realize the unencumbered value, the lessor would have to pay the tenant the difference between the unencumbered value and the encumbered value to be free of the lease. This amount, the encumbrance, can in some circumstances be treated as an asset of the tenant. The circumstances are that it is both legally possible and is practicable for the tenant to sublet the apartment to a third party. Because of the difficulty of identifying when such assets may exist, it is recommended that in practice these assets be recorded only when there is evidence that they have been realized.

The encumbered value of the apartment may be higher than the unencumbered value if rentals have fallen since the lease was agreed. In this case, it is the landlord who benefits from the discrepancy between the contract price and the market price because the value of the apartment in his balance sheet is still the encumbered value. If the tenant wishes to cancel the lease, he may have to pay the landlord the difference between the encumbered value and the unencumbered value. Only in the exceptional case where the tenant pays a third party to assume the lease at the price specified in the lease does this payment represent an asset of negative value to the tenant. Once the lease expires or is cancelled, the value of the apartment returns to its unencumbered value.

Public-Private Partnerships

Introduction

A4.58 Public-private partnerships (PPPs) are long-term contracts between two units, whereby one unit acquires or builds an asset or set of assets, operates it for a period, and then hands the asset over to a second unit. Governments engage in PPPs for a variety of reasons, including the expectation that private management may lead to more efficient production and that access to a broader range of financial sources can be obtained. Such arrangements are usually between a private corporation and government, but other combinations are possible, with a public corporation as either party or a private nonprofit institution as the second unit. For ease of reference, the second unit will be referred to as the private corporation. These schemes are referred to by different names depending on the type of contracts that are in place. Examples are: private finance initiatives (PFIs); design, build, operate, and transfer schemes (DBOT); build, own, and transfer schemes (BOTs); or build, own, operate, and transfer schemes (BOOTs). For ease of reference, the remainder of this section will refer to PPPs.

A4.59 The nature of activities that PPPs are involved with varies greatly. Generally, the private corporations construct and operate assets of a kind that are usually the responsibility of the general government or public corporations. These commonly include roads, bridges, water supply and sewerage treatment works, hospitals, prison facilities, electricity generation and distribution facilities, and pipelines.

A4.60 The private corporation expects to recover its costs and to earn an adequate rate of return on its investment. The government may make periodic payments during the contract period,[14] or, alternatively, the private corporation may sell the services to the public (e.g., a toll road), or a combination of the two. The price is often regulated by the government and set at a level that will allow the private corporation to recover its costs and earn a return on its investment (benchmark price). If the regulated price is set at a level below such a benchmark price, the government will have to compensate the private partner, usually through subsidies or other transfers. There can be many variations in PPP contracts regarding aspects such as the disposition of the assets at the end of the contract, the required operation and maintenance of the assets during the contract, and the price, quality, and volume of services produced. At the end of the contract period, the

[14] The contract period refers to the length of the contractual agreement between the parties involved in the PPP.

Box A4.4 Determining the Economic Ownership of PPP-Related Assets

The economic owner of the assets related to a PPP is determined by assessing which unit bears the majority of the risks and which unit is expected to receive a majority of the rewards of the asset.

The factors that need to be considered in assessing economic ownership of PPP-related assets include those associated with acquiring the asset and those associated with using the asset.

Some of the risks associated with acquiring the asset are:

- The degree to which the government controls the design, quality, size, and maintenance of the assets
- Construction risk, which includes the possibility of additional costs resulting from late delivery, not meeting specifications, or building codes, and environmental and other risks requiring payments to third parties.

Some of the risks associated with operating the asset are:

- Supply risk, which covers the degree to which the government is able to control the services produced, the units to which the services are provided, and the prices of the services produced
- Demand risk, which includes the possibility that the demand for the services, either from government or from the public at large in the case of a paying service, is higher or lower than expected
- Residual value and obsolescence risk, which includes the risk that the value of the asset will differ from any price agreed for the transfer of the asset to government at the end of the contract period
- Availability risk, which includes the possibility of additional costs or the incurrence of penalties because the volume and/or quality of the services do not meet the standards specified in the contract.

The relative importance of each factor is likely to vary with each PPP. It is not possible to state prescriptive rules that will be applicable to every situation. The provisions of each PPP arrangement must be evaluated to decide which unit is the economic owner.

government may gain legal and economic ownership of the assets, possibly without payment.

A4.61 The decision about economic ownership of the asset and whether to record PPP-related assets and liabilities in the government's or the private corporation's balance sheet is not straightforward. The private corporation is responsible for acquiring/constructing the fixed assets, although the acquisition/construction is often supported by the backing of the government. The contract often allows government to specify the design, quality, capacity use, and maintenance of the asset in accordance with government standards. Typically, the assets have service lives much longer than the contract period so that, for this reason alone, the government will control the assets, bear the risks, and receive the rewards for a major portion of the assets' service lives. Thus, it is frequently not obvious whether the private corporation or the government controls the assets over their service lives or which party bears the majority of the risks and benefits from the majority of the rewards.[15]

Determining Economic Ownership of PPP-Related Assets

A4.62 The statistical treatment depends on the economic ownership of the asset(s) involved. In macroeconomic statistics, a distinction is made between legal ownership and economic ownership (see paragraphs 3.38–3.41) based on risks and benefits. With a PPP, the legal and economic owner may be different parties. Box A4.4 summarizes the associated risks to be considered.

A4.63 The macroeconomic statistics approach is broadly consistent with considerations listed by the International Public Sector Accounting Standards Board (IPSASB) for the recognition and measurement of a service concession asset.[16] While it is not possible to prescribe rules applicable to every PPP type of arrangement, the considerations presented in Box A4.4 should guide the decision on which party is the economic owner of the asset(s) during and at the end of the PPP contract period. The International

[15] "Majority" should be assessed from an economic point of view. A single risk and reward may imply the "majority" in some cases, while in other cases, a number of separate risks and rewards combined may do so.

[16] *IPSAS 32* spells out some guidelines for recognizing and measuring assets and liabilities relating to service concession assets (i.e., PPP-related assets).

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Box A4.5 Practical Applications of the Economic Ownership Concept

To operationalize the criteria for economic ownership—that is, whether the majority of risks and rewards accrue to government or to the private corporation—countries have followed different approaches.

Under Eurostat's guidelines to its member states, a sufficient condition for a PPP to be excluded from government's accounts has been that the private corporation bears the construction risk in the project and either the availability or the demand risks in using the asset in production. In 2010, Eurostat clarified how other elements, in addition to these three principal risk categories, should be analyzed to determine the distribution of risks between the public and private sectors—notably: the existence and scope of grantor guarantees; majority financing by the grantor of capital cost during the construction phase; and financial aspects of termination clauses (see *Manual on Government Deficit and Debt – Implementation of ESA 95, 2012 Edition*, section VI.5).

Some countries are following internationally accepted accounting standards (e.g., IPSAS) applicable to financial leases (see paragraphs A4.10–A4.15). If a PPP contract is deemed to be a financial lease, an asset and liability are recorded on the public sector unit's balance sheet, interest and depreciation are recorded as operating expenses, and amortization is recorded as a transaction in financial assets and liabilities. IPSASs treat a lease as a financial lease to the extent that the following criteria are met: (i) the contract period covers most of the useful life of the asset; (ii) the asset is transferred to the lessee (the public sector unit in this case) at the end of the contract; (iii) the lessee can purchase the asset at a bargain price at the end of the contract; (iv) the present value of payments prescribed in the contract is close to the fair market value of the asset; and (v) the asset is useful mainly to the lessee.

Public Sector Accounting Standards (IPSASs) considerations of control of the asset include aspects of risks and rewards, and should, in principle, lead to the same conclusions on economic ownership. Box A4.5 presents a brief discussion on how some countries apply, in practice, the concept of economic ownership related to PPPs.

Statistical Treatment

A4.64 The following description of the statistical treatment of PPPs is based on the guidelines prescribed in the *2008 SNA*.[17] If the government is considered the economic owner of the asset(s) during the contract period but does not make any explicit payment at the beginning of the contract, a transaction must be imputed to cover the acquisition of the asset(s). The recording of these depends on the specific contract provisions, how they are interpreted, and possibly other factors. Most frequently, these contracts will be recorded as the acquisition of the asset through an imputed financial lease because of the similarity with actual financial leases. In other cases, for example, a loan that equals the market value of the asset at acquisition could be imputed, the actual government payments to the private corporation could be partitioned, so that a portion of each payment represents the repayment of the loan (see paragraphs A4.10–A4.15), and the remainder could represent an expense for *use of goods or services*, *subsidies*, etc., in accordance with the contract.

A4.65 If the private corporation is considered the economic owner of the asset(s) during the contract period, any debt associated with the acquisition of the asset(s) should be attributed to the private corporation. Normally, the government obtains legal and economic ownership of the assets at the end of the contract without any significant payment. However, two approaches are possible to account for the acquisition of the asset(s) by government:

- Over the contract period, government gradually builds up a financial claim (e.g., *other accounts receivable*) and the private corporation gradually accrues a corresponding liability (e.g., *other accounts payable*), such that both values are equal to the residual value of the assets at the end of the contract period. At the end of the contract period, government records the acquisition of the asset, with a reduction in the financial claim (*other accounts receivable*) as the counterpart entry. The other unit records the disposal of the asset, with a reduction in the liability (*other accounts payable*) as the counterpart entry. Implementing this approach may be difficult because it requires new

[17] The *PSDS Guide* presents examples of the recording of financial leases (see Box 4.11) and the recording of debt and flows arising from PPPs (see Box 4.16).

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

transactions to be constructed using assumptions about expected asset values and interest rates.

- An alternative approach is to record the change of legal and economic ownership from the private unit to government as a capital transfer at the end of the contract period. At the end of the contract period, government records revenue in the form of a capital transfer that finances the acquisition of the asset and the private unit records an expense in the form of a capital transfer payable to government, financed by the disposal of the asset. The capital transfer approach does not reflect the underlying economic reality as well as the first alternative, but data limitations, uncertainty about the expected residual value of the assets, and contract provisions allowing various options to be exercised by either party make recording a capital transfer in GFS acceptable on pragmatic grounds.

Insurance and Standardized Guarantee Schemes

Introduction

A4.66 An insurance policy is an agreement between an insurer and another institutional unit, the policyholder. Under the agreement, the policyholder makes a payment (premium) to the insurance corporation, which makes a payment (claim) to the policyholder if or when a specified event occurs. The policyholder protects itself against certain forms of risk. By pooling the risks, the insurer aims to receive more from the receipt of premiums than it has to pay out as claims to the insured.

A4.67 This section describes types of insurance and standardized guarantee schemes. It first defines some terminology and then provides statistical guidance on the recording of the relevant flows and stock positions related to nonlife insurance and standardized guarantee schemes.

Types of Insurance and Standardized Guarantee Schemes

A4.68 The most common form of insurance is called *direct insurance*, whereby the policy is issued by an insurer to another type of institutional unit.[18] There are two types of direct insurance—namely, life and nonlife insurance. Both types of insurance involve pooling risks. Insurers receive many (relatively) small regular payments of premiums from policyholders and pay much larger sums to claimants when the contingencies covered by the policy occur. During the interval between the receipt of premiums and the payment of claims, the insurance corporation earns income from investing the premiums received. This investment income affects the levels of premiums and benefits set by the insurer.

A4.69 Life insurance is an activity whereby a policyholder makes regular payments to an insurer, in return for which the insurer guarantees to provide the policyholder (or in some cases another nominated person) with an agreed sum, or an annuity, at a given date or earlier if the policyholder dies beforehand. For life insurance, an important relationship exists between premiums and benefits during the policy period. For policyholders, the benefits receivable are expected to be at least as great as the premiums payable, and this type of insurance can be seen as a form of saving. The insurer combines this aspect of a single policy with the actuarial calculations about the insured population concerning life expectancy (including the risks of fatal accidents) when determining the relationship between the levels of premiums and benefits. Life insurance mainly redistributes premiums payable over a period of time as benefits payable later to the policyholders or his/her beneficiaries. Essentially, life insurance premiums and benefits are transactions in financial assets and liabilities and not transactions in revenue and expense. Public sector units' involvement in life insurance is most often provided in the context of social protection in the form of employment-related pension schemes and other social protection schemes, such as compulsory saving schemes. The GFS treatment of these types of schemes is elaborated in Appendix 2.

A4.70 Nonlife insurance is an activity similar to life insurance except that it covers all other risks, accidents, sickness, fire, etc. For nonlife insurance, the risks are spread over all policyholders, and the number of claimants is typically much smaller than the number of policyholders. Nonlife insurance includes policies that provide a benefit in the case of death within a given period but in no other circumstances, usually called term insurance. With nonlife insurance, a claim is payable only if a specified contingency occurs and not otherwise. This type of insurance consists of redistribution in the current period

[18] Another form of insurance is provided by one insurer to another insurer, which is referred to as reinsurance.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

between all policyholders and a few claimants. While public corporations may be involved in various types of insurance schemes, general government units are usually not involved in nonlife insurance other than social insurance, as discussed in Appendix 2.

A4.71 Standardized guarantees are those kinds of guarantees that are issued in large numbers, usually for fairly small amounts, along identical lines. There are three parties involved in these arrangements, the borrower (debtor), the lender (creditor), and the guarantor. Either the borrower or lender may contract with the guarantor to repay the creditor if the debtor defaults. Similar to nonlife insurance, it is not possible to determine the likelihood of any particular debtor defaulting. Nevertheless, because the guarantees are very similar and numerous, it is possible to estimate the general likelihood of defaults the guarantor will have to cover. It is standard practice to estimate how many out of a batch of similar debts will default.[19] Therefore, standardized guarantees are based on the same paradigm as that for nonlife insurance, and a similar treatment is adopted for these guarantees. Standardized guarantees are distinguished from one-off guarantees based on two criteria:

- They are characterized by often repeated transactions with similar features and pooling of risks.
- Guarantors are able to estimate the average loss based on available statistics by using probability-weighted concepts.

A4.72 Standardized guarantees may be provided by a financial institution, including, but not limited to, insurance corporations. It is possible (but unlikely) that nonfinancial corporations provide these kinds of guarantees. However, government units are often involved as the guarantor in standardized guarantee schemes. The most common examples are export credit guarantees, deposit insurance schemes,[20] and student loan guarantees. Specifically, when a government unit provides standardized guarantees without fees or at such low rates that the fees are significantly less than the calls and administrative costs, the unit should be treated as a nonmarket producer within the general government. If government recognizes the probability of having to finance some of the calls under the guarantee scheme to the extent of including a provision in its accounts, a transfer of this size from government to the units concerned and a liability of this amount (under provisions for calls under standardized guarantees) should be recorded. If a standardized guarantee scheme is operated by a corporation or quasi-corporation on behalf of government, any transfers to cover recurrent losses are classified as subsidies (see paragraph 6.89) and any transfers to cover large operating deficits accumulating over two or more years or exceptional losses due to factors outside the control of the corporation/quasi-corporation are recorded as capital transfers (see paragraphs 6.91–6.124).

Defining Terminology Used in Insurance

A4.73 Defining some of the terms peculiar to the insurance industry is helpful in clarifying the discussion on the statistical treatment of insurance and standardized guarantees. The term "premiums" is used for payment to the insurer, while the term "fees" is used to describe the payment to the guarantor in the case of standardized guarantees. Payments by the insurer are called "claims" in the case of nonlife insurance policies and "benefits" in the case of life insurance policies. In the case of standardized guarantees, "calls" relate to expected defaults on the guarantees.

A4.74 The *actual premium* (fee) is the amount payable to the insurer (guarantor) to secure insurance coverage for a specific event over a stated time period. Coverage is frequently provided for one year at a time, with the premium payable at the outset, though coverage may be provided for shorter (or longer) periods and the premium (fee) may be payable in installments—for example, monthly.

A4.75 The *premium earned* is the part of the actual premium that relates to coverage provided in the reporting period. For example, if a new annual policy with a premium of 120 units comes into force on April 1, and GFS are being prepared for a calendar year, the premium earned in the calendar year is 90. The **unearned premium** is the amount of the actual premium received that relates to the period past the reporting period. In the example just given, at the end of the reporting period there will be an unearned

[19] This default risk establishes the liability arising from standardized guarantees.

[20] If participation in such a deposit insurance or other guarantees is compulsory—that is, if beneficiaries cannot opt out of the scheme and the payment is clearly out of proportion to the service provided—it will not constitute a standardized guarantee scheme, but should be recorded as *taxes on use of goods and on permission to use goods or perform activities* (1145) as described in paragraphs 5.73–5.76.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

premium of 30, intended to provide coverage for the first three months of the next reporting period.

A4.76 *Net premiums* are defined as actual premiums plus premium supplements minus the insurance service charge payable by the policyholders. Premiums are usually payable regularly, often at the start of an insurance period, whereas claims fall due later, in the case of life insurance, often many years later. The amounts accumulating between the periods the premiums were payable and when a claim becomes payable create a liability (reserves) for the insurer. These amounts are at the disposal of the insurer to invest in assets and earn income from it. The income allows the insurance corporation to charge lower premiums than would be the case otherwise. The property income earned in this way is attributed to the policyholders and is subsequently recorded as premium supplements from the policyholders.

A4.77 A *claim (benefit or call)* is the amount payable to the policyholder by the insurer in respect of an event covered by the policy occurring in the period for which the policy is valid. Claims generally become due when the event occurs, even if the payment is made some time later. An exception is made in cases where making a claim is possible only long after the event has happened.[21] In such a case, the claim is recorded at the time the insurance company accepts the liability. Claims that become due are described as claims incurred. In some contested cases, the time between the occurrence of the event giving rise to the claim and the settlement of the claim may be several years. Claims on an accrual basis are recognized as due when an event takes place that gives rise to a valid claim, regardless of whether paid, settled, or reported during that period.

Statistical Treatment of Nonlife Insurance and Standardized Guarantees

A4.78 Under a nonlife insurance policy (or standardized guarantee), the insurer (or guarantor) accepts a premium (or fee) from a client and holds it in reserve (liability) until a claim (or call) is made or the period of the insurance expires. In the meantime, the insurer (guarantor) invests the amounts available due to prepayments of premiums, reserves held against outstanding claims, and actuarial reserves held against outstanding risks. These assets generate investment income. The property income represents income forgone by the client, and so is treated as property expense attributed to the policyholders. It is therefore rerouted and subsequently recorded as an implicit supplement to the actual premiums. The insurer (guarantor) sets the level of the actual premiums (fees) to be such that the sum of the actual premiums plus the property income earned on assets, minus the expected outstanding claims will leave a margin that the insurer can retain. As an insurer or guarantor, the general government or public sector unit incurs liabilities equal to the present value of the expected claims or calls on outstanding guarantees, net of any recoveries.[22] The statistical treatment of nonlife insurance and standardized guarantee schemes in GFS will depend on whether the general government or public sector unit acts as the insurer (guarantor), or whether they are policyholders.

Flows and stock positions recorded by public sector units as nonlife insurers or guarantors

A4.79 General government units are not likely to operate an insurance scheme, but if they do and if they maintain separate reserves, they would record transactions related to the nonlife insurance in the same way as other insurers. On the other hand, general government units are often involved as the guarantor in standardized guarantee schemes. For general government or public sector institutional units acting as an insurer or guarantor of standardized guarantees, recording these events would require recording the following entries in GFS:

- *Actual premiums (fees) receivable*—The amount of actual premiums (fees) receivable represents premiums earned and prepayment of premiums.[23] The portion of actual premiums (fees) receivable representing premiums (fees) earned for the reporting period represents revenue, classified as *premiums* (14511) or *fees for standardized guarantees* (14512), respectively. Prepaid

[21] For example, an important series of claims were recognized only when exposure to asbestos was established as a cause of serious illness and was judged to give rise to claims under an insurance policy valid at the time of the exposure.

[22] These recoveries could include recoveries from the insured, reinsurance, defaulting borrowers, or third parties.

[23] An implicit service charge is implied by nonlife premiums. However, these charges can be calculated only in the context of an analysis of the whole of the economy. Therefore, the implicit service charge is not recognized in GFS.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

premiums (fees) represent a transaction in financial asset and liabilities, and are recorded as an increase in liabilities for *nonlife insurance technical reserves* (33061) or *provisions for calls under standardized guarantee schemes* (33065).

- *Property income earned on the investment of reserves*—Usually, the reserves related to insurance or standardized guarantees are invested in financial assets and the revenue generated by these investments is generally in the form of *interest* (1411) or *dividends* (1412). Sometimes, however, the reserves may be used to generate net operating surpluses either in a separate establishment or as a secondary activity. The most common example is *rent* (1415) generated from real estate assets.
- *Property income attributed to policyholders*—Property income generated by the investment of reserves is deemed to be an implicit premium supplement.[24] Therefore, the insurer or guarantor should attribute the property income to the policyholders[25] by recording an expense, classified as *property expense for investment income disbursements* (2813). The counterpart entry to this expense is a transaction resulting in an increase in liabilities for *nonlife insurance technical reserves* (33061) or *provisions for calls under standardized guarantee schemes* (33065).
- *Claims (calls) payable*—An expense for expected claims (calls) should be recognized in *premiums, fees, and current claims* (2831) or *capital claims* (2832), as relevant, and with a counterpart entry as an increase in the liability related to *nonlife insurance technical reserves* (33061) or *provisions for calls under standardized guarantee schemes* (33065). For standardized guarantee schemes, the expense recorded is the expected level of calls (minus any expected asset recoveries) on the standardized guarantees provided in the recording period. When claims (calls) are paid, transactions are recorded reducing liabilities related to nonlife insurance technical reserves or provisions for calls under standardized guarantees with a corresponding reduction in assets or an increase in other liabilities.
- *Holdings gains and losses*—In some exceptions, if an amount for a claim outstanding has been agreed upon and it has been agreed that it will be indexed pending payment, there may be a holding gain or loss recorded for it.
- *Other changes in volume of assets and liabilities*—Changes to provisions for calls under standardized guarantee schemes not resulting from transactions and holding gains and losses are shown as other changes in volume of assets—for example, whenever a significant change to the expected level of calls is recognized, beyond any asset recovery.

Flows and stock positions recorded by public sector units as nonlife policyholders and holders of standardized guarantees

A4.80 The recording of flows and stock positions related to standardized guarantees differs from the recording of one-off guarantees (see paragraph 7.256). For general government or public sector institutional units as nonlife insurance policyholders, or holders of standardized guarantees, the recording of their activities would require the following entries in GFS:

- *Actual premiums (fees) payable* — The amount of actual premiums payable represents premiums incurred, prepayment of premiums, and an implicit services charge payable. Because the implicit service charge can be calculated only in the context of an analysis of the whole of the economy, it is not recognized in GFS as an expense. The portion of actual premiums payable representing premiums incurred for the reporting period is an expense, classified as *premiums* (28311) or *fees for standardized guarantees* (28312), respectively. Prepaid premiums represent a transaction in financial assets and liabilities, and should be recorded as an increase in the financial assets in the form of *nonlife insurance technical reserves* (32061) or *provisions for calls under standardized guarantee schemes* (32065).
- *Property income attributed to policyholders*—As explained in paragraph A4.78, property income generated by insurers (guarantors) on the investment of reserves is deemed to be an implicit

[24] The attribution should, in principle, be made according to the proportion of reserves (stock of reserves) attributed to the different classes of insurance and policyholders. In practice, the usual method is to distribute the investment income in proportion to the actual premiums.

[25] In the case of standardized guarantees, the institutional unit that benefits from the guarantee may not be the same as the unit paying the fee for the guarantee. In this case, the property income is distributed to the unit paying the fee. The distributed property income is treated as a supplementary fee.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

premium supplement, attributed to the policyholders. Conceptually, general government or public sector institutional units as policyholders might potentially record property income revenue, classified as *property income from investment income disbursements* (1414). The counterpart entry to this revenue is an increase in the financial asset for *nonlife insurance technical reserves* (32061) or *provisions for calls under standardized guarantee schemes* (32065). However, the revenue related to this item is not always known to GFS compilers. Therefore, this revenue is not recorded in GFS and remains an adjustment item between GFS and national accounts.

- *Claims receivable*—Claims become due when the event that gives rise to a valid claim occurs, regardless of whether paid, settled, or reported during the reporting period. The policyholder recognizes revenue for the claim at the time an event giving rise to a claim occurred, or in the case of a standardized guarantee, at the time a call can be made in terms of the contract. These claims receivable should be recognized as revenue classified as *premiums, fees, and current claims* (1451) or *capital claims* (1452), as relevant, and with a counterpart entry as an increase in a financial asset in the form of *nonlife insurance technical reserves* (32061) or *provisions for calls under standardized guarantee schemes* (32065). Upon actual payment of the claims, a decrease is recorded in the relevant insurance reserve, with a corresponding increase in cash or other financial assets.

APPENDIX

5 Regional Arrangements

This appendix describes various regional arrangements for monetary and economic cooperation and the implications of these arrangements for government finance statistics.

Introduction

A5.1 This appendix addresses the main issues for GFS that arise from regional arrangements. **Regional arrangements** involve coordination of institutional units in several countries for a particular monetary or economic purpose. These arrangements are often supported by regional organizations that operate across borders that need harmonized macroeconomic statistics to monitor economic development and the progress toward meeting the goals of the regional arrangement. The statistical issues that may arise in compiling harmonized data tend to be the same as those addressed in the GFS framework: definitions, coverage, time of recording, frequency, classifications, and presentation formats. An effective way of achieving this harmonization is by using a common methodology, such as the *GFSM 2014*.

A5.2 Where regional arrangements create regional organizations by means of an intergovernmental legal arrangement (e.g., a treaty), these institutions are classified as an international/regional organization if they satisfy the criteria to be an institutional unit and satisfy the criteria to be an international organization.[1] Regional organizations are created for many purposes, including supporting, guiding, and even governing aspects of the economic relationships or integration processes among the region's economies. Regional organizations can be financial (e.g., regional central or development banks) or nonfinancial (e.g., administrative or economic organizations).

[1] International organizations are discussed in paragraphs 2.16–2.21.

A5.3 Regional arrangements tend to strengthen economic relations among the governments of the participating countries and between the regional organizations and the governments of the participating countries. As these economic relations can lead to significant flows and stock positions, it is important to have guidelines on their recording in GFS.

A5.4 This appendix presents the major types of regional arrangements, and points out the main GFS issues observed in each case. The appendix then examines using GFS under regional arrangements and, finally, it analyzes the requirements for harmonization to promote optimal coordination of policies and consistency in data.

Types of Regional Arrangements

A5.5 In the course of the last decades, numerous regional arrangements have been set up with various degrees of cooperation and integration between the participating countries. Such regional arrangements include:

- Customs unions, which have common tariff and other trade policies with nonmember economies
- Economic unions, which harmonize certain economic policies to foster greater economic integration
- Monetary and currency unions, which provide for a single monetary policy and the use of a single currency across an area.

Custom Unions

A5.6 A **custom union** is a form of regional arrangement whereby agreement exists on a common tariff (custom duties) vis-à-vis the other economies, while the movement of goods within the arrangement tends to be duty-free, although it may exclude exemptions

in certain sectors.[2] This type of arrangement is different from bilateral cooperation agreements between two countries in commercial areas that have little impact, if any, on GFS.[3]

A5.7 In compiling GFS for members of a customs union, the main issue is the recording of custom duties in the accounts of the member governments participating in the union. Duties on imports from countries outside the customs union are usually collected on a mutually agreed basis at custom union entry points. As these entry points may be concentrated in one or a small group of members of the customs union, revenue-sharing formulas among member countries are implemented. Recording customs duties in the GFS of individual members of the customs union is thus affected by the institutional and administrative organization of the customs union.

A5.8 The following paragraphs set out four possible types of regional arrangements:[4]

- A designated agency levies,[5] collects, and distributes the proceeds from the duties.
- A designated agency levies and distributes duties, but member governments collect duties on behalf of the designated agency.
- Member governments have collective rights (i.e., the right is shared by everyone in the group) to levy, collect, and distribute the duties.
- Member governments have collective rights to levy the duties, but only one member collects and distributes the duties.

[2] Examples of such arrangements are: the Mercosur, which comprises Argentina, Bolivia, Brazil, Paraguay, Uruguay, and Venezuela; and the Southern African Customs Union, which comprises Botswana, Lesotho, Namibia, South Africa, and Swaziland.

[3] Bilateral trade agreements may also be observed between a regional arrangement and third countries or between regional arrangements. "Free trade agreements" generally fall under this category.

[4] There could be other, less formal or less complete arrangements. In the case of Mercosur countries, for instance, duties have so far been recorded for each individual country as taxes on international trade and transactions, as goods from third countries transiting from one union member to another are regarded as imports and exports among different custom union members. In 2010, Mercosur members agreed on a customs code that will allow the final confirmation of a genuine customs union and the redistribution of customs duties among members.

[5] To levy a tax implies that the agency has the authority to impose the tax, either as principal or through the delegated authority of a principal, and the agency has final discretion to set and vary the rate of the tax.

A5.9 In all four scenarios where there are economic arrangements involving a small group of economies, it is recommended that the governments involved agree on common, appropriate recording procedures to avoid bilateral asymmetries.[6] The required information should be readily available from customs services. If a portion of the amount of customs duties is retained as collection fees (regardless of how the amount is calculated by the collecting agency or government), these fees should be recorded gross of the grants expense when the customs pool is distributed to the members. The retained amount should be recorded as *incidental sales by nonmarket establishments* (1423) in the accounts of the collecting agency or government, and *use of goods and services* (22) in the accounts of the member government receiving the grants.

A5.10 Tax attribution rules (see paragraphs 5.33–5.38) should be used to determine the attribution of customs duties revenue and the transfers associated with sharing the revenue pool among the members. The recording of such customs duties and grant transfers for four types of arrangements are discussed in paragraphs A5.11–A5.18.

A designated agency levies, collects, and distributes the proceeds from the duties

A5.11 In this case, the designated agency has the right to levy and collect the customs duties and distribute the proceeds. If the designated agency is recognized as an institutional unit, it may satisfy the criteria to be an international organization (see paragraphs 2.16–2.21), in which case all the transactions described should be between this international organization and the member governments. Otherwise it would be a resident of one member country, in which case all the transactions described should be between that government and all the other member governments. If the designated agency is not a separate institutional unit, it should be classified with the government unit that controls it.

[6] Member countries of the Central American Common Market (CACM) (Costa Rica, El Salvador, Guatemala, Honduras, Nicaragua) apply a common external tariff for products manufactured and imported from outside of the CACM. However, each CACM member is allowed to determine any product exceptions.

A5.12 The customs duty revenue is attributed to the designated agency and should be recorded as *customs and other import duties* (1151) at the time the underlying economic event occurs (e.g., imports of goods or services) that gives rise to the customs duties, along with a counterpart entry increasing *currency and deposits* (3202) or *other accounts receivable* (3208).

A5.13 A revenue-sharing agreement may determine that the designated agency is to distribute the revenue pool to the participating national governments on the basis of an underlying economic event (e.g., imports of goods or services). In this case, revenue in the form of a *grant* (13), with a counterpart entry in *other accounts receivable* (3208), is recorded in the accounts of the member countries at the time the underlying economic event occurs. In the accounts of the designated agency, an equal amount of expense in the form of a *grant* (26) with a counterpart entry in *other accounts payable* (3308) should be recorded. Depending on the sector classification of the designated agency, the grant revenue should be recorded as either *current grants from international organizations* (1321) or *current grants from foreign governments* (1311), while the grant expense should be classified as *grants to foreign governments* (261) or *grants to other general government units* (263). The size of the grant depends on the nature of the revenue-sharing agreement. However, these revenue distributions may display an element of income redistribution among the members of a regional arrangement. That is, the distributions are not based on underlying economic events but are rather made to an agreed and negotiated formula. In this case, the grant should be recorded at the time the member economy acquires an unconditional claim on the designated agency. At the time of distribution, the member economies extinguish the *other accounts receivable* (3208), with a corresponding increase in the financial asset *currency and deposits* (3202). Conversely, the designated agency would record a decrease in *other accounts payable* (3308) and a decrease in the financial asset *currency and deposits* (3202).

A designated agency levies and distributes duties but member governments collect duties on behalf of the designated agency

A5.14 If national governments act as collecting agents on behalf of the designated agency for the customs duties from importers in their own economy, the collecting national government should record only transactions in financial assets and liabilities when the economic event occurs. A liability in the form of *other accounts payable* (3308) to the designated agency should be recorded, with a counterpart entry in *currency and deposits* (3202) or *other accounts receivable* (3208). Because the customs duty revenue is attributed to the designated agency, they should record a financial claim on the member collecting the customs duties, in the form of *other accounts receivable* (3208) as the revenue in the form of customs duties accrues. When the collecting national government makes the payment to the designated agency, this member government records a reduction in financial assets in the form of *currency and deposits* (3202), with a counterpart entry to extinguish the liability in the form *other accounts payable* (3308).

A5.15 Distributions of the revenue pool by the designated agency are treated as described in paragraph A5.13.

Member governments have collective rights to levy, collect, and distribute the duties

A5.16 If member governments have collective rights to levy the customs duties under the customs union agreement, the custom duty revenue is attributed to the member governments according to the underlying economic activity that gives rise to the customs duties. The total customs duty revenue attributed to each member government is in proportion to the respective underlying economic activity that gives rise to the customs duties. Each member government records customs duties due on their imports on an accrual basis (i.e., when the underlying economic event occurred), regardless of how the revenue pool is to be shared or where the customs duties are collected. Should the customs union agreement provide for any member government to receive a larger share of the customs pool than is evidenced by the underlying economic activities, a *grant revenue* (13)/*expense* (261) should be recorded between member governments at the time the unconditional claims are established, with a corresponding entry in *other accounts receivable* (3208)/*payable* (3308).

A5.17 It is possible that the ports of entry for the customs union are situated in one or a small group of member economies. If so, there could be a

discrepancy between the customs duty revenue collected by a member state and that member's share of the customs pool. In these circumstances, an increase in liabilities in the form of an *other accounts payable* (3308) is recorded for the collecting government at the time that such a claim can be established, with the corresponding increase in financial assets in the form of *currency and deposits* (3202) for the collecting government. The differences between the customs revenue collected by each of the customs union members and the total of each member's share of the customs pool should sum to zero across the customs union, as the customs revenue collected by the customs union equals the revenue to be shared among member governments.

Member governments have collective rights to levy the duty, but only one member collects and distributes the duties

A5.18 If member governments have collective rights to levy the duty, the tax revenue is attributed to the member governments according to the underlying economic activity that gives rise to the customs duties. If one of the member governments collects all the customs revenue, the recording is as described in paragraphs A5.16–A5.17. In this case, however, only the collecting government will record an increase in liabilities in the form of *other accounts payable* (3208), as all other economies will have claims in the form of *other accounts receivable* (3308) on the collecting economy for their share of the customs revenue.

Economic Unions

Introduction

A5.19 For statistical purposes, an economic union is a union to which two or more economies belong. **Economic unions** are established by means of an intergovernmental legal agreement among sovereign countries or jurisdictions with the intention of fostering greater economic integration. In an economic union, some of the legal and economic characteristics associated with a national economic territory are shared among the different countries or jurisdictions. These elements include: (i) the free movement of goods and services within the economic union and a common tax regime for imports from nonmember economies (free trade zone); (ii) the free movement of financial resources within the economic union; and (iii) the free movement of (individual and legal) persons within the economic union.[7] Also, in an economic union, specific regional organizations are created to support the functioning of the economic union. Some form of cooperation and coordination in fiscal and monetary policy usually exists within an economic union.

A5.20 This type of regional arrangement represents greater cooperation than in a customs union agreement (which may have been a first step) because the members agree to harmonize a significant part of the conditions in which economic activity is undertaken over the whole union territory. The main example is the European Union (EU). The EU takes the form of common legislation in some areas, most notably in competition or product norms. Harmonization of taxes is also being envisaged in some areas. The aim of such unions is to unify markets by enlarging their size, improving efficiency, and developing specialization. Economic unions usually achieve a large, if not total, freedom of circulation for goods, services, capital, and individuals by removing the obstacles to such movements.

A5.21 Economic unions may also cover common policies in other fields. These may take a range of forms, from simple coordinated policy measures to a strongly harmonized framework and even to a centralized, direct management by supranational bodies having an autonomous budget and strict policy rules.

A5.22 An economic union requires specific entities endowed with the authority to manage an autonomous budget. These entities may have more or less autonomy to perform their tasks, in accordance with the institutional arrangements agreed between the members of the union.

A5.23 There may be significant grants payable and receivable between member states of an economic union to support certain economic activities or to develop the region. Nevertheless, the size of common budgets observed in existing economic unions is much smaller than member states' budgets. The flows involved are a small portion of total revenue and expense of the individual member states.[8] All requirements related to fiscal policy are generally seen as

[7] As noted in paragraph 2.11, an economy and, by extension, an economic union can include physical or legal (special) zones to which, to some extent, separate laws are applied.

[8] In the European Union, the common budget amounted to about 1 percent of GDP of the union at the time of drafting this *Manual*.

cooperation/coordination arrangements rather than effective common fiscal policies.

Residence in an economic union

A5.24 The economic territory of an economic union consists of the economic territory of the member countries or jurisdictions, and the regional institutions that comprise the same, or a subset of the same, economies and are set up to manage the functioning of the economic union.

A5.25 Being a resident of an economy of an economic union implies being a resident of the economic union. Regional organizations that operate within the boundaries of the economic union territory are also residents of the union. However, regional organizations whose membership of economies is not the same as, nor a subset of, those in the economic union should be regarded as nonresidents of the economic union.[9]

Recording some specific transactions related to regional organizations

A5.26 The common budget of the union that is managed by a regional organization may be funded by different types of sources. The main sources are taxes and grants. For example, in the EU, the majority of EU budget resources is based on gross national income (GNI) and value-added tax revenues of individual countries.

A5.27 Direct levies for the account of the common budget—in practice often collected by member governments—are recorded as taxes of the common budget in accordance with the tax attribution principle (see paragraphs 5.33–5.40). Such revenue cannot be considered as part of government revenue of the member economy because they are collected by the member economy on behalf of the union. In accordance with the accrual basis of recording, the collection of the taxes will give rise to *other accounts payable* (3308) for the collecting member government, and *other accounts receivable* (3208) in the accounts of the regional organization, at the time the taxes accrue to the international organization. These tax flows must be recorded gross of any collection fees. If there are specific provisions related to collection fees (based on actual expenses, a forfeited amount, or a percentage), the latter should be considered as revenue generated by *incidental sales by nonmarket establishments* (1423) in the accounts of the member government, and an expense for *use of goods and services* (22) in the accounts of the regional organization.

A5.28 The union agencies may also be financed directly by contributions from the members, according to agreed criteria. Such contributions may be agreed portions of certain taxes and fees. These taxes and other revenues are attributed to the member governments and are not collected on behalf of the union, but for their own account. Therefore, the respective member governments record the full collectable amount as taxes and other revenues in their accounts, and a subsequent grant payable to the regional organization.

A5.29 Expense of the regional organization covers its administrative and operating costs, but also costs associated with executing common policies for the benefit of the members of the union. Administrative and operating costs impact mainly the economy where the regional organization is physically located. These amounts are usually not significant and, where a common budget is developed, they represent a small portion of total expense of the regional organization. Of these, a small part could possibly be transactions with the host government and should be recorded in the government accounts of the member in accordance with the economic nature of the transaction.

A5.30 Expense associated with executing common policies for the benefit of the members of the economic union impacts specific categories of beneficiaries in the respective member countries. To accurately record these transactions, the ultimate beneficiary and nature of the expense should be identified regardless of the practical and/or institutional arrangements for channeling the amounts payable from union agencies to these economic beneficiaries.

- Where such expenses from the union budget managed by the regional organization cover costs directly benefiting the recipient member government units (in the context of a given program—e.g., projects for infrastructures, research and development), revenue in the form of *grants from international organizations* (132) should be recorded in the member government accounts when all conditions have been met.
- Where member government units act as agents on behalf of the union, all transactions conducted

[9] See paragraphs 2.6–2.21 for a description of the use of the residence criteria in GFS.

on behalf of the union should, over time, be neutral on the member government revenue and expense.[10] For example, if the member government receives amounts from the regional organization to distribute on behalf of the union to beneficiaries, only transactions in financial assets and liabilities should be recorded in the member government accounts. The national government records the incurrence of a liability for amounts received, classified as *other accounts payable* (3308) that are distributable to other economic beneficiaries. The actual distribution to the ultimate beneficiary reduces this account payable by the government unit. For the beneficiary, these amounts should be recorded as the appropriate category of revenue receivable—usually some kind of transfer receivable such as *grants* (13), *subsidies* (14411), or *transfers not elsewhere classified* (144). The regional organization would record the amounts payable in the corresponding categories of expense such as *grants* (26), *subsidies* (25), or *transfers not elsewhere classified* (282).

- Amounts distributable by government, acting as an agent for the union, may take the form of reimbursements claimed by the final beneficiary. These claims are usually on the basis of documents evidencing spending by the beneficiaries. Any amounts distributed by government on the basis of such claims by the beneficiaries give rise to a financial claim of government on the regional organization, notably *other accounts receivable* (3208), while the regional organization incurs a liability, *other accounts payable* (3308). Where the member government is acting on behalf of nongovernment units, it is possible that the member government anticipates repayments from the common union budget. Such anticipated repayments are also recorded as transactions in financial assets and liabilities, notably *other accounts receivable/payable* (3208/3308) between the government and the regional organization.
- When governments' claims on the regional organization for amounts reimbursed on the regional organization's behalf are not fully redeemed by the regional organization, the member government's recording depends on the circumstances:
  - The member government could decide to cover the expense made by final beneficiaries from the member government budget sources. The expense is recorded with a counterpart entry in the reduction of the claims on the regional organization. Such an expense should be classified according to the economic nature of the transfer—usually some type of transfer payable such as *grants* (26), *subsidies* (25), or *transfers not elsewhere classified* (282). The time of recording the expense is determined by the time of the government decision to cover the expense.
  - The regional organization could indicate that a reimbursement by the member country should not have been made. The member government could recover the funds from the beneficiaries, or record the amount as expense of the member country.

A5.31 Full coverage of data for an economic union requires that these data include data from member countries as well as from the union agencies. Furthermore, to consolidate the accounts of the union—that is, eliminating all the flows and stock positions among member countries and the union agencies—sectors of the counterparties should be available for data on transactions, stock positions, and other economic flows. Compiling union accounts will allow an analysis of the whole union's flows and stock positions. This will also allow monitoring of the contributions of individual members to the union and measure the impact of the union on each member economy through redistribution mechanisms.

Monetary and Currency Unions

A5.32 A **monetary union** exists where there is the presence of a single monetary policy among economies, established by an intergovernmental legal agreement. In a monetary union, the decision-making related to monetary policy is transferred to a centralized body. There are different models—for instance, a single central bank for the whole union (possibly having only branches in the national economies)[11] or a federal-like system where national central banks

[10] In some cases, by agreement, a part of the expense, in the context of programs managed at the union level, may be financed by the member government; for this portion of the expense the impact on the member government finances will not be neutral.

[11] This arrangement is applied in the case of the West African Economic and Monetary Union (WAEMU) and the Economic and Monetary Community of Central Africa (CEMAC). WAEMU includes Benin, Burkina Faso, Côte d'Ivoire, Guinea-Bissau, Mali, Niger, Senegal, and Togo. CEMAC includes Cameroon, the Central African Republic, Chad, the Republic of Congo, Equatorial Guinea, and Gabon.

still exist, keeping some specific activities not directly linked to monetary policy.[12]

A5.33 However, the core characteristic of a monetary union is that the monetary policy is exclusively conducted at the union level. There is a single set of intervention rates, and the national central banks (or branches) may in no way autonomously adjust the monetary policy to national conditions. They may, however, perform some specific tasks in the implementation process of the monetary policy, such as the management of collaterals that may be required for access to central bank liquidity and the delivery of banknotes in the different economies.[13]

A5.34 If a monetary union replaces national currencies with a common currency, they form a currency union. For statistical purposes, a **currency union** is defined as a union to which two or more economies belong and that has a regional central decision-making body, commonly a currency union central bank, endowed with the legal authority to conduct a single monetary policy and issue the single currency of the union.

A5.35 Monetary and currency unions do not raise specific issues for GFS, even in cases where a single, common central bank is a substitute for a domestic central bank in the context of the relationships between central bank and government. The currency union central bank is an institutional unit in its own right, owning assets and incurring liabilities, and is nonresident of any currency union member economy but resident in the currency union (see paragraph 2.21). Distributions of profits of such regional central banks should be classified as income on the financial asset to which member economies' subscriptions are attributed.

Using the *GFSM* Statistical Framework under Regional Arrangements

A5.36 Participation in regional economic arrangements may require some cooperation and coordination of fiscal policies. However, it is only in the context of monetary unions where such cooperation and coordination are generally viewed as an indispensable element for ensuring its optimal functioning.

A5.37 In a monetary union, there is one single monetary policy that interacts with fiscal policies primarily carried out at the national level of each member country. At the same time, fiscal conditions may impact monetary policies.

A5.38 Therefore, to conduct proper monetary policies, monitor macroeconomic imbalances in member economies, and consolidate accounts for the union, fiscal statistics should be compiled in a consistent manner for all members of the union. Consistency in compiling fiscal data will allow the accurate measurement of differences in aggregates such as the tax burden, the share of government expense to GDP, the respective weight of different types of taxes in the total tax burden, the composition of expense, the implementation of budgetary rules, etc.

A5.39 Where coordinated fiscal policies are agreed in a union, the scope of such fiscal cooperation/coordination has consequences for the statistical reporting framework. Fiscal targets may be defined and monitored at the union level. Examples of such key variables are the level of *gross/net debt*, *operating balance*, *net lending/net borrowing*, or, in the case of the cash basis of recording, the *cash surplus/deficit*. Quantitative targets (or "reference values") may be set at the union level, and these targets may be expressed as nominal amounts or ratios to gross domestic product.[14]

A5.40 Coordinated fiscal policies may also call for more disaggregated data. For instance, the calculation of primary balances requires that data on interest income and expense are available. Similarly, eliminating the influence of the business cycle on the level of revenue and expenditure by calculating the structural balance may require additional information (see annex to Chapter 4). In addition, measuring the outcome of specific economic objectives may require data on very detailed types of expenses, such as those related to social development goals or the government employee wage bill. The statistical framework for a union should be designed with a sufficient degree of detail, and should be applied by all members in a fully consistent manner, in order to capture the relevant information

[12] This arrangement is applied in the case of the European Monetary Union with the "Euro system" made up of the national central banks of the EU member states.

[13] See the *BPM6*, Appendix 3.

[14] In the case of the West African Economic and Monetary Union (WAEMU), these quantitative targets, called "convergence criteria," are important for the multilateral surveillance exercised by the WAEMU Commission to ensure the convergence of the economic performance and policies of the member countries.

needed to monitor the progress with the implementation of fiscal coordination objectives.

Harmonization Requirements for GFS in Economic or Monetary Unions

A5.41 The harmonization of GFS in the context of economic and monetary unions is important. It may be useful to introduce guidelines additional to the *GFSM* for economic and monetary unions. Additional guidelines could provide "rulings" or "fiscal policy rules" on specific transactions, aggregates, or balancing items that may occur in the member countries of the regional arrangement. It may also be useful to further clarify existing guidelines on concepts and definitions where it is observed that countries in a union interpret these guidelines differently, or application of these guidelines poses practical problems for members. Some examples of harmonizing regional arrangements are presented in Box A5.1.

A5.42 A common reason for fiscal data not being comparable across countries is the delineation of the general government sector. In most countries, there are borderline cases relating to units selling goods or service as their principal activity with various levels of financial support from government units (in the form of *subsidies*, *grants*, and *other current transfers*). Agreement on precise guidelines for the classification and sectorization of such units is an important factor in ensuring comparable data. When in doubt about these classifications, an appropriate dispute resolution mechanism should exist. In this context, the concept of economically significant prices might be clarified with a practical perspective. It is also recommended to publish institutional lists of general government and public sector units of individual countries to show transparently which units are included in the general government and public sectors.

A5.43 Another possible reason for data not being comparable across countries is the time of recording of economic events. In many countries, government units still apply the cash basis of accounting. International statistical guidelines and accounting standards have adopted the accrual basis of recording. Although an increasing number of governments have adopted accrual recording, many countries still use various mixes of source data based on cash- and accrual-based accounts. The differences in time lags between the economic events and the associated cash flows could distort the assessment of fiscal stance during a given year if a cash basis of accounting is mainly used. It is, therefore, preferable that fiscal targets include both cash and accrual measures. If no accrual source data are available, the countries in a union should agree on the methodology used to estimate the adjustments to convert cash data into accrual data. In practice, the adjustments required are especially relevant for *taxes*, *social contributions*, and *interest*.

A5.44 Attaining comparability in the measurement of *gross* and *net debt* across all countries in an economic or monetary union may be difficult in practice. In this *Manual* and the *PSDS Guide*, all debt instruments issued by government units are considered to be part of the coverage of debt (see paragraphs 7.236–7.245). Where the definition of gross and net debt in a union departs from international agreed definitions of debt, the data should be clearly labeled, and any departure from the required coverage and standard definition should be disclosed to the users of the data. Debt instruments excluded from the union definition of debt could be shown in memorandum items to allow comparability between data of the union members and other countries and to avoid the problem of "hidden" liabilities.

Box A5.1 Regional Arrangements in the Harmonizing of GFS

Customs Union of Belarus, Kazakhstan, and Russian Federation

The Customs Union between Belarus, Kazakhstan, and Russia came into existence in 2010. Common trade controls and external tariffs exist, and two regional organizations make decisions related to the union. These agencies are financed by transfers from member countries. Customs duties collected at the first point of entry are redistributed to members via special accounts of members in the respective treasuries and the central banks. While no specific harmonization effort for fiscal data was implemented, the importance of consistency in recording trade data and valuations, and recording collection and redistributions related to customs collections is being considered by the member countries.

Eastern Caribbean Currency Union

In 2012, a proposal to migrate from the existing reporting format (based on the *GFSM 1986*) to a presentation highlighting the integration of stocks and flow as recommended by the *GFSM 2001* was endorsed by the Eastern Caribbean Central Bank and the member countries.

European Union

The excessive deficit procedure, defined by the Maastricht Treaty (article 104) and in force in the European Union since 1994, is a well-known regional arrangement in the compilation of fiscal data. The conceptual references for the debt and deficit aggregates are based on the *European System of Accounts (ESA)*. The compilation practices and reporting requirements are legally binding in the European Union; regulations adopted by the European Commission form the basis for reporting. Eurostat issued the *Manual on Government Deficit and Debt* to aid member states in the application of *ESA* principles. This *Manual* addresses the most common statistical issues raised in the EU.

Mercosur

At the 40th meeting of Mercosur economy ministers and central bank chairmen in December 1998, the need to have statistical data based on a common methodology in Mercosur was acknowledged. This common methodology materialized in 2000, as a result of the member countries' decision to coordinate their macroeconomic policies with joint convergence targets. The preparation of harmonized statistics was agreed on, starting with six indicators: nominal fiscal balance of the national government, primary fiscal balance of the national government, net debt of the national government, net debt of the consolidated public sector, change of net debt of the consolidated public sector, price level, and the construction of a new indicator of the structural fiscal balance. Further efforts have been made since then in order to harmonize the Mercosur statistics according to international standards.

South African Development Community (SADC)

In 2010, participants from member countries of SADC endorsed a proposal by the SADC Secretariat to adopt the *GFSM 2001* presentation of fiscal statistics, beginning in 2012. Preliminary work on converting the historical SADC fiscal database (based on the *GFSM 1986*) was completed, and countries made a commitment to begin compiling a *Statement of Sources and Uses of Cash* and a *financial balance sheet*.

West African Economic and Monetary Union (WAEMU) and Economic and Monetary Community of Central Africa (CEMAC)

In June 2009, the Council of Ministers of WAEMU adopted five regulations (directives) related to public finance management. One of the directives is related to the common reporting format of government fiscal operations known as Tableau des operations financières de l'État (TOFE). The TOFE directive is based on the *GFSM 2001* methodology. The long-term objective of this directive is for member countries to produce comparable general government data for both flows and stocks. In December 2001, similar directives, including a TOFE directive, were adopted by the Council of Ministers of the CEMAC. In both monetary unions, a transition period was determined to fully implement the directives. (At the time of publishing this *Manual*, CEMAC was undertaking a revision of its public finance directives, one of which is related to common reporting formats for government fiscal operations.)

APPENDIX

6 GFS and International Public Sector Accounting Standards

This appendix provides a generalized description of the relationship between the government finance statistics reporting guidelines and the International Public Sector Accounting Standards.

Introduction

A6.1 This *Manual* recognizes the close relationship between guidelines for reporting GFS and accruals-based public sector accounting standards. Many of the accounting rules, concepts, and procedures used in macroeconomic statistics are based on those used in public sector accounting. International developments in statistical methodology and accounting standards for the public sector have been coordinated over recent years, to improve government reporting and fiscal transparency. A government's preparation of fiscal statistics that meet the guidelines set out in this Manual is facilitated by application of high-quality accrual accounting standards, such as International Public Sector Accounting Standards (IPSASs). This is because a comprehensive accruals accounting system greatly improves the source data necessary for compilation of GFS. Governments should be aware of the scope that exists for them to design their Chart of Accounts so that data capture works efficiently for the dual purpose of generating GFS and accounting information.

A6.2 The Task Force on Harmonization of Public Sector Accounting, created in 2003, was the first formal initiative at the international level with the objective to harmonize statistical guidelines and accounting standards. The Task Force's major outputs were: (i) guidance in the area of public sector statistics that informed the update of the *2008 SNA*, and (ii) a research report that systematically documented similarities and differences between the two reporting systems. International organizations and the International Public Sector Accounting Standards Board (IPSASB) continue efforts to align guidelines as far as possible, while identifying and reconciling unavoidable differences that may continue to exist.

A6.3 Because both IPSASs and statistical reporting guidelines are dynamic and change over time, this appendix focuses only on the basic principles that explain why the two reporting frameworks differ. Detailed information on specific differences can be found on the IPSASB's website and through reference to individual IPSASs and detailed chapters of the *GFSM 2014*.

A6.4 This appendix focuses specifically on the links between GFS and IPSASs, because IPSASs are international standards and recognized as best practice for public sector financial reporting. IPSASs form a comprehensive set of full accruals accounting standards. Public sector accounting standards developed in many national jurisdictions are based on IPSASs. This means that comparison with IPSASs provides a clear, comprehensive basis for a GFS reporting guidelines comparison with accounting standards, while leaving scope for those who apply other, non-IPSAS-based, full accruals accounting standards to adjust this overview for their own national differences.

Comparison of IPSASs and GFS Reporting Guidelines

A6.5 There is considerable overlap between IPSASs and GFS reporting guidelines. This section provides a generalized description of the relationship between IPSASs and the GFS reporting guidelines, focusing on the conceptual differences that explain why the two reporting frameworks differ in certain areas. It provides a summary of how to reconcile these two very similar yet—in important ways—different sets of information. If suitable adjustments are made to address the differences described here, IPSAS-based

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

financial reporting information can be used as a high-quality source for the data necessary for GFS reports. Independent audit of IPSAS-based financial reports enhances their reliability for GFS purposes.

A6.6 The description in this appendix is the same as the one included in Section 2 of the IPSASB Consultation Paper, *IPSASs and Government Finance Statistics Reporting Guidelines*.[1] Readers are referred to the *GFSM 2014* or the latest edition of the *Handbook of International Public Sector Accounting Pronouncements* for more detailed explanations of the applicable reporting guidelines and standards.

A6.7 The information provided here is at a high level, and focuses on identification of differences between the two frameworks. It is not designed to provide detailed current information about either IPSASs or GFS reporting guidelines. Detailed information on specific topics can be found through reference to individual IPSASs, the *2008 SNA*, the *ESA 2010*, and the *GFSM 2012*. Both IPSASs and GFS reporting guidelines are dynamic and change over time. IPSASs, for example, have annual improvements, which typically impact on a number of different standards. The IPSASB's Conceptual Framework Project may also result in changes to IPSASs. For the most current IPSASs and detailed information on them, it is important to refer to the Standards themselves.

A6.8 Differences between IPSASs and GFS reporting guidelines are of two main types: (i) underlying conceptual differences, and (ii) presentation and terminology differences.

Conceptual Differences between IPSASs and GFS Reporting Guidelines

A6.9 The conceptual differences between IPSASs and GFS reporting guidelines are discussed under the following headings:

- Objectives
- Reporting entity
- Recognition criteria for some assets, liabilities, revenue, and expense
- Valuation (measurement) differences for certain types of assets and liabilities
- Revaluations and other volume changes.

[1] See www.ifac.org/publications-resources/ipsass-and-government-finance-statistics-reporting-guidelines.

A6.10 Box A6.1 compares IPSASs and GFS reporting guidelines in these areas.

Objectives

A6.11 GFS reporting guidelines and IPSASs have different objectives for the two sets of financial information produced. GFS reports are used to: (i) analyze fiscal policy options, make policy, and evaluate the impact of fiscal policies, (ii) determine the impact on the economy, and (iii) compare outcomes nationally and internationally. The focus is on evaluating the impact of the general government and public sector on the economy, and the influence of government on other sectors of the economy. The GFS reporting framework was developed specifically for public sector input to other macroeconomic accounts, although a range of countries adopt GFS reporting for their fiscal reporting, and for measuring compliance with fiscal rules. By contrast, IPSAS-based financial statements are used to: (i) evaluate financial performance and position, (ii) hold management accountable, and (iii) inform decision-making.

A6.12 Although the two sets of financial information necessary to meet these different objectives have many similarities, the different objectives do result in some fundamental differences in how and what information is reported. For example, in GFS reports, one distinction for transactions in financial assets and liabilities is whether the counterparty of the transactions is a resident or nonresident. In contrast, IPSAS-based financial statements report these transactions according to whether they are current or noncurrent assets or liabilities, with classification also in terms of their maturities and supplementary information provided on risks.

Reporting entity

A6.13 One of the fundamental differences between GFS reporting guidelines and IPSASs relates to the definition of the reporting entity and the process of consolidation (collectively often referred to as "identification of the reporting entity boundary"). Under GFS reporting guidelines, as described in Chapter 2 of the *GFSM 2014* and in Chapter 4 of the *2008 SNA*, institutional units are aggregated and consolidated into statistical sectors and subsectors. The focus of statistical reporting is primarily on consolidated sectors and subsectors. Although it is theoretically possible to

Box A6.1 Summary Comparison of GFS and IPSASs

There is considerable commonality between IPSAS and GFS reporting guidelines. There are also some important conceptual differences within each area. Presentation and terminology differences are described in paragraph A6.34.

Government Finance Statistics	IPSASs
Objectives	
Evaluate economic impact: Government finance statistics are used to (i) analyze and evaluate the outcomes of fiscal policy decisions, (ii) determine the impact on the economy, and (iii) compare national and international outcomes. The GFS reporting framework was developed specifically for public sector input to other macroeconomic datasets.	Evaluate financial performance and position: General purpose financial statements are used to (i) evaluate financial performance and financial position, (ii) hold management accountable, and (iii) inform decisionmaking by users of the general purpose financial statements.
Reporting entity	
Institutional units and sectors: The statistical reporting unit is an institutional unit, defined as an entity that is capable, in its own right, of owning assets, incurring liabilities, and engaging in economic activities in its own name. The reporting entity may be an institutional unit, but the primary focus is on a group of institutional units (consolidated sector or subsector). Control and the nature of economic activities determine consolidation and the scope of the reporting entity. The general government sector does not include institutional units primarily engaged in market activities.	Economic entity and consolidation: The reporting unit for financial statements is an economic entity, defined as a group of entities that includes one or more controlled entities. Control is the main criterion that determines consolidation. The whole of the government reporting entity, at the highest level of consolidation, may include, in addition to government departments, subnational bodies such as state governments, and government-owned businesses that primarily engage in market activities.
Recognition criteria	
The key difference relates to some liabilities.	
Economic events recognized: GFS recognize economic events on the accrual basis of recording when economic value is created, transformed, exchanged, transferred, or extinguished. To maintain symmetry for both parties to the transaction, some provisions recognized in IPSAS reporting may not be recognized under GFS reporting. While not recognized, those provisions may instead be disclosed as GFS memorandum items, as is the case, for example, with exposures to explicit one-off guarantees and provisions for doubtful debts.	Past events with probable outflows recognized: IPSASs recognize liabilities, including provisions, when a past economic event has taken place; the amount can be reliably estimated; and future outflows are probable. These factors allow, in certain cases, recognition of items that do not involve a counterparty recognizing a symmetrical amount. For example, so long as criteria are met, IPSASs require recognition of restructuring provisions.
Valuation (measurement)	
Current market prices: Current market prices are used for all flows and stocks of assets/liabilities, but allowance is made for the use of alternative valuation methods where an active market does not exist.	Fair value, historic cost, and other bases: Fair value, historic cost, or other bases are used for the measurement of assets and liabilities. Similar assets and liabilities must be valued consistently and the bases disclosed. Where an entity reports an item using historic cost, IPSASs often encourage disclosure of fair value if there is a material difference between the reported cost and the item's fair value. Often IPSASs also allow entities to choose between fair value and historic cost.
Revaluations and other value changes	
Record all revaluations and changes in volume in the Statement of Other Economic Flows: Separating all these "other economic flows" is viewed as useful for fiscal analysis, on the basis that revaluations and changes in volume do not represent fiscal policy decisions directly within the control of government. GFS distinguishes between value changes and volume changes.	Realized and unrealized gains and losses: Some gains or losses due to revaluations or changes in volume of assets are reported in the Statement of Financial Performance, while others are reported directly in the Statement of Changes in Net Assets/Equity. Some other gains and losses—for example, market value changes for property, plant, and equipment carried at historic cost—are not reported at all.

Note: IPSASs = International Public Sector Accounting Standards.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

create GFS reports for individual institutional units, separate statistical reports for individual units are usually not disseminated. Each individual entity in the economy is analyzed with respect to its ability to hold assets and liabilities and exercise full economic ownership over them, to determine if it can be considered an institutional unit.

A6.14 Those government-controlled units that are primarily engaged in nonmarket (including redistributive) activities are included within the general government sector. Although all resident government-controlled entities, including public corporations engaged in market activities, are included within the public sector, nonmarket activities determine the delineation of the general government sector, as a distinct subsector within the public sector. The general government sector does not include institutional units primarily engaged in market activities. The general government sector presents consolidated data, which means that transactions and stock positions between general government sector units are eliminated.

A6.15 In IPSASs, the "reporting entity" is a government or other public sector organization, program, or identifiable activity that prepares general purpose financial reports (GPFRs). Within a jurisdiction, reports may be prepared on either a compulsory or voluntary basis. A key characteristic of a reporting entity is that there are users who depend on GPFRs for information about the entity. A reporting entity may be a "group reporting entity."

A6.16 A group reporting entity consists of two or more separate entities that present GPFRs as if they are a single entity. A group reporting entity is identified where one entity has the authority and capacity to direct the activities of one or more other entities so as to benefit from the activities of those entities. It may also be exposed to a financial burden or loss that may arise as a result of the activities of entities whose activities it has the authority and capacity to direct. If these conditions are met, then the entity is described as a "controlling entity," with control defined according to the principle of exercisable power to govern the financial and operating policies of another entity so as to benefit from its activities.

A6.17 The requirement to consolidate entities differs in IPSASs and GFS. Under IPSAS 6, Consolidated and Separate Financial Statements, consolidated financial statements are the financial statements of a group of entities presented as those of a single entity. This means that a controlling entity will consolidate the financial statements of all of its controlled entities, irrespective of whether they are: (i) resident units, (ii) market/nonmarket entities, or (iii) the IPSAS equivalent of a market entity—that is, a "government business enterprise" (GBE). This contrasts with the general government sector consolidation approach, described earlier, where nonresident and resident market institutional units are included as a single line showing net investment, rather than fully consolidated into the general government sector.

A6.18 Nevertheless, IPSASs provide for the disclosure of financial information about the general government sector. IPSAS 22, Disclosure of Financial Information about the General Government Sector, specifically sets aside the application of IPSAS 6 while retaining the application of all other IPSASs. This allows—though does not require—an aggregate presentation that does not consolidate controlled interests in entities in other sectors.

A6.19 IPSASs also have a requirement (see IPSAS 18, Segment Reporting) that a reporting entity provides disaggregated financial information about each of its segments. The information provided includes segment assets, liabilities, revenue, and expense. Segments are usually defined either in terms of geographical regions or services. GFS include data on expenditure by function of government.

Recognition criteria

A6.20 GFS reporting guidelines and IPSASs both aim to recognize economic events in the period in which they occur. Neither GFS reporting guidelines nor IPSASs allow the application of precaution or prudence to justify the reporting of provisions that anticipate future possible events. However, they differ in their recognition criteria for certain liabilities, because GFS treats uncertainty about future economic outflows differently from IPSASs. The effect of this difference is that IPSASs require more items to be recognized as liabilities than does GFS.

A6.21 In macroeconomic statistics, a liability is not recognized until a claim by the counterparty exists. Maintaining symmetry in the macroeconomic statistical system is a fundamental principle. Therefore,

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

GFS guidance is that probable exposures such as contingencies and one-off guarantees should be disclosed in memorandum items, until such time as these are called. Some liabilities for government employee benefit payments and certain guarantee schemes are not contingencies, but instead are recognized as liabilities. IPSASs require that where there is a present obligation and an outflow will probably occur, the amount should be estimated and, if it can be reliably estimated, should be recognized as a liability in the statement of financial position (balance sheet).

A6.22 The key area of difference is that of "provisions," which IPSASs define as liabilities of uncertain timing or amount (see IPSAS 19, Provisions, Contingent Liabilities and Contingent Assets, paragraph 18). Provisions include obligations for which there is no counterparty—for example, provisions for restructuring and environmental restoration. Provisions may also involve an estimate of economic outflow for a group of obligations (e.g., warranties), on the basis that it is probable that the entity will have to meet a claim by a proportion of the overall group.

A6.23 This difference with respect to liability recognition will have consequential differences for expense and asset recognition. For example, recognition of a provision for restructuring will, under IPSASs, require recognition of a related expense, because there is no compensating increase in asset value. Recognition of a provision for eventual site restoration during construction of a landfill will, under IPSASs, be capitalized, adding to the overall investment in the asset. Under IPSASs, it is also possible for an increase or decrease in the amount of a provision to occur due to an improved estimate. An increase could result in expense recognition, while a decrease could result in revenue recognition. GFS would not recognize either these changes in assets/liabilities or the resulting revenue/expense until a point in the process where another party can be identified as receiving value.

A6.24 GFS and IPSASs apply the same broad recognition criteria to assets, with the result that, with a few exceptions such as assets arising from oil and gas exploration, the same financial and nonfinancial assets are recognized. Revenue related to asset recognition is generally also reported at the same point. But other differences, such as asset measurement differences, can affect the asset value recognized and therefore the amount of revenue recognized. The timing of revenue recognition may differ due to differences between when GFS and IPSASs consider either that related obligations have been discharged or that related conditions have been removed.

Valuation (measurement) bases

A6.25 The valuation principles in GFS and IPSASs provide scope for the majority of assets and liabilities to be valued on the same basis—that is, at current market values, except where IPSASs require the use of historic cost or some other measurement basis. Both GFS and IPSASs allow proxies for current market value. For example, depreciated replacement cost can be used as a proxy for the current value of specialized assets, if no market price information is available.

A6.26 The general valuation principle of GFS is to use current market prices for all assets, liabilities, and related value changes—that is, for all stocks and flows. As explained in Chapter 3 of the *GFSM 2014*, where an active market does not exist, the GFS reporting guidelines recommend the use of nominal values for financial instruments, and an estimate of the value of other assets/liabilities. These estimates could be based on: (i) prices of similar products in similar markets, (ii) the costs of production of similar assets at the reporting date, or (iii) the discounted present value of expected future returns on the asset. (See also paragraphs 3.107–3.129 for a complete discussion of the valuation principles of GFS.)

A6.27 IPSASs allow, but generally do not require, the use of "fair value" for many, but not all, assets, liabilities, and related value changes. IPSASs define "fair value" as the amount for which an asset could be exchanged, or a liability settled, between knowledgeable, willing parties in an arm's-length transaction. This is similar to the basis for market price used in GFS. IPSASs also allow assets and liabilities to be valued at historic cost.

A6.28 Under IPSASs, financial liabilities (with some exceptions) and financial assets that are (i) held-to-maturity investments, (ii) loans and receivables, or (iii) investments in equity instruments that cannot be measured at fair value because fair value cannot be determined reliably are measured at either cost or amortized cost, usually minus impairment losses (see IPSAS 29, Financial Instruments: Recognition and

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Measurement). Other marketable financial instruments are measured at fair value. Employee-related liabilities and long-term provisions other than financial instruments are measured at net present value, which may approximate market price. Property, plant, and equipment (PP&E) and intangible assets can be valued either at fair value or at depreciated historic cost. Inventory is valued at cost, with a requirement to reduce to net realizable value, if the inventory's net realizable value falls below cost. IPSASs allow investment properties to be measured at fair value, except for those for which a fair value is not reliably determinable on a continuing basis (see IPSAS 16, Investment Property, paragraph 62). Biological assets are valued at fair value minus costs to sell, provided that fair value can be reliably measured.

A6.29 Where an item is reported at its historic cost, IPSASs often encourage or require disclosure of fair value, if there is a material difference between the item's historic cost and its fair value. For example, this is the case for property, plant, and equipment, intangible assets, and investment properties. In these three cases, the use of historic cost is optional under IPSASs. This means that governments can choose to value such assets at fair value. If an entity chooses fair value, then an initial valuation is made at cost, followed by subsequent measurements at fair value. Fair value measurement is not necessarily done annually. Interim measurements will be at the fair value determined at the most recent revaluation minus accumulated depreciation or amortization. While the choice of fair value should, theoretically, align IPSAS measurement with GFS measurement, other factors can, in practice, result in differences. Statisticians' measurement practices can involve sampling, indexing to inflation, and other estimation techniques that can generate different values from those produced by financial accountants.

A6.30 IPSASs require disclosure of the valuation basis for assets and liabilities. This means that IPSAS information makes clear whether a current market price has been used to value assets and liabilities. If historic cost has been used to value assets or liabilities, then the IPSAS source data will need to be adjusted from historic cost to current market price before it can be used for GFS. The adjustment will be straightforward where IPSASs already require disclosure of a market price valuation, which may be the case for some types of assets and liabilities where fair value is materially different from cost.

Treatment of revaluations and other volume changes

A6.31 GFS differentiates between transactions (economic flows by mutual agreement) and other economic flows. GFS records all holding gains and losses (revaluations) and other changes in the volume of assets and liabilities in the *Statement of Other Economic Flows*, which separates them from transactions. This distinction is useful for fiscal analysis. Other economic flows represent economic value gained or lost due to events that are not directly under the control of the government.

A6.32 IPSASs require the majority of changes in value to be recorded in the Statement of Financial Performance. Gains and losses recorded in the Statement of Financial Performance are then included in the total net amount that flows from the Statement of Financial Performance into the Statement of Changes in Net Assets/Equity. As a result, the Statement of Changes in Net Assets/Equity reports the total impact of all recognized value changes. Some unrealized gains and losses are not allowed to be recorded in the Statement of Financial Performance and must, instead, be recorded directly in the Statement of Changes in Net Assets/Equity. The main items are foreign exchange gains and losses related to foreign subsidiaries, and revaluations of property, plant, and equipment.

A6.33 Traditionally, the distinction between realized and unrealized gains/losses was viewed as the main difference between items recorded in the Statement of Financial Performance versus those excluded from this statement and, instead, recorded only in the Statement of Changes in Net Assets/Equity. The Statement of Financial Performance was viewed as showing realized gains/losses, while the Statement of Changes in Net Assets/Equity showed unrealized gains/losses. However, IPSASs now require many unrealized value changes to be included in the Statement of Financial Performance. For example, value changes due to unrealized revaluations of employee liabilities and impairments are included in the Statement of Financial Performance. The two main exceptions recorded in the Statement of Changes in Net Assets/Equity (foreign exchange fluctuations and revaluations of property, plant, and equipment, and intangible assets) are both unrealized, but they are also viewed as potentially obscuring an entity's financial performance, partly because they are viewed as outside of management's control, and

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

partly because gains in one year may be reversed in subsequent years.

Presentation and Terminology Differences

A6.34 Presentation and terminology differences between IPSASs and GFS reporting guidelines also exist. As a result, the GFS and IPSAS financial statements and disclosures look different, even though the information reported is largely the same, apart from the recognition and measurement differences discussed elsewhere in this paper. This subsection describes the main presentation and terminology differences between GFS guidance and IPSAS requirements.

A6.35 The main presentation and terminology differences are as follows:

- Different names for the IPSAS equivalents of the GFS statements.
- The types of classification structures included in the balance sheet (statement of financial position), operating statement (statement of financial performance), and cash flow statement for the two reporting frameworks differ, which, in some cases, also necessitate differences in terminology.
- GFS sets out a minimum level of detail for a comprehensive list of standard line items that all entities must report in their GFS statements, while IPSASs establish a minimum set of standard line items, while providing principles and guidance on further line items that a reporting entity may need to report.
- The way in which additional information about the data is disclosed differs in the two frameworks.
- The definition and/or value of key statement totals (such as total assets, net worth, total revenue, and surplus/deficit) may differ.

A6.36 Each of these main differences is discussed in paragraphs A6.37–A6.46.

Different names for statements

A6.37 The IPSAS equivalents to the GFS statements have different names (see IPSAS 1, Presentation of Financial Statements). The IPSAS equivalent to the GFS Balance Sheet is a "Statement of Financial Position," although "Balance Sheet" and "Statement of Assets and Liabilities" are acceptable alternatives under IPSASs. The IPSAS equivalent to the GFS Statement of Operations is a "Statement of Financial Performance," although "Income Statement," "Statement of Revenues and Expenses," "Operating Statement," and "Profit and Loss Statement" are acceptable alternatives under IPSASs. The GFS Statement of Other Economic Flows is partly captured in the IPSAS "Statement of Changes in Net Assets/Equity" and partly in the IPSAS "Statement of Financial Performance." The IPSAS equivalent to the GFS Statement of Sources and Uses of Cash is called a "Cash Flow Statement."

A6.38 IPSAS financial statements may also include a "Comparison of Budget and Actual Amounts," for which there is no GFS equivalent. This information must be provided by all entities that publish an approved budget (see IPSAS 1, Presentation of Financial Statements and IPSAS 24, Presentation of Budget Information in Financial Statements). It is presented either as a separate financial statement or as additional columns in the financial statements. A separate statement must be used when the budget is on a different basis from the actual reported results. For example, if the budget is prepared on a cash basis, while the results reported in financial statements are prepared on an accrual basis, the Comparison of Budget and Actual Amounts Statement is separate. If they are prepared on the same basis, the budgeted amounts can be fully integrated into the financial statements through the use of additional columns, and a separate statement is not necessary.

Classification structures

A6.39 The GFS reporting guidelines classify and group items in its statements differently from IPSASs. At the highest level, the terminology used for classifications is the same—for example, assets, liabilities, revenue, and expense. However, within these items there are conceptual differences and differences in the structure of subclassifications. The differences reflect the different objectives of the two information sets. For example, IPSASs require that assets and liabilities be presented as current or noncurrent, or that a liquidity structure be followed. This is important for assessing an entity's liquidity and solvency. GFS does not make this distinction in its core statements, but allows a supplementary table on the maturity structure of government's financial assets and liabilities to be compiled. However, GFS requires that assets be presented as financial or nonfinancial, which IPSASs do not require.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

A6.40 For GFS, standardized economic and functional classifications serve the specific objectives of: (i) comparability of the accounts of various government entities and subsectors, and (ii) international comparability. These classifications are devised to evaluate the impact of the general government and public sector on the economy as a whole, and to identify government's involvement with other sectors. For example, financial assets and liabilities are classified and presented according to whether they are domestic or foreign instruments, to allow an assessment of the government's interaction with the rest of the world. Such a classification is important because fiscal policy decisions on domestic versus foreign instruments are based on different criteria, and also because this classification allows the derivation of a government's impact on the balance of payments of the country. IPSASs do not require this distinction. The standardized GFS presentation also allows the calculation and comparison of analytical measures of fiscal policy, such as the primary balance, tax incidence ratio, expenditure by function, etc.

A6.41 Counterparty information is collected for both GFS and IPSAS reporting. The GFS economic classification requires counterparty information for flows and stocks (balance sheet) to be reported as standard line items. These identify items for consolidation, and establish the linkages with other sectors of the economy. IPSASs generally do not require counterparty information to be reported on the face of the financial statements or their related notes. However, IPSASs do require counterparty information to be collected: (i) by a parent entity to identify intra-group transactions, so that the entity can eliminate those in preparing the consolidated financial statements, and (ii) by a subsidiary to identify transactions with the parent entity and other entities that are under common control, so that information about those transactions can be disclosed in the notes. Counterparty information can also be important for risk-related note disclosures and related party disclosures.

Minimum level of detail

A6.42 GFS requires a minimum level of detail to be reported according to a comprehensive list of standard items. The level of detail is presented in standardized items to facilitate consistency over time, comparability, and consolidation of data across units and sectors. However, preparers may choose to provide additional detail.

A6.43 IPSASs also require some minimum items to be reported. However, presentation is less prescriptive compared to GFS reporting, with preparers required to make decisions about what items are shown, with reference to the purposes and understandability of statements, information relevance, and the principle that material items should be presented separately in the financial statements (see IPSAS 1). For example, preparers may choose between a presentation based on nature or function.

Disclosure of additional information

A6.44 To facilitate the correct interpretation of their GFS reports, compilers are encouraged to present information on the sources, methods, and procedures of the statistics as metadata or footnotes to statistical reports. In particular, information that may have an impact on assessing the statistics should be disclosed in the statistical reports. GFS also uses standard categories of memorandum items to report on items that are not reported in the body of the statements.

A6.45 IPSASs require that information that may have a significant impact for users be disclosed in notes to the financial statements. Notes include a summary of significant accounting policies. They also include further detailed information about individual items reported on the face of a statement—for example, (i) a breakdown of property, plant, and equipment into classes, (ii) information about items that are not recognized but nonetheless important (e.g., contingencies), and (iii) risk information related to financial instruments.

A6.46 GFS information is usually presented as a time series of data, so that comparative data for multiple years are presented at the same time. The periodicity of these data could be monthly, quarterly, or annually. IPSASs require only annual reporting, but allow more frequent reporting. Consistent GFS time series may be very long, decades for some countries. Following from this, corrections to data will be required to be made in the period in which errors occurred, irrespective of when the need for such corrections is determined. Financial statements presented according to IPSASs require comparative information for only one previous year, though the number of years involved in calculating adjustments

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

of prior year figures for policy changes and errors is not specified.

Mapping from IPSAS financial statement aggregates to GFS aggregates

Total assets and total liabilities

A6.47 Some broad classification differences exist between the classification of assets and liabilities in GFS and IPSASs.

- GFS classify assets and liabilities in terms of whether they are financial or nonfinancial. IPSASs do not require assets and liabilities to be grouped in these terms, nor do they require summary totals for financial and nonfinancial assets. However, they do require financial and nonfinancial assets and liabilities to be separately disclosed, which means that there is sufficient information in an IPSAS statement of financial position (balance sheet) to determine totals for financial and nonfinancial assets and liabilities.
- GFS classify financial assets and liabilities into domestic and foreign. IPSASs do not use this classification, although some of these disclosures may be included in an entity's risk management disclosures related to financial instruments.
- GFS classify assets and liabilities according to standardized GFS characteristics and purposes, which can differ from the classifications required by IPSASs. For example, in IPSASs, the classification of property is determined by whether it is an investment property, while GFS distinguishes property according to whether it is a produced/nonproduced asset and whether it is a dwelling, other building, other structure, or land improvement. IPSASs classify financial instruments into whether they are for trade or to be held until maturity, whether liabilities are employee liabilities, and whether provisions relating to environmental restoration all differ from the GFS classification.

Net worth

A6.48 The GFS concept of net worth plus equity (also referred to as own funds) is equal to IPSASs' net assets/equity:

- In GFS, net worth for a specific period is defined as total assets minus total liabilities. The balance sheet opening net worth + operating balance + changes in all assets and liabilities due to other economic flows = balance sheet closing net worth.
- According to IPSASs, net assets/equity is calculated as the opening net assets/equity + surplus/deficit + items shown directly on changes in equity statement = closing net assets/equity. Net assets/equity is also equal to the net of all assets minus liabilities, excluding equity.

A6.49 These differences in the calculation of the net balancing item primarily result from the differences between how GFS and IPSASs allocate items to their respective statements (GFS showing other economic flows separately). In addition, it should be noted that, in the GFS net worth concept, equity is treated symmetrically as part of financial assets and liabilities—that is, equity investments within assets, and any equity of the government entity held by nongovernment units—usually rare for government entities—within liabilities. In contrast, the IPSAS net assets/equity concept includes equity that GFS treats as a liability, whereas investments in another entity's equity are recognized as financial assets.

A6.50 In addition to these presentational differences, the values of these items can also differ due to valuation and recognition differences.

Revenue and expense

A6.51 Although the GFS and IPSAS accrual concepts of revenue and expense are different, they can be reconciled as follows:

- GFS revenue + other economic inflows = IPSAS revenue + economic inflows recognized directly in Statement of Changes in Net Assets/Equity
- GFS expense + other economic outflows = IPSAS expense + outflows recognized directly in Statement of Changes in Net Assets/Equity.

A6.52 IPSASs refer to materiality as a classification criterion for revenue and expense. In this context, GFS requires reporting on standard items. In addition to the economic classification (as shown), the *GFSM 2014* and the SNA/ESA also have a Classification of Functions of Government (COFOG).

A6.53 Under IPSASs and GFS, cash flows resulting from acquisitions or disposals of assets are recognized in the Cash Flow Statements. However, in the accrual-based accounts, the time of recording asset

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

revaluations and the statement in which changes in valuations are recorded may differ. Under IPSASs, assets may be recorded at historical cost or fair value, depending on their nature. Any gain or loss on disposal is a realized holding gain or loss recorded in revenue and expense at the time of disposal. As such, these gains/losses are shown as part of the surplus/deficit that is recognized in the Statement of Financial Performance. Under GFS, assets are valued at current market prices and any holding gains or losses are recognized as they occur. These valuation changes are reflected in the *Statement of Other Economic Flows*. For assets disposed of at prices different from the valuation of the asset, it is deemed that such an other economic flow occurred right before disposal, so that at disposal there is no gain or loss reflected in the *Statement of Operations*. Therefore, the amounts of revenue/expense recognized will differ from that recorded under IPSASs.

Consumption of fixed capital (assets)

A6.54 In theory, the GFS concept of consumption of fixed capital differs from the IPSAS concept of "depreciation." The IPSAS concept of "depreciation" involves allocating changes in an asset's historic cost or current value to the reporting period in which the asset is used, as a measure of the asset's consumption. The GFS concept of consumption of fixed capital is based on a current value concept—described in the *2008 SNA* (paragraph 6.240) as the decline, during the course of the accounting period, in the current value of the stock of fixed assets owned and used by a producer as a result of physical deterioration, normal obsolescence, or normal accidental damage. Consumption of fixed capital is a forward-looking measure that is determined by the benefits that institutional units expect to derive in the future from using the asset in production over the remainder of its service life. In practice, consumption of fixed capital is usually calculated according to aggregated asset groups using a model approach.

A6.55 In practice, depreciation would approximate GFS consumption of fixed capital, if similar valuation methods and service lives are assumed for assets, and IPSAS-based asset values are close to replacement values through revaluations. Where IPSAS asset values are based on historic cost values, depreciation would usually represent an underestimate of consumption of fixed capital. The difference will be large for governments that have a large stock of fixed assets, as many governments do.

Operating balance

A6.56 The GFS net operating balance is calculated in the same way as the IPSAS "surplus/deficit." Both are calculated as revenue minus expense. However, the value of these two balancing items is likely to differ, because there may be differences between items included in the GFS revenue and expense and those included in IPSAS revenue and expense. This difference can be mainly attributed to the conceptual difference in the treatment of other economic flows.

APPENDIX

7 GFS and Other Macroeconomic Statistics

This appendix describes the relationships between government finance statistics and national accounts, balance of payments and international investment position, monetary and financial statistics, and the System of Environmental-Economic Accounting (SEEA) Central Framework. This appendix is intended to provide an overview of the major similarities and differences between government finance statistics and other major datasets, as well as an indication of how to reconcile the data in cases where there are differences in presentation. The text of this appendix is not intended to take preference over the methodological guidance provided elsewhere in this Manual.

Introduction

A7.1 It is important for compilers and users of GFS data to understand how GFS relate to the other macroeconomic datasets. More specifically, an understanding of the linkages fosters consistency in the respective datasets and supports whole-of-economy analysis.

A7.2 The institutional arrangements for compiling and producing macroeconomic statistics differ from country to country. These could range from a single entity being responsible for the compilation of source data and the final GFS to several national agencies being involved in the compilation of various components of the data. Agencies such as ministries of finance (MOFs), national statistics offices (NSOs), central banks (CBs), and other government agencies may be involved. The MOFs are often involved in compiling budget data from accounting and other administrative records to monitor implementation of the government budget. NSOs are often responsible for compiling, producing, and disseminating macroeconomic statistics in line with the *2008 SNA*[1] principles. They may use source data from MOFs that are based on national classifications and make necessary adjustments according to the requirement of the statistical guidelines. CBs are primarily involved in compiling monetary and financial data to allow them to monitor financial conditions and the implementation of monetary policies. All these data should be based on consistent methodological guidance, and where multiple agencies are involved in compiling macroeconomic data compilation, it is essential that these national agencies coordinate efforts to best ensure consistency in data outputs.[2]

A7.3 A clear understanding of the linkages between datasets will assist countries in producing comparable and consistent statistics needed for economic analysis and policy decisions. The primary purpose of GFS is to provide a comprehensive conceptual and statistical reporting framework for analyzing and evaluating fiscal policy. In addition, detailed GFS also provide a measurement of the impact of government on other sectors of the economy. Therefore, these fiscal data serve as input for other datasets, while other datasets may be used to derive and/or verify GFS data. Harmonization in practice allows compilers to share source data, where appropriate, and also fosters coherent developments in the source data systems.

A7.4 The remainder of this appendix provides an overview of the important similarities and differences between the GFS and other major datasets. It describes the similarities related to coverage and accounting rules and then provides a comparison of the analytical framework of GFS with that of the national accounts, balance of payments and international investment position, and the monetary and financial statistics. Last, the appendix describes how the GFS

[1] In this appendix, most references to the *SNA* concern the general content of the volume rather than the citation of a specific portion of the text. The expression "in the SNA" is used to refer to the national accounts compiled in accordance with the *2008 SNA* as a body of thought.

[2] See Dziobek and Tanase, *Institutional Cooperation between Central Banks and the Statistical Offices for Producing Macroeconomic Statistics*, IFC Bulletin No 28, August 2008.

framework relates to the *System of Environmental-Economic Accounting* (*SEEA*) *Central Framework*. Where there are differences in presentation, the appendix provides an indication of how to reconcile the data.

Overview of Similarities and Differences

A7.5 This *Manual* is harmonized with the *2008 SNA*, which provides the conceptual basis for national accounts. The *BPM6* serves as the standard framework for statistics on the transactions and positions between an economy and the rest of the world. The *Monetary and Financial Statistics Manual (MFSM)* provides guidelines on compiling statistics for the financial corporations sector. These manuals are also harmonized with the *2008 SNA*.[3]

A7.6 Broadly, the principles and concepts are defined in a consistent manner in all these statistical manuals. The delineation between resident and nonresident entities, sectorization of the domestic economy, and definitions and classifications of financial instruments are the same. The accounting rules used are the same with respect to basis of recording and valuation. While the accrual basis of recording flows and stock positions is used consistently in all data-sets, GFS also include the compilation of a *Statement of Sources and Uses of Cash*. With a few exceptions, as described in the detailed comparisons, the flows and stock positions of GFS are defined and valued in the same way.

A7.7 For analytical reasons, the structure and presentation of the GFS framework in Chapter 4 and the GFS treatment of a few activities differ from the framework and presentation of the data of the general government sector in the *2008 SNA* and other datasets. While all the datasets have balancing items, the aggregation and consolidation rules are not exactly the same.

A7.8 GFS focus on measuring the impact of economic events on the finances of government, and the impact of government activities on the economy through taxing, spending, borrowing, and lending. The SNA focuses on the linkages between sectors of the economy, and the economic processes of production, income generation and distribution, consumption of goods and services, and accumulation. The balance of payments summarizes economic transactions between residents and nonresidents during a specific period, while the international investment position shows the value of the financial assets and liabilities stock positions between the residents of an economy and nonresidents at a reporting date. Monetary statistics focus on assessing monetary conditions and the impact of monetary policy decision on the money and capital markets. These differences in focus require that the recording of government activities in GFS occasionally differ from the recording of those activities in the other macroeconomic datasets. However, such differences are the exception to the general principle, as consistent application of conceptual standards applies across related datasets. Where there are differences in presentation, reconciliation of the differences should routinely be made to ensure consistency in the macroeconomic data.

Coverage and Accounting Rules

A7.9 The identification of institutional units and their sectorization are conceptually the same in all macroeconomic datasets. Where analytically useful, certain datasets may require that the primary sectors be further divided into subsectors according to need. For example, GFS present data for the subsectors of the general government as separate datasets, while monetary statistics present data for subsectors of the financial corporations. As described in paragraph 2.58, the general government sector in GFS is defined identically to the general government sector in the national accounts, balance of payments, and monetary statistics. Although the public sector is not one of the five primary sectors in the SNA, it is recognized as an additional grouping.[4] The residence concept used to delineate resident and nonresident entities and the sectors used in identifying counterpart transactions are the same across all datasets. Compilers of macroeconomic data should therefore ensure that the actual coverage used in their statistics is identical.

A7.10 Most of the accounting rules employed in these macroeconomic frameworks are identical. In

[3] Revision of the *MFSM*, 2000 edition, to align with the *2008 SNA*, is pending at the time of publication of this *Manual.*

[4] The definition of public sector as defined in the *2008 SNA*, Chapter 22, Section B, is identical to the definition in paragraph 2.63 of this *Manual*.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

particular, the rules for time of recording, the valuation of flows and stock positions, and the rules governing the gross or net recording of flows and stock positions are identical.

A7.11 The principal difference between GFS and the SNA regarding accounting rules concerns consolidation (see paragraph 3.167 of this *Manual*). In principle, GFS requires the elimination of all intra- and intersector flows and stock positions between units of the same sector and subsectors. Consolidation can be applied to the statistics of any group of units, including subsectors of the general government sector, the entire public sector, or any other grouping depending on analytical interest.

A7.12 As a matter of principle, consolidation is not used in the SNA, although it is acknowledged that consolidation may be useful for the general government sector (see the *2008 SNA*, paragraphs 2.69, 3.197, and 22.79). Even when used in the national accounts, transactions appearing in different accounts are never consolidated so that balancing items are not affected. For example, in national accounts, interest receivable by one government unit that is payable by another government unit is shown as both revenue and expense in the accounts of the general government sector. In contrast, full consolidation is used in GFS. Such interest is recorded neither as an expense nor as revenue in the data for the consolidated general government sector as a whole, although such interest could appear in the subsector accounts of general government if the two parties involved are in different subsectors of the general government. Because SNA statistics are not consolidated, the GFS compiler should preserve the unconsolidated statistics for use by the national accounts compiler.

Comparison of the Analytical Frameworks of GFS and the SNA

A7.13 Both GFS and the SNA can be described as the systematic recording and presentation of flows and stock positions, with the flows comprising transactions and other economic flows. While the recording of flows and stock positions are generally the same in the two datasets, the accounts in which these are recorded differ because of the unique objectives of the two datasets. In general, both datasets have the same interest in the activities of general government and public sectors, although the arrangement of the data differs and the actual flows recorded differ in some instances. These differences could be summarized as follows (see Table A7.1):

- The GFS framework primarily records the operations of the general government or public sector according to revenue, expense, and transactions in nonfinancial and financial assets, and liabilities. These transactions and other economic flows are integrated with balance sheets. The SNA records general governments' transactions according to their involvement in the measurement of production, generation, distribution and use of income, and capital and financial account transactions. These transactions and other economic flows are also integrated with balance sheets.
- The SNA reconciles the current accounts, accumulation accounts, and balance sheet positions across all institutional sectors, whereas GFS undertake such reconciliations only for the general government and public sectors.
- The two datasets differ in recording practices. GFS are based on the principle of double-entry recording, similar to business accounting, but the SNA is based on the principle of quadruple-entry accounting, because most transactions involve two institutional units. Each institutional unit involved in a transaction must record the transactions according to the double-entry system for the accounts to be in balance.
- The focus of the SNA is on various kinds of economic processes. Therefore, where the recording of a single transaction is sufficient in GFS, multiple entries may be required in the SNA to correctly reflect all the relevant economic processes.

Comparison of the Accounts in GFS and the SNA

A7.14 The GFS analytic framework consists of four statements (see Chapter 4). The *Statement of Operations* is a presentation of all transactions recorded in the GFS framework. Other economic flows are presented in the *Statement of Other Economic Flows*,[5] and the stock positions are presented in the *Balance Sheet*.

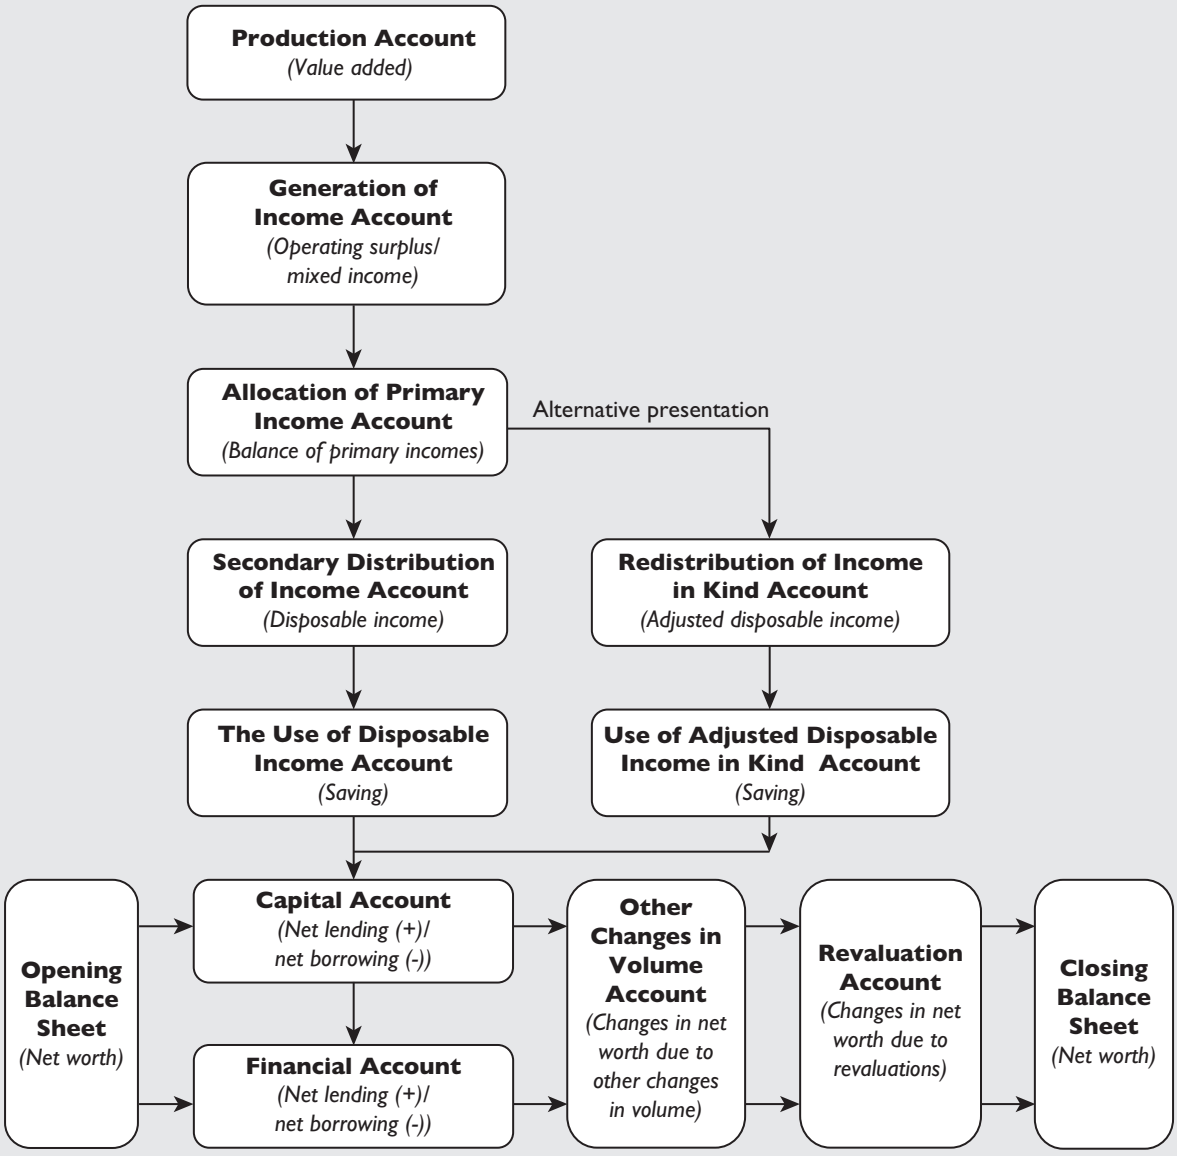
[5] For analytical reasons, the *Statement of Other Economic Flows* could also be presented as separate statements to record *Holding Gains and Losses* and *Other Changes in Volume of Assets and Liabilities*.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Table A7.1 Main Differences between GFS and the SNA

Indicator	Differences identified
Analytical framework	GFS are mainly presented in four statements, including a cash-flow statement. In the SNA, transactions are presented in a sequence of seven accounts (see Figure A7.1), other economic flows are presented in two accounts, and stock positions are presented in the Balance Sheet. There is no equivalent to the GFS cash-flow statement.
Focus	GFS focus on measuring the impact of economic events on the finances of government. The SNA focuses on measuring economic processes and their impact on the various sectors of the economy.
Consolidation	In principle, GFS eliminate all intra- and intersector flows and stock positions between units of the same sector and subsectors. In the SNA, consolidation is not used as a matter of principle, although it is acknowledged that consolidation may be useful for the general government sector.
Unfunded employment-related pension funds	GFS require that a liability be recognized for all unfunded employment-related pension obligations. SNA allows some pension obligations to be excluded from the core accounts and reported in supplementary tables. The SNA recognizes all social contribution revenue and expense, and records an adjustment item for the change in liabilities, while GFS recognize social contributions and benefits as either revenue and expense or transactions in liabilities.
FISIM, insurance services, and fees related to standardized guarantees	In GFS, the services fees related to interest, nonlife insurance premiums, and fees for standardized guarantees are not separately identified because they can be estimated only indirectly by considering data for all sectors of the economy, such as in the national accounts. In the SNA, the values for FISIM, insurance services, and standardized guarantees are derived by partitioning interest, nonlife insurance premiums, and fees for standardized guarantees.
Transfers in kind—goods and services produced by government	In GFS, goods and services produced by government and transferred in kind are recorded as imputed sales only when provided to employees as wages in kind. In all other cases, only the cost of producing these goods and services is recognized in the respective expense categories. In the SNA, all goods and services produced by government and transferred in kind are recorded as a transfer and an imputed sale of goods and services.
Internal transactions in respect of own-account capital formation	In GFS, compensation of employees, use of goods and services, and consumption of fixed capital incurred in own-account capital formation are excluded from expense and are recorded as a component of the cost of the acquisition of the nonfinancial asset. In the SNA, the full costs of compensation of employees, use of goods and services, and consumption of fixed capital are recorded as well as the acquisition of the nonfinancial asset.

Finally, the *Statement of Sources and Uses of Cash* provides information on liquidity.



A7.15 In the SNA, transactions are presented in a sequence of seven accounts (see Figure A7.1), other economic flows are presented in two accounts, and stock positions are presented in the *Balance Sheet*. There is no SNA equivalent to the GFS *Statement of Sources and Uses of Cash*.

A7.16 Each flow in the SNA relates to a particular kind of economic process or activity, such as production, or the generation, distribution, redistribution or use of income, and accumulation. Each of the current accounts shows the resources available to the institutional units and the uses of these resources. These accounts are balanced by introducing a balancing item defined residually as the difference between the total resources recorded on one side of the account and the total uses recorded on the other side. The balancing item from one account is carried forward as the first item in the following account, on the opposite side, thereby making the set of accounts an articulated whole.

A7.17 In the SNA, the sequence of transaction accounts is grouped into current and accumulation accounts. The current accounts record the production of goods and services, and the generation, distribution, redistribution, and use of income. The accumulation

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Figure A7.1 Diagram of the Sequence of SNA Accounts

Note: Balancing items are shown in italics.

accounts record capital transfers, the acquisition and disposal of assets and liabilities, and other economic flows related to assets and liabilities. Despite the large number of accounts in the SNA, there is broad correspondence between the structures of the GFS and SNA datasets.[6]

[6] Explicit provision is made in the SNA for flexibility in the presentation of stock positions and flows. The accounts described here comprise the basic presentation described in Chapters 6 through 13 of the *2008 SNA*.

A7.18 As illustrated in Table A7.2, the GFS *Statement of Operations* can be divided into three sections—namely:

- Transactions affecting net worth
- Transactions in nonfinancial assets
- Transactions in financial assets and liabilities.

The GFS transactions affecting net worth (revenue and expense) are shown as transactions in the current

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Table A7.2 Linkages of the Statement of Operations in GFS with Sequence of SNA Transaction Accounts

GFS Statement of Operations		SNA Sequence of Accounts	
Main aggregates	**Balances**	**SNA current accounts**	**Balances and main aggregates**
Revenue, Expense[2]	Net operating balance (or change in net worth due to transactions)	Production account	Value added / GDP
		Generation of income account	Operating surplus and mixed income
		Allocation of primary income account	Balance of primary income / GNI
		Secondary distribution of income account	Disposable income / NDI
		Use of disposable income account[1]	Saving / National saving
Conceptually, net operating balance differs from saving with the value of capital transfers and taxes on capital transactions, and capitalized expense. Additional differences in calculated values may arise due to differences in treatment of some employment-related pension schemes.			
		SNA accumulation accounts	**Balances and main aggregates**
Operating balance[2] minus net acquisition of nonfinancial assets	Net lending (+)/net borrowing (–)	Capital account[2]	Net lending (+)/net borrowing (–)
Conceptually, net lending (+)/net borrowing (–) in GFS is the same as in the SNA. In practice calculated values may differ due to difference in treatment of some employment-related pension schemes.			
Net acquisition of financial assets minus net incurrence of liabilities	Change in financial worth due to transactions = net lending(+)/net borrowing (–)	Financial account	Net lending (+) / net borrowing (–)
Conceptually, transactions in financial assets and liabilities in GFS are the same as in the SNA. In practice, calculated values may differ due to differences in treatment of some employment-related pension schemes.			

[1]The use of the disposable income account is replaced by the use of the adjusted disposable income account by an alternative sequence of accounts in which the secondary distribution of income account is augmented with the redistribution of income in kind account (see Chapters 8 and 9 of the *2008 SNA* for additional details on these accounts).

[2]Capital transfers as recorded in the SNA capital account are included in GFS as revenue and expense.

accounts of the SNA with one exception: capital transfers are shown in the capital account of the SNA, one of the accumulation accounts. All of the GFS transactions in nonfinancial assets presented in the second section of the *Statement of Operations* are shown in the capital account of the SNA, while the GFS transactions in financial assets and liabilities correspond to the transactions shown in the financial account of the SNA.

A7.19 Because each of the SNA accounts has its own balancing item, there are more balancing items in the SNA than in GFS. However, some of the SNA balancing items can be derived from GFS. The different placement of capital transfers means that the GFS balancing item for the first section of the *Statement of Operations*, the net operating balance, differs from saving, the final balancing item in the sequence of current accounts in the SNA. The net operating balance of GFS minus capital transfers is comparable to saving as calculated in the SNA. Net capital transfers are recorded as an aggregate in the capital account of the SNA. Conceptually, net lending/net borrowing, the balancing item in GFS, is equivalent to the net lending/net borrowing calculated in the capital and financial accounts of the SNA. However, the difference in the treatment of certain activities, such as some employment-related pension arrangements (see paragraph A7.46–A7.47), means that the value of net lending/net borrowing in GFS may differ from the SNA. These differences are reconcilable.

A7.20 The GFS *Statement of Other Economic Flows* covers all other economic flows, classified by type of asset or liability affected and according to whether the flow is a holding gain or an other change in the

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

volume of assets. In the SNA, the same distinction between holding gains and other changes in the volume of assets is made. In the SNA, these accounts are the revaluation account, in which effects of price changes in values of assets and liabilities are recorded, and the other changes in volume of assets account, in which changes in the amounts of the assets and liabilities as a result of factors other than transactions and revaluations are recorded.[7]

A7.21 The coverage of the GFS *Balance Sheet* is identical to the coverage of the Balance Sheet in the SNA, except for some employment-related pension entitlements. Due to different institutional arrangements in countries, some flexibility is given in the SNA, but not in GFS, regarding the recording of pension entitlements for unfunded pension schemes sponsored by government. Some of these pension entitlements may be recorded within the main sequence of the SNA accounts (also referred to as the core accounts) and others may be reported in supplementary tables.

Linkages between GFS and the SNA

A7.22 Despite the structural consistencies, the different objectives of GFS and the SNA require that a few transactions and other economic flows recorded in the various statements and accounts be recorded and presented differently. This section reviews and summarizes the relevant linkages between the two datasets. In order to facilitate references to the respective datasets, the items are referred to by their names and the relevant SNA and GFS classification codes.[8] Tables A7.3 and A7.4 indicate how the GFS revenue and expense categories link with the SNA classifications, and Table A7.5 identifies the correspondence of GFS and SNA transactions in nonfinancial assets, with corresponding classification codes. The SNA also provides volume measures (including of government components), an important type of measure for fiscal analysis that makes the SNA complementary to GFS.

Current accounts

A7.23 The current accounts of the SNA record the production of goods and services, the generation of income by production, the subsequent distribution and redistribution of income among institutional units, and the use of income for purposes of consumption or saving. This section describes the GFS linkages with each of these current accounts.

The production account

A7.24 The production account records the transactions relating to the activity of producing goods and services as defined in the SNA. The balancing item, **gross value added**, is defined as the value of output minus the value of intermediate consumption. The production measure of **gross domestic product** is defined as gross value added plus any taxes minus subsidies on products not already included in the value of output. **Output** is the value of goods and services produced during an accounting period. Intermediate consumption comprises the cost of goods and services used in production. Value added is a measure of the contribution to gross domestic product made by an individual producer, industry, or sector. For general government, the production account represents the general government's contribution to the domestic production.

A7.25 Value added can be presented gross or net of consumption of fixed capital. **Net value added** is the value of output minus the values of both intermediate consumption and consumption of fixed capital. Intermediate consumption of goods and services (P2) and consumption of fixed capital (P51c) are included as uses, while the output (P1) of all goods and services produced by a general government unit is a resource. Total output is divided into market output (P11), output for own final use (P12),[9] and other nonmarket output (P13).

A7.26 Output is not recorded as such in GFS. Nevertheless, the total output of the general government sector can be determined as the sum of the output of

[7] "Revaluations" and "holding gains" are used interchangeably in the *2008 SNA*.

[8] The SNA classification codes for transactions and other flows have the form of a letter: D for distributive transactions, F for financial assets and liabilities, K for other changes in assets accounts, or P for transactions in products, each followed by a number. The SNA codes for the balance sheet are AN for nonfinancial assets and AF for financial assets and liabilities. The SNA coding system uses the letter B for balancing items. The GFS coding system is presented in Appendix 8.

[9] Output for own final use in the SNA consists of products retained by the producer for its own use as final consumption or capital formation. Therefore, *own-account capital formation*, as referred to in GFS, is a narrower definition than the SNA concept of output for own final use.

nonmarket establishments and the output of market establishments. The output of the two types of establishments is derived quite differently:

- The output of market establishments is equal to the sales of those establishments (GFS revenue item *sales by market establishments* (1421)) plus changes in their inventories of *work in progress* (31222) and *finished goods* (31223). Thus, to establish a direct link with the SNA, GFS data on the changes in inventories need to be divided into separate data for market and nonmarket establishments.
- The output of nonmarket establishments cannot be determined from sales statistics because most of it is distributed without charge or sold at prices that are not economically significant. Instead, the output of nonmarket establishments is defined to be equal to the sum of their production costs: *compensation of employees* (21), *use of goods and services* (22), *consumption of fixed capital* (23), other taxes on production paid, and other subsidies on production received (as a negative value).

Therefore, in order to calculate the output of nonmarket establishments from GFS data, it is necessary to divide the total values of each of the relevant expense categories into expenses incurred by market establishments and expenses incurred by nonmarket establishments.[10]

A7.27 In the national accounts, the total output of the general government sector is allocated among three components: market output, output for own final use, and other nonmarket output.

- Output for own final use is the value of goods and services produced for own final use or nonfinancial assets constructed for own use by general government units. The latter data are available directly from the details of GFS expenditure as memorandum item 3M1 in Table 8.1. In the SNA, provision is made to value this output at market prices if the assets constructed on own account are also offered for sale on the market. In the GFS framework, it is assumed that assets constructed on own account by the general government sector are not offered for sale on the market so that valuation should be based on the cost of production.
- Market output and other nonmarket output are not directly available from GFS, and do not necessarily correspond to the output of market and nonmarket establishments because nonmarket establishments can produce market output, and vice versa.
  - The value of market output is calculated as the sum of the entire output of market establishments, actual sales of nonmarket establishments at market prices[11] (part of GFS revenue item *incidental sales by nonmarket establishments* (1423)), and other output that is imputed to have been sold (part of GFS revenue item *imputed sales by nonmarket establishments* (1424)). Imputed sales are in-kind transactions that are valued at market prices (see Box A7.1).
  - The value of other nonmarket output can be calculated residually as the total output of the general government sector minus output for own final use and market output.

A7.28 Intermediate consumption consists of the goods and services consumed as inputs by a process of production, excluding fixed assets whose consumption is recorded as consumption of fixed capital. For general government or public sector units, intermediate consumption includes the following GFS items:

- Use of goods and services (GFS expense item 22) minus the portion of goods purchased for resale that was actually sold during the reporting period (reduction in GFS item 31224 due to sales)
- Goods and services used in own-account capital formation (GFS memorandum item 3M12)
- Consumption of financial intermediation services indirectly measured (FISIM), which is already taken into account in *interest* revenue and expense of GFS (GFS items 1411 and 24, respectively)

[10] Market establishments included in the general government sector are usually a small fraction of the general government total output.

[11] Sales of nonmarket goods or services at prices that are not economically significant remain a part of the value of nonmarket output (see the *2008 SNA*, paragraph 6.132).

- Consumption of insurance services and service charge/fee related to standardized guarantees that are components of *premiums, fees, and current claims related to nonlife insurance and standardized guarantee schemes* (GFS items 1451 and 2831).

A7.29 For SNA purposes, the values for FISIM, insurance services, and standardized guarantees schemes are derived by partitioning interest, nonlife insurance premiums, and fees for standardized guarantees (see paragraphs 6.81 and 6.125). In concept, the value of these services should be treated as a use of goods and services expense for the consumer and revenue from the sale of a service for the financial intermediary providing the service. However, in GFS, these partitions are not made because they can be estimated from data for the entire economy. Instead, in GFS, the entire values of the transactions are recorded as interest, nonlife insurance premiums, or fees for standardized guarantees, respectively.[12]

A7.30 Consumption of fixed capital (P51) in the SNA is identical to the concept in GFS. However, the amounts of consumption of fixed capital may differ because of the differing treatment of own-account capital formation. Consumption of fixed capital as recorded in the national accounts should be equal to the *consumption of fixed capital [GFS]* (23) plus the consumption of fixed capital recorded as a component of own-account capital formation in GFS (GFS memorandum item 3M13).

[12] See the *2008 SNA*, paragraphs A3.24–A3.27, for additional details on the estimation of these services.

The distribution of income accounts

A7.31 The distribution of income accounts are decomposed into three main accounts. These separated accounts each have different balancing items that have meaningful interpretations of income and comprise:

- Primary distribution of income account, comprising the generation of income account and the allocation of primary income account
- Secondary distribution of income account
- Redistribution of income in kind account.

The primary distribution of income account

A7.32 The primary distribution of income account shows how GDP is distributed to labor, capital, government, and, where necessary, flows to and from the rest of the world. The primary distribution of income is always presented in two subaccounts—namely, the generation of income account and the allocation of primary income account.

Box A7.1 In-Kind Transactions

Although GFS and the SNA recognize in-kind transactions, recording these may differ in the two datasets, specifically in the case of goods and services produced by general government. Due to the SNA's focus on economic processes, such transactions may be recorded at various stages in the SNA, while in general they are recorded only once in GFS. Imputed sales, as recorded in GFS, are called nonmonetary transactions in the SNA.

GFS and the SNA record such an imputed sale in the case of:

- Goods and services *produced* by the general government sector and provided to *employees as wages in kind*—Treated as compensation of employees paid in cash followed by a sale to the employees (GFS item 1424). The compensation is recorded in the generation of income account as compensation of employees, as wages and salaries (D11), and the output is recorded as household final consumption expenditure. In GFS, goods and services *produced* by the general government sector and provided to employees as wages in kind are treated similarly to the SNA treatment. The government is deemed to be acting in two capacities: as an employer and as a general producer of goods and services. In order to indicate the total amount paid as compensation of employees, it is necessary to treat the amount payable in kind as if it had been paid in cash as wages and salaries and then the employees had used the cash to purchase the goods and services.

The SNA records transactions in imputed sales that are not recorded in GFS in the following cases:

- Goods and services *produced* by the general government sector and provided as social benefits in kind in accordance with *employment-related social benefits*—Treated in the SNA as if there had been a transfer to the beneficiaries in cash followed by a sale of the output to the beneficiaries. Thus, the goods and services are recorded in the SNA as final consumption expenditure of the households while the transfer is recorded as a social benefit (recorded in the secondary distribution of income account as social benefits other than social transfers in kind (D62 in SNA), social insurance benefits (D622 in SNA). This item is divided further into pension benefits (D6221 in SNA) and nonpension benefits (D6222 in SNA). In GFS, goods and services produced by general government units and provided as social benefits are recorded in GFS as costs of production in the various GFS expense categories, such as compensation of employees and use of goods and services, and consumption of fixed capital, and not as social benefits.
- Goods and services *produced* by the general government sector and provided as grants in kind to *other governments and international organizations*—Treated in the SNA as if there had been a transfer in cash followed by a sale of the output to the recipients of the goods and services. The output is shown as exports (P6 in SNA) in the case of grants to foreign governments and international organizations and either government final consumption expenditure or gross fixed capital formation (P51 in SNA) in the case of grants to other domestic general government units. The transfer is shown in the secondary distribution of income account as other current transfers (D9), either as current transfers within general government (D73 in SNA) or current international cooperation (D74 in SNA), or in the capital account as capital transfers, as investment grants (D92 in SNA) or other capital transfers (D99 in SNA). In GFS, such grants in kind are recorded as grants to foreign governments (GFS expense item 261) or grants to international organizations (GFS expense item 262).
- Goods and services *produced* by the general government sector and provided as transfers in kind to nonprofit institutions serving households or to individuals or households as compensation for *damage to property or personal injury or as the settlement of an insurance claim*—Treated as a transfer in cash and a sale of market output. The transfer is recorded in the secondary distribution of income account of the SNA as other current transfers, as nonlife insurance claims (D72) or miscellaneous current transfers (D75), and the output is recorded as final consumption expenditure of the households sector or the nonprofit institutions serving households sector. In GFS, these goods and services provided in kind are recorded as other transfers (GFS expense item 282).

The generation of income account

A7.33 The generation of income account shows from the point of view of resident institutional units or sectors, in their capacity as producers, how the value added generates income for labor, capital, and government. The account starts with value added as a resource and then includes as uses:

- Compensation of employees (D1)
- Other taxes on production[13] (D29) payable

[13] Other taxes on production consist of all taxes except taxes on products that enterprises incur as a result of engaging in production. A tax on products is a tax that is payable per unit of some good or service. (See the *2008 SNA*, paragraphs 7.88–7.97.)

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

- Other subsidies on production (D39) receivable as a negative use.

A7.34 The balancing item of the generation of income account is the operating surplus (B2), which can be presented gross or net of consumption of fixed capital. It measures the surplus accruing from production before deducting any explicit or implicit income: interest charges, rent, or other property incomes payable on financial assets, land, or other natural resources held to carry on the production process.

A7.35 Compensation of employees in the SNA corresponds to the sum of the GFS expense item *compensation of employees* [GFS] (21) and the amount of compensation of employees recorded as a component of own-account capital formation (GFS memorandum item 3M11).

A7.36 The taxes and subsidies that are included in the valuation of the output of nonmarket establishments consist of other taxes on production payable by general government units to other government units and other subsidies on production receivable by general government units from other government units, both national and foreign. These amounts are likely to be rare and/or small in magnitude. Taxes payable by one level of government to another level of government are classified in GFS as *transfers not elsewhere classified* (282) in the subcategory *current* (2821). Subsidies on production (D39) receivable are a portion of the *subsidies* (14411) classified under *transfers not elsewhere classified* (144).[14] In GFS, these items, involving general government units, would be eliminated in consolidation when statistics for the general government or public sector are compiled.

The allocation of primary income account

A7.37 The allocation of primary income account focuses on resident institutional units or sectors in their capacity as recipients of primary incomes. It shows where the items payable in the generation of income account are receivable, and also includes the amounts of property income receivable and payable by institutional unit or sectors. It contains the operating surplus or mixed income as a resource and records for each sector, property income receivable and payable, compensation of employees receivable, and taxes *minus* subsidies on production and imports receivable. The balancing item is the balance of primary income (B5), which represents the sector's contribution to the national income. The balance of primary income or national income can be presented gross or net of consumption of fixed capital.

A7.38 For the general government sector, the account records the following resources:

- Taxes on production and imports (D2), which are divided into taxes on products (D21) and other taxes on production (D29)
- Subsidies as a negative resource (D3)
- Property income as both a resource and a use (D4).

A7.39 In the SNA, taxes are classified according to their role in economic activities as:

- Taxes on production and imports (D2) in the production account, generation of income account, and allocation of primary income account
- Current taxes on income, wealth, etc. (D5) in the secondary distribution of income account
- Capital taxes (D91) in the capital account.

A7.40 GFS include a detailed classification of taxes based on common practices in tax administration. The result is that some tax categories in GFS, such as motor vehicle taxes, need to be allocated between two of the SNA tax categories according to whether they are payable by producers or final consumers. This allocation is required in the SNA and, in the absence of a split in GFS or source data, national accounts compilers will need to employ various methods to identify the payer (i.e., a producer or final consumer).

A7.41 A breakdown of these taxes is shown in Table A7.3, which indicates, among other things, the linkages between the GFS and the SNA tax categories. The table shows which GFS tax categories directly correspond to the SNA tax category, which SNA tax category consists of two or more GFS subcategories, and which GFS tax item requires further breakdowns to allow linkage to the SNA categories.

A7.42 Subsidies (D3) in the SNA are the equivalent of subsidies in GFS (GFS revenue item 14411 and GFS expense item 25), but the classification of the type of subsidies is quite different in the two datasets. In the SNA, the subsidies are divided into subsidies on products (D31) and other subsidies on production (D39). The subsidies on products are divided further into

[14] While a general government unit, public and private corporations, NPISH, or households may be recipients of subsidies, these are payable by government units only.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

subsidies on imports (D311), exports (D312), and other subsidies on products (D319). In GFS, to allow consolidation of the public sector, subsidies are classified by recipients. To allow correspondence between the SNA and GFS, a building block approach can be used to identify all subsidies according to whether they are on production or products, as well as identification of the recipients.

A7.43 There are several types of property income included as resources in the allocation of primary income account:

- Dividends (D421) in the SNA are the equivalent of dividends recorded in GFS (GFS revenue item 1412 and GFS expense item 2811, respectively).
- Withdrawals of income from quasi-corporations (D422) in the SNA are the equivalent of these withdrawals recorded in GFS (GFS revenue item 1413 and GFS expense item 2812).
- Rent (D45) in the SNA is the equivalent of rent recorded in GFS (GFS revenue item 1415 and GFS expense item 2814).
- Interest (D41) in the SNA is the equivalent of interest in GFS (GFS revenue item 1411 and GFS expense item 24), adjusted for FISIM (see paragraph A7.29).
- Reinvested earnings on direct foreign investment (D43) in the SNA are the equivalent of reinvested earnings recorded in GFS (GFS revenue item 1416 and GFS expense item 2815).
- Imputed property income on investment income disbursements (D44), such as income attributable to insurance policy holders, etc., in the SNA is conceptually the equivalent of property income/expense related to investment income disbursements (GFS revenue item 1414 and GFS expense item 2813). However, for government sector units as holders of insurance policies, the revenue related to this item is likely to be unknown, and would probably be calculated only in the context of the whole of the economy. It therefore remains an adjustment item between GFS and national accounts. This imputed property income is also recorded as payable by the beneficiaries to the operator of the scheme as a household contribution supplement (D6141) in the secondary distribution of income account. In the case of pension schemes for general government, this imputed transaction primarily relates to employment-related nonautonomous pension schemes. If these pension schemes are autonomous, the transactions affect only households and the financial corporations sector. In GFS, an imputed property expense on existing pension entitlements, recorded under GFS expense item 2813, is equal to the increase in the liability of a defined-benefit pension scheme resulting from the passage of time. Thus, the imputed household pension contribution supplements, recorded in the secondary distribution of income account in the SNA, should be recorded in GFS as incurrence of pension liabilities (GFS transactions in liabilities item 33063) and not as revenue from social contributions (GFS revenue item 12). The SNA values can be derived from the detailed records of the pension schemes.

The secondary distribution of income account

A7.44 The secondary distribution of income account covers redistribution of income through current transfers (other than social transfers in kind made by government and NPISHs to households).[15] In addition to carrying forward the balance of primary income, this account records:

- Current taxes on income, wealth, etc. (D5 in SNA) as a resource for government, divided further into taxes on income (D51 in SNA) and other current taxes (D59 in SNA)
- Net social contributions (D61 in SNA) as a resource for government
- Social benefits other than transfers in kind (D62 in SNA) as a use for government
- Other current transfers (D7 in SNA), both as a resource and a use.

A7.45 The net social contributions (D61) are the actual and imputed contributions made by households to social insurance schemes. The net contributions exclude fees charged by the administrators of the schemes, which should be recorded as an expense for households for services rendered. The net social contributions are divided into four subcategories in the SNA, with each of the net social contribution subcategories further divided into pension and nonpension contributions. The subcategories for net social contributions are:

- Employers' actual social contributions (D611)
- Employers' imputed social contributions (D612)

[15] Social transfers in kind are recorded in the redistribution of income in kind account.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

- Households' actual social contributions (D613)
- Households' social contributions supplements (D614).

A7.46 The amount recorded for net social contributions receivable by units operating social insurance schemes can be different in the GFS and SNA datasets due to differences in the treatment of contributions to employment-related pension schemes. In the SNA, amounts payable to the operator of the scheme as social contributions (D6111, D6121, and D6131) are included in the secondary distribution of income, with a subsequent adjustment for the change in pension entitlements to record the incurrence of pension liabilities (F63 in SNA). GFS record social contributions payable to employment-related schemes providing pensions and other retirement benefits directly as transactions increasing the scheme's liabilities for pension entitlements (GFS item 33063) by the operator of the scheme.[16] In the SNA, all social benefits payable, including pensions and other retirement benefits, are recorded either in the secondary distribution of income account as social benefits other than social transfers in kind (D62), or in the redistribution of income account as social transfers in kind (D63). In addition, all pensions and other retirement social benefits payable are recorded as a reduction in pension entitlements (F63).

A7.47 Unlike the SNA, transfer expense in GFS excludes government employee pension and retirement benefits payable. These benefits are reported only as a transaction reducing liabilities for *pension entitlements* (GFS liability item 33063). As a result, GFS does not need the item for adjustment for change in pension entitlements. Also, unlike in the SNA, benefits in the form of goods and services produced by general government units are not recorded as social benefits in GFS, but in the various GFS expense categories corresponding to the costs of producing these goods and services, such as compensation of employees, and use of goods and services, etc.

A7.48 As stated in Box A7.1, goods and services produced by the general government sector and provided as social benefits in kind, grants in kind, or transfers in kind are recorded in the SNA as the production of output and a transfer to the beneficiaries. These transfers are recorded in the secondary distribution of income account, as if received in cash by the beneficiaries, accompanied by a sale of the output to the beneficiaries.

A7.49 Other current transfers (D7) in the SNA are a disparate collection of entries that are found in various categories in GFS:

- Net nonlife insurance premiums (D71) is the equivalent of net nonlife insurance *premiums* (GFS revenue item 14511 and GFS expense item 28311), adjusted for the imputation of the sale or purchase of insurance services, as described in paragraph A7.29.
- Nonlife insurance claims (D72) are the equivalent of the current nonlife insurance claims in GFS (GFS revenue item 14513and GFS expense items 28313).
- Current transfers within general government (D73) and current international cooperation (D74) in the SNA are recorded in GFS as *current grants* receivable (GFS revenue categories 1311, 1321, or 1331) or payable (GFS expense categories 2611, 2621, or 2631) except for goods and services produced by general government units and distributed in kind (see Box A7.1).
- Miscellaneous current transfers (D75) in the SNA are recorded in GFS as *fines, penalties, and forfeits* (GFS revenue item 143), *other current transfers not elsewhere classified* (GFS revenue item 14412), *current transfers not elsewhere classified* (GFS expense item 2821), adjusted with transfers of goods and services produced by general government units and distributed in kind (see Box A7.1).

A7.50 The balancing item of the secondary distribution of income account is disposable income. For households, this income can be used for final consumption expenditure and saving. For nonfinancial and financial corporations, disposable income is income not distributed to owners of equity minus taxes payable on income. The disposable income can be presented gross or net of consumption of fixed capital.

The redistribution of income in kind account

A7.51 The redistribution of income in kind account records social benefits in kind and transfers of individual nonmarket goods and services from the government sector to the household sector using the goods or services. Because of the nature of the transactions

[16] Actual and imputed contributions to pension and other retirement benefit schemes are therefore excluded from GFS revenue from *social contributions* (GFS revenue category 12).

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

concerned, this account is significant only for government, households, and NPISHs. The account records two elements of the redistribution process. The first is nonmarket production by government and NPISHs of individual services, and the second is the purchase by government and NPISHs of goods and services for transfer to households free of charge or at prices that are not economically significant. The redistribution of income in kind account records social transfers in kind as resources for households and as uses of government and NPISHs. The balancing item of the redistribution of income in kind account is adjusted disposable income.

A7.52 The Classification of Functions of Government (COFOG) can be used to assist in deriving the government individual consumption expenditure (P31 in SNA). Government's social benefits in kind should be equal to the nonmarket produced social transfers in kind (D631 in SNA). See Table A7.4 for a presentation of the corresponding GFS expense items. Government collective consumption (P32 in SNA) is equal to its actual final consumption (P4 in SNA).

The use of disposable income account

A7.53 The use of income accounts exists in two variants, the use of disposable income account and the use of adjusted disposable income account. Both accounts show for the three sectors that undertake final consumption—namely, the household sector, the NPISH sector, and the general government sector—how disposable income or adjusted disposable income is allocated between final consumption and saving. It measures that part of income, domestically or abroad, that is not used for final consumption. Savings can be shown on a gross or a net basis (depending on whether consumption of fixed capital is included).

A7.54 In the SNA, gross saving is the balancing item before capital transactions and can be derived by excluding from the net lending/net borrowing the capital transfers receivable/payable, gross capital formation and acquisitions minus disposals of nonfinancial nonproduced assets. Gross saving can also be derived as disposable income minus final consumption. Since net lending/net borrowing in the SNA and GFS is conceptually the same, for the general government or public sector, gross saving can be derived from GFS, as follows:

Net lending/net borrowing

Minus: Capital grants/transfers receivable

Plus: Capital grants/transfers payable

Plus: Net acquisition of nonfinancial assets.

To get from net saving to gross saving, consumption of fixed capital needs to be added.

A7.55 The use of disposable income account and the use of adjusted disposable income account calculate saving as a balancing item. The two measures of saving are the same, but calculated differently.

- The use of disposable income account calculates saving using:
  - Disposable income as a resource
  - Final consumption expenditure as a use
  - An adjustment item showing the adjustment for the change in pension entitlements.
- The use of adjusted disposable income account calculates saving as a balancing item using:
  - Adjusted disposable income as a resource
  - Actual final consumption as a use
  - An adjustment item showing the adjustment for the change in pension entitlements.

A7.56 Final consumption is a key component of the use of disposable income account and gross domestic product. The concept is implemented in the SNA in two ways: final consumption expenditure (P3) and actual final consumption (P4). The difference between them is social transfers in kind (D63), which represents the final consumption of goods and services purchased by general government units but actually consumed by households.

A7.57 Final consumption expenditure is not an element of GFS. Final consumption expenditure can be calculated using linkages with GFS data established earlier. It can be calculated as:

Total output minus output related to own-account capital formation;[17]

Plus: Purchases of goods and services that are transferred to households without further transformation;[18]

[17] As illustrated in Tables A7.3 and A7.4, this corresponds to the sum of the following GFS categories: 1421+21.2+22.2+23.2+FISIM.

[18] As illustrated in Tables A7.3 and A7.4, this corresponds to the sum of the following GFS categories: 2712+2722+2732+2821.32+2821.42.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Minus: Actual and imputed sales of goods and services (GFS revenue item 142);[19]

Minus: Changes in inventories of work in progress and finished goods (GFS items 31222 and 31223).

A7.58 In GFS, purchases of goods and services that are transferred to final consumers without further transformation are classified as *social security benefits in kind* (GFS expense item 2712), *social assistance benefits in kind* (GFS expense item 2722), *employment-related social benefits in kind* (GFS expense item 2732), or the in-kind portion of *current transfers not elsewhere classified* (GFS expense item 2821), depending on the nature and the organization of the distribution.

A7.59 The GFS expense categories for social benefits in kind include reimbursements to households for purchases of goods and services receivable as social benefits in kind, and direct purchases by general government units of goods and services from market producers and provided as social benefits in kind. In addition, the GFS item for *transfers not elsewhere classified* (2821) may include purchases of goods and services from market producers that are distributed directly to households for final consumption other than social benefits. Goods and services produced by government themselves and subsequently used as transfers in kind are not reported as in-kind transactions in GFS, but are included in the SNA concept for social transfers in kind (D63).

A7.60 Because the SNA separately measures production and distribution of goods and services, transactions in kind are normally recorded in the accounts as if they are monetary transfers followed by the beneficiary spending the transfer to obtain the goods and services concerned. Therefore, social transfers in kind (D63) consist of final consumption expenditure undertaken by government and NPISHs on behalf of households. For this reason they are described as individual goods and services. Information on these individual goods and services may be obtainable from the cross-classification of the COFOG and economic type of expense in Table 6A.2. The annex to Chapter 6 lists the services that are considered individual.

[19] When an existing good is sold, the amount receivable from its sale is recorded as negative final consumption expenditure if the initial outlay on the good was classified as final consumption expenditure.

A7.61 In the SNA, an adjustment is made in the use of disposable income account, as well as in the use of adjustment disposable income account for the change in pension entitlements (D.8). This adjustment for the change in pension entitlements is equal to:

The total value of the actual social contributions payable to funded pension schemes,

Plus: The total value of the imputed social contributions payable to employment-related pension schemes,

Plus: The total value of social contribution supplements,

Minus: The value of the associated service charges;

Minus: The total value of the pensions paid out as pension benefits by the pension schemes.

The different treatment of pension schemes eliminates the need for this adjustment item in the GFS framework (see paragraph 5.95).

The accumulation accounts

A7.62 Saving is the balancing item of the last of the current account in the SNA and the starting point for the accumulation accounts. The first group of accumulation accounts, comprising the capital and financial accounts, covers transactions in assets or liabilities and changes in net worth due to capital transfers. A second group of accumulation accounts, comprising the other changes in volume of assets account and revaluation account, relates to changes in assets and liabilities caused by factors other than transactions.

The capital account

A7.63 The capital account records transactions linked to the acquisition of nonfinancial assets and capital transfers. The account starts with net saving, the final balancing item of the current accounts, and records transactions in nonfinancial assets and capital transfers. The balancing item is either *net lending (+)*, which measures the net amount available to finance other sectors, or *net borrowing (–)* which corresponds to the net financing from other sectors.

A7.64 Most of the entries in the capital account of the SNA can be derived from the corresponding entries in GFS. For example, the gross fixed capital

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

formation (P51g) minus the consumption of fixed capital (P51c) is the net investment in fixed assets in GFS (GFS item 311). As indicated in Table A7.5, the *2008 SNA* classification of categories of nonfinancial assets has been fully incorporated in GFS. However, in the SNA, fixed assets are also classified into:

- Acquisition of new fixed assets (item 311.P5111 in Table A7.5)
- Acquisition of existing fixed assets (item 311. P5112 in Table A7.5)
- Disposal of existing fixed assets (item 311.P5113 in Table A7.5).

This distinction between new and existing assets is not available from GFS, and would require supplementary information from source data systems.

A7.65 Consumption of fixed capital in the SNA (P51c) equals the sum of the expense item of the same name in GFS (GFS expense item 23) and the consumption of fixed capital that was capitalized as part of own-account capital formation (GFS item 3M13).

A7.66 Changes in inventories (P52), acquisitions minus disposals of valuables (P53), and acquisitions minus disposals of nonproduced assets (NP) are the same as the net investment in the corresponding items in GFS (GFS items 312, 313, and 314, respectively).

A7.67 In the SNA, capital transfers receivable and payable (D9r) are recorded as capital taxes (D91r), investment grants (D92r), and other capital transfers (D99r). These transfers are included in GFS as follows:

- Capital taxes (D91r) receivable by the general government sector can directly be related to GFS revenue recorded in *estate, inheritance, and gift taxes* (GFS revenue item 1133) and *other nonrecurrent taxes on property* (GFS revenue item 1135). Where these taxes are payable by one level of government to another, they are included in the expense item *capital transfers not elsewhere classified* (2822) of the payee.
- Investment grants (D92r) consist of all capital transfers made by governments to other resident or nonresident institutional units to finance all or part of the costs of their acquiring fixed assets. These investment grants receivable/payable are a component of *capital grants receivable* (GFS revenue items 1312, 1322, or 1332), and a component of *capital grants payable* (GFS expense items 2612, 2622, and 2632).
- Other capital transfers (D99r) consist of all capital transfers except capital taxes and investment grants. One notable category included here is capital transfers related to debt cancellation by mutual agreement. In GFS, these are a component of *capital grants* (GFS revenue items 1312, 1322, or 1332 or GFS expense items 2612, 2622, and 2632), *capital transfers not elsewhere classified* (GFS revenue item 1442 and GFS expense item 2822), and *capital claims* related to nonlife insurance (GFS revenue item 1452 and GFS expense item 2832).

The financial account

A7.68 The financial account in the SNA records transactions in financial assets and liabilities, classified by instruments. It therefore records the net acquisition of financial assets, and the net incurrence of liabilities. The balancing item, *net lending (+)/ net borrowing (–)*, is in principle equal to the *net lending (+)/ net borrowing (–)* in the capital account, although measured differently.

A7.69 Conceptually, the transactions recorded in the financial account of the SNA are identical to the transactions in financial assets and liabilities recorded in GFS (see Table A7.6). At the general government or public sector level the value of transactions in financial assets and liabilities could differ due to the different approach to consolidation (see paragraph A7.11). Some investment income disbursements (see paragraph A7.43) would likely be unknown to government, and would be calculated only in the context of the whole of the economy and therefore remain an adjustment item between GFS and national accounts. Amounts recorded as transactions in insurance, pension, and standardized guarantee schemes may also differ due to the option in the SNA to treat some employment-related liabilities in supplementary rather than the main tables (see paragraph 5.95).

The other changes in the volume of assets accounts

A7.70 The other changes in the volume of assets account in the SNA records the same economic events as those recorded in GFS (GFS items 5***); the total value of changes should therefore be consistent in

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

the two datasets. In both datasets, the other changes in volume of assets are recorded for each type of assets and liabilities. In addition, the SNA also classifies these changes according to specific events that give rise to the change in the volume of the assets or liabilities. Data are separately recorded for economic appearance of assets (K1), economic disappearance of nonproduced nonfinancial assets (K2), catastrophic losses (K3), uncompensated seizures (K4), other changes in volume not elsewhere classified (K5), and changes in classification (K6). Source data for recording these events should therefore provide for identification of the relevant assets and liabilities, but also identify the underlying event that caused the change in the volume.

The revaluation account

A7.71 The revaluation account in the SNA records the same holding gains or losses as those recorded in GFS (GFS items 4***). The total value of nominal holding gains for the general government or public sector should therefore be the same in the two datasets. In addition, the SNA recommends that nominal holding gains and losses be further subdivided between neutral and real holding gains and losses. GFS do not make this distinction:

- *Neutral holding gains and losses* (B1031) over a period are the increase (decrease) in the value of an asset that would be required, in the absence of transactions and other changes in the volume of assets, to maintain command over the same amount of goods and services as at the beginning of the period. The value is obtained by applying, during the same periods of time, an index of the change in the general price level to the initial value of all assets or liabilities. The result of this operation is called neutral holding gains and losses because all assets and liabilities are revalued so as to preserve exactly their purchasing power.
- *Real holding gains and losses* (B1032) record the difference between nominal holding gains and losses and neutral holding gains and losses.

The balance sheet

A7.72 The opening and closing balance sheets for the general government or public sector are conceptually the same in the SNA and GFS. Both datasets display assets on the left-hand side, and liabilities and net worth on the right-hand side. The changes in the *Balance Sheet* in the SNA are the sum of the entries in the four accumulation accounts corresponding to the respective asset or liability. Similarly, in GFS the changes in the *Balance Sheet* for each category of assets and liabilities are equal to the sum of transactions, holding gains and losses, and other changes in volume. The classification of assets and liabilities in the two frameworks are fully consistent. However, at the general government or public sector level the value of stock positions in financial assets and liabilities could differ due to the different approach to consolidation (see paragraph A7.11). In practice amounts recorded as stock positions may also differ in two cases:

- Liabilities in respect of employment-related pension schemes may differ, due to the option in the SNA to treat some employment-related liabilities in supplementary tables (see paragraph 5.95).
- Assets and liabilities subject to investment income disbursements may differ in cases where these amounts are unknown to government, and therefore excluded from GFS, and would be calculated only in the context of the whole of the economy (see paragraph A7.43).[20]

Comparison of the Analytical Frameworks of GFS and the Balance of Payments and the International Investment Position

A7.73 The *BPM6* serves as the standard framework for statistics on the flows and stock positions between an economy and the rest of the world. Since the *BPM6* is harmonized with the *2008 SNA*, it is also harmonized with the other macroeconomic datasets, including GFS. Because of conceptual linkages, compilers of the international accounts and GFS should consult to ensure the consistent application of definitions of coverage and concepts, and accounting rules.

Comparison of the Accounts in GFS and Balance of Payments and the International Investment Position

A7.74 The structure of the international statistical framework is similar to the structure used in the GFS framework, and comprises (i) *the balance*

[20] The SNA also provides volume measures (including of government components)—an important type of information for fiscal analysis that makes the SNA complementary to GFS.

of payments, which summarizes economic transactions between residents and nonresidents during a specific time period; (ii) *the other changes in financial assets and liabilities*, which show flows due to economic events other than transactions between residents and nonresidents, and include valuation changes; and (iii) *the international investment position* (IIP), which shows the value of the financial asset and liability stock positions between the residents of an economy and nonresidents at a reporting date. The difference between the opening and closing stock positions of the IIP is explained by the sum of transactions and other changes in financial assets and liabilities.

Linkages between GFS and Balance of Payments and the International Investment Position

A7.75 The *BPM6* framework provides a sequence of accounts, each encompassing a separate economic process or phenomenon and a balancing item. The remainder of this section describes how the various international accounts correspond to GFS.

The balance of payments

A7.76 The **balance of payments** summarizes economic transactions between residents and nonresidents during a specific time period. The different accounts within the balance of payments are distinguished according to the nature of the economic resources provided and received, and comprise the following:

- *The current account* shows flows of goods and services, primary income, and secondary income between residents and nonresidents.
- *The capital account* shows flows for transactions in nonproduced nonfinancial assets, and capital transfers between residents and nonresidents.
- *The financial account* shows net acquisition and disposal of financial assets and liabilities.
- The sum of the balances on the current and capital accounts represents the net lending (surplus) or net borrowing (deficit) by the resident economy with the rest of the world. This is conceptually equal to the net balance of the financial account. It is also conceptually equal to the sum of net lending/borrowing for all the resident sectors.

The current account

A7.77 The *current account* shows flows of goods and services, primary income, and secondary income between residents and nonresidents. The balance on this account, known as the current account balance, shows the difference between the sum of exports and income receivable and the sum of imports and income payable. The current account balance represents the saving-investment gap for the economy.

The goods and services account

A7.78 The goods and services account shows transactions in items that are outcomes of production activities. The focus of the account is the point at which goods and services[21] are exchanged between a resident and a nonresident. Production is an activity in which an enterprise uses inputs (intermediate inputs, labor, produced and nonproduced assets) in order to transform them to an output that can be supplied to other units.

A7.79 The GFS *Statement of Operations* has a linkage to the goods and services account to the extent that general government/public sector units enter into transactions with nonresidents, involving goods and services, either as a producer/seller or user of these goods or services. GFS will usually not separately identify these transactions, which limits opportunities for reconciliation between the goods and service account and GFS. However, in some cases, supplementary information in the underlying source data may identify such transactions—either because of their nature, large volumes, or large values of the transactions. Specifically, where produced assets are exchanged, contractual arrangements may be publicly available and should be consistently treated in the goods and services account of the balance of payments and GFS.

A7.80 The goods and services account requires that goods and services be classified according to the nature of the good or service. One of these specifically requires the separate disclosure of *government goods and services not included elsewhere*, which cover:

- Goods and services supplied by and to enclaves, such as embassies, military bases, and international organizations

[21] Goods as used in this context include both consumer goods and produced nonfinancial assets.

[1]Both financial assets and liabilities are classified further into domestic and external in the same subcategories except that liabilities and domestic assets exclude monetary gold.

[2]To the extent that nonpension entitlement reserves exist, such liabilities are included with those for pension entitlements for pragmatic reasons (see paragraph 7.195).

- Goods and services acquired from the host economy by diplomats, consular staff, and military personnel located abroad and their dependents
- Services supplied by and to governments and not included in other categories of services.

A7.81 Government and international organization enclaves are not residents of the territory in which they are physically located. Therefore, their transactions with residents of that territory or location are international transactions. However, all expenditure on goods and services by locally engaged staff of the enclave is excluded from international transactions. In addition, government supply of licenses and permits to nonresidents that are classified as fees and some activities related to technical assistance provided by one country to another are included in goods and

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

services.[22] The GFS classifications do not specifically require the identification of transactions in goods and services with nonresidents. However, where these transactions can be identified and classifications are built into the underlying general government sector accounting system, the information should be provided to balance of payments compilers. The value of transactions in goods and services entered into with nonresidents in GFS may differ from the international statistics that follow the SNA treatment of insurance services and standardized guarantee fees (see paragraph A7.29).

The primary income account

A7.82 The *primary income account* shows primary income flows between resident and nonresident institutional units. Primary income represents the return that accrues to an institutional unit for its contribution to the production process or for the provision of financial assets and renting natural resources to other institutional units.

A7.83 The international accounts distinguish the following types of primary income:

- Compensation of employees
- Investment income
  - Dividends
  - Reinvested earnings
  - Interest
  - Investment income attributable to policyholders in insurance, standardized guarantees, and pension funds
- Other primary income
  - Rent
  - Taxes on production and imports
  - Subsidies.

A7.84 The consistency in data between the GFS and primary income account can be established only to the extent that sufficient supplementary details are separately identified in GFS, or the underlying source data. The following linkages exist between the primary income account and GFS:

- *Compensation of employees*: To the extent that the resident government employs nonresident individuals, compensation of employees of government would include amounts payable to nonresidents that should be recorded in the primary income account of the balance of payments. Because government employment usually has some residence criteria as a precondition, these amounts are often not very large. However, in the case of territorial enclaves, all compensation of employees payable by government to residents of the host country should be included in the primary income account. The GFS classifications do not specifically require the identification of compensation of employees to nonresidents. However, when such payments are identified in the underlying source data system, the information should be reported consistently in the GFS and primary income account.
- *Investment income*: The contribution of the general government sector to investment income is mainly derived from the nonresident portion of the GFS items *interest* (GFS revenue item 1411 and GFS expense item 24) and *dividends* (GFS revenue item 1412 and GFS expense item 2811). It can therefore be linked with the GFS accounts, if underlying source data distinguish between receivables and payables from/to residents and nonresidents. While the categories of investment income are conceptually the same for GFS and the international accounts, the value of transactions with nonresidents in GFS may differ from the international statistics due to the treatment of FISIM (see paragraph A7.29). Where general government sector units control insurance, standardized guarantees or pension schemes, they attribute investment income to policyholders in these schemes. These policyholders may include nonresidents, in which case the relevant portion of the *property expense for investment income disbursement* (GFS expense item 2813) should be consistent with the corresponding item recorded in the primary income account. Where a general government unit or public corporation has foreign direct investments in nonresident special purpose entities (SPEs), or foreign branches of public corporations, reinvested earnings, as reported in the primary income account, should be recorded separately in GFS (GFS revenue item 1416). Similarly, where public corporations have foreign direct investors or investment fund shares/units, reinvested earnings should be

[22] See the *BPM6*, paragraphs 10.173–10.181. The criteria for the identification of these fees are the same as in the SNA and GFS.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

included in the primary income accounts, and should be consistent with amounts reported in GFS (GFS expense item 2815).

- *Other primary income*: In calculating other primary income, linkages with the GFS data arise from the transactions with nonresidents related to *subsidies* (GFS revenue item 144111 and GFS expense item 25) and *rent* (GFS revenue item 1415 and GFS expense item 2814). Where information on such payments or receipts is provided in the underlying source data, these data should be consistent with the primary income account. The taxes on production and on imports reported in the balance of payments primary income account constitute the portion of these taxes collected from nonresidents and are the same tax categories as the corresponding item in the SNA (D2 in SNA). Taxes on production and on imports are the sum of several detailed GFS tax categories:
  - *Recurrent taxes on immovable property* (GFS item 1131)
  - *Recurrent taxes on net wealth* (GFS item 1132)
  - *Other recurrent taxes on property* (GFS item 1136)
  - *General taxes on goods and services* (GFS item 1141)
  - *Excises* (GFS item 1142)
  - *Profits of fiscal monopolies* (GFS item 1143)
  - *Taxes on specific services* (GFS item 1144)
  - *Taxes on use of goods and on permission to use goods or perform activities*—Payable by producers (GFS item 1145)
  - *Other taxes*—Payable by business (GFS item 1161).

A7.85 To allow consistency checks with the primary income account in the balance of payments, these GFS tax categories need to be divided between amounts receivable from residents and nonresidents. These subcategories are normally not available from GFS, and would be useful only for deriving credits in the primary income account. While certain taxes on production and imports are easier to divide between residents and nonresidents, others are more difficult. Also, the portion attributable to nonresidents may vary from one tax category to the next and from one year to the next.

The secondary income account

A7.86 The secondary income account in the balance of payments shows current transfers between residents and nonresidents. This account shows redistribution of income; that is, when resources for current purposes are provided by one party without anything of economic value being supplied as a direct return to that party. Various types of current transfers are recorded in this account to show their role in the process of income distribution between economies. The extent to which governments are involved in these transfers will determine the linkages between the GFS *Statement of Operations* and this account.

A7.87 The standard components of the secondary income account make a distinction at the first level between current transfers receivable/payable by general government and by other sectors, comprising the financial corporations, nonfinancial corporations, households, and NPISHs. For the general government, these transfers include the transfers in respect of:

- Current taxes on income, wealth, etc.
- Social contributions
- Social benefits
- Net nonlife insurance premiums
- Nonlife insurance claims
- Current international cooperation
- Miscellaneous current transfers.

A7.88 To the extent that the current transfers of general government are identifiable and reported in GFS as being from or to nonresidents, these data should be consistently reported in the secondary income account of the balance of payments.

- Current taxes on income, wealth, etc. reported in the secondary income account make up the nonresident portion of the same tax categories as in the *2008 SNA* (D5 in SNA). Current taxes on income, wealth, etc. are the sum of several detailed tax categories as reported in GFS, and comprise *taxes on income, profits and capital gains* (GFS item 111) and several other tax categories mainly payable by final consumers (see paragraph A7.40).
- Social contributions (D61 in SNA) receivable from nonresidents by general government sector units or social benefits payable to nonresidents

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

(D62 and D63 in SNA) may be different from the corresponding GFS items (see paragraphs A7.45–A7.47).

- Current international cooperation is separately reported in the GFS *Statement of Operations* and should be reported consistently in the secondary income account. *Grants payable to foreign government* and *international organizations* (GFS item 2611 and 2621 respectively) and *grants receivable from foreign governments* and *international organizations* (GFS item 1311 and 1321 respectively) are usually the most important linkage between the GFS and the secondary income account.
- Other miscellaneous current transfers (D75 in SNA)[23] comprise various items of current transfers receivable and payable (see paragraph A7.49).
- Current transfers of government sector units related to nonlife insurance premiums and claims and miscellaneous current transfers would require a distinction of those receivable or payable to resident and nonresidents.

The capital account

A7.89 The capital account in the international accounts shows transactions between residents and nonresidents related to capital transfers receivable and payable and the acquisition and disposal of nonproduced nonfinancial assets. It records acquisitions and disposal of nonproduced nonfinancial assets, such as land sold to embassies and sales of leases and licenses, as well as capital transfers—that is, the provision of resources for capital purposes by one party without anything of economic value being supplied in direct return to that party.

A7.90 Nonproduced nonfinancial assets consist of five items: *land*, *mineral and energy resources*, and *other naturally occurring assets*, *contracts, leases, and licenses*, and *marketing assets and goodwill* (GFS items 3141, 3142, 3143, 31441, and 31442, respectively). There is full consistency in the macroeconomic statistical framework with regards to the items of nonproduced nonfinancial assets that exist. Where general government sector units acquire or dispose of these assets in transactions with nonresidents, supplementary information would be required from the GFS transactions to allow compilation or consistency checks with the international accounts.

A7.91 It should be noted that the capital account in the balance of payments does not show produced nonfinancial assets, as is the case in the SNA and GFS. It shows only transactions in nonproduced nonfinancial assets. Transactions in produced nonfinancial assets are included in the goods and services account, which does not distinguish whether those goods or services are destined for capital or current purposes.

A7.92 Conceptually capital transfers are the same as the capital transfers recorded in the SNA and GFS. Governments are often involved in these transfers, which should be reported in a consistent way in GFS and the capital account of the balance of payments. These capital transfers consist of compulsory transfers to governments, transfers under court orders, and voluntary transfers. There may also be imputed capital transfers as a result of governments' use of special purpose entities resident in other economies, for fiscal purposes (see paragraph 2.138 and paragraphs 8.24–8.26 of the *BPM6*). The capital account of the balance of payments includes the following main types of capital transfers:

- *Debt forgiveness*: When government/public sector entities are involved in debt forgiveness (see paragraphs A3.7–A3.9), either as a recipient or grantor, the event is usually well known and it should be identifiable in the GFS accounts. In the balance of payments capital account, debt forgiveness received from nonresidents is reflected as revenue in *capital grants* received from either foreign governments, international organizations, or included in *capital transfers not elsewhere classified*, when received from other nonresident entities. The corresponding entries in GFS are recorded in GFS items 1312, 1322, or 1442 respectively. A corresponding reduction in the appropriate foreign debt instrument will be recorded. When the government sector unit is the provider of debt relief to a nonresident, an expense is reflected as *capital grants* to foreign governments or international organizations, or is included in *capital transfers not elsewhere classified*, when provided to other nonresident entities. The GFS expense is recorded in GFS items 2612, 2622, or 2822, respectively. A corresponding

[23] The detailed corresponding GFS categories are shown in Tables A7.3 and A7.4.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

reduction in the appropriate foreign financial asset is recorded.

- *Exceptionally large nonlife insurance claims*: Where these claims are receivable/payable by government sector units, they are recorded as capital claims (GFS revenue item 1452 or GFS expense item 2832, respectively). Due to the extraordinary nature of this item, it is usually well known and visible in the GFS data, and will allow inclusion in the international accounts.
- *Investment grants in the balance of payments*: These are capital transfers in cash or in kind made by governments or international organizations to other institutional units to finance all or part of the cost of their acquiring fixed assets. Government/public sector units can be the grantor or recipient of these investment grants. These transfers are recorded in GFS *capital grants*, as described earlier.
- *One-off guarantees and other debt assumption*: When government/public sector units and nonresidents are involved in these transactions (see paragraph 7.256–7.260), it should be consistently treated in the capital account and GFS.
- *Capital taxes* (defined in paragraph 5.51): Those capital taxes recorded in the capital account of the balance of payment comprise the same tax categories as the corresponding item in the SNA (D91 in SNA), but represent only the portion of these taxes collected from nonresidents (see paragraph A7.67). Consistency for this item in the capital account and GFS requires a breakdown of these taxes in supplementary GFS data between amounts receivable from residents and nonresidents.
- *Other capital transfers*: These consist of major nonrecurrent payments in compensation for extensive damage or serious injuries not covered by insurance policies. Where government/public sector units are the recipient of this type of transfer from nonresidents, it is recorded as part of *capital grants* receivable from either foreign governments, international organizations, or included as *capital transfers not elsewhere classified*, when received from other nonresident entities (GFS revenue items 1312, 1322, or 1442, respectively). When the government/public sector unit is the grantor of this type of transfer to a nonresident, an expense is reflected as *capital grants* to foreign governments, international organizations, or as *capital transfers not elsewhere classified*, when provided to other entities (GFS expense items 2612, 2622, or 2822, respectively). Consistency for this item in the capital account and GFS also requires a further breakdown of the transfers to identify amounts receivable or payable to nonresidents.

The financial account

A7.93 The financial account of the balance of payments records transactions that involve financial assets and liabilities that take place between residents and nonresidents. Financial account transactions appear in the balance of payments and, because of their effect on the stock of assets and liabilities, also in the integrated IIP statement. The net balance on the financial account is conceptually equal to the sum of the balances on the current and capital accounts (*net lending (+)/net borrowing (–)*). The financial account therefore measures how the net lending to or net borrowing from nonresidents is financed.

A7.94 The international accounts use functional categories as the primary classification for each of the financial transactions, other changes in assets and liabilities, and stock positions.[24] Five functional categories of investment are distinguished in the international accounts:

- Direct investment
- Portfolio investment
- Financial derivatives (other than reserves) and employee stock options
- Other investment
- Reserve assets.

This functional classification takes into consideration some aspects of the relationship between the parties and the motivation for investment (see the *BPM6*, Chapter 6). In addition, data in the financial account are also presented according to the financial asset or liability instrument employed, the sector or the resident counterpart to the transaction, and maturity. Although the classification of financial assets and liabilities as presented in GFS does not follow

[24] The term functional classification is used in a different context in the classification of the functions of government.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

a functional classification, it is fully consistent with the instrument breakdown and sector classification as used in the international accounts. As regards financial assets and liabilities the GFS framework distinguishes between transactions with residents and nonresidents. GFS follow the same criteria for determining residence as the international accounts. Conceptually, therefore, the GFS data are consistent with the data for general government as presented in the financial account of the balance of payments.[25]

The other changes in financial assets and liabilities account

A7.95 In the international accounts, the other changes in financial assets and liabilities account shows changes in financial positions that arise for reasons other than transactions between residents and nonresidents. These changes are also called other flows, and, similar to GFS, they include holding gains and losses, and other volume change in financial assets and liabilities (including reclassifications). Because of the importance of different currencies in the IIP, revaluations (holding gains and losses) are broken down between changes due to exchange rates and other price changes. As described in earlier paragraphs, the classification of assets and liabilities by financial instruments is conceptually fully consistent in the GFS and international accounts. It should result in consistency in the data reported for these other flows in the two datasets, except in the case of liabilities for pension entitlements that may differ.

The international investment position

A7.96 The international investment position (IIP) is a statistical statement that shows at a point in time the value of: financial assets of residents of an economy that are claims on nonresidents and gold bullion held as reserve assets, and the liabilities of residents of an economy to nonresidents. The difference between the assets and liabilities is the net position in the IIP and represents either a net claim on or a net liability to the rest of the world. The IIP represents a subset of the assets and liabilities included in a country's balance sheet. In addition to the IIP, this balance sheet incorporates nonfinancial assets as well as financial assets and liability positions between residents.

A7.97 As is the case for the financial account, the highest level of classification used in the IIP is the functional classification (see paragraph A7.94). Because of the growing importance of the balance sheet approach to analyze sustainability and vulnerability, the recording in the IIP of information by currency composition is part of the standard presentation, while remaining maturity is encouraged.

A7.98 General government's financial asset/liability positions with nonresidents, as reported in the GFS balance sheet, follow the same accounting rules and classification by instruments as the IIP. Additional reporting requirements on remaining maturity breakdowns and currency breakdowns, as recommended in the *PSDS Guide* and GFS, are also fully consistent.

Comparison of the Analytical Frameworks of GFS and the Monetary and Financial Statistics

A7.99 The *MFSM* is part of international macroeconomic statistical guidelines and can therefore be seen as extending and elaborating on the *2008 SNA*. The *MFSM* framework is consistent with the *1993 SNA* with respect to principles and concepts, like the delineation of resident and nonresident entities, sectorization of the economy, classification of the various categories of financial assets and liabilities, time of recording, valuation, and data aggregation. On consolidation, the *MFSM* follows GFS in consolidating sectoral balance sheets. The main principles and concepts of the *MFSM* also accord with those in the *BPM6* and this *Manual.*

Comparing the Accounts in GFS and Monetary and Financial Statistics

A7.100 The purpose of the *MFSM* is to provide guidelines for the compilation and the presentation of monetary and financial statistics. *Monetary statistics* consist of a comprehensive set of stock and flow data on the financial and nonfinancial assets and liabilities of an economy's financial corporations sector. The organization and presentation of monetary statistics follow a hierarchical approach based on two general data frameworks—sectoral balance sheets and surveys. Stock position data reported by individual

[25] The international accounts identify general government, but do not present data for the subsectors of the general government, as is the case in GFS.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

institutional units are aggregated into sectoral balance sheets, which contain the comprehensive data for the financial corporations subsectors. At a second level, the data in the sectoral balance sheets are consolidated into surveys.

A7.101 *Financial statistics*, on the other hand, consist of a comprehensive set of flows and stock position data on financial assets and liabilities of all sectors of an economy. These data are organized and presented in formats designed to show financial flows among the sectors of an economy and corresponding financial asset and liability positions. Also included in monetary and financial statistics are the *flow of funds* data, presented in a matrix format. A detailed flow of funds accounting cross-classifies financial assets acquired by each sector, by instrument with the counterpart debtor sector. It also cross-classifies liabilities incurred by each sector by instrument and counterpart creditor sector. Therefore, this matrix shows the financial transactions among all subsectors of an economy and the rest of the world. Such a presentation is particularly useful to analyze the allocation of financial resources and users in an economy.

Linkages between GFS and Monetary and Financial Statistics

A7.102 Linkages between GFS and the monetary and financial statistics (MFS) result from the financial relations between government and financial corporations. As clients (and in addition to holding currency), governments hold deposit assets with financial corporations and contract liabilities by borrowing from and selling debt securities to the corporations. As investors, governments generally are often the sole owner of public financial corporations or hold equity in other financial corporations. These financial relationships result in either a net claim of government on the financial corporations or a net claim of these corporations on government. The net asset/liability position between the general/central government sector and the financial corporations sector should be consistent, and reconcilable in the two datasets. The extent to which these data are similar is often a good indicator of the consistency in macroeconomic statistics in a country.

A7.103 Differences in the amounts reported as net claims between the government sector and the financial corporations sector could be used to check the accuracy and consistency of the respective datasets. Where the two sets of data are materially different, the reasons for the differences must be ascertained, and documentation on the size and reasons for the discrepancy should be provided to users of the data. Good statistical practice is for the compilers to investigate and try to resolve differences. Reasons for differences can often be found in:

- *Coverage*—In many cases, governments have numerous accounts held in several financial institutions. The institutional coverage of general/central government should be the same in both datasets. A common case exists where certain government institutions have accounts with financial institutions and MFS cover these accounts, but the accounts of these institutions are not covered in GFS because these GFS data are confined to budgetary accounts, thereby not covering the data of the extrabudgetary units. Differences may also arise if government has accounts with a financial institution, but this financial institution is not covered in the monetary and financial statistics.
- *Sectorization*—Some of the statistical institutional units may not be appropriately and consistently identified and classified as general government or public sector units or the sector classification of the subsectors may be different in the two datasets. For example, an institutional unit that manages and organizes externally financed projects and foreign grants may not be appropriately designated as a government account in financial corporations' records.
- *Classification and coverage of financial instruments*—The classification of financial instruments included in financial assets and liabilities may differ, or an instrument may not be consistently classified in the two datasets. For example, differences may arise when an instrument such as accounts receivable/payable is not treated the same way in the data, or when a loan is incorrectly reported as equity investment in one of the datasets.
- *Time of recording*—Complementary periods used in government accounting may result in transactions being recorded at a time other than when economic ownership changed hands.
- *Accrual versus cash recording*—Although conceptually both datasets should be recorded on an accrual basis, GFS compilers often use cash-based

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

data as a proxy for data compiled on an accrual basis, or make adjustments to cash data to approximate accrual data. The financial corporations sector is often more advanced in implementing accrual accounting. Often, certain items may not be correctly accrued to the time when the economic event occurred—for example, they may be using different methods to accrue discount or premiums on bonds.

- *Valuation*—While conceptually both datasets should follow the same valuation principles for assets and liabilities, national practices may differ. Where valuation differences in source data exist, differences may occur between GFS and monetary and financial statistics, unless valuation adjustments are made when the respective datasets are prepared.
- *Dematerializing of debt instruments*—Where governments issue tradable securities, they often have no knowledge or record of transactions in the secondary market, so the sector holding such securities can usually be determined either by surveying the ultimate purchaser of such securities or by using data from a centralized securities depository. However, quite often these instruments are held by nominees of the financial corporations sector, which may complicate the identification of the owners of claims of the government. The complexity of determining ownership of tradable instruments may further introduce inconsistency in the data.

A7.104 Due to the financial asset/liability positions held between general/central government and the financial corporations sector, some additional revenue and expense flows occur between these sectors. Further consistency checks can be performed on these revenue and expense transactions where the level of detail in the source data permits them. These relate specifically to receivables/payables in respect of interest, dividends, other property income, subsidies, and capital transfers between the general/central government sector and the financial corporations sector.

Comparison of the Analytical Framework of GFS and the System of Environmental-Economic Accounting Central Framework

A7.105 The *System of Environmental-Economic Accounting* (*SEEA*) *Central Framework* is the international statistical standard for environmental-economic accounting. The *SEEA Central Framework* contains the internationally agreed standard concepts, definitions, classifications, and accounting rules and tables for producing internationally comparable statistics on the environment and its relationship with the economy. The *SEEA Central Framework* is a multipurpose conceptual framework that presents the stock positions and changes in these stock positions (flows) of environmental assets.

Comparing the Accounts in GFS and SEEA Central Framework

A7.106 The *SEEA Central Framework* follows a similar accounting structure to the *2008 SNA* and this *Manual*, and uses consistent concepts, definitions, and classifications to facilitate the integration of environmental and other macroeconomic statistics. Consequently, the *SEEA Central Framework* allows for the integration of environmental information (often measured in physical terms) with economic information (often measured in monetary terms) in a single framework. However, given the specific analytical focus of the *SEEA Central Framework* on the environment and its linkages with the economy, as well as its focus on the measurement of flows and stock positions in physical and monetary terms, there are some limited differences between the *SEEA Central Framework* and the *2008 SNA*.[26] To the extent that *SEEA Central Framework* is consistent with the *2008 SNA*, it is also consistent with this *Manual.*

The Nature of Environmental Protection Activities and Accounting

A7.107 Environmental protection activities are those activities whose primary purpose is the prevention, reduction, and elimination of pollution and other forms of degradation of the environment. These activities include, but are not limited to, the prevention, reduction, or treatment of waste and wastewater; the prevention, reduction, or elimination of air emissions; the treatment and disposal of contaminated soil and groundwater; the prevention or reduction of noise and vibration levels; the protection of biodiversity and landscapes, including their ecological functions; monitoring of the quality of the natural environment (air, water, soil, groundwater); research

[26] See *SEEA Central Framework*, paragraphs 1.39–1.52.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

and development on environmental protection; and the general administration, training, and teaching activities oriented toward environmental protection.

A7.108 Resource management activities are those activities whose primary purpose is preserving and maintaining the stock of natural resources and hence safeguarding against depletion. These activities include, but are not limited to, reducing the withdrawals of natural resources (including through the recovery, reuse, recycling, and substitution of natural resources); restoring natural resource stocks (increases or recharges of natural resource stocks); the general management of natural resources (including monitoring, control, surveillance, and data collection); and the production of goods and services used to manage or conserve natural resources.

A7.109 To account for environmental protection and resource management activities the *SEEA Central Framework* comprises the following types of tables and accounts:

- Supply and use tables in physical and monetary terms showing flows of natural inputs, products, and residuals
- Asset accounts for individual environmental assets in physical and monetary terms showing the stock of environmental assets at the beginning and end of each accounting period and the changes in the stock
- A sequence of economic accounts that highlights depletion-adjusted economic aggregates
- Functional accounts that record transactions and other information about economic activities undertaken for environmental purposes.

The analysis of these data can also be extended by linking the tables and accounts to relevant employment, demographic, and social information.

A7.110 The *SEEA Central Framework* relies on basic environment statistics, such as statistics on natural resources—for example water, energy, forest, flows of materials and pollutants—which are usually collected for specific purposes. The *SEEA Central Framework* adds value to individual information components by bringing them together to inform integrated policies, evaluate trade-offs between different policies, and evaluate their impacts across domains of the economy, the environment, and society.

Linkages between GFS and SEEA Central Framework

A7.111 There is a wide range of transactions and stocks positions related to the environment that are recorded in the GFS framework. The type of transaction often flows from governments' role of owner of natural resources, such as land and subsoil assets, user of these resources, or other ways in which governments influence the use of these resources by other sectors, such as governments' control over the use of the atmosphere as a sink for pollution. Of particular interest in this regard are flows of taxes and subsidies related to the environment.

A7.112 Many of the mechanisms by which economic behavior is influenced toward meeting environmental policy objectives involve payments to government, most commonly in the form of taxes, permits, and rent; and payments by government in the form of subsidies and other transfers. These transactions are recorded in the GFS framework but are generally not separately identifiable as relating to the environment. In order to allow comparisons of GFS and the *SEEA Central Framework*, such data would need to be provided separately in the underlying source data of GFS.

A7.113 Similar to GFS, the *SEEA Central Framework* records only taxes and subsidies for which an actual transaction takes place between institutional units. In some cases there is interest in the value of so-called implicit subsidies—for example, via tax exemptions or preferential tax rates. However, as there are no transactions recorded in relation to these amounts they are not recorded in either dataset.

A7.114 The remainder of this section discusses payments to government related to the environment, and payments by government related to the environment.[27]

Environmental payments to government

Environmental taxes

A7.115 The decision as to whether a payment regarded as a tax is environmental is based on consideration of the tax base. An **environmental tax** is a tax whose tax base is a physical unit (or a proxy of it) of something that has a proven, specific, negative impact on the environment. In practice, this definition is applied by looking at all of the various taxes levied in a

[27] See *SEEA Central Framework*, section 4.4, for a detailed description on accounting for transactions related to the environment.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

country and making an assessment as to whether the tax base in each circumstance is something that has a negative environmental impact.

A7.116 Since the application of this definition may vary across countries, for the purposes of international comparison of environmental taxes, lists of relevant taxes bases that satisfy this definition have been developed by the Organisation for Economic Co-operation and Development and Eurostat.

A7.117 The consideration of the tax base in the determination of the environmental status of a tax is an exception to the general approach to defining the environmental status on the basis of the purpose of the transaction. However, in the case of taxes, generally the taxpayer does not know in advance as to what the tax payment might be used for by the government. Nor are the reasons for levying a tax as stated by the legislator a reliable basis for international comparisons. The primary purpose of taxation may sometimes be to create incentives to reduce environmental pressures, or to raise revenue for the purpose of financing environmental protection. However, in many cases, the specific reason may not be stated and often the primary purpose of taxation is the raising of funds to pay for general social services, such as health and education.

A7.118 In cases where the use of the tax revenue is known, these taxes are considered "earmarked taxes." Those taxes that are earmarked for environmental protection are relevant in the calculation of environmental protection expenditure.

A7.119 There are four broad categories into which environmental taxes are generally grouped. These are:

- *Energy taxes*—This category includes taxes on energy products used for both transport and stationary purposes. Taxes on fuel used for transport purposes should be shown as a separate subcategory of energy taxes. Energy products for stationary use include fuel oils, natural gas, coal, and electricity. Taxes on carbon are included under energy taxes rather than under pollution taxes. If they are identifiable, carbon taxes should be reported as a separate subcategory within energy taxes. A special type of carbon taxes is payments for tradable emission permits. The treatment of payments for these permits is discussed later in this section.
- *Transport taxes*—This category mainly includes taxes related to the ownership and use of motor vehicles. Taxes on other transport equipment (e.g., planes) and related transport services (e.g., duty on charter or scheduled flights) are also included here as are taxes related to the use of roads. The transport taxes may be "one-off" taxes related to imports or sales of the equipment or recurrent taxes, such as an annual road tax. Taxes on petrol, diesel, and other transport fuels are included under energy taxes.
- *Pollution taxes*—This category includes taxes on measured or estimated emissions to air and water, and the generation of solid waste. An exception is taxes on carbon, which are included under energy taxes, as discussed earlier. Taxes on sulphur are included here.
- *Resource taxes*—This category typically includes taxes on water abstraction, extraction of raw materials, and other resources (e.g., sand and gravel). Consistent with the general scope of environmental taxes, payments to government for the use of land or natural resources are treated as rent and therefore are excluded from resource taxes.

Treatment of value-added taxes

A7.120 Generally, value-added taxes (VAT) are excluded from the definition of environmental taxes because they are considered to have no influence on relative prices in the same way that other taxes on environmental tax bases do (i.e., VAT is levied on a broad range of goods and services regardless of their impact on the environment). This lack of direct influence is also reflected in the deductible nature of VAT for many taxpayers. There is one relatively specific exception to this general treatment. In principle, where VAT is calculated on a price that includes a duty or tax already determined to be an environmental tax, the relevant amount of nondeductible VAT (equal to the VAT rate multiplied by the amount of the environmental tax excluding the part that is deductible by the taxpayer) can also be considered to be part of environmental taxes and classified based on the nature of the underlying tax base. Such a situation may occur when VAT on petrol/gasoline is calculated, including the fuel duty paid on hydrocarbon oils. In practice, the ability to separately identify this amount of VAT may require additional information.

Other payments to government

A7.121 Only those payments that are considered to be taxes according to the definitions of GFS and the SNA are within the scope of environmental taxes in the SEEA. At the same time, there may also be particular interest in identifying and recording other payments to government that are also related to the environment, such as payments of rent, some sales of goods and services, and some fines and penalties. In determining the environmental status of these payments, focus should remain on the basis for the payment rather than on either the name used to describe the payment or the purpose for which the revenue raised may be used. The following paragraphs describe these other environment-related types of payments to government. To allow comparisons of GFS and *SEEA Central Framework*, data on these environment-related payments to government would need to be provided separately in the underlying source data of GFS, or added as subitems of the GFS categories.

Rent

A7.122 There are certain environmental assets, particularly mineral and energy resources, that are owned by government, and payments to government by extractors are often required. These payments are treated as rent. Payments of rent in respect of mineral and energy resources are commonly referred to as royalties, and in resource-endowed countries these payments may represent an important component of total government revenue. These are often also referred to as resource leases (see paragraph A4.16).

Sales of goods and services

A7.123 In a number of situations the government could undertake a range of activities that provide goods and services to households and businesses that are environmental in nature. Such provision of goods and services constitutes production by government units, and payments made by users are often referred to as "fees." A common situation is the payments made to general government units that operate waste collection schemes for the disposal of waste. Whether these payments are purchases of goods and services or taxes can be difficult to assess, since it must be determined as to whether the purchaser has received a commensurate service from the government in return for the payment. The general guidance in the paragraphs 5.73–5.75 should be followed to make the distinction.

Fines and penalties

A7.124 Fines and penalties are distinguished from taxes as being compulsory payments imposed on institutional units by courts of law or quasi-judicial bodies. These payments to governments are treated as *fines, penalties and forfeits* (GFS item 143). It may well be that some fines and penalties are related to illegal environmental activities—for example, fines for polluting water bodies. The recording of environment-related fines and penalties also arises in the case of the use of environmental assets as sinks.

Environmental transfers by nongovernment institutional units

A7.125 Where information on these flows is of interest, the amounts to be recorded as environmental should follow the same principles as applied in the case of government flows—that is, transfers paid to other institutional units should be based on whether the primary purpose of the payer is environmental protection or resource management. Within GFS further breakdown or "of which" lines may be added to the classification structure to specifically identify these flows.

A7.126 A particular instance of transfers between institutional units concerns flows between international organizations and national governments and other resident institutional units. In certain countries these flows may be significant. In line with the general principles outlined here, transfers paid by international organizations to institutional units within a country should be considered to be environmental if the primary intent of the international organization is that the money is spent for environmental protection or resource management purposes. Supplementary breakdowns in *grants from foreign governments or international organizations* (GFS item 131 and 132) could provide for this data need.

Permits to use environmental assets

A7.127 A common and important mechanism for managing the interaction between the economy and the environment is the use of permits and licenses to access, extract, or use environmental assets. In some cases, the permits and licenses may relate to the physical removal of environmental assets, such as in the

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

case of fishing licenses, and in other cases they may relate to the use of the environment as a sink for emissions. For a discussion of licenses and permits to use natural resources, see A4.18–A4.50.

Environmental payments by governments

A7.128 Payments by government related to environmental issues are recorded in a number of places in GFS and the SNA. The treatment largely depends on how the payments relate to production and consumption and whether they are considered to be current or capital in nature.

A7.129 All of the payments considered in this section are transfers (see paragraph 3.10). Consequently, this section does not include payments by government for the purchase of goods and services related to the environment.

Environmental subsidies and similar transfers

A7.130 An environmental subsidy or similar transfer is a transfer that is intended to support activities that protect the environment or reduce the use and extraction of natural resources. It includes those transfers defined in GFS as *subsidies* (25), *social benefits to households* (27), *grants* (26), and *transfers not elsewhere classified* (282).

A7.131 Subsidies or other transfers should be treated as environmental when the primary intent or purpose of the government is that resources be used for either environmental protection or resource management purposes. The determination of primary purpose should not be based on whether the use of the resources by the recipient of the transfer results in positive outcomes for the environment. While it is reasonable to consider that the purpose of the government in making the transfer and the purpose of the recipient are the same, it may not be the case that the expenditure of the transferred resources results in beneficial environmental outcomes even if this was the intent. For detailed descriptions of the classification of these transfers, refer to Chapter 6.

A7.132 In principle, a decision as to whether the primary purpose of a transfer is environmental should be made for each individual transfer. Then, once a decision on the primary purpose has been made, the total value of the transfer is treated as being for that primary purpose.

A7.133 In practice, information on transfers by government is usually contained in budget and other government expenditure data. Generally, these data do not show individual transactions and more commonly show information by type of government program, thus including a large number of individual transfers. It is usually the case that such programs have multiple purposes, and hence determining the number and value of individual transfers that have a primary purpose of environmental protection or resource management may require additional information.

A7.134 In these situations, it may be necessary to estimate the share of the value of transfers for a given government program that reflects the value of individual transfers within the program that have environmental protection or resource management as their primary purpose.

APPENDIX

8 GFS Classifications

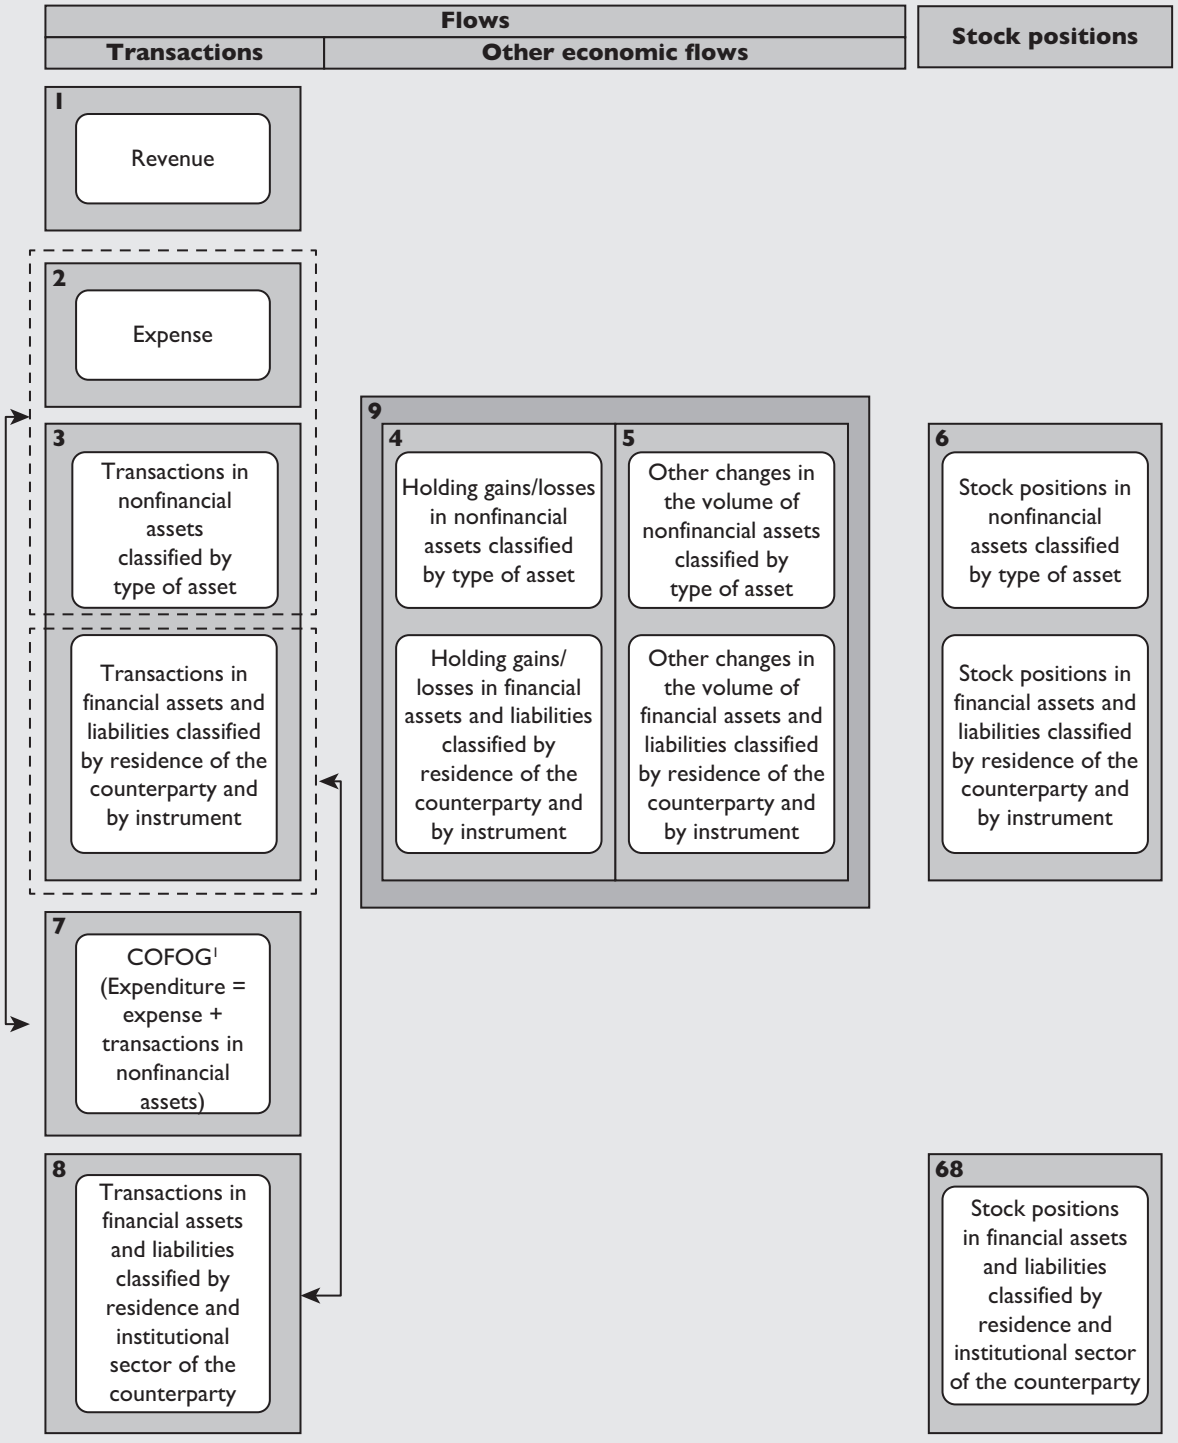
This appendix provides all of the classification codes used in the GFS framework.

A8.1 Classification codes are used in the GFS system to identify types of transactions, other economic flows, and stock positions of assets and liabilities. This appendix presents in one place all of the codes that were presented in Chapters 5 through 10. The overall organization of the codes is shown in Figure A8.1.

A8.2 Codes beginning with 1 refer to revenue; codes beginning with 2 refer to expense; and codes beginning with 3 refer to transactions in nonfinancial assets, financial assets, and liabilities. For financial assets and liabilities, the code 3 signifies transactions that have been classified by financial instrument.

A8.3 The first digit of the classification code for a specific type of other economic flow is 4 or 5: codes beginning with 4 refer to holding gains and losses, while codes beginning with 5 refer to other changes in the volume of assets and liabilities. The first digit for total other economic flows is 9. For a stock position in a type of asset or liability, the first digit of the classification code is 6.

A8.4 Codes for transactions, other economic flows, and stock positions in assets and liabilities also identify types of assets and liabilities. Hence, the second and subsequent digits of each code are identical for each type of asset or liability. That is, 311 refers to transactions in fixed assets, 411 to holding gains in fixed assets, 511 to other changes in the volume of fixed assets, 911 to total other economic flows in fixed assets, and 611 to the stock position of fixed assets.



A8.5 Expense transactions and transactions in nonfinancial assets (i.e., expenditure) can also be classified using the Classification of Functions of Government (COFOG), as described in the annex to Chapter 6. All COFOG classification codes begin with 7.

A8.6 Transactions and stock positions in financial assets and liabilities can be classified according to the residence and institutional sector of the other party to the financial instrument, as well as according to the type of financial instrument. When classified by residence and institutional sector of the counterparty, the classification codes for transactions begin with 8 and the classification codes for stock positions begin with 68. The counterparty to the transactions is not necessarily the same as the counterparty to the stock positions. While the parties are the same at the inception of the instrument, they may differ for transactions in that instrument. As explained in paragraph 9.25, in principle, the classification of general government units' transactions in financial assets and liabilities by residence is based on the residence of the units that were a party to the transaction being recorded, whereas the classification of stock positions in financial assets and liabilities in a government unit's balance sheet is based on the residence of the issuer of financial instruments (assets), and the residence of the holder of the financial instruments (liabilities). If a transaction in financial assets or liabilities is between a resident and a nonresident unit that involves an instrument originally issued by a resident, an entry in other changes in the volume of assets (reclassification) is recorded to maintain the integrated GFS framework of flows and stock positions.

A8.7 In this appendix, the classification codes are presented in Tables A8.1–A8.6, which illustrate the standard presentation of these items in GFS. In practical applications, this standard presentation could be used to select subsets of data for various presentational formats. It may also be possible and desirable to use more detailed classifications. Such an expansion can be accomplished by adding another digit to any given classification code. For example, the classification code for the stock of transport equipment is 61121. If types of transport equipment were to be classified separately, the codes 611211, 611212, and so forth could be used.

Table A8.1 Classification of Revenue

1	**Revenue**
11	**Taxes**
111	Taxes on income, profits, and capital gains
1111	Payable by individuals
1112	Payable by corporations and other enterprises
1113	Other taxes on income, profits, and capital gains
11131	Payable by general government
11132	Unallocable taxes on income, profits, and capital gains
112	Taxes on payroll and workforce
113	Taxes on property
1131	Recurrent taxes on immovable property
1132	Recurrent taxes on net wealth
1133	Estate, inheritance, and gift taxes
1135	Capital levies
1136	Other recurrent taxes on property
114	Taxes on goods and services
1141	General taxes on goods and services
11411	Value-added taxes
11412	Sales taxes
11413	Turnover and other general taxes on goods and services
11414	Taxes on financial and capital transactions
1142	Excise
1143	Profits of fiscal monopolies
1144	Taxes on specific services
1145	Taxes on use of goods and on permission to use goods or perform activities
11451	Motor vehicle taxes
11452	Other taxes on use of goods and on permission to use goods or perform activities
114521	Business and professional licenses
114522	Pollution taxes
114523	Radio and television licenses
114524	Licenses and permits for households
114525	Other taxes on use of goods and on permission to use goods or perform activities not elsewhere classified
1146	Other taxes on goods and services
115	Taxes on international trade and transactions
1151	Customs and other import duties
1152	Taxes on exports
1153	Profits of export or import monopolies
1154	Exchange profits
1155	Exchange taxes
1156	Other taxes on international trade and transactions
116	Other taxes
1161	Payable solely by business
1162	Payable by other than business or unidentifiable
12	**Social contributions [GFS]**
121	Social security contributions [GFS]
1211	Employee contributions [GFS]
1212	Employer contributions [GFS]
1213	Self-employed or nonemployed contributions [GFS]
1214	Unallocable contributions [GFS]
122	Other social contributions [GFS]
1221	Employee contributions [GFS]
1222	Employer contributions [GFS]
1223	Imputed contributions [GFS]
13	**Grants**
131	From foreign governments
1311	Current
1312	Capital
132	From international organizations
1321	Current
1322	Capital
133	From other general government units
1331	Current
1332	Capital
14	**Other revenue**
141	Property income [GFS]
1411	Interest [GFS]
14111	From nonresidents
14112	From residents other than general government
14113	From other general government units
1412	Dividends
14121	From nonresidents
14122	From residents
1413	Withdrawals of income from quasi-corporations
1414	Property income from investment income disbursements
1415	Rent
1416	Reinvested earnings on foreign direct investment
142	Sales of goods and services
1421	Sales by market establishments
1422	Administrative fees
1423	Incidental sales by nonmarket establishments
1424	Imputed sales of goods and services
143	Fines, penalties, and forfeits
144	Transfers not elsewhere classified
1441	Current transfers not elsewhere classified
14411	Subsidies
14412	Other current transfers not elsewhere classified
1442	Capital transfers not elsewhere classified
145	Premiums, fees, and claims related to nonlife insurance and standardized guarantee schemes
1451	Premiums, fees, and current claims
14511	Premiums
14512	Fees for standardized guarantee schemes
14513	Current claims
1452	Capital claims

Note: Further breakdown/"of which" lines may be analytically useful and could be presented as indicated in the detailed tables in Chapter 5.

Table A8.4 Classifications of the Counterparty of Transactions and Stock Positions in Financial Assets and Liabilities by Institutional Sector

	Classification of transactions in financial assets and liabilities[1]	Classification of stock positions in financial assets and liabilities[1]
Change in net financial worth due to transactions / net financial worth	**8**	**68 (=6)**
Financial assets	**82 (=32)**	**682 (=62)**
Domestic debtors	821 (=321)	6821 (=621)
General government	8211	68211
Central bank	8212	68212
Deposit-taking corporations except the central bank	8213	68213
Public deposit-taking corporations except the central bank	82131	682131
Private deposit-taking corporations	82132	682132
Other financial corporations	8214	68214
Other public financial corporations	82141	682141
Other private financial corporations	82142	682142
Nonfinancial corporations	8215	68215
Public nonfinancial corporations	82151	682151
Private nonfinancial corporations	82152	682152
Households and nonprofit institutions serving households	8216	68216
External debtors	822 (=322)	6822 (=622)
General government	8221	68221
International organizations	8227	68227
Financial corporations other than international organizations	8228	68228
Central banks	82281	682281
Financial corporations not elsewhere classified	82282	682282
Other nonresidents	8229	68229
Liabilities	**83 (=33)**	**683 (=63)**
Domestic creditors	831 (=331)	6831 (=631)
General government	8311	68311
Central bank	8312	68312
Deposit-taking corporations except the central bank	8313	68313
Public deposit-taking corporations except the central bank	83131	683131
Private deposit-taking corporations	83132	683132
Other financial corporations	8314	68314
Other public financial corporations	83141	683141
Other private financial corporations	83142	683142
Nonfinancial corporations	8315	68315
Public nonfinancial corporations	83151	683151
Private nonfinancial corporations	83152	683152
Households and nonprofit institutions serving households	8316	68316
External creditors	832 (=332)	6832 (=632)
General government	8321	68321
International organizations	8327	68327
Financial corporations other than international organizations	8328	68328
Central banks	83281	683281
Financial corporations not elsewhere classified	83282	683282
Other nonresidents	8329	68329

Note: Transactions in monetary gold are classified according to the counterparty involved. Although gold bullion has no counterparty, by convention, the counterparty to the stock position in gold bullion is shown as "other nonresidents" in this table.

[1]The counterparty to the transactions is not necessarily the same as the counterparty to the stock positions. While the parties are the same at the inception of the instrument, they may differ for transactions in that instrument. As explained in paragraph 9.25, in principle, the classification of general government units' transactions in financial assets and liabilities by residence is based on the residence of the units that were a party to the transaction being recorded, whereas the classification of stock positions in financial assets and liabilities in a government unit's balance sheet is based on the residence of the issuer of financial instruments (assets), and the residence of the holder of the financial instruments (liabilities). If a transaction in financial assets or liabilities is between a resident and a nonresident unit that involves an instrument originally issued by a resident, an entry in other changes in the volume of assets (reclassification) is recorded to maintain the integrated GFS framework of stock positions and flows.

APPENDIX

9 Glossary

Accrual basis of recording
In the accrual basis of recording, flows are recorded at the time economic value is created, transformed, exchanged, transferred, or extinguished 3.62

Actual employers' social contributions
Actual employers' social contributions consist of actual contributions payable to social security funds, employment-related pension funds, and other employment-related social insurance schemes to obtain entitlement to social benefits for their employees 6.21

Actual premium (fee)
The actual premium (fee) is the amount payable to the insurer (guarantor) to secure insurance coverage for a specific event over a stated time period ..A4.74

Aggregates
Aggregates are summations of individual entries and elements in a class of flows or stock positions 3.141

Allocated gold accounts
Allocated gold accounts provide ownership of a specific piece of gold 7.127

Amortized value of a loan
Amortized value of a loan reflects the gradual elimination of the liability by regular payments over a specified period of time 3.115

Ancillary activity
An ancillary activity is a supporting activity providing services within an enterprise in order to create the conditions within which the principal or secondary activities can be carried out.....2.45

Arrears
Arrears are defined as amounts that are both unpaid and past the due date for payment 3.71, 7.247, 9.20

Asset
An asset is a store of value representing a benefit or series of benefits accruing to the economic owner by holding or using the resource over a period of time..... 3.42, 7.6

Asset-backed securities and collateralized debt obligations
Asset-backed securities and collateralized debt obligations are arrangements under which payments of interest and principal are backed by payments on specified assets or income streams..... 7.151

Balance of payments
The balance of payments summarizes economic transactions between residents and nonresidents during a specific time period.....A7.76

Balance sheet
A balance sheet is a statement of the values of the stock positions of assets owned and of the liabilities owed by an institutional unit or group of units, drawn up in respect of a particular point in time 3.56, 4.39, 7.1

Balancing items
Balancing items are economic constructs obtained by subtracting one aggregate from a second aggregate..... 3.142

Banker's acceptance
A banker's acceptance is created when a financial corporation endorses, in return for a fee, a draft or bill of exchange and the unconditional promise to pay a specific amount at a specified date 7.145

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Bills — Bills are defined as securities (usually short-term) that give holders the unconditional rights to receive stated fixed sums on a specified date 7.144

Bonds and debentures — Bonds and debentures are securities that give the holders the unconditional right to fixed payments or contractually determined variable payments on a specified date or dates 7.146

Book value — Book value generally refers to the value recorded in the entities' records... 3.115

Budgetary central government — The budgetary central government is often a single unit of the central government that encompasses the fundamental activities of the national executive, legislative, and judiciary powers.....2.81

Buildings other than dwellings — Buildings other than dwellings include whole buildings or parts of buildings not designated as dwellings. Fixtures, facilities, and equipment that are integral parts of the structures are included.....7.46

Capital account in the international accounts — The capital account in the international accounts shows transactions between residents and nonresidents related to capital transfers receivable and payable and the acquisition and disposal of nonproduced nonfinancial assets A7.89

Capital claims payable — Capital claims payable comprise exceptionally large insurance settlements payable in the wake of a catastrophic event or disaster 6.125

Capital claims receivable — Capital claims receivable comprise exceptionally large insurance settlements receivable in the wake of a catastrophic event or disaster 5.151

Capital grants — Capital grants are capital transfers receivable by government units, from other resident or nonresident government units or international organizations, that do not meet the definition of a tax, subsidy, or a social contribution.....5.103

Capital levies — Capital levies cover taxes on the values of the assets or net worth owned by institutional units levied at irregular and very infrequent intervals of time 5.52

Capital taxes — Capital taxes are taxes levied at irregular and very infrequent intervals on the values of the assets or net worth owned by institutional units or on the values of assets transferred between institutional units as a result of legacies, gifts, or other transfers 5.52

Capital transfers — Capital transfers are transfers in which the ownership of an asset (other than cash or inventories) changes from one party to another or that oblige one or both parties to acquire or dispose of an asset (other than cash or inventories) 3.16

Capital transfers not elsewhere classified — Capital transfers not elsewhere classified are gifts and transfers of a capital nature (other than grants) from individuals, private nonprofit institutions, nongovernmental foundations, or corporations.....5.148

Captive financial institutions and money lenders — Captive financial institutions and money lenders are institutional units providing financial services other than insurance, where most of their assets or liabilities are not available on open financial markets.....2.54

Cash basis of recording — In the cash basis of recording, flows are recorded when cash is received or disbursed.....3.67

Catastrophic loss — A catastrophic loss is the partial or complete destruction of a significantly large number of assets within any of the asset categories resulting from a large-scale, discrete, and recognizable event 10.60

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Center of predominant economic interest An institutional unit has a center of predominant economic interest in an economic territory when there exists, within the economic territory, some location, dwelling, place of production, or other premises on which, or from which, the unit engages and intends to continue engaging, either indefinitely or over a finite but long period of time, in economic activities and transactions on a significant scale 2.12

Central bank The central bank is the national financial institution that exercises control over key aspects of the financial system 2.118

Central government subsector The central government subsector consists of the institutional unit(s) of the central government plus those nonmarket NPIs that are controlled by the central government. The political authority of the central government extends over the entire territory of the country 2.85

Change in net worth due to holding gains or losses Change in net worth due to holding gains or losses is defined as the sum of the positive or negative holding gains and holding losses on all assets and liabilities 4.37

Change in net worth due to other changes in the volume of assets and liabilities Change in net worth due to other changes in the volume of assets and liabilities is defined as the sum of the positive and negative other changes in the volume of assets and liabilities 4.38

Change in net worth due to other economic flows Change in net worth due to other economic flows is defined as the sum of the change in net worth due to holding gains or losses and the change in net worth due to other changes in the volume of assets 4.36, 10.2

Claim (benefit or call) A claim (benefit or call) is the amount payable to the policyholder by the insurer in respect of an event covered by the policy occurring in the period for which the policy is valid A4.77

Collective service A collective service is a service provided simultaneously to all members of the community or to all members of a particular section of the community, such as all households living in a particular region 6.134

Commitments basis of recording In the commitments basis of recording, flows are recorded when an institutional unit has committed itself to a transaction 3.65

Compensation of employees Compensation of employees is the total remuneration, in cash or in kind, payable to an individual in an employer-employee relationship in return for work performed by the latter during the reporting period 6.9

Computer software Computer software includes computer programs, program descriptions, and supporting materials for both systems and applications software that are expected to be used for more than one year 7.70

Consolidation Consolidation is a method of presenting statistics for a set of units (or entities) as if they constituted a single unit 3.153, 9.18

Consumption of fixed capital Consumption of fixed capital is the decline, during the course of the reporting period, in the current value of the stock of fixed assets owned and used by a government unit as a result of physical deterioration, normal obsolescence, or normal accidental damage 6.53

Contingent liabilities Contingent liabilities are obligations that do not arise unless a particular, discrete event(s) occurs in the future 4.47, 7.251

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Contracts, leases, and licenses
Contracts, leases, and licenses are treated as assets only when both the following conditions are satisfied: (i) the terms of the contract, lease, or license specify a price for the use of an asset or provision of a service that differs from the price that would prevail in the absence of the contract, lease, or license, and (ii) one party to the contract must be able legally and practically to realize this price difference 7.105

Control of a corporation
Control of a corporation is defined as the ability to determine general corporate policy of the corporation ..... 2.107, Box 2.2

Control of an NPI
Control of an NPI is defined as the ability to determine the general policy or program of the NPI ..... Box 2.1

Corporations
Corporations are defined as entities that are capable of generating a profit or other financial gain for their owners, are recognized by law as separate legal entities from their owners, and are set up for purposes of engaging in market production 2.31

Costs of ownership transfer
Costs of ownership transfer are the costs associated with acquiring and disposing of nonfinancial assets (other than inventories) 8.6

Credit derivatives
Credit derivatives are financial derivatives whose primary purpose is to trade credit risk 7.218

Credit entry
A credit entry is a decrease in an asset, an increase in a liability, or an increase in net worth 3.55

Cultivated biological resources
Cultivated biological resources cover animal resources yielding repeat products and tree, crop, and plant resources yielding repeat products whose natural growth and regeneration are under the direct control, responsibility, and management of institutional units 7.59

Currency
Currency consists of notes and coins that are of fixed nominal values and are issued or authorized by the central bank or government 7.135

Currency union
A currency union is defined as a union to which two or more economies belong and that has a regional central decision-making body, commonly a currency union central bank, endowed with the legal authority to conduct a single monetary policy and issue the single currency of the union A5.34

Current account
The current account shows flows of goods and services, primary income, and secondary income between residents and nonresidents A7.78

Current grants
Current grants are current transfers receivable by government units, from other resident or nonresident government units or international organizations, and that do not meet the definition of a tax, subsidy, or a social contribution 5.103

Current transfers
Current transfers consist of all transfers that are not capital transfers 3.17

Custom union
A custom union is a form of regional arrangement whereby agreement exists on a common tariff (custom duties) vis-à-vis the other economies while the movement of goods within the arrangement tends to be duty-free A5.6

Databases
Databases consist of files of data organized in such a way as to permit resource-effective access and use of the data 7.70

Debit entry A debit entry is an increase in an asset, a decrease in a liability, or a decrease in net worth....3.55

Debt assumption Debt assumption is a trilateral agreement between a creditor, a former debtor, and a new debtor (typically a government unit), under which the new debtor assumes the former debtor's outstanding liability to the creditor, and is liable for repayment of debt....A3.26

Debt conversion (swap) Debt conversion (swap) is an exchange of debt—typically at a discount—for a nondebt claim (such as equity), or for counterpart funds that can be used to finance a particular project or policy....A3.20

Debt forgiveness (or debt cancellation) Debt forgiveness (or debt cancellation) is defined as the voluntary cancellation of all or part of a debt obligation within a contractual arrangement between a creditor and a debtor....A3.7

Debt payments on behalf of others Rather than assuming a debt, a public sector unit may decide to repay that debt or make a specific payment on behalf of another institutional unit (original debtor), without a guarantee being called or the debt being taken over....A3.30

Debt prepayment Debt prepayment consists of a repurchase, or early payment, of debt at conditions that are agreed between the debtor and the creditor A3.24

Debt refinancing Debt refinancing involves the replacement of an existing debt instrument or instruments, including any arrears, with a new debt instrument or instruments....A3.14

Debt reorganization (also referred to as debt restructuring) Debt reorganization (also referred to as debt restructuring) is defined as an arrangement involving both the creditor and the debtor (and sometimes third parties) that alters the terms established for servicing an existing debt A3.2

Debt rescheduling Debt rescheduling is a bilateral arrangement between the debtor and the creditor that constitutes a formal postponement of debt service payments and the application of new and generally extended maturities....A3.11

Debt securities Debt securities are negotiable financial instruments serving as evidence of a debt.... 7.143

Debt write-offs or write-downs Debt write-offs or write-downs refer to unilateral reductions by a creditor, of the amount owed to it....A3.32

Deep-discount bonds Deep-discount bonds are long-term securities that require periodic coupon payments during the life of the instrument, but the amount is substantially below the market rate of interest at issuance 7.147

Defeasance With defeasance, a debtor unit removes liabilities from its balance sheet by pairing them with financial assets, the income and value of which are sufficient to ensure that all debt-service payments are met....A3.37

Defined-benefit pension scheme A defined-benefit pension scheme is one where the benefits payable to an employee on retirement are determined by the use of a formula, either alone or as a minimum amount payable....A2.54

Defined-contribution pension scheme A defined-contribution pension scheme is one where the benefits payable to an employee on retirement are defined exclusively in terms of the level of the funds built up from the contributions made over the employee's working life and the increases in value that result from the investment of these funds by the manager of the scheme....A2.55

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Depository receipts Depository receipts are securities that represent ownership of securities listed in other economies 7.167

Deposits Deposits are all claims, represented by evidence of deposit, on the deposit-taking corporations (including the central bank) and, in some cases, general government or other institutional units 7.137

Distributable income Distributable income of a corporation is equal to entrepreneurial income, plus all current transfers receivable, minus all current transfers payable and minus the adjustment for the change in pension entitlements relating to the pension scheme of that corporation 5.116

Dividends Dividends are the distributed earnings allocated to government or public sector units, as the owners of equity, for placing funds at the disposal of corporations 5.111, 6.109

Domestic currency Domestic currency is that which is legal tender in the economy and issued by the monetary authority for that economy—that is, either that of an individual economy or, in a currency union, that of the common currency area to which the economy belongs..... 3.134

Due-for-payment basis of recording In the due-for-payment basis of recording, flows that give rise to cash payments are recorded at the latest times they can be paid without incurring additional charges or penalties or, if sooner, when the cash payment is made.....3.66

Dwellings Dwellings are buildings, or designated parts of buildings, that are used entirely or primarily as residences, including any associated structures, such as garages, and all permanent fixtures customarily installed in residences 7.44

Economic assets Economic assets are resources over which ownership rights are enforced and from which economic benefits may flow to the owners..... 3.43, 4.43

Economic classification of expense The economic classification of expense identifies the types of expense incurred according to the economic process involved 6.2

Economic flows Economic flows reflect the creation, transformation, exchange, transfer, or extinction of economic value; they involve changes in the volume, composition, or value of a unit's assets, liabilities, and net worth 3.4

Economic owner The economic owner of resources such as goods and services, natural resources, financial assets, and liabilities is the institutional unit entitled to claim the benefits associated with the use of these resources by virtue of accepting the associated risks..... 3.39, 7.5

Economic territory Economic territory, in its broadest sense, can be any geographic area or jurisdiction for which statistics are required 2.8

Economic unions Economic unions are established by means of an intergovernmental legal agreement among sovereign countries or jurisdictions with the intention of fostering greater economic integration A5.19

Economically significant prices Economically significant prices are prices that have a significant effect on the amounts that producers are willing to supply and on the amounts purchasers wish to buy 2.66

Economy An economy consists of a set of resident institutional units.....2.6

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Embedded derivative An embedded derivative arises when a derivative feature is inserted in a standard financial instrument and is inseparable from the instrument..... 7.148

Employee stock options Employee stock options are options to buy the equity of a company, offered to employees of the company as a form of remuneration 7.221

Employers' social contributions Employers' social contributions are social contributions payable by employers, to social security funds, employment-related pension funds, or other employment-related social insurance schemes to obtain entitlement to social benefits for their employees.....6.19

Employment-related social benefits Employment-related social benefits are social benefits payable in cash or in kind by government or public sector units to their employees or employees of other government or public sector units participating in the scheme (or to survivors and dependents of the employees who are eligible for such payments) 6.104

Enterprise An enterprise is the view of an institutional unit as a producer of goods and services.....2.25

Entertainment, literary, and artistic originals Entertainment, literary, and artistic originals are original films, sound recordings, manuscripts, tapes, and models in which drama performances, radio and television programming, musical performances, sporting events, and literary and artistic output are recorded or embodied. 7.72

Entitlement to future goods and services on an exclusive basis Entitlement to future goods and services on an exclusive basis relates to the case where one party that has contracted to purchase goods or services at a fixed price at a time in the future is able to transfer the obligation of the second party to the contract to a third party 7.112

Environmental protection activities Environmental protection activities are those activities whose primary purpose is the prevention, reduction, and elimination of pollution and other forms of degradation of the environment..... A7.107

Environmental tax An environmental tax is a tax whose tax base is a physical unit (or a proxy of it) of something that has a proven, specific, negative impact on the environment A7.115

Equity Equity consists of all instruments and records that acknowledge claims on the residual value of a corporation or quasi-corporation, after the claims of all creditors have been met..... 7.165

Establishment An establishment is an enterprise, or part of an enterprise, that is situated in a single location and in which only a single productive activity is carried out or in which the principal productive activity accounts for most of the value added.....2.24

Estate, inheritance, and gift taxes Estate, inheritance, and gift taxes cover taxes on transfers of property at death and on gifts, including gifts made between living members of the same family to avoid, or minimize, the payment of inheritance taxes.....5.51

Exchange An exchange is a transaction in which one unit provides a good, service, asset, or labor to a second unit and receives a good, service, asset, or labor of the same value in return.....3.9

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Excises Excises are taxes levied as a product-specific unit tax on a predefined limited range of goods....5.62

Expenditure Expenditure is the sum of expense and the net investment in nonfinancial assets....4.21

Expense Expense is a decrease in net worth resulting from a transaction.... 4.24, 6.1

Explicit contingent liabilities Explicit contingent liabilities are defined as legal or contractual financial arrangements that give rise to conditional requirements to make payments of economic value 7.252

Extrabudgetary General government entities with individual budgets not fully covered by the main (or general) budget are considered extrabudgetary....2.82

Face value Face value of a debt instrument is the undiscounted amount of principal to be repaid at (or before) maturity 3.115, 7.242

Fair value Fair value is a market-equivalent value defined as the amount for which an asset could be exchanged, or a liability settled, between knowledgeable, willing parties in an arm's-length transaction 3.115

Financial account of the balance of payments The financial account of the balance of payments records transactions that involve financial assets and liabilities that take place between residents and nonresidents....A7.93

Financial assets Financial assets consist of financial claims and gold bullion held by monetary authorities as a reserve asset 3.48

Financial auxiliaries Financial auxiliaries consist of financial corporations that are principally engaged in activities associated with transactions in financial assets and liabilities or with providing the regulatory context for these transactions but in circumstances that do not involve the auxiliary taking ownership of the financial assets and liabilities being transacted....2.54

Financial claim A financial claim is an asset that typically entitles the owner of the asset (the creditor) to receive funds or other resources from another unit, under the terms of a liability 3.47, 7.15

Financial corporations Financial corporations are corporations that are principally engaged in providing financial services, including insurance and pension fund services, to other institutional units 2.115

Financial corporations sector The financial corporations sector consists of resident corporations that are principally engaged in providing financial services, including insurance and pension fund services, to other institutional units 2.53

Financial derivative contract A financial derivative contract is a financial instrument that is linked to another specific financial instrument or indicator or commodity and through which specific financial risks (e.g., interest rate risk, foreign exchange risk, equity and commodity price risks, and credit risk) can be traded in their own right in financial markets 7.204

Financial intermediaries Financial intermediaries are institutional units that incur liabilities on their own account for the purpose of acquiring financial assets by engaging in financial transactions on the market....2.54

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Financial lease A financial lease is a contract under which the lessor, as legal owner of an asset, conveys substantially all risks and rewards of ownership of the asset to the lessee..... 7.158, A4.10

Fines and penalties Fines and penalties are compulsory current transfers imposed on units by courts of law or quasi-judicial bodies for violations of laws or administrative rules..... 5.142

Finished goods Finished goods consist of goods that are the output of a production process, are still held by their producer, and are not expected to be processed further by the producer before being supplied to other units 7.83

Fiscal policy Fiscal policy is the use of the level and composition of the general government and public sectors' spending and revenue—and the related accumulation of government assets and liabilities—to achieve such goals as the stabilization of the economy, the reallocation of resources, and the redistribution of income 1.2

Fixed assets Fixed assets are produced assets that are used repeatedly or continuously in production processes for more than one year 7.18, 7.35

Forfeits Forfeits are amounts that were deposited with a general government unit pending a legal or administrative proceeding and that have been transferred to the general government unit as part of the resolution of that proceeding..... 5.142

Forward-type contract A forward-type contract (forward) is an unconditional contract by which two counterparties agree to exchange a specified quantity of an underlying item (real or financial) at an agreed-on contract price (the strike price) on a specified date..... 7.212

Functional classification of expense The functional classification of expense provides information on the purpose for which an expense was incurred.....6.3

General government sector The general government sector consists of resident institutional units that fulfill the functions of government as their primary activity 1.2, 2.58, 2.76

General taxes on goods and services General taxes on goods and services are levied on the production, leasing, delivery, sale, purchase, or other change of ownership of a wide range of goods and the rendering of a wide range of services 5.57

Gold bullion Gold bullion takes the form of coins, ingots, or bars with a purity of at least 995 parts per 1,000, including such gold held in allocated gold accounts 7.128

Gold swap A gold swap involves an exchange of gold for foreign exchange deposits with an agreement that the transaction be reversed at an agreed future date at an agreed gold price 7.161

Goods and services account The goods and services account shows transactions in items that are outcomes of production activities.....A7.78

Goods for resale Goods for resale are goods acquired for the purpose of reselling or transferring to other units without being further processed.....7.84

Government units Government units are unique kinds of legal entities established by political processes that have legislative, judicial, or executive authority over other institutional units within a given area 2.38

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Grants
Grants are transfers receivable by government units, from other resident or nonresident government units or international organizations, and that do not meet the definition of a tax, subsidy, or social contribution..... 5.5, 5.101

Gross debt at market value
Gross debt at market value means that debt securities are valued at market prices; insurance, pension, and standardized guarantee schemes are valued according to principles that are equivalent to market valuation; and all other debt instruments are valued at nominal prices, which are considered to be the best generally available proxies of their market prices 7.240

Gross debt at nominal value
Gross debt at nominal value means that debt securities are valued at their nominal values. The nominal value of a debt instrument at any moment in time is the amount that the debtor owes to the creditor 7.241

Gross value added or gross domestic product (GDP)
Gross value added is defined as the value of output minus the value of intermediate consumption A7.24

Historic cost
Historic cost, in its strict sense, reflects the cost at the time of acquisition, but sometimes it may also reflect occasional revaluations 3.115

Holding gain or loss
A holding gain or loss is a change in the monetary value of an asset or liability resulting from changes in the level and structure of prices, excluding qualitative or quantitative changes in the asset or liability 3.33, 10.1

Household
A household is a group of persons who share the same living accommodation, who pool some, or all, of their income and wealth, and who consume certain types of goods and services collectively, mainly housing and food 2.28

Households sector
The households sector consists of all resident households 2.60

Implicit contingent liabilities
Implicit contingent liabilities do not arise from a legal or contractual source but are recognized after a condition or event is realized 7.252

Imputed employers' social contributions
Imputed employers' social contributions are the amounts calculated and added to actual contributions, sufficient to exactly match the increases in employees' social benefit entitlements.....6.22

Index-linked securities
Index-linked securities are instruments for which either the coupon payments (interest) or the principal or both are linked to another item, such as a price index, an interest rate, or the price of a commodity 7.153

Individual consumption good or service
An individual consumption good or service is one that is acquired by a household and used to satisfy the needs or wants of members of that household..... 6.135

Information, computer, and telecommunications equipment
Information, computer, and telecommunications (ICT) equipment consists of devices using electronic controls and also the electronic components forming part of these devices 7.56

Institutional sector
An institutional sector groups together similar kinds of institutional units according to their economic objectives, functions, and behavior 2.50

Institutional unit
An institutional unit is an economic entity that is capable, in its own right, of owning assets, incurring liabilities, and engaging in economic activities and in transactions with other entities 2.22

Intangible nonproduced assets
Intangible nonproduced assets are constructs of society evidenced by legal or accounting actions..... 7.104

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Intellectual property products Intellectual property products are the result of research, development, investigation, or innovation leading to knowledge that the developers can market or use to their own benefit in production because use of the knowledge is restricted by means of legal or other protection 7.64

Interest Interest is a form of investment income that is receivable by the owners of certain kinds of financial assets (SDRs, deposits, debt securities, loans, and other accounts receivable) for putting these financial assets and other resources at the disposal of another institutional unit..... 5.108

Intermediate consumption Intermediate consumption consists of the goods and services consumed as inputs by a process of production, excluding fixed assets whose consumption is recorded as consumption of fixed capital A7.28

International investment position The international investment position (IIP) is a statistical statement that shows at a point in time the value of: financial assets of residents of an economy that are claims on nonresidents and gold bullion held as reserve assets; and the liabilities of residents of an economy to nonresidents A7.96

Intersectoral consolidation Intersectoral consolidation is consolidation between subsectors of the public sector to produce consolidated statistics for a particular grouping of public sector units.....3.156

Intrasectoral consolidation Intrasectoral consolidation is consolidation within a particular subsector to produce consolidated statistics for that particular subsector 3.155

Inventories Inventories are produced assets consisting of goods and services, which came into existence in the current period or in an earlier period, and that are held for sale, use in production, or other use at a later date 7.18, 7.75

Investment funds Investment funds are collective investment undertakings through which investors pool funds for investment in financial or nonfinancial assets.....7.174

Joint operating arrangements Joint operating arrangements can be in the form of jointly controlled operations or jointly controlled assets.....2.143

Joint venture A joint venture involves the establishment of a corporation, partnership, or other institutional unit in which, legally, each party has joint control over the activities of the joint venture unit.....2.141

Land Land consists of the ground, including the soil covering and any associated surface waters, over which ownership rights are enforced and from which economic benefits can be derived by their owners by holding or using them 7.92

Land improvements Land improvements are the result of actions that lead to major improvements in the quantity, quality, or productivity of land, or prevent its deterioration 7.49

Legal or social entity A legal or social entity is one whose existence is recognized by law or society independently of the persons or other entities that may own or control it.....2.30

Legal owner The legal owner of resources such as goods and services, natural resources, financial assets, and liabilities is the institutional unit entitled by law and sustainable under the law to claim the benefits associated with the resource 3.38, 7.5

Liability A liability is established when one unit (the debtor) is obliged, under specific circumstances, to provide funds or other resources to another unit (the creditor)..... 3.45, 4.45, 7.15

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Life insurance Life insurance is an activity whereby a policyholder makes regular payments to an insurer in return for which the insurer guarantees to provide the policyholder (or in some cases another nominated person) with an agreed sum, or an annuity, at a given date or earlier if the policyholder dies beforehand....A4.69

Life insurance and annuities entitlements Life insurance and annuities entitlements are financial claims policyholders have against an enterprise offering life insurance or providing annuities....7.187

Listed shares Listed shares are equity securities listed on an exchange and may be referred to as quoted shares. (Unlisted shares are equity securities not listed on an exchange)....7.168

Loan A loan is a financial instrument that is created when a creditor lends funds directly to a debtor and receives a nonnegotiable document as evidence of the asset....7.157

Loans and other debt instrument guarantees Loans and other debt instrument guarantees are commitments by one party to bear the risk of nonpayment by another party....7.259

Local government units Local government units are institutional units whose fiscal, legislative, and executive authority extends over the smallest geographical areas distinguished for administrative and political purposes....2.95

Machinery and equipment Machinery and equipment cover transport equipment, machinery for information, computer, and telecommunications (ICT) equipment, and machinery and equipment not elsewhere classified....7.52

Margins Margins are payments of cash or deposits of collateral that cover actual or potential obligations incurred....7.219, 9.75

Market establishment A market establishment is an establishment that charges economically significant prices....2.75

Market prices Market prices refer to current exchange value—that is, the value at which goods, services, labor, or assets are exchanged or else could be exchanged for cash (currency or transferable deposits)....3.107

Market prices for transactions Market prices for transactions are defined as amounts of money that willing buyers pay to acquire something from willing sellers; the exchanges are made between independent parties and on the basis of commercial considerations only, sometimes called "at arm's length"....3.108

Market producer A market producer is an institutional unit that provides all or most of its output to others at prices that are economically significant....2.65

Market regulatory agencies Market regulatory agencies act on behalf of a government (or a regional organization with governments as its members) and influence the market for specific goods or services directly and/or indirectly....2.156

Marketable operating leases Marketable operating leases are third-party property rights relating to fixed assets....7.108

Marketing assets Marketing assets consist of items such as brand names, mastheads, trademarks, logos, and domain names....7.115

Materials and supplies Materials and supplies consist of all goods held with the intention of using them as inputs to a production process....7.79

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Maturity of a debt instrument — The maturity of a debt instrument refers to the time until the debt is extinguished according to the contract between the debtor and the creditor....7.266

Military inventories — Military inventories consist of single-use items, such as ammunition, missiles, rockets, bombs, etc., delivered by weapons or weapons systems....7.86

Mineral and energy resources — Mineral and energy resources consist of mineral and energy reserves located on or below the earth's surface that are economically exploitable, given current technology and relative prices....7.97

Mineral exploration and evaluation — Mineral exploration and evaluation consists of the value of expenditure on exploration for petroleum and natural gas and for nonpetroleum deposits and subsequent evaluation of the discoveries made....7.68

Monetary gold — Monetary gold is gold to which the monetary authorities (or others who are subject to the effective control of the monetary authorities) have title and is held as a reserve asset....7.126

Monetary transaction — A monetary transaction is one in which one institutional unit makes a payment (receives a payment) or incurs a liability (acquires an asset) to (from) another institutional unit stated in units of currency....3.8

Monetary union — A monetary union exists where there is the presence of a single monetary policy among economies, established by an intergovernmental legal agreement....A5.32

Motor vehicle taxes — Motor vehicle taxes include taxes on the use of motor vehicles or permission to use motor vehicles....5.80

Net debt — Net debt is calculated as gross debt minus financial assets corresponding to debt instruments....7.243

Net financial worth — The net financial worth of an institutional unit (or grouping of units) is the total value of its financial assets minus the total value of its liabilities....4.41, 7.235

Net investment in inventories (change in inventories) — Net investment in inventories (change in inventories) is measured by the value of the additions to inventories minus the value of withdrawals from inventories minus the value of any recurrent losses of goods held in inventories during the reporting period....8.44

Net premiums — Net premiums are defined as actual premiums plus premium supplements minus the insurance service charge payable by the policyholders....A4.76

Net value added — Net value added is the value of output minus the values of both intermediate consumption and consumption of fixed capital....A7.25

Net worth — The net worth of an institutional unit (or grouping of units) is the total value of its assets minus the total value of its liabilities....4.39, 7.1

Neutral holding gain — Neutral holding gains and losses over a period are the increase (decrease) in the value of an asset that would be required, in the absence of transactions and other changes in the volume of assets, to maintain command over the same amount of goods and services as at the beginning of the period....10.11, A7.71

Nominal value — Nominal value at any moment in time is the amount that the debtor owes to the creditor....3.115

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Noncultivated biological resources Noncultivated biological resources consist of animals, birds, fish, and plants that yield both once-only and repeat products over which ownership rights are enforced but for which natural growth or regeneration is not under the direct control, responsibility, and management of any institutional units 7.101

Nonfinancial assets Nonfinancial assets are economic assets other than financial assets 3.50

Nonfinancial corporations Nonfinancial corporations are corporations whose principal activity is the production of market goods or nonfinancial services 2.114

Nonfinancial corporations sector The nonfinancial corporations sector consists of resident institutional units that are principally engaged in the production of market goods or nonfinancial services 2.52

Nonlife insurance Nonlife insurance is an activity similar to life insurance except that it covers all other risks, accidents, sickness, fire, etc. A4.70

Nonlife insurance technical reserves Nonlife insurance technical reserves consist of (i) prepayments of net nonlife insurance premiums and (ii) reserves to meet outstanding nonlife insurance claims 7.183

Nonmarket producer A nonmarket producer provides all or most of its output to others for free or at prices that are not economically significant 2.65

Nonmonetary transactions Nonmonetary transactions are transactions that are not initially stated in units of currency 3.19

Nonparticipating preferred stocks or shares Nonparticipating preferred stocks or shares are those that pay a fixed income but do not provide for participation in the distribution of the residual value of an incorporated enterprise on dissolution 7.150

Nonpension social benefits Nonpension social benefits include payments made to individuals when they are temporarily unemployed, suffering from a medical condition, or suffering from an event that prevents them from working for a period A2.7

Nonperforming loans Nonperforming loans are those for which (i) payments of principal and/or interest are past due by three months (90 days) or more; or (ii) interest payments equal to three months (90 days) interest or more have been capitalized (reinvested to the principal amount) or payment has been delayed by agreement; or (iii) evidence exists to reclassify a loan as nonperforming even in the absence of a 90-day past due payment, such as when the debtor files for bankruptcy 7.262

Nonprofit institutions Nonprofit institutions (NPIs) are legal or social entities created for the purpose of producing or distributing goods and services, but they cannot be a source of income, profit, or other financial gain for the institutional units that establish, control, or finance them 2.36

Nonprofit institutions serving households The nonprofit institutions serving households (NPISHs) sector consists of resident nonmarket nonprofit institutions (NPIs) that are not controlled by government 2.61

Notional resident unit A notional resident unit is a unit identified for statistical purposes to be the resident owner of immovable assets legally owned by nonresidents 2.13

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Off-market swap An off-market swap is a swap contract that has a nonzero value at inception as a result of having reference rates priced differently from current market values—that is, "off-the-market" 7.162, A3.68

On-balance sheet securitization On-balance sheet securitization involves debt securities backed by a future revenue stream generated by the assets. The assets remain on the balance sheet of the debt securities issuer (the original asset owner), typically as a separate portfolio. There is no securitization unit involved A3.66

One-off guarantees One-off guarantees comprise those types of guarantees where the debt instrument is so particular that it is not possible to calculate the degree of risk associated with the debt with any degree of accuracy 7.256

On-lending On-lending of borrowed funds refers to a resident institutional unit, A (usually central government), borrowing from another institutional unit(s), B (usually a nonresident unit), and then on-lending the proceeds from this borrowing to a third institutional unit(s), C (usually state or local governments, or a public corporation(s)), where it is understood that unit A obtains an effective financial claim on unit C A3.72

Operating leasing Operating leasing is the activity of renting out produced assets under arrangements that provide use of a tangible asset to the lessee, but do not involve the transfer of the bulk of risks and rewards of ownership to the lessee A4.6

Option contract In an option contract (option), the purchaser acquires from the seller a right to buy or sell (depending on whether the option is a call (buy) or a put (sell)) a specified underlying item at a strike price on or before a specified date 7.209

Original maturity Original maturity is the period from the issue date until the final contractually scheduled payment date 7.267

Other accounts receivable/payable Other accounts receivable/payable consist of trade credit and advances and miscellaneous other items due to be paid or received 7.224

Other changes in the volume of assets Other changes in the volume of assets are any changes in the value of an asset or liability that do not result from a transaction or a holding gain/loss 3.35, 10.1

Other current transfers not elsewhere classified Other current transfers not elsewhere classified are gifts and transfers of a current nature (other than grants or subsidies) from individuals, private nonprofit institutions, nongovernmental foundations, or corporations 5.147

Other economic flows Other economic flows are changes in the volume or value of assets or liabilities that do not result from transactions 3.31

Other employment-related social insurance schemes Other employment-related social insurance schemes derive from an employer-employee relationship in the provision of pension entitlement and other social benefit to employees as part of the conditions of employment A2.40

Other equity Other equity is equity that is not in the form of securities 7.169

Other intellectual property products Other intellectual property products consist of new information and specialized knowledge not elsewhere classified 7.73

Other public financial corporations Other public financial corporations comprise all resident financial corporations, except public deposit-taking corporations, controlled by general government units or other public corporations 2.121

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Other recurrent taxes on property — Other recurrent taxes on property include all recurrent taxes on property other than immovable property or net wealth....5.53

Other revenue — Other revenue is all revenue receivable excluding taxes, social contributions, and grants....5.6, 5.106

Other social contributions — Other social contributions are actual and imputed contributions receivable by social insurance schemes operated by employers on behalf of their employees....5.98

Other structures — Other structures consist of all structures other than buildings....7.48

Other subsidies on production — Other subsidies on production are subsidies that enterprises receive as a consequence of engaging in production but that are not related to specific products....6.90

Other taxes — Other taxes cover revenue from taxes levied predominantly on a base or bases not elsewhere classified, and unidentified taxes....5.93

Other taxes on goods and services — Other taxes on goods and services includes taxes on the extraction of minerals, fossil fuels, and other exhaustible resources from deposits owned privately or by another government and any other taxes on goods or services not included in categories 1141 through 1145....5.82

Other taxes on use of goods and on permission to use goods or perform activities — Other taxes on use of goods and on permission to use goods or perform activities include business and professional licenses that consist of taxes paid by enterprises in order to obtain a license to carry on a particular kind of business or profession and taxes payable by individuals to perform certain activities....5.81

Own funds — Own funds are defined as the difference between total assets (at market values) and total liabilities excluding shares and other equity (at market value)....7.231

Partitioning — Partitioning records a transaction that is a single transaction from the perspective of the parties involved as two or more differently classified transactions....3.29

Pension entitlements — Pension entitlements are financial claims that existing and future pensioners hold against either their employer or a fund designated by the employer, to pay pensions earned as part of a compensation agreement between the employer and employee....7.190

Pensions and other retirement benefits — Pensions and other retirement benefits are payable when individuals cease employment upon retirement....A2.6

Permit to undertake a specific activity — A permit to undertake a specific activity is an asset for the holder when: (i) the permits are limited in number and so allow the holders to earn monopoly profits, (ii) the monopoly profits do not come from the use of an asset belonging to the permit-issuer, and (iii) a permit holder is able both legally and practically to sell the permit to a third party....7.110

Permits to use natural resources — Permits to use natural resources are third-party property rights relating to natural resources....7.109

Premium earned — The premium earned is the part of the actual premium that relates to coverage provided in the reporting period....A4.75

Premiums, fees, and claims payable related to nonlife insurance and standardized guarantee schemes
Premiums, fees, and claims payable related to nonlife insurance and standardized guarantee schemes include nonlife insurance premiums payable to insurance schemes/corporations to secure entitlement to insurance against risks, claims payable by insurance schemes to beneficiaries, and fees payable to obtain standardized guarantees....6.125

Premiums, fees, and claims receivable related to nonlife insurance and standardized guarantee schemes
Premiums, fees, and claims receivable related to nonlife insurance and standardized guarantee schemes comprise nonlife insurance premiums receivable by insurance schemes to provide entitlement to insurance against risks; claims receivable from insurance schemes by beneficiaries; and fees receivable for the issuance of standardized guarantees....5.149

Premiums, fees, and current claims payable
Premiums, fees, and current claims payable comprise nonlife insurance premiums expense and fees payable for the issuance of standardized guarantees, as well as insurance settlement expense that is not exceptional....6.125

Premiums, fees, and current claims receivable
Premiums, fees, and current claims receivable comprise nonlife insurance premium revenue and fees receivable for the issuance of standardized guarantees, as well as insurance settlement revenue that is not exceptional....5.150

Present value
Present value is the value today of a future payment or stream of payments discounted at some appropriate compounded interest rate....7.33

Primary income account
The primary income account shows primary income flows between resident and nonresident institutional units....A7.82

Production measure of gross domestic product
The production measure of gross domestic product is defined as gross value added plus any taxes minus subsidies on products not already included in the value of output....A7.24

Profits of fiscal monopolies
Profits of fiscal monopolies cover that part of the profits of fiscal monopolies that is transferred to the government. Fiscal monopolies are public corporations, public quasi-corporations, or government-owned unincorporated enterprises that have been granted a legal monopoly over the production or distribution of a particular kind of good or service in order to raise revenue and not in order to further the interests of public economic or social policy....5.63

Property expense
Property expense is the expense payable to the owners of financial assets or natural resources when they put them at the disposal of another unit....6.108

Property expense for investment income disbursements
Property expense for investment income disbursements includes property income attributed to insurance policyholders, pension entitlements, and holders of investment fund shares....6.113

Property income
Property income is the revenue receivable in return for putting financial assets and natural resources at the disposal of another unit....5.107

Property income from investment income disbursements
Property income from investment income disbursements includes property income attributed to insurance policyholders and holders of investment fund shares....5.120

Provident funds
Provident funds are compulsory saving schemes that maintain the integrity of the contributions for individual participants....2.148

Public corporations subsector
The public corporations subsector consists of all resident corporations controlled by government units or by other public corporations....2.104

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Public deposit-taking corporations
Public deposit-taking corporations are financial corporations controlled by general government units or other public corporations whose principal activity is financial intermediation and who have liabilities in the form of deposits or financial instruments that are close substitutes for deposits 2.117

Public deposit-taking corporations except the central bank
Public deposit-taking corporations except the central bank consist of all resident depository corporations, except the central bank, that are controlled by general government units or other public corporations 2.120

Public financial corporations subsector
All resident financial corporations controlled by general government units or other public corporations are part of the public financial corporations subsector....2.115

Public monuments
Public monuments are identifiable because of particular historical, national, regional, local, religious, or symbolic significance 7.42

Public nonfinancial corporations subsector
All resident nonfinancial corporations controlled by general government units or other public corporations are part of the public nonfinancial corporations subsector 2.114

Public-private partnerships (PPPs)
Public-private partnerships (PPPs) are long-term contracts between two units, whereby one unit acquires or builds an asset or set of assets, operates it for a period, and then hands the asset over to a second unit....A4.58

Public sector
The public sector consists of all resident institutional units controlled directly, or indirectly, by resident government units—that is, all units of the general government sector and resident public corporations 1.2, 2.63

Quasi-corporation
A quasi-corporation is (i) either an unincorporated enterprise owned by a resident institutional unit that has sufficient information to compile a complete set of accounts and is operated as if it were a separate corporation and whose relationship to its owner is effectively that of a corporation to its shareholders, or (ii) an unincorporated enterprise owned by a nonresident institutional unit that is deemed to be a resident institutional unit because it engages in a significant amount of production in the economic territory over a long or indefinite period of time 2.33

Quasi-fiscal operations
Quasi-fiscal operations are government operations carried out by institutional units other than general government units....2.4

Real holding gain
A real holding gain is defined as the value accruing to an asset as a result of a change in its price relative to the prices of goods and services in general.....10.11

Realized holding gain
A holding gain is realized when an asset is sold, redeemed, used, or otherwise disposed of, or a liability incorporating a holding gain or loss is repaid 10.6

Reassignment
Reassignment records a transaction arranged by a third party on behalf of others as taking place directly by the two principal parties involved....3.30

Recurrent taxes on immovable property
Recurrent taxes on immovable property cover taxes levied regularly on the use or ownership of immovable property, which includes land, buildings, and other structures 5.49

Recurrent taxes on net wealth
Recurrent taxes on net wealth cover taxes levied regularly on net wealth 5.50

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Regional arrangements Regional arrangements involve coordination of institutional units in several countries for a particular monetary or economic purpose A5.1

Reinvested earnings Reinvested earnings are the direct investor's share of the retained earnings of the direct investment enterprise 5.134, 6.121

Remaining maturity or residual maturity Remaining maturity or residual maturity is the period from the reference date (balance sheet date) until the final contractually scheduled payment date 7.267

Rent (expense) Rent is the expense payable to the owners of a natural resource (the lessor or landlord) for putting the natural resource at the disposal of another institutional unit (a lessee or tenant) for use of the natural resource in production 6.120

Rent (revenue) Rent is the revenue receivable by the owners of a natural resource (the lessor or landlord) for putting the natural resource at the disposal of another institutional unit (a lessee or tenant) for use of the natural resource in production 5.122

Rerouting Rerouting records a transaction as taking place through channels that differ from the actual ones, or as taking place in an economic sense when no actual transactions take place..... 3.28

Research and development Research and development consists of the value of expenditure on creative work undertaken on a systematic basis in order to increase the stock of knowledge, including knowledge of man, culture, and society, and use of this stock of knowledge to devise new applications..... 7.66

Residence The residence of each institutional unit is the economic territory with which it has the strongest connection (i.e., its center of predominant economic interest) 2.7

Resource lease A resource lease is an agreement whereby the legal owner of a natural resource that macroeconomic statistics treat as having an infinite life makes it available to a lessee in return for a regular payment recorded as property income and described as rent..... A4.16

Resource management activities Resource management activities are those activities whose primary purpose is preserving and maintaining the stock of natural resources and hence safeguarding against depletion..... A7.108

Restructuring agencies Restructuring agencies are entities set up to sell corporations and other assets, and for the reorganization of companies 2.129

Revenue Revenue is an increase in net worth resulting from a transaction..... 5.1

Sales of goods and services Sales of goods and services consist of the sales by market establishments, administrative fees charged for services, incidental sales by nonmarket establishments, and imputed sales of goods and services..... 5.136

Sales taxes Sales taxes are all general taxes levied on sales at one stage only, whether at manufacturing or production stages or on wholesale or retail trade 5.59

Securities Securities are debt and equity instruments that have the characteristic feature of negotiability..... 7.119

Securities lending Securities lending is an arrangement whereby a security holder transfers securities to another party (security taker), subject to the stipulation that the same or similar securities be returned on a specified date or on demand..... 7.160

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Securities repurchase agreement (repo) A securities repurchase agreement (repo) is an arrangement involving the sale of securities for cash, at a specified price, with a commitment to repurchase the same or similar securities at a fixed price either on a specified future date (often one or a few days hence) or with an open maturity 7.159

Securitization Securitization occurs when a unit, named the originator, conveys the ownership rights over financial or nonfinancial assets, or the right to receive specific future flows, to another unit, named the securitization unit. In return, the securitization unit pays an amount to the originator from its own source of financing. The securitization unit obtains its own financing by issuing debt securities using the assets or rights to future flows transferred by the originator as collateral A3.59

Sinking fund A sinking fund is a separate account, which may be an institutional unit, made up of segregated contributions provided by the unit(s) that makes use of the fund (the "parent" unit) for the gradual redemption of the parent unit's debt. A sinking fund may also be established to provide for major repairs or replacements 2.144

Social assistance Social assistance provides social protection benefits to all persons who are in need without any formal requirement to participate as evidenced by the payment of contributions A2.25

Social assistance benefits Social assistance benefits are transfers payable in cash or in kind to households to meet the same needs as social insurance benefits but are not made under a social insurance scheme 6.101, A2.25

Social benefits Social benefits are current transfers receivable by households intended to provide for the needs that arise from social risks A2.4

Social contributions Social contributions are actual, or imputed, revenue receivable by social insurance schemes to make provision for social insurance benefits payable 5.4, 5.94, A2.4

Social insurance contribution A social insurance contribution is the amount payable to a social insurance scheme in order for a designated beneficiary to be entitled to receive the social benefits covered by the scheme A2.31

Social insurance schemes Social insurance schemes provide social protection and require formal participation by the beneficiaries, evidenced by the payment of contributions (actual or imputed) 2.101, A2.30

Social protection Social protection is the systematic intervention intended to relieve households and individuals of the burden of a defined set of social risks. A2.1

Social risks Social risks are events or circumstances that may adversely affect the welfare of the households concerned either by imposing additional demands on their resources or by reducing their income 2.46, 6.96, A2.1

Social security benefits Social security benefits are social benefits expense payable in cash or in kind to households by social security schemes 6.99

Social security contributions Social security contributions are actual revenue receivable by social security schemes organized and operated by government units, for the benefit of the contributors to the scheme 5.97

Social security fund A social security fund is a particular kind of government unit that is devoted to the operation of one or more social security schemes 2.100, A2.34

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Social security schemes Social security schemes are social insurance schemes covering the community as a whole, or large sections of the community, and are imposed and controlled by government units..... 2.101, A2.33

Sovereign wealth funds Created and owned by the general government for macroeconomic purposes, sovereign wealth funds hold, manage, or administer assets to achieve financial objectives, and employ a set of investment strategies that include investing in foreign financial assets 2.152

Special Drawing Rights Special Drawing Rights (SDRs) are international reserve assets created by the International Monetary Fund (IMF) and allocated to its members to supplement reserve assets 7.131

Standardized guarantees Standardized guarantees are those kinds of guarantees that are issued in large numbers, usually for fairly small amounts, along identical lines..... 7.201, A4.71

State governments State governments consist of institutional units exercising some of the functions of government at a level below that of central government and above that of the government institutional units existing at a local level 2.90

Stock position A stock position is the total holdings of assets and/or liabilities at a point in time.....3.36

Stripped securities Stripped securities are securities that have been transformed from a principal amount with coupon payments into a series of zero-coupon bonds, with a range of maturities matching the coupon payment date(s) and the redemption date of the principal amount(s) 7.152

Subsidies Subsidies are current unrequited transfers that government units make to enterprises on the basis of the level of their production activities or the quantities or values of the goods or services they produce, sell, export, or import 5.146, 6.84

Subsidy on products A subsidy on products is a subsidy payable per unit of a good or service.....6.89

Swap contract A swap contract involves the counterparties exchanging, in accordance with prearranged terms, cash flows based on the reference prices of the underlying items 7.162, 7.215

Synthetic securitization Synthetic securitization involves transfer of the credit risk related to a pool of assets without transfer of the assets themselves, either through a securitization unit or through the direct issuing of debt securities by the original asset owner.....A3.65

Tax credit A tax credit is an amount subtracted directly from the tax liability due by the beneficiary household or corporation after the liability has been computed 5.29

Tax expenditures Tax expenditures are concessions or exemptions from a "normal" tax structure that reduce government revenue collection.....5.28

Tax refunds Tax refunds are adjustments for overestimation of taxes payable or the return of amounts to taxpayers due to overpayments.....5.27

Tax relief measures Tax relief measures are incentives that reduce the amount of tax owed by an institutional unit.....5.28

Taxes Taxes are compulsory, unrequited amounts receivable by government units from institutional units 5.2, 5.23

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Taxes on capital gains Taxes on capital gains consist of taxes on the capital gains (including capital gain distributions of investment funds) of persons or corporations that become payable during the current reporting period, irrespective of the periods over which the gains have accrued 5.41

Taxes on financial and capital transactions Taxes on financial and capital transactions are taxes levied on the change in ownership of property, except those classified as gifts, inheritance, or estate transactions 5.61

Taxes on goods and services Taxes on goods and services are taxes that become payable as a result of the production, sale, transfer, leasing, or delivery of goods and rendering of services, or as a result of their use for own consumption, or own capital formation 5.55

Taxes on income, profits, and capital gains Taxes on income, profits, and capital gains consist of taxes assessed on the actual or presumed incomes of institutional units 5.41

Taxes on individual or household income Taxes on individual or household income consist of personal income taxes, including those deducted by employers (pay-as-you-earn taxes), and surtaxes 5.41

Taxes on international trade and transactions Taxes on international trade and transactions are taxes that become payable when goods cross the national or customs frontiers of the economic territory, or when transactions in services exchange between residents and nonresidents 5.83

Taxes on payroll or workforce Taxes on payroll or workforce are taxes payable by enterprises assessed either as a proportion of the wages and salaries paid or as a fixed amount per person employed 5.45

Taxes on property Taxes on property are taxes payable on the use, ownership, or transfer of wealth 5.46

Taxes on specific services Taxes on specific services are levied on payments for specific services 5.69

Taxes on the income of corporations Taxes on the income of corporations consist of corporate income taxes, corporate profits taxes, corporate surtaxes, etc. 5.41

Taxes on use of goods and on permission to use goods or perform activities Taxes on use of goods and on permission to use goods or perform activities are fees levied for the issuance of a license or permit that are not commensurate with the cost of the control function of government 5.72

Taxes on winnings from lotteries or gambling Taxes on winnings from lotteries or gambling are taxes payable on the amounts receivable by winners 5.41

Total gross debt Total gross debt—often referred to as "total debt" or "total debt liabilities"—consists of all liabilities that are debt instruments. A debt instrument is defined as a financial claim that requires payment(s) of interest and/or principal by the debtor to the creditor at a date, or dates, in the future 7.236

Transaction A transaction is an economic flow that is an interaction between institutional units by mutual agreement or through the operation of the law, or an action within an institutional unit that is analytically useful to treat like a transaction, often because the unit is operating in two different capacities 3.5

Transfer A transfer is a transaction in which one institutional unit provides a good, service, or asset to another unit without receiving from the latter any good, service, or asset in return as a direct counterpart 3.10

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Transfers not elsewhere classified (payable) Transfers not elsewhere classified payable include a number of gifts and transfers to individuals, private nonprofit institutions, nongovernmental foundations, corporations, or government units that are not included in other categories of transfers, and serving quite different purposes 6.122

Transfers not elsewhere classified (receivable) Transfers not elsewhere classified receivable include subsidies, as well as gifts and transfers from individuals, private nonprofit institutions, nongovernmental foundations, corporations, or sources other than governments and international organizations....5.145

Transport equipment Transport equipment consists of equipment for moving people and objects ...7.54

True-sale securitization True-sale securitization involves debt securities issued by a securitization unit where the underlying assets have been transferred from the original asset owner's (i.e., the originator's) balance sheet to that of the securitization unit A3.62

Turnover and other general taxes on goods and services Turnover and other general taxes on goods and services are multistage cumulative taxes and taxes where elements of consumption taxes are combined with multistage taxes 5.60

Unallocated gold accounts Unallocated gold accounts represent a claim against the account custodian to deliver gold 7.127

Unearned premium The unearned premium is the amount of the actual premium received that relates to the period past the reporting period A4.75

Unrealized holding gain An unrealized holding gain is one accruing on an asset that is still owned or a liability that is still outstanding at the end of the reporting period 10.6

Valuables Valuables are produced assets of considerable value that are not used primarily for purposes of production or consumption, but are held primarily as stores of value over time 7.18, 7.87

Valuation of stock positions Stock positions should be valued at market value—that is, as if they were acquired in market transactions on the balance sheet reporting date (reference date)....3.113

Value of goodwill and marketing assets The value of goodwill and marketing assets is the difference between the value paid for an enterprise as a going concern and the sum of its assets minus the sum of its liabilities, each item of which has been separately identified and valued....7.116

Value-added taxes Value-added taxes (VAT) are taxes on goods or services collected in stages by enterprises but ultimately charged in full to the final purchasers....5.58

Wages and salaries Wages and salaries are compensation of employees payable in cash and/or in kind, except for social contributions payable by employers 6.12

Wages and salaries in cash Wages and salaries in cash are the amounts payable in cash, or any other financial instruments used as means of payments, to employees in return for work performed....6.13

Wages and salaries in kind Wages and salaries in kind are amounts payable in the form of goods, services, interest forgone, and shares issued to employees in return for work performed..... 6.17

Water resources Water resources consist of surface and groundwater resources used for extraction to the extent that their scarcity leads to the enforcement of ownership or use rights, market valuation, and some measure of economic control....7.102

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Weapons systems Weapons systems include vehicles and other equipment such as warships, submarines, military aircraft, tanks, missile carriers and launchers, etc. 7.74

Withdrawals of income from quasi-corporations Withdrawals of income from quasi-corporations consist of that part of distributable income that the owner withdraws from the quasi-corporation 5.118

Work in progress Work in progress consists of goods and services that are not yet sufficiently processed to be in a state in which it is normally supplied to other institutional units 7.80

Written-down replacement cost Written-down replacement cost is the current acquisition price of an equivalent new asset minus the accumulated consumption of fixed capital, amortization, or depletion 3.115

Zero-coupon bonds Zero-coupon bonds are long-term securities that do not involve periodic payments during the life of the bond 7.147

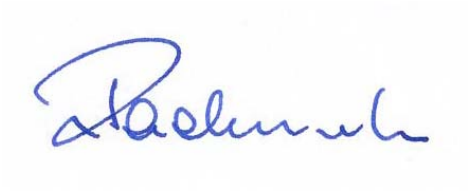
Foreword

The Technical Compilation Guide for Pension Data in National Accounts is a handbook for compilers and users of data on pension schemes in social insurance. It has been produced by Eurostat and the European Central Bank based on a mandate given by the Committee on Monetary, Financial and Balance of Payments Statistics to a Eurostat/ECB Task Force on the statistical measurement of the assets and liabilities of pension schemes in general government in 2006.



The Compilation Guide aims at supporting the work of National Statistical Institutes, Central Banks and other compilers within the European Union to derive estimates for position and flow data for pension entitlements. Such entitlements of households are reflected by corresponding obligations of various pension schemes in social insurance - either privately managed or managed by general government. Data on pension obligations need to be included in the supplementary table on pension schemes in social insurance. Such a table is described in chapter 17 of the System of National Accounts, 2008 (2008 SNA) and also in Annex A (chapter 17) of the European System of Accounts (ESA 2010). As table 29, it is also part of the Transmission Programme of ESA 2010, Annex B.

Most of the government-managed pension schemes in Europe are based on the pay-as-you-go principle whereby current contributions finance current benefits. To examine and especially improve the recording of such schemes, the various steps on how to derive actuarial estimates are described in the Compilation Guide. Moreover, the required data sources are mentioned and the results are demonstrated in various case studies and worked examples.

In this regard, we thank Mr. Bernd Raffelhüschen and Mr. Christoph Müller, Forschungszentrum Generationenverträge of the University of Freiburg, for providing a first draft of the Compilation Guide and also the numerical examples. Mr. Peter Parlasca and Mr. Ismael Ahamdanech-Zarco, both from Eurostat, and Mr. Reimund Mink, from the ECB, have contributed to the preparation of this Compilation Guide.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

We encourage all European Union countries to use this Compilation Guide for estimating the pension obligations of such schemes for which no actuarial estimates are made available from other data providers such as from business accountants or from supervisory agencies.

Introduction

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

1 Introduction

Demographic projections for the European Union (EU), as for many other industrialised countries, are characterised by an ageing of the population. This will have a substantial impact on general government spending. A declining European workforce combined with a rapidly expanding number of retirees will force up spending on pensions, health-care and long-term care, while populations will start to decrease in the coming years. The dynamics of general government-managed pension schemes in Europe are usually based on the pay-as-you-go principle whereby current contributions finance current benefits. To examine and improve the recording of these schemes in the System of National Accounts (SNA), the Committee on Monetary, Financial and Balance of Payments Statistics (CMFB) agreed, in 2006, to establish a Eurostat/ECB Task Force on the statistical measurement of the assets and liabilities of pension schemes in general government. This Task Force made significant input to the SNA update process for pensions, notably through the design and compilation of a *supplementary table on pension schemes* in social insurance in the 2008 SNA and also in the European System of Accounts (ESA 2010) as adopted by the Commission.

Pension entitlements were already partly recorded in the 1993 SNA. However, the 1993 SNA did not recognise pension entitlements of defined benefit (unfunded) pension schemes as assets of households and as liabilities of such schemes. The ESA 95 treated defined benefits pension schemes in the same way.[1] The 2008 SNA and the ESA 2010 as the new statistical standards provide detailed guidelines for compiling supplementary data on pension entitlements under defined benefit schemes. They cover schemes managed by non-general government units and schemes managed by the general government and also social security schemes.[2] According to these standards, pension entitlements of households (and pension obligations of the schemes) are recorded in national accounts (NA).[3] However, the new international standards define a set of rules which provide compilers with guidance on when to include pension schemes in the core system of accounts and when to

[1] According to ESA 95, 'provisions or similar funds constituted by employers to provide employees with pensions (non-autonomous pension funds) are only included in the category insurance technical reserves if they are calculated according to actuarial criteria similar to those used by insurance corporations and autonomous pension funds' (see ESA95, paragraph 5.101).
[2] For a description of the recent steps taken to reform the SNA, see Mink (2007), p. 203 et seq. For a short explanation of the reasons to change the SNA, see Mink and Rother (2007), Semeraro (2007) or Dippelsman (2010).
[3] According to the SNA 2008, paragraph 11.107: 'pension entitlements show the extent of financial claims both existing and future pensioners hold against either their employer or a fund designated by the employer to pay pensions earned as part of a compensation agreement between the employer and employee.'.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

include the outstanding amounts of pension entitlements only in the supplementary table on pension schemes in social insurance[4].

The supplementary table records all positions and flows in pension obligations of all pension schemes in social insurance. This new table provides a complete and consistent coverage of all pension entitlements and obligations across countries.[5] It shows all positions and flows of pension obligations of pension schemes in an economy and (as a counterpart) the corresponding pension entitlements as held by households.

In the context of the ESA 2010, it may be mandatory in the coming years for EU countries to record a full set of position and flow data on pension obligations of all pension schemes including the schemes managed by general government for its own employers and social security pension schemes.

In 2007, the Eurostat/ECB Task Force on the statistical measurement of the assets and liabilities of pension schemes in general government had started to model and estimate position and flow data for defined benefit schemes for general government employees and for social security pension schemes. First benchmark estimations of pension entitlements were made based on harmonised assumptions for 19 EU countries. In March 2008, this work was taken over by the Eurostat/ECB Contact Group on Pensions.[6]

To compile position and flow data for government pension schemes source data may be made available from government entities and also from supervisory agencies. Such data are usually the basis to carry out actuarial estimates for defined benefit schemes for government employees and for social security pension schemes. Actuarial estimates are broadly applied in the insurance and pension fund business.

This Technical Compilation Guide for Pension Data in National Accounts (the Technical Compilation Guide) helps countries compile pension entitlements and obligations to be included in the supplementary table as described above. The Technical Compilation Guide covers:

[4] The supplementary table on pensions in social insurance is described in Chapter 17 of the 2008 SNA and in Chapter 17 of the ESA 2010 (Annex A). It is also part of the ESA 2010 Transmission Programme (Annex B, Table 29).

[5] The data reported on pension entitlements based on the 1993 SNA and the ESA 93 show considerable differences in the accounts from country to country due to the institutional variety in pension schemes. While pension entitlements and obligations of government-managed defined benefit schemes for general government employees and of social security pension schemes (like in France, Germany or Italy) were not recorded as positions in the national accounts, pension entitlements and obligations in countries with mainly defined contribution schemes were covered as assets and liabilities in the national accounts.

[6] For an overview on the recent work of the Task Force and of the Contact Group see Task Force (2008) and Contact Group (2009).

Estimating pension entitlements and obligations in national accounts

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

2 Estimating pension entitlements and obligations in national accounts

2.1 Concepts of pension entitlements and obligations

Pension entitlements of households can be recorded either as financial assets in the national accounts or as contingent assets. Those treated as financial assets constitute financial claims that beneficiaries have vis-à-vis either their employer or a pension manager designated by the employer to pay pension benefits earned as part of a compensation agreement concluded between the employer and the employee. Those treated as contingent assets usually represent 'conditional claims' on defined benefit schemes managed by general government, including social security pension schemes. As counterparts, they are recorded as contingent liabilities of the government.

The aim of the supplementary table is to give an overview of pension obligations (of general government but also of other institutional sectors) vis-à-vis households covering all pension schemes in social insurance. The figures in the supplementary table present the perspective of the debtor (the pension scheme) indicating pension obligations (either liabilities or contingent liabilities) as well as that of the creditor (households) showing pension entitlements (either assets or contingent assets). In the supplementary table, the positions and flows of the pension obligations always correspond to the positions and flows of pension entitlements.[7]

Table 1: Concepts of pension obligations

Time horizon	Gross liabilities (incl. expenditures)	Net liabilities (incl. expenditures & revenues)
	Accrued-to-date liabilities (ADL)	
	Current workers' and pensioner's liabilties (CWL)	
infinite ↓	Open-system gross liabilities (OSGL)	Open-system net liabilities (OSNL)

[7] When the text refers to positions or flows of pension obligations, it corresponds to positions or flows of pension entitlements and vice versa.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

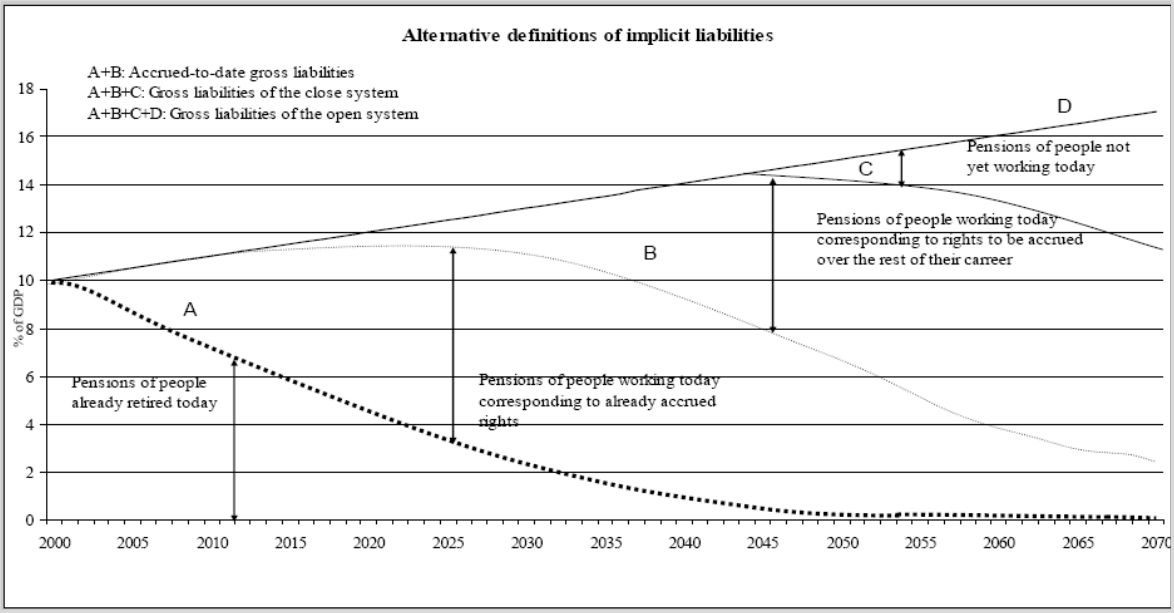
Pension obligations or pension entitlements in national accounts always refer to a gross concept. It means that these obligations or entitlements are not netted against expected revenue of government or expected social contributions of households. In the case of defined contribution pension schemes or social security pension schemes, no future revenue or future social contributions are taken into account to compile any type of net pension entitlements or pension obligations (see Box 1). Only pension entitlements or obligations are considered. They are based on (actual and future) pension benefits.

Box 1

Three concepts of pension obligations

In recent literature (see Franco, 1995, pg. 2) three main concepts of pension obligations have been introduced: the concepts of (a) *accrued-to-date liabilities (ADL);* (b) *current workers and pensioners liabilities;* and (c) *open-system liabilities*. Box 1 gives a detailed description of these concepts.All pension obligations of pension schemes or pension entitlements of households are assessed as part of extended balance sheets of pension schemes or households in the national accounts (showing assets and contingent assets or liabilities and contingent liabilities) at a certain point in time, usually at the year-end. The pension entitlements or obligations under defined benefit (unfunded) social insurance pension schemes are recorded in gross terms, meaning that no accrued-to-date obligations reflecting future social contributions to finance the pension entitlements are taken into account; instead only the accrued-to-date pension entitlements for current and future pension benefits (ADL) are covered, i.e. the pension entitlements accrued by current workers (including deferred pension entitlements) and the remaining pension entitlements of existing pensioners. As for all national accounts data, the data are measured ex post, as they include only the current values of the entitlements that arise from already accrued pension rights. The method is based on observable past events and transactions, such as membership of the pension scheme and contributions paid. However, these ex post measures also rely on some assumptions in the modelling process. The probability that current contributors may die or become disabled before reaching pensionable age needs to be estimated. The approach also covers future changes to the (defined) pension benefits owing to any legislation enacted prior to the year for which pension entitlements are calculated. Finally, the method requires assumptions about future developments, notably the development of the discount rate for future pension disbursements. As with all other assets, the pension entitlements are entered into the extended household balance sheet at their value on the balance sheet date. Since actuarial values for pension entitlements or obligations related to defined benefit (unfunded) pension schemes in social insurance in the EU countries are typically not made available by the manager of the pension scheme, compilers of national accounts have to estimate the actuarial value.

a) *Accrued-to-date liabilities (ADL)*: These pension entitlements or obligations contain the present value of pensions to be paid in the future on the basis of accrued rights. Accrued pension rights are due to already paid social contributions by current workers and remaining pension entitlements of existing pensioners. No rights accrued after the current year — by present or by future workers — are considered. The time horizon of this concept is, therefore, somewhat limited. As shown in Figure 1 ADL covers only integral amounts below curve B (also taking a discount rate into consideration).



b) *Current workers' and pensioners' liabilities (CWL)*: For CWL, allowance is made for the pension scheme to continue until the last current contributor dies. However, new entrants are not included. This concept covers ADL and the present value of pension entitlements that will be accrued by current contributors due to their future contributions. CWL corresponds to the integral amounts below curve C (considering additionally a discount rate) in Figure 1.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

c) *Open-system liabilities (OSL)*: In addition to CWL, this liability concept also includes the present value of pensions of new workers entering the respective pension scheme. It is assumed that the pension scheme will be continued under current rules for a relatively long time horizon. The present value of OSL may be compiled over an infinite time horizon. For practical reasons, however, a perspective, e.g. 200 years, is usually chosen.

Figure 1

Alternative definitions of implicit liabilities

Source: European Commission Public Finance Report 2006.

Applying one of the three liability concepts depends on the specific purpose of the analysis. To assess the fiscal sustainability of a defined benefit (unfunded) pension scheme managed by government for its employees, for example, it is natural to apply the widest possible time horizon. This means using the OSL concept to examine long-term fiscal sustainability. By contrast, policy issues concerning the possible termination of an existing defined benefit pension scheme should be addressed on the basis of the ADL or the CWL concept, depending on the remaining time horizon of the scheme taking also into consideration that only the ADL concept complies fully with the methodology used in national accounts.

In line some other valuation procedures used for financial instruments like unlisted shares or other equity, for which market values are not or not always available, the compilation of ADL is based on a net present value approach. In fact, estimating position and flow data for defined benefit pension schemes for government employees and for social security pension schemes to fill in the corresponding cells of the supplementary table involves projecting historical data into the future. For this purpose, actuarial estimates have to be carried out as described in further detail in Chapter 5 and Chapter 7. This method is commonly used in the insurance and pension fund sector, where actuarial figures are estimated on a frequent and standardised basis. Source data for the general government sector, however, are often limited to annual cash reporting. Moreover, actuarial estimations are not widely used there at present.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

These actuarial calculations require a number of careful assumptions to be made. They include assumptions about future life expectancy, which determine the payout period of future pensions. In particular, assumptions on future wage growth and on an appropriate discount rate play a crucial role in projecting pension entitlements or obligations accrued-to-date.[8]

It is important to stress that pension entitlements (derived as accrued-to-date and applied in national accounts) do not allow any conclusions to be drawn as to the fiscal sustainability of a pension scheme. Large pension entitlements do not necessarily mean unsustainable pension schemes, and by the same token small pension entitlements do not mean that the respective pension schemes are fiscally stable in the long term (for a detailed discussion see Box 2).

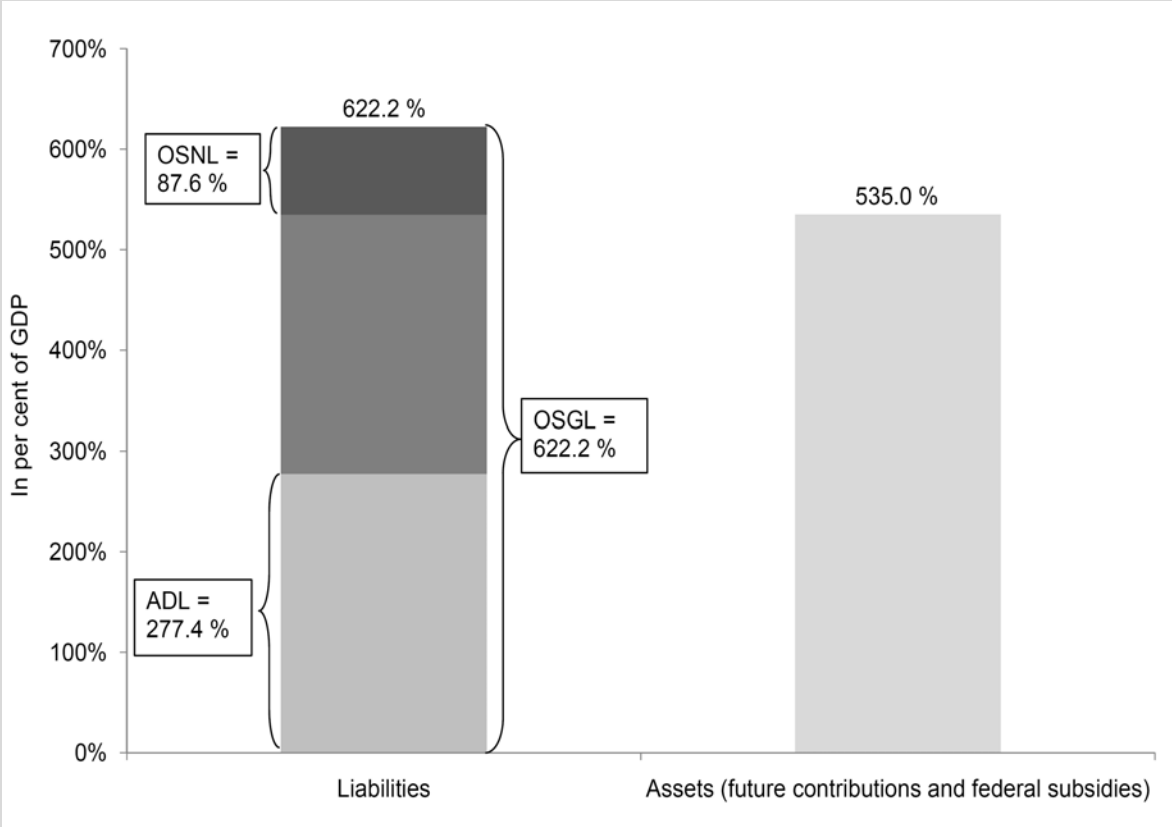
Box 2

Pension entitlements are not sustainability indicators

Measures of pension entitlements accrued-to-date are the appropriate data to be reported in the system of national accounts. In this respect, they are useful for economic and policy analyses. They provide an estimate of the cost of a hypothetical termination of a pension scheme without reneging on accrued entitlements. As measures of household wealth (assets and contingent assets), they are also valuable statistical information to understand positions and flows in household wealth also in relation to saving and consumption. Furthermore, ADL help in assessing pension reforms of various kinds, such as establishing a new system for new contributions or new contributors, while maintaining the current system for already accrued entitlements.

Pension entitlements accrued-to-date are not an appropriate indicator of fiscal sustainability. They can be interpreted as the amount of resources which has to be set aside today in order to finance all pension rights which have been earned up to a given year. Entitlements that will accrue after that year are not included. In contrast to other liability concepts such as OSL, therefore, the time horizon of ADL is somewhat limited. As illustrated in Figure 2 for the German statutory pension scheme, the ADL represent only one part of the OSL. Moreover, the ADL are compiled gross without including the net present value of future social contributions. To assess fiscal sustainability it is vital to compare (future) pension obligations with the corresponding future pension-related assets.

Figure 2 outlines the difference between ADL and sustainability indicators for the German statutory pension scheme. It shows that a considerable amount of ADL (equivalent to about 280% of GDP in 2006) is accumulated in this scheme. If future entitlements are also considered — applying the open system gross liability concept (OSGL) — pension obligations add up to more than 600 percent of GDP. However, it is only possible to draw conclusions about the sustainability of a pension scheme by comparing these pension obligations with the respective assets. The resulting residual amount of obligations and assets represents the open-system net liabilities (OSNL), also known as the sustainability or fiscal gap. In contrast to the ADL, it represents the stock which has to be set aside today to sustain the present pension system (in its legal status quo) in the long term. While the ADL only take into account a fraction of the future demographic development, namely the change in the number of retirees, the OSNL consider the long-term development of the overall population. Figure 2 also illustrates that the ADL estimates can indeed be extended to measure open system gross and net liabilities, provided that a longer time horizon



[8] The assumptions of the actuarial approach are outlined in detail in Section 5.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

is used and the corresponding assets are included.[9]

Figure 2

Accrued-to-date liabilities and related sustainability indicators

Source: Müller et. al. (2010), p. 117.

2.2 Projected and accumulated benefit obligations

When estimating the ADL, one of the following two approaches may be applied: either the *projected benefit obligations approach (PBO)* or the *accumulated benefit obligations approach (ABO)*. The main difference between these two compilation methods refers to the treatment of future wage increases. In the case of the PBO approach, (expected) future increases in income — either through promotions or through a general increase of wages — are taken fully into account. The ABO approach, on the other hand, considers only the present value of benefits earned to date. Future wage increases are not taken into account.

The choice between the two concepts may have a significant impact on the level of pension entitlements. Results are usually by 10 to 20% higher when applying PBO instead of ABO.[10]

[9] For a description of extending the ADL approach, see Müller et al. (2010).
[10] Of course, this differential depends to a large degree on the promotions during working life, i.e. it depends on the progression of the age-specific wage profile — shown exemplarily in figure 8. The higher promotions are

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Therefore, clear guidelines have to be applied which of the two approaches should be chosen to ensure comparability of results across pension schemes and also across EU countries.

Each method has its advantages and disadvantages. The probability of a termination or of a freezing of the respective pension scheme (before the end of a worker's career) should determine which method to apply. If the pension scheme is likely to exist until the end of a worker's career, his or her future wage growth needs to be taken into account, applying the PBO method. This approach is often recommended for pension schemes established for government employees.[11] The International Public Sector Accounting Standards (IPSAS25) also recommend applying the PBO approach to measure pension obligations of defined benefit plans.[12] Business accounting standards, in particular the International Accounting Standards 19 (IAS 19), also recommend the PBO approach. For social security pension schemes, the PBO approach seems the appropriate valuation method, since, in normal circumstances, an early termination of these schemes is not expected.

Furthermore, the PBO approach is a more suitable way of reflecting certain pension reforms. While an extension of the contribution periods relevant for the benefit formula (e.g. from best 25 income years to lifetime earnings), for example, may have no effect in the case of the ABO approach, it can change the entitlements when the PBO approach is applied. The PBO approach is also the most appropriate method to take into account the different indexation rules of pension schemes.

In conclusion, most arguments are in favour of the PBO approach rather than the ABO approach to estimate pension obligations of pension schemes managed by general government. This method has already been used in most countries which have already estimated corresponding pension obligations.[13]

To maintain consistency across pension schemes it is recommended to apply the ***PBO approach for the estimation of pension obligations of defined benefit schemes for government employees and of social security pension schemes. However, the ABO may be applied if there are good reasons to do so.***[14]

expected, i.e. the steeper the wage profile the more significant is the difference between ABO and PBO outcomes.

[11] See Reinsdorf (2010), p. 190 et seq.

[12] In fact, the IPSAS25 requires an entity to use the Projected Unit Credit Method, which is equivalent to the PBO approach.

[13] See Contact Group (2009), p. 10f. Only Sweden applies the ABO approach for its calculations.

[14] Some actuarial estimates provided by external institutions may apply only an ABO approach. It is feasible to use such figures to compile pension entitlements if no PBO estimations are available.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

In practice, various modifications of the PBO approach are applied, depending on how indexation effects are taken into account. These are the PBO approach with:

1) no future indexation of pensions;
2) price indexation;
3) wage indexation;
4) pensions indexed in accordance with indexation rules.[15]

To estimate defined benefit pension obligations, the PBO approach as described under 4) should be applied. This would allow country-specific differences in indexation policies to be reflected in the estimations.

[15] For a description of indexation rules, see Chapter 7.3.

3 Pension schemes in social insurance covered by the supplementary table

The supplementary table on pension schemes in social insurance as reflected in the 2008 SNA and in the ESA 2010 covers positions and flows of pension obligations in all pension schemes regarded as social insurance. In order to complete this table, the various types of pension schemes (in the columns of the table) must be distinguished and the positions and flows in pension obligations (in the rows of the table) defined. In addition the concepts of pension benefits and other social benefits, of social insurance social assistance and individual insurance policies have to be distinguished.[16]

3.1 Pension benefits and non-pension benefits

In the 2008 SNA and in the ESA 2010 social insurance benefits (and the corresponding contributions) are divided between those related to pensions (pension benefits) and those related to all other forms of benefit.[17] All other benefits are grouped together as non-pension benefits.

Box 3

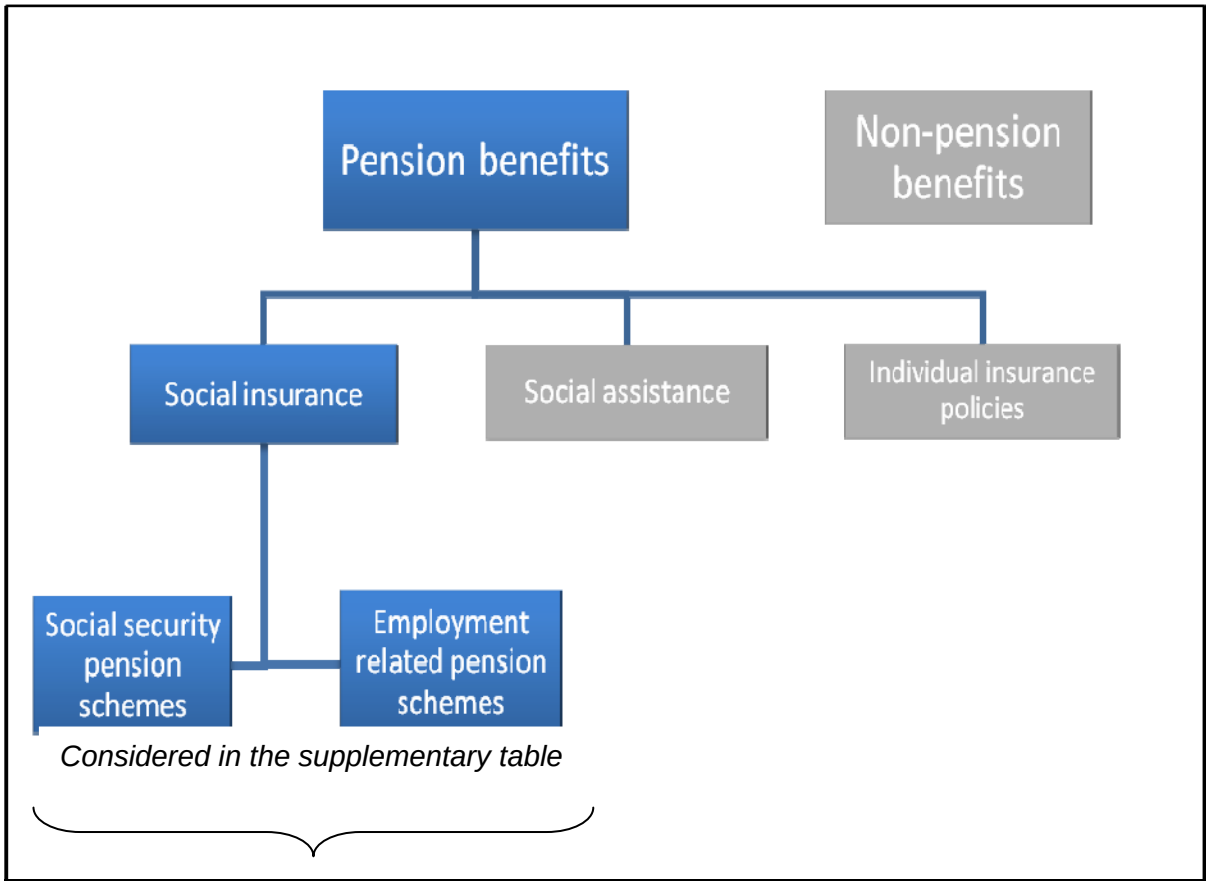
Pension benefits

Pension benefits are predominantly old-age pensions. However, survivors' pensions — consisting of widows' and orphans' pension benefits — and disability and early retirement pensions also fall under the term pension benefits.

Pensions are generally disbursed in the form of a guaranteed annuity[18] and received under predetermined legal or contractual terms. It is important to stress that, in the supplementary table, pension benefits are recorded in gross terms, i.e. there are no deductions made for taxes, social contributions or any service charge associated with the respective pension scheme.

Only pension benefits (and the corresponding contributions) are covered by the supplementary table. A definition of the term pension is given in Box 3Box . The distinction between pension benefits and non-pension benefits is important since the 2008 SNA recognises liabilities for pensions whether there are actually assets set aside to meet the entitlements or not, but recognises reserves for non-pension benefits only when these actually exist.[19]

[16] This chapter follows closely Chapter 17 of the ESA 2010 and Chapter 17 of the 2008 SNA.
[17] See 2008 SNA, paragraph 17.98.
[18] For a definition of annuities, see 2008SNA, paragraphs 17.66-17.75.
[19] See 2008 SNA, paragraph 17.99.



Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

3.2 Social insurance, social assistance and individual insurance policies

Pensions can be provided to beneficiaries in the form of (i) social insurance pension schemes; (ii) social assistance; and (iii) individual insurance policies related to pensions (see Figure 3).

Figure 3

Social insurance, social assistance and individual insurance policies

Social insurance is the predominant form of pension scheme in EU countries, covering social security pension schemes (classified as belonging to the general government sector) which, in many cases, are organized for major parts of the population, and employment-related pension schemes established by employers, including government, for their own employees. The distinction between social security schemes and employment-related schemes varies considerably from country to country, with the consequence that the coverage and, therefore, the national perception of what the term “social security” means also vary considerably, especially between European and non-European countries.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Figure 4

Characteristics of social insurance

Characteristics	Social insurance			
	The beneficiary is obliged or encouraged to take out insurance against contingencies (old age, unemployment, illness, long-term care) by intervention of a third party.			
	Social security		**Employment-related social insurance**	
Form of organisation	Organised by general government via social security schemes		Organised by employers on behalf of their employees and their dependants or by others on behalf of a specified group	
Type of social insurance	Social security pension schemes	Other social security	Employment-related pension schemes	Other employment-related social insurance
Sector	Social security funds		Sector or sub-sector of employer, or pension funds	

In contrast to social insurance benefits, **social assistance benefits** are payable without qualifying contributions having been made to a social insurance scheme. Usually all resident households are entitled to apply for social assistance but the conditions under which it is granted are often restrictive. Generally, benefits are means-tested, including an assessment of available income and property. Only those households falling below a given income/property threshold may be granted this type of social assistance.

Sometimes it may not be feasible (or not sufficiently important) to separate elements of social assistance within pension schemes organised as social insurance. In these exceptional cases, social assistance benefits are included in the supplementary table.

Individual insurance policies related to pensions are policies that beneficiaries take out in their own names without being members of a scheme organized collectively for groups of employees, as in the case of social insurance. They are based on contracts which are (generally) made with individuals and which are not organised collectively. These individual insurance policies are not employment related and therefore are not recorded in the supplementary table.

Employment-related social insurance pension schemes may be managed by general government or by non-government entities, and they may be funded or unfunded. Funded

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

schemes finance pension benefits by drawing down segregated and earmarked assets. Their design requires them to hold assets equal to their liabilities. These schemes can be exactly funded, under-funded or over-funded, depending on the size of the accumulated assets in relation to the pension entitlements. Unfunded schemes finance current pension payments with the ongoing contributions paid by future pensioners and/or other ongoing revenue, such as taxes or transfers; unfunded schemes may nevertheless hold assets (for liquidity reasons, for example, or as buffer funds).

The supplementary table covers social insurance-type pension schemes but not schemes based on social assistance-type benefits and private savings benefits. To draw a clear line between these different types of schemes, the following definitions are essential:

(i) ***Social insurance*** refers to a contractual insurance scheme where the beneficiaries are obliged or encouraged to insure against certain contingencies by the intervention of a third party. According to 2008 SNA a ***social insurance scheme must fulfil the following two conditions***:

a) The benefits received are conditional on participation in the scheme and constitute social benefits as this term is used in the 2008 SNA.

b) At least one of the three following conditions is met:

- Participation in the scheme is obligatory either by law or under the terms and conditions of employment of an employee, or group of employees.
- It is a collective scheme operated for the benefit of a designated group of workers, whether employed or non-employed, participation being restricted to members of that group.
- An employer makes a contribution (actual or imputed) to the scheme on behalf of an employee, regardless of whether the employee contributes.

Social insurance pensions are broken down into benefits provided by general government — so-called social security pensions — and pensions provided by employers, namely employment-related pensions (other than social security pensions). This distinction is applied in the supplementary table for government-managed pension schemes.

- ***Social security pension schemes*** are contractual insurance schemes where the beneficiaries, as participants of a social insurance scheme, are obliged or encouraged by government to insure against old age, unemployment and so forth. Social security pensions are provided to beneficiaries by general government.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Contributions towards a social security pension scheme are often compulsory for a large part of the population. Furthermore, social security pension schemes are generally defined benefit schemes which means that they are unfunded and are financed on a pay-as-you-go basis.

The narrowest form of a social security pension is very basic. The level may be fixed independently of the size of contributions. Such flat-rate pension schemes are found in Ireland and the Netherlands. Most countries in Europe have earnings-related social security pension schemes, e.g. Germany and France. In these systems, the level of future pensions depends on the earnings history of contributors.

No pension entitlements for social security pension schemes are recognised in the core system of national accounts. They are only displayed in the supplementary table described in Section 4.

- ***Employment-related pension schemes***, other than the most basic form of social security pension schemes, are seen as part of the compensation package for employees. Negotiations between employees and employers may focus on pension entitlements as much as on current conditions of service and pay scales.

The relative importance of social security pension schemes relative to other social insurance schemes varies quite considerably across Europe. In some countries, such as Malta and France, almost all pension obligations accruing to employees of corporations and other legal entities may be rerouted through social security pension schemes. Other countries, such as the Netherlands and the United Kingdom, restrict their social security pension schemes mainly to the provision of basic pensions based on the dominant *employment-related pension schemes.* Social insurance contributions — paid by employees or by employers vis their employees — entitle designated beneficiaries to receive social benefits (covered by the respective scheme).

Most positions in pension obligations of employment-related pension schemes are recorded in the core system of national accounts and in the supplementary table. For government employee pension schemes, however, the classification is not so straightforward. Based on a convention, **positions in pension obligations of defined benefit pension schemes for government employees in EU countries are to be recorded in the supplementary table only**. See Section 3.4 for a detailed description of the division between core and non-core accounts.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

3.3 Defined contribution, defined benefit and other pension schemes

The supplementary table distinguishes between two types of pension schemes:

- *defined contribution schemes* (columns A and D); and
- *defined benefit schemes* (columns B, E, F and G).

In a ***defined contribution (DC)*** scheme, the level of eventual pension benefits is exclusively determined by contributions over the employee's working life and the return on funds invested. Defined contribution schemes are always organised in the form of a pension fund.[20]

The risk that an adequate retirement income may not be forthcoming is borne solely by the employees. An underfunded defined contribution scheme is impossible by definition. Measuring pension obligations of defined contribution schemes is relatively straightforward; their development is determined by the development of the assets attributed to the fund.

Defined benefit (DB) schemes, on the contrary, are pension schemes in which the pension benefits are determined by the use of a formula, either independently or in combination with a guaranteed minimum amount payable. Generally, the factors considered to estimate the defined benefits are the years of service, the salary over a defined period of time, the age at retirement and the indexation rule.

Unlike in a defined contribution scheme, the manager[21] of the pension scheme bears the risk of providing an adequate pension in defined benefit schemes. Defined benefit schemes can be, but are not necessarily, based on a pension fund. Social security pension schemes are usually designed as defined benefit schemes which are unfunded and arranged as pay-as-you-go arrangements. Therefore, pension entitlements need to be estimated using actuarial methods, which are described in detail in Section 5 to Section 8.

Other non-defined contribution schemes are recorded together with defined benefit schemes in the supplementary table; they are often described as hybrid schemes in that they combine the characteristics of defined contribution schemes and defined benefit schemes. In these schemes, the risk of providing an adequate retirement income is shared between the pension manager and the beneficiary of the scheme. The most important forms of such hybrid schemes are notional defined contribution (NDC) schemes, which are similar to

[20] A pension fund can be defined as a pool of assets that is used to pay pension benefits. It can be contrasted with the term 'pension scheme' which represents a bundle of rules for paying out pensions.
[21] For a definition of the term *manager* see below.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

defined contribution schemes but, usually, include a guaranteed minimum amount payable. In notional defined contribution schemes, contributions (from both, employees and employers) are credited to, and accumulated on, individual accounts. These individual accounts are notional in the sense that the contributions to the schemes are used to pay pension benefits to current pensioners.

3.4 Core and non-core accounts

The supplementary table on pensions in social insurance distinguishes between pension schemes whose positions are recorded in the core system of national accounts (and in the supplementary table) and those recorded only in the supplementary table. There is essentially one type of pension scheme, namely social security pension schemes, recorded only in the supplementary table. For EU countries however, by convention, all defined benefit schemes for general government employees are also recorded only in the supplementary table. Positions and flows of these two types of pension schemes are recorded in columns G and H of the supplementary table.

3.5 Pension manager, multi-employer pension scheme and pension administrator

The supplementary table classifies pension schemes according to the sector classification of the manager[22] of the pension scheme. A **pension manager** is mandated by the employer to manage the pension scheme. He is responsible for setting the terms of an employment-related pension scheme and bears the ultimate responsibility for pension entitlements. The pension manager also has a significant degree of responsibility for the long-term policy of investment in assets, including the selection of an investment strategy and the structure of administrative providers.

A single unit may often contract with several employers to manage their pension schemes. This unit is called a **multi-employer pension scheme**. As a pension manager, it bears the responsibility for any shortfall in the funds to meet the entitlements in return for the right to keep any excess funds. By pooling the risks of various employers, the multi-employer pension scheme expects to balance under- and over-funding and run a surplus in the schemes taken as a whole. This resembles the way in which an insurance corporation pools risk for many clients.

[22] Please note that the term 'manager' is used synonymously for the word 'sponsor' which has been frequently used in recent years.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

When general government takes responsibility for providing benefits to large sections of the society, the social security function fills the role of a multi-employer scheme. Like the insurance corporation, the government then takes on the responsibility for any shortfall in funds to meet the pension obligations, and may be entitled to retain any surplus generated. As social security pension schemes are financed on a pay-as-you-go basis there is usually no surplus or deficit; if there is a shortfall of the scheme, government may have the power to adjust pension obligations not only in relation to future employment but also to past employment.

Besides the pension manager, the employer may also appoint a **pension administrator** responsible for the day-to-day administration of the pension scheme. The pension administrator, however, does not take any responsibility for a shortfall of the scheme or the benefit of any surplus. The same unit may in practice carry out both functions of pension manager and pension administrator.

4 Columns and rows in the supplementary table

The supplementary table on pensions in social insurance (see overleaf) provides a complete and comparable overview of pension obligations from the debtor (pension scheme) perspective and also (as a counterpart) of pension entitlements from the creditor (household) perspective. In Europe, entitlements of defined benefit pension schemes represent a significant share of overall pension entitlements. Thus far figures on positions for specific government-managed pension schemes have not been compiled and included in the system of national accounts. The supplementary table (see Figure 5) bridges this information gap by showing all positions and flows of all pension schemes in social insurance including government-managed defined benefit schemes for government employees and social security pension schemes. This chapter describes in detail the columns (Section 4.1) and rows (Section 4.2) in the table. The outline follows closely Chapter 17 of the ESA 2010.

4.1 Columns of the supplementary table

Rela-tions	Row No.	Recording	Core national accounts						Not in the core national accounts			
		Pension manager	Non-general government			General government					Total pension schemes	Counter-parts: Pension entitle-ments of non-resident house-holds[4]
			Defined con-tribution schemes	Defined benefit schemes and other[1] non-defined contri-bution schemes	Total	Defined contri-bution schemes	Defined benefit schemes for general government employees[2]			Social security pension schemes		
							Classi-fied in financial corpora-tions	Classi-fied in general govt 3)	Classi-fied in general govern-ment			
		Column number	A	B	C	D	E	F	G	H	I	J

Pension schemes are recorded in different categories as shown in the columns of the supplementary table. The table distinguishes pension schemes by four criteria:

- by type of recording: positions and flows of pension schemes recorded in the core accounts (pension schemes in columns A to F), and positions of pension schemes recorded only in the supplementary table (pension schemes in columns G and H);
- by type of pension manager: non-general government (columns A to C), and general government pension schemes (columns D to H);
- by institutional sector: pension schemes classified in non-government sectors (columns A to E), and pension schemes including social security pension schemes classified in the general government sector (columns F, G and H);
- by type of pension scheme: defined contribution schemes[23] (columns A and D), and defined benefit schemes including other non-defined contribution schemes (columns B and E to G).

For further explanations of the terms used above, see Chapter 3.

Column I sums up all pension entitlements acquired or held by resident households. Generally, the beneficiaries of pension schemes are predominantly resident households. In some countries, however, the number of non-resident households receiving pension benefits may be considerable. In this case, Column J should be filled in and added indicating the positions and flows of pension entitlements of non-resident households.

[23] In defined contribution schemes, assets should always be equal to equal to liabilities. The figures in Columns A and D are therefore always based on actual data and not on necessarily on actuarial estimations.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

4.2 Rows in the supplementary table

The rows in the supplementary table contain a full reconciliation between the opening stock of pension obligations (entitlements) at the beginning of a period and the closing stock at the end of a period. Within this framework, all transactions and other economic flows which lead to changes in the opening and the closing stock within a given period are taken into account.

i. *Pension obligations (entitlements)* — rows 1 and 10

Row 1 illustrates the opening stock of pension obligations (entitlements), which is identical with the closing stock of the previous year. The corresponding closing stock of pension obligations (entitlements) at the end of the relevant period is given in **row 10**.

ii. *Social contributions* — rows 2.1 to 2.4

Employer and employee actual social contributions are recorded in rows 2.1 and 2.3. Note that all actual social contributions are recorded in the core accounts. For some pension schemes (notably for social security pension schemes), actual social contributions related to pensions need to be separated from social contributions related to other social risks (such as unemployment).

In Columns H and G, the actual social contributions made by both employers (row 2.1) and employees (row 2.3) appear in the core accounts, while all other entries in these columns (G and H) are shown only in the supplementary table (except row 4); they are shaded grey in the table and are explained below.

For defined benefit pension schemes, employer-imputed social contributions are generally measured as the balancing item. Any changes in pension entitlements over the year not included in the other rows of the table are captured by **row 2.2**.

Row 2.2 also covers any ‘experience effects’ where the observed outcome of pension modelling assumptions (real wage growth rate, discount rate, etc.) differs from the levels assumed. It should be noted that, for social security pension schemes, such ‘experience effects’ are not recorded in row 2.2 but in row 3. By definition, there are no entries in this row for defined contribution schemes. Row 2.2 is therefore shaded black for these schemes.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

The imputed social contributions by employers to government schemes (column G) require special consideration. In the non-core accounts, imputed contributions are to be estimated on the basis of actuarial calculations. Only in cases where the actuarial calculations are not sufficiently reliable may two other approaches be applied to estimate government employers' imputed pension contributions:

i. on the basis of a reasonable percentage of wages and salaries paid to current employees; or
ii. as the difference between current benefits payable and actual contributions payable (by both employees and government as employer).

Items for household social contribution supplements and the other changes in entitlements are shown in the same way as for non-government pension schemes.

Row 2.4 relates to the property income earned, or imputed, on the schemes; it is routed via the household (or the rest of the world) sector. For all defined benefit pension schemes including social security schemes, property income is equivalent to the unwinding of the discount rate, meaning that its value is equal to the discount rate times the pension entitlements at the beginning of the accounting period. An illustrative example is given in Section 8.1. For defined contribution pension schemes, row 2.4 denotes interest earned on assets, i.e. the investment income during a period. Any loss in defined contribution funds is recorded in row 9.

iii. *Other (actuarial) changes of pension entitlements in social security pension schemes* — row 3

Given that the supplementary table provides a complete overview of the changes in pension entitlements over the accounting period, a specific row is needed to show cases where actual social contributions to the social security pension scheme are not actuarially based. Such cases reflect an imputed contribution (which is not the responsibility of any employer). Row 3 shows these imputed transactions of social security pension schemes (as other (actuarial) increases to pension entitlements in social security pension schemes).

The entries in this row can be positive or negative. Negative cases arise in a social security pension scheme when the discount rate is higher than the scheme's internal rate of return[24], e.g., where contributions have been increased above the actuarially

[24] The internal rate of return of a pension scheme is the discount rate that equalises the actual contributions paid and the discounted value of pension entitlements accrued through those contributions.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

required level to finance a short-run cash shortfall. By contrast, positive values can occur when the discount rate is lower than the scheme's internal rate of return.

Row 3 does not show cash transfers from tax revenues, which are recorded in the core accounts as current transfers between government units, unless they affect pension entitlements. In some EU countries, however, governments make transfers to pension schemes that do increase pension entitlements (for example where transfers are made for specific social groups which are unable to contribute directly), which would indicate that the amounts should be implicitly included in this row calculated by difference.

'Experience effects' found in social security pension schemes in which the observed outcome of pension modelling assumptions (real wage growth rate, discount rate, etc.) differs from the levels assumed in the previous estimation are also recorded in Row 3. For other types of pension schemes, these experience effects are recorded in Row 2.2 (employer-imputed social contributions).

iv. ***Pension benefits*** **— Row 4**

Row 4 comprises the pension benefits that are paid during the period of time. The payment of pension benefits has the effect of 'settling' some of the pension entitlements included in the opening stock in Row 1.

v. ***Change to pension entitlements*** **— Row 5**

Row 5 shows the changes to pension entitlements due to contributions and benefits. It is equal to Row 2 + Row 3 – Row 4. This balancing item measured in the non-financial account is conceptually equivalent to that measured in the financial account.

vi. ***Transferring pension entitlements*** **— Row 6**

With increasing work mobility, the portability of pension entitlements from one employer to another has significantly increased in recent years. A change of jobs does not usually lead to a change in pension entitlements for the household concerned. However, there are transactions between the two pension funds as one assumes the liability of the other. First, there is a transfer of pension entitlements from the original manager to the new manager. Second, there may be a transfer in cash or other financial assets to compensate the new manager. The value of the transfer of financial assets may not be exactly equal to the value of the pension entitlements transferred. In that case, a third entry is needed (in the core accounts) in transactions (capital transfers) to correctly reflect the changes in net worth of the two units concerned.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

If a government assumes responsibility for pension obligations for the employees of a non-government unit through an explicit transaction, a pension liability should be recorded in the balance sheet of the government. If the government does not receive matching assets in return, the difference between the increase in the government's liability and the assets received is shown as a capital transfer to the non-government employer.

vii. *Pension reforms* — Row 7

Due to demographic and economic developments, employers may reform the pension schemes they manage. Such reforms often take the form of parametric changes, e.g. a change of the retirement age, the indexation rules or the benefit formula. In some cases, systemic reforms can be observed, e.g. a shift from a defined benefit scheme to a defined contribution scheme. It is important to underline that not all reforms lead to a change of pension entitlements in the supplementary table.

First, only enacted pension reforms are recorded in the national accounts. They affect the estimates of pension entitlements in the year in which the reform is enacted and subsequently. An announcement by an employer of an intention to undertake a pension reform is not a sufficient basis for introducing the effects of the reform into national accounts data.

Some reforms, although formally enacted, may not have an impact on current pension entitlements. This is the case when the employer chooses to leave the rights of existing members untouched, confining the reformed arrangements to new entrants to the pension scheme. The impact of such reforms would be seen in future measures of pension entitlements, in line with the accrued-to-date liabilities concept described in Section 2.

In many cases, reform measures affect not only future entrants into the pension scheme but also existing members. An example would be a general change to the pension indexation rules that has an impact on present pensioners as well as on present and future contributors. Such reforms change the stock of pension entitlements during the period in which they are enacted. They must be accounted for as a transaction in the supplementary table. The impact of a reform may be very high if it affects current and future pension benefits — i.e. present pensioners and present contributors — since this affects the entire stock of existing entitlements.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Pension reforms are treated differently in national accounts, depending on whether they have been negotiated or whether they are imposed without negotiation.

Negotiated reforms are recorded as transactions in the following manner:

(i) If the entitlements of a pension scheme are included in the core accounts, and the employer/manager agrees to change the terms of pension entitlements via negotiation with the employees concerned, this change should be recorded as a transaction in the supplementary table under row 7;

(ii) If the entitlements of a pension scheme are not recorded in the core accounts, and the employer/manager agrees to a change in the terms of pension entitlements via negotiation with the employees concerned, this change should be recorded as a transaction in Row 7 in the supplementary table;

(iii) Changes agreed in parliament to pension entitlements under social security schemes are recorded as if the changes had been negotiated.

Changes to pension entitlements that are imposed without negotiation are recorded as other changes in the volume of assets (row 9).

viii. *Other flows* — rows 8 and 9

Rows 8 and 9 show other flows as revaluations and other changes in volume associated with pension schemes in social insurance. Table 2 breaks down the other flows into revaluations and other changes in volume.

Table 2

Other flows as revaluations and other changes in the volume of assets

Revaluations:
Changes in assumed discount rate
Changes in assumed wage developments
Changes in assumed price developments
Other changes in the volume of assets:
Changes in demographic assumptions
Other changes in the volume of assets

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Revaluations are due to changes to the key model assumptions in the actuarial calculations and are covered in **row 8**. These assumptions are the discount rate, the wage rate and, if used in the model, the inflation rate.[25] Other changes in prices such as write-downs are also covered in row 8.[26] Experience effects are not to be included here in principle, though in some circumstances it may not be possible to single them out.

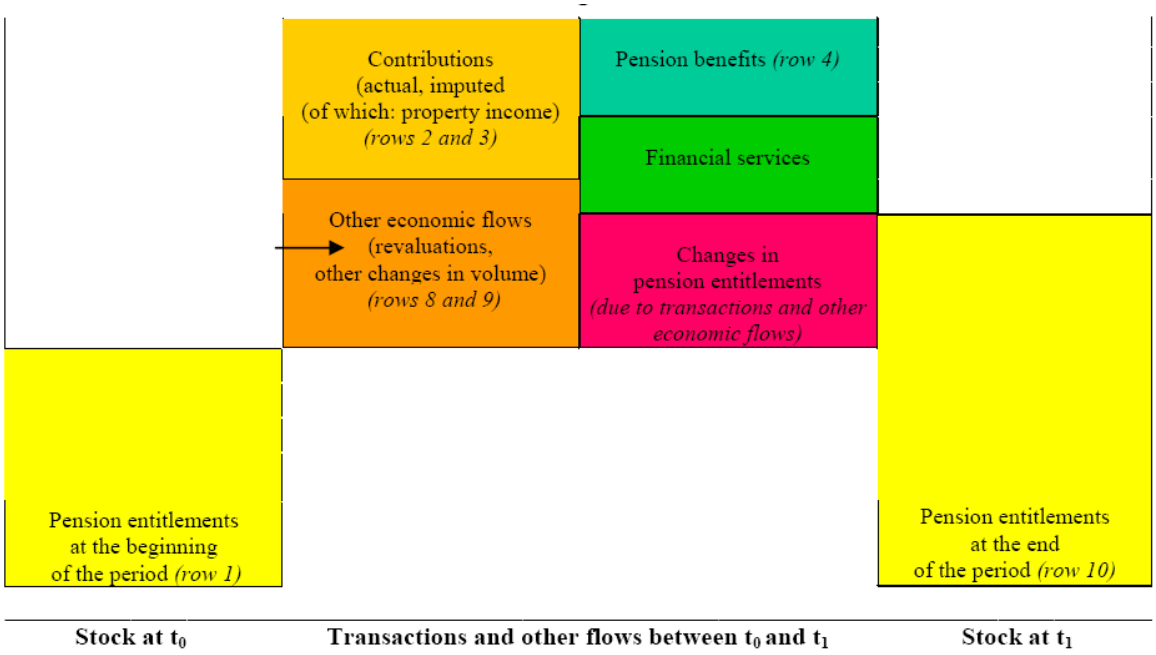
When the demographic assumptions used in the actuarial calculations are changed, they are recorded as other changes to the volume of assets (**row 9**).Any other changes to assumptions which are not revaluations are covered in row 9. This includes presumptions on future retirement behaviour. If these retirement patterns are altered in the model, the resulting changes to the outcomes are recorded in row 9. However, such changes are only covered in row 9 if they are not derived from a legislative reform.[27]

Besides changes to the underlying assumptions, the general framework of the actuarial model applied may also change from one year to the next to improve the accuracy of the results. Row 9 records these changes to the estimation approach which are not due to altered assumptions but result from a change in the model framework.

Row 9 also covers a number of other changes in the volume of assets. This includes changes to pension entitlements that are imposed without negotiation and defined contribution pension schemes that hold losses of pension funds.

ix. *Financial services* — row 11

Financial services provided by all pension schemes are recorded as being paid by scheme members (thus the costs of pension schemes will never be recorded as intermediate consumption of the employer operating the scheme). Accordingly, Figure 6 shows financial services separately from social contributions. Presenting financial services in this way means that the figures shown as social contributions received by employees from their employers are exactly the same as the share of contributions paid by the employees to the pension fund. It is not necessary to show which element of social contributions covers the service fee. It is the household contribution supplement for a defined contribution scheme and either the employer or the household contribution for a defined benefit scheme.



[25] For a further discussion on the use of the inflation rate, see Section 5.4.1.
[26] Note that, while write-downs are covered in row 8, write-offs are recorded in row 9.
[27] All changes due to enacted reforms are covered in row 7.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Output covers financial services. They are the costs of running the pension scheme for a given period. The output data provide additional information to be included in the supplementary table.

Key assumptions in measuring pension entitlements

5

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

5 Key assumptions in measuring pension entitlements

Pension entitlements are recorded as positions in national accounts representing future payments of pension benefits. Moreover, the changes in positions between two points in time are also registered; these changes cover transactions, revaluations and other changes in the volume of assets as described in Section 4. Positions in pension entitlements are derived by applying actuarial estimation methods which are based on the net present value concept. Such actuarial estimation methods are used for all pension schemes. For pension schemes managed by non-government units, position data on pension entitlements are usually available based on business accounting or supervisory data sources (see Section 6).

For defined benefit schemes for general government employees and for social security pension schemes, such data are not available and need to be compiled based on data taken from government finance and population statistics. For such estimations various assumptions have to be made.

First of all, a suitable **discount rate** has to be chosen since pension entitlements are calculated in present value terms — i.e. they reflect the discounted sum of present and future flows compared to a certain base year. Another key assumption concerns future **wage growth**. Often, the development of future pension levels is highly dependent on wage assumptions, e.g. via pension indexation. Further, **demographic assumptions** — mainly concerning life expectancy — play a significant role in estimating pension entitlements. Following the appropriate choice of these three key assumptions, the estimation of pension entitlements is described for such government-managed pension schemes. In addition, some **other assumptions** such as assumed inflation rates are discussed.

5.1 Discount rate

a) The concept of the discount rate

The choice of the discount rate is one of the most crucial assumptions for estimating pension entitlements, since its accumulated impact over many decades is quite high.[28]

[28] See e.g. ECB (2010), p. 95.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Pension entitlements as positions are compiled based on the net present value method, i.e. they reflect the value of a future payment stream for a given base year. When calculating pension entitlements, the crucial question is: what are future payments of pension benefits worth today?

One tool for valuing a future stream of payments is the discount factor (DF). The DF is compiled based on the following Equation 1:

$$(1) \qquad DF_t = \frac{1}{(1+r)^{s-t}}$$

The discount rate r as part of the denominator determines the level of the DF. To calculate the present value in year t of a future pension benefit in year s this future payment needs to be multiplied by the DF_t.

Generally, there are two approaches of interpreting this factor. From the point of view of the creditor who earns the pension entitlements, the discount factor reflects the time value of money. It is the value of a future payment in terms of a present payment. Present payments are seen as worth more than future payments due to opportunity costs and possible risks associated with future payment streams. It means that the discount factor is generally smaller than one.

From the debtor's point of view the discount rate is used to calculate the pension reserves to be set aside today to finance future pension obligations. For a more detailed description of these two perspectives, see Box 4.

Box 4
The creditor's and the debtor's perspective: two interpretations of the discount rate

For pension entitlements (obligations), the discount rate can be interpreted from two perspectives, from the perspective of the creditor and from the perspective of the debtor.

From the perspective *of the creditor*, a future payment is influenced by the opportunity costs of 'waiting'. If a future pension benefit were available today, it could e.g. be saved and therefore could yield a return in the coming period. In such cases, the opportunity costs are reflected by the interest rate on the possible investment. Additionally, the discount rate of the creditor may be affected by the uncertainty of future payments. For example, there is the risk that the pension scheme may default. From the individual perspective of the creditor, therefore, the discount rate may be higher than the risk-free interest rate. Obviously, the discount rate from this viewpoint is difficult to measure and might vary considerably across individuals and time depending on individual preferences. However, for the estimation of pension entitlements in national accounts, such aspects of risk and preferences need to be taken into account.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

The discount rate can also be interpreted from the debtor's perspective, representing a tool to measure the present capital costs of financing future payments. Due to gains through interest rates, the amount of money to be set aside today to finance a future payment can be smaller than the actual payment in the future. On the basis of these interest rates (discount rates), therefore, present pension reserves can be estimated to finance future pension payments. In the case of defined benefit schemes, notional reserves may be quantified. In practice, most accounting standards require debtors to calculate using relatively risk-free interest rates such as corporate bonds or central government bonds.

b) The choice of the discount rate

The choice of the discount rate in business accounting standards differs. International accounting standards (IAS) aim for a discount rate that reflects market yields on the balance sheet of 'high-quality corporate bonds'. In this context, 'high quality' is generally defined by business accountants as bonds with a high rating. Where the markets for corporate bonds are thin, it is possible to use yields on central government bonds.

For **government-managed pension schemes**, it is generally agreed that central government debt securities provide a suitable basis for the discount rate.[29] Furthermore, the choice of the discount rate should be based on the following criteria:

1) In order to obtain a suitable proxy for a risk-free interest rate, it is advisable to base it not on central government debt securities of one single country but on a basket of e.g. European central government debt securities.
2) The maturity of these debt securities should be similar to that of pension entitlements, i.e. at least 10 years, but preferably longer.
3) In order to guarantee comparability across countries, the same discount rate should be applied to all EU countries and all government-managed pension schemes (including social security pension schemes) at whatever level of government.
4) A stable discount rate should be applied to avoid the *noise* resulting from frequent changes.

In line with the above criteria, **it is recommended to set the discount rate at three per cent in real terms and five per cent in nominal terms.** This will considerably improve the comparability of results across EU countries and will be in line with the assumptions made by the Ageing Working Group.

[29] E.g. IPSAS recommends (long-term) government bonds as a basis for the discount rate.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

The appropriate choice of discount rate for pension obligations under unfunded public pension schemes is discussed in more detail in Box 5.

Box 5

The appropriate choice of a discount rate for government pension obligations

In order to produce comparable estimates for pension entitlements (obligations) in national accounts across pension schemes, countries and time, the following criteria should be met with regard to the discount rate:

1) To obtain a suitable proxy for a risk-free interest rate it is advisable to base it not on the central government debt securities of one single country but on a basket of e.g. European government long-term debt securities.

The first argument for such a portfolio of bonds is based upon risk considerations. Government bonds are usually not absolutely risk-free and generally include the risk of default by the country concerned in the shape of a risk premium. This risk premium can vary across countries and over time.
Another argument in favour of a basket of European bonds is the issue of interdependence, or more specifically the interdependence between a country's pension entitlements and its government bonds. The following example illustrates this issue. Imagine a country increases future pension levels via new pension legislation. Such a reform may lead to a higher default risk for the country and thus to increased interest rates on government bonds. Despite the increase in pension levels, therefore, the pension entitlements recorded in national accounts may actually decrease due to a higher discount rate. To avoid such a possible interdependence between the pension policy and the discount rate, it is advisable to choose a basket of European government bonds as a basis for the discount rate — which is (almost) unaffected by national pension policies.

2) The maturity of these bonds should be similar to that of pension entitlements, i.e. at least 10 years but preferably longer.

When calculating the accrued-to-date liabilities (ADL) of government-managed defined benefit pension schemes and of social security pension schemes, one projects future pension benefits accrued to date into the future. These benefits will arise after a period of some several decades. The government bonds used should cover (at least) a similar period of time. Therefore, only government bonds with a maturity of at least 10 years should be considered as a basis for the discount rate. Preferably, duration of 30 years should be chosen, which reflects the average length of pension entitlement payments.

3) To guarantee comparability across Europe, the same discount rate should be applied to all EU countries and all government-managed defined benefit pension schemes (including social security pension schemes) at whatever level of government.

In theory, there is only one risk-free interest rate. This interest rate should be equal for all countries and all levels of general government. Therefore, only one value should be approximated for the corresponding discount rate and used for estimations across Europe. Furthermore, differing discount rates across European countries would make it difficult to compare cross-country pension entitlements since outcomes can differ widely. A discount rate lower by just 2 to 3 per cent (in real terms) may increase outcomes by about 20 per cent. Therefore, using a single discount rate also ensures the comparability of results across countries.

4) A stable discount rate should be applied to avoid the noise resulting from frequent changes.

Frequent changes in the discount rate can make it difficult to explain to the public and compare time series of pension entitlements since outcomes can differ widely. As stated above, variation in the discount rate may change outcomes considerably. Excessive changes to the discount rate

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

should therefore be avoided.

Why to choose a discount rate of three per cent per annum?

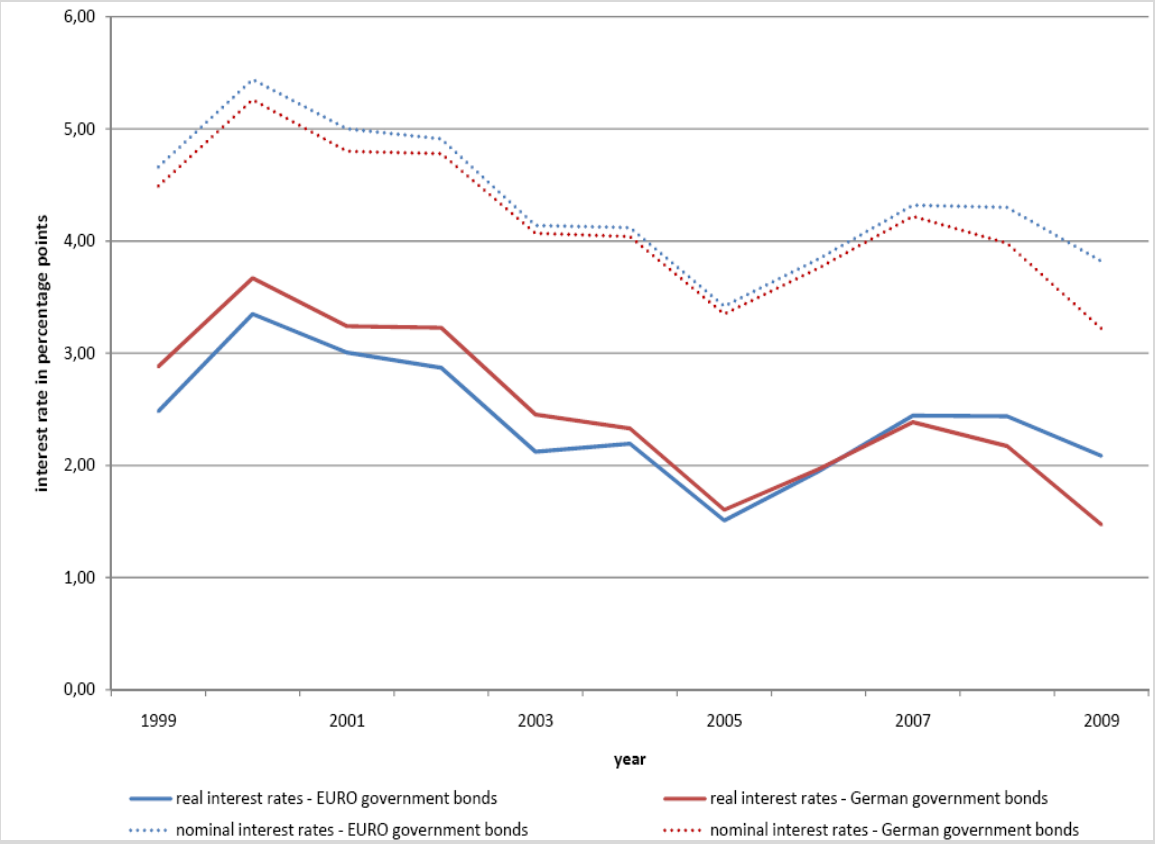

Figure shows the average yield on government bonds (with 10-year duration) in euro countries compared to German central government bonds yields. The chosen discount rate of three per cent p.a. (in real terms) is close to the average interest rate over this time period.

A discount rate of three percent p.a. corresponds closely to the interest rates applied by European institutions and some national regulations. The Ageing Working Group agreed with Member States a constant real discount rate of three percent p.a. for its long-term projections. For estimating pension entitlements in the business sector, the reformed German Commercial Code also prescribes a long-term interest rate of about five percent p.a.[30] in nominal terms — corresponding to three percent p.a. in real terms. Of course, there remains some uncertainty about the future development of the real interest rate.[31] Therefore, the choice of discount rate should be reviewed regularly.

Figure 7

Interest rates of euro and German government bonds

% p.a., 1999-2009

[30] The discount factors to apply to pension liabilities under the German GAAP are published monthly by the Deutsche Bundesbank and based on the average yields over the period of the last 7 years. In accordance with the yield curve interest rates are published for different maturities. For pension liabilities with a duration of 30 years the interest rate in June 2010 was set at a level of 5.28 %.

5.2 Wage growth

To estimate the pension entitlements of defined contribution schemes, no assumptions regarding wage growth are required. In such systems, pension entitlements depend solely on the financial assets accumulated through contributions.

In contrast, in defined benefit schemes the level of pension entitlements depends also significantly on future wage growth.[32] These schemes usually apply a formula to the member's salary (final salary, an average over a period of years, or lifetime earnings) to determine the level of the initial pension. When using the PBO approach — described in Section 2.2 — the future wage development is taken into account. Therefore, assumptions have to be made regarding future wage growth, through promotion/career progression but also due to general economic growth.[33]

a) The choice of wage growth

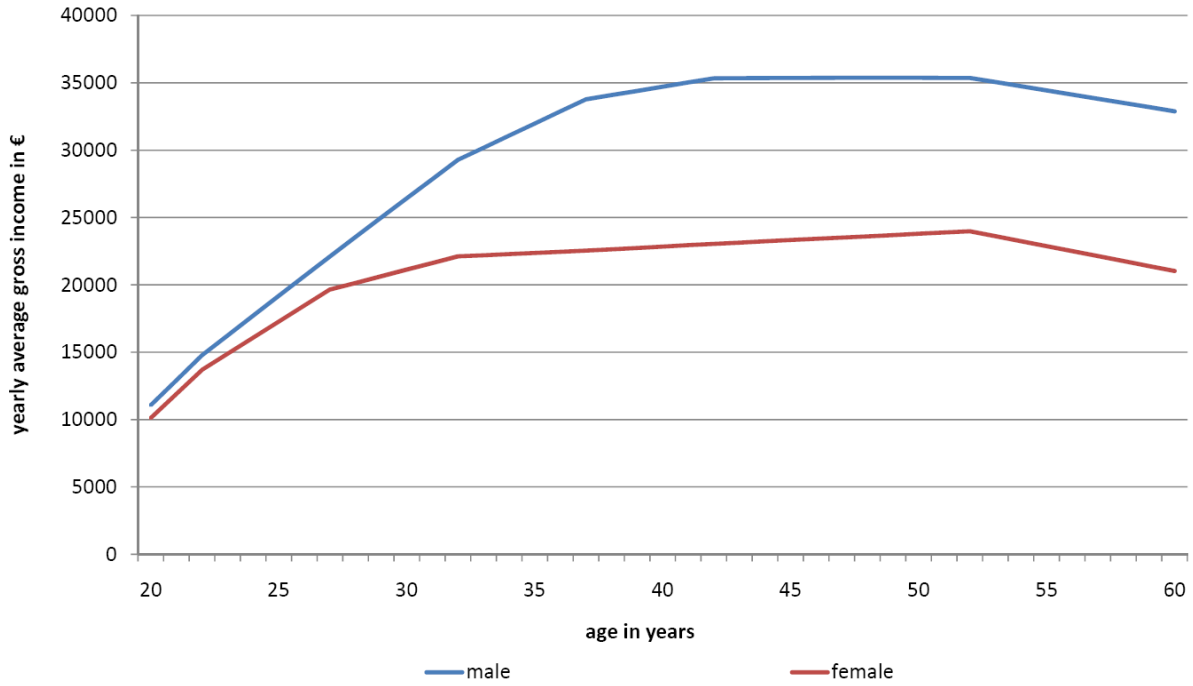
Assumptions as to the future development of wages have a significant impact on the level of pension entitlements when the PBO method is used. Therefore, guidelines for determining this essential parameter for actuarial estimations are given below.

Generally, two factors lead to future wage growth:

1) Promotions and the career progression; and
2) The general wage growth in the economy

The **career path** of individuals is usually relatively age-specific. Most countries show a hump-shaped wage development over the employment cycle — as illustrated in Figure 8. Younger cohorts (here aged around 20-30 years) generally earn less than their older counterparts in the workforce. With an increasing age, average earnings rise and reach their maximum usually around the age of 50. In many countries, the average earnings profile — shown in Figure 8 — decreases at ages close to retirement (here: 55-60 years). To approximate future career paths, it is useful to take the earnings profile for the base year as the basis (for an example see Figure 8). It is assumed that the present age- and gender-

[31] Some authors (see. e.g. Börsch-Supan et al. (2004) or Canton et al. (2003)) assume that due to an ageing population and resulting changes in investment and saving behaviour real interest rates might drop in the coming two decades. However, it is not clear to which extent this is already anticipated in the current interest rates of long-term government bonds.
[32] In NDC systems, generally, future pension levels are determined by the wage growth or more precisely the wage bill growth in the economy.
[33] When applying the ABO method no assumptions have to be made about the future development of wages. With this approach the members' pensions are determined solely on the basis of their current salary in the base year.



Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

specific salary structure will remain constant over time. In the example given, a male individual aged 25 in the base year 2006 can thus expect to earn 75 per cent more at the age of 40 (in 2021) due simply to career progression.

Career progression might differ between members of government-managed pension schemes for its employees and members of social security pension schemes. This is mainly due to differences in promotions in the private sector compared to the public sector. Therefore, earnings profiles should distinguish between private and public employees, if possible.

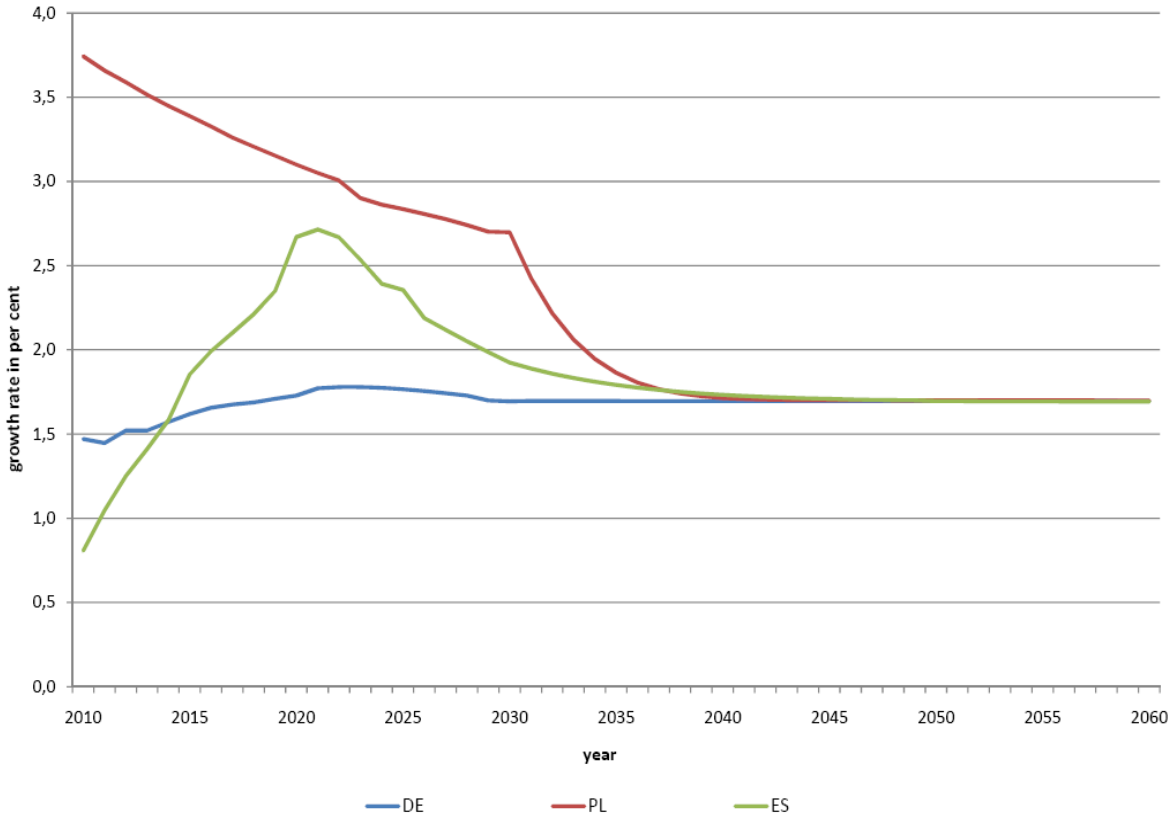
Figure 8

Age- and gender-specific earnings profile (German statutory pension scheme 2006)

Source: Forschungszentrum Generationenverträge, University of Freiburg, based on data provided by the German statutory pension scheme.

General wage growth in the economy will also affect future pension levels, and therefore PBO pension entitlements. Since the development of future wages is uncertain, assumptions have to be made here as well. Generally, it is assumed that, over the long term, wages follow labour productivity growth per capita in the economy.

An overview of EU countries shows that this growth rate is relatively heterogeneous (see Figure 9). Specifically, countries with lower GDP per capita rates have seen higher productivity growth rates in recent years. According to the projections of the Ageing Working Group (AWG), this trend will continue in the coming decades. In particular, central eastern EU countries are expected to experience higher growth paths, catching up to the



Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

productivity levels of the 'old' EU Member States (see e.g. the example of Poland in Figure 9).

In order to reflect heterogeneous growth paths across the EU, the wage growth assumptions of the AWG — reflecting productivity growth per capita — should if possible be used for the estimation of pension entitlements. This provides a basis for harmonised growth assumptions and at the same time allows for heterogeneous growth paths across EU Member States.

Figure 9

Ageing Working Group productivity and wage growth paths for Germany, Poland and Spain

Source: Ageing Working Group.

In most government-managed pension schemes of the EU countries, wage growth also plays a crucial role in the indexation of pension benefits. In the Netherlands, for example, pension benefits are adjusted twice a year in line with the average wage growth. To ensure consistency, the AWG assumptions for future wage and productivity growth should be used to estimate the future indexation of pensions.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Changes in the wage growth assumptions

The assumptions for wage growth should be reviewed and updated on a regular basis. The latest productivity projections of the AWG should always be applied. These forecasts are revised generally every three years, and the last update has been made available in September 2011.[34] The AWG assumptions can be obtained from the national representatives in the AWG. If there are changes in the assumptions for future real wages, this will be recorded as other flows (revaluations).

5.3 Demographic assumptions

5.3.1 Life expectancy

The level of pension entitlements is also dependent on future demographic developments. Assumed future life expectancy plays a significant role. It determines the expected number of years the pension annuity is to be paid out. As a consequence, pension entitlements may vary if different life expectancies are applied. Life expectancies are calculated on the basis of mortality tables already established for the modelling of pension and life insurance schemes.

Choice of life expectancy

In the case of social security pension schemes covering a large part of the population, demographic data provided by Eurostat should generally be used. This ensures a comparable data set across EU countries. Eurostat provides age- and gender-specific mortality tables for all EU countries. Only if specific data on the mortality of social security members are available such data should be used. Since mortality rates differ widely between men and women, a gender-specific differentiation of mortality data is necessary.

An increase in life expectancy has been observed over recent decades. This trend is generally expected to continue in the coming years. **Assumptions provided by Eurostat regarding future life expectancy should thus be applied as well**. In doing so:

- Eurostat's most recent population projections must always be used. The most recent update of EUROPOP has been made available in spring 2011.
- There are several possible population change scenarios. In the case of EUROPOP, the convergence scenario must always be assumed.

[34] To contact the national representatives in the AWG see 'The 2012 Ageing Report: Underlying Assumptions and Projections Methodologies' (2011), p. 4-6 on the following link: http://ec.europa.eu/economy_finance/publications/european_economy/2011/pdf/ee-2011-4_en.pdf.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

- Furthermore, assumptions regarding future life expectancy must again be differentiated by gender.

Eurostat's mortality data are available at:
http://epp.eurostat.ec.europa.eu/portal/page/portal/population/data/database

If the mortality of pension scheme members is assumed to differ widely from the general population mortality, scheme-specific mortality data should be used if available. This might be the case for e.g. civil servants, who are generally assumed to have a higher life expectancy than the population average. In contrast, the beneficiaries of disability pensions might have significantly higher mortality rates than average members of the population.

5.3.2 Fertility rate

The modelling of some pension schemes may involve the use of other demographic assumptions such as future fertility rates. This may play a role in estimating entitlements for an orphan's pension. The right to these benefits is accrued today by present contributors to the pension scheme. When they die at some point in the future, however, their dependent children — whether born or unborn at present — will generally receive an orphan's pension. A higher future fertility rate will therefore lead to a higher number of children receiving an orphan's pension. However, this should play only a minor role since orphans' pensions account only for a small part of overall pension entitlements.

In addition, the future fertility rate may play a role in certain benefit formulas under European pension schemes, as e.g. in the German general pension scheme. Here, future pensions are linked — via a so-called sustainability factor — to demographic developments, which are partly determined by future fertility rates.

Choice of future fertility rate

Here too, Eurostat provides a suitable harmonised basis for choosing future fertility levels. They are available at:
http://epp.eurostat.ec.europa.eu/portal/page/portal/population/data/database

5.3.3 Migration

Migration is another factor that might be relevant for the estimation of pension entitlements. In some countries, individual pension levels may differ if contributors migrate. Sometimes, as e.g. in the case of the United Kingdom, different pension rules apply to pensioners who choose to emigrate. Also, migration may play a role in the pension benefit formula — e.g. if

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

a sustainability factor is applied as in notional defined contribution schemes. Here, national modellers have to make assumptions about how migration will develop in future.

Choice of future migration rates

Eurostat also provides a suitable basis for choosing future migration levels at:http://epp.eurostat.ec.europa.eu/portal/page/portal/population/data/database

5.4 Other assumptions

5.4.1 Inflation

For calculating pension entitlements, it has to be decided whether future flows are to be projected in nominal or in real terms. If nominal values are chosen, both the discount rate and the wage growth rate should include future inflation expectations. If the projection is based on real values, inflation expectations are not considered. The latter approach has the advantage of avoiding further assumptions regarding future price levels. Generally, for calculating present values both approaches (nominal and real values) should lead to similar results (see Box). Therefore, both approaches can be used for the estimation of pension entitlements. However, it is essential to check which is being taken as the basis for the assumptions. Discount rates are usually quoted in real terms, but not always. Wage growth is sometimes presented in nominal terms. Hence, it is important to verify whether inflation is considered in the financial assumptions or not.[35]

Choice of future inflation

For the future, an inflation rate of two per cent should be applied. This is in line with the ECB's inflation rate target of just under two per cent over the medium term.

[35] For some examples how to apply inflation for the estimation of pension entitlements see also section 7.3, Box .

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Box 6

Projecting future flows — nominal terms versus real terms

To estimate the present value (PV) in year t of a pension benefit P paid out in t+1, the following growth-discount factor (GDF) is applied:

(2) $$GDF_{real} = \frac{(1+g)}{(1+r)}$$

The discount rate is denoted by r and the growth in the pension benefit, e.g. due to pension indexation, is denoted by g. The present value is then calculated by multiplying the pension level with the GDF:

(3) $$PV_t = P_{t+1} \times GDF_{real}$$

If a nominal approach is adopted, expected inflation (π^e) is considered for future wage growth and for the discount rate, leading to the following growth-discount factor:

(4) $$GDF_{nominal} = \frac{(1+g+\pi^e)}{(1+r+\pi^e)}$$

Since expected inflation (π^e) is in both the nominator and the denominator it (π^e), it is almost cancelled out. GDF_{real} and $GDF_{nominal}$ therefore have a similar value, with the consequence that the results calculated in nominal terms are rather close to the outcomes estimated in real terms.

5.4.2 (Un)employment rates

In some countries such as Poland and Germany the level of future pensions is directly linked to (un)employment rates in the economy. In Poland, for example, entitlements are (annually) recalculated in accordance with recent employment growth. Therefore, employment assumptions may be required for the estimation of pension entitlements.

The choice of future (un-)employment rates

For the choice of future (un-)employment rates, the AWG provides a basis comparable across EU countries. Therefore, these assumptions should be used if required for the estimation of pension entitlements.

5.4.3 Future prevalence of disability

The supplementary table covers all types of pensions, including disability and invalidity pensions. In order to estimate entitlements to disability and invalidity pensions, assumptions thus need to be made regarding the probability of becoming disabled in the future. This probability is reflected in the so-called *prevalence rate*, which is defined in this context as the total number of disabled persons divided by the total population.

Pension entitlements take into account the probability of receiving a pension in future. Therefore, they are generally higher — other things being equal — the higher the assumed

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

future prevalence rates for disability. Accordingly, the crucial question is whether the present health status will remain constant in the future.

The choice of future prevalence rates for disability

In recent decades, a rise in disability due to mental illness has been observed. Whether this trend will continue in the coming years is uncertain, and is not clearly evident from academic studies. Moreover, some countries have seen disability pension claims rise as a behavioural feedback loop in response to legal changes, e.g. an increase in legal retirement ages. Also, future behavioural responses of this kind are difficult to forecast. Due to this uncertainty, constant prevalence rates should be used for the estimation of pension entitlements.

6

Data sources for compiling pension entitlements

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

6 Data sources for compiling pension entitlements

Different data sources can be utilised to fill in the supplementary table on pension schemes. For the figures in columns A to F, accounting data (see Section 6.1) and regulatory data (see Section 6.2) generally provide a suitable basis. The information for columns G and H can be partly obtained from annual government finance data.[36] Some rows in columns G and H, however, have to be estimated on the basis of an actuarial model (see Section 6.3). The various data sources that can be used to complete the supplementary table are outlined in the following sections.

6.1 Accounting data (rows A to F)

The accounting statements of both private businesses and (for some countries) public bodies are guided by accounting principles for pension schemes. These principles may be based on one of the following international or national accounting standards:

a) International Accounting Standard (IAS) for private businesses
b) National accounting standards for private businesses
c) International Public Sector Accounting Standard (IPSAS) for the employer pension schemes of public bodies

These standards are explained below to facilitate the interpretation and use of pension data from sources that apply these accounting standards[37].

a. International Accounting Standard (IAS)

The accounting treatment of pension schemes in private businesses is set out in International Accounting Standard 19 (IAS19 – 'Employee Benefits'). This standard is mandatory for the consolidated accounts of listed companies in Europe, with some countries extending its application (obligatory or voluntary) to individual accounts and unlisted companies.

IAS19 does not distinguish between funded and unfunded pension schemes. It is based on the principle that all schemes should be recorded in company accounts. However, IAS19 does distinguish between defined contribution (DC) and defined benefit (DB) schemes, and differentiates between the accounting treatment applied: (i) Defined contribution schemes entail a cost to the employer in the current period, but the only balance sheet obligations recorded are for employer contributions not paid by

[36] The figures of column F may also be estimated by an actuarial model depending on the accounting practices.
[37] In all cases, data from any source have to be adjusted according to National Accounts valuation and principles.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

year-end; (ii) Defined benefit schemes entail costs to the employer in the current period along with balance sheet obligations representing the discounted value of future pension payments.

For defined benefit schemes, the balance sheet obligations for pension schemes under ISA19 are calculated using an actuarial model with the following characteristics:

- A discount rate equivalent to the market yield (on the balance sheet date) on high-quality corporate bonds (by convention with an AA ranking or better) should be used.
- The 'Projected Unit Credit Method' should be used; this method is equivalent to the Projected Benefit Obligation (PBO) approach described in Section 2.
- Valuations should be carried out regularly and assumptions should be mutually consistent.

Accounts should therefore record the following on the income (profit and loss) statement for a company pension scheme: (i) current service cost (the actuarial estimate of benefits earned by employee service in the period); (ii) interest cost (the increase in the present value of the obligation as a result of moving one period closer to settlement); (iii) expected return on the pension scheme's assets[38]; (iv) actuarial gains and losses[39], to the extent recognised; (v) past service cost, to the extent recognised; (vi) the effect of any plan curtailments or settlements (e.g. pension reforms).

During the process of designing IAS19, there was a widespread fear that fully recognising actuarial gains and losses on the income statement would lead to excessive volatility. Therefore, a smoothing process was introduced, whereby actuarial gains and losses would be reflected only if they exceeded higher and lower bands (known as the 'corridor'). However, it should be noted that IAS19 is currently under review by the International Accounting Standards Board (IASB). According to the latest draft proposal published in April 2010,[40] the 'corridor' approach is to be abolished. In other words, it is planned to include all estimated changes in the cost of providing defined benefits and all changes in the value of plan assets. Furthermore, a

[38] This is the source of some controversy because the basis for calculating the expected return on assets is left to the discretion of the company.
[39] Representing the experience effect of outcomes compared to assumptions, and also changes in assumptions between one modelling exercise and the next.
[40] On the current revision of the IAS19 see http://www.iasplus.com/standard/ias19.htm#0908ed .

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

new presentation approach that clearly distinguishes between different types of gains and losses arising from defined benefit plans is envisaged.[41]

b. National accounting standards for private businesses

As regards companies that do not apply IAS, accounting practices differ across Europe. In some jurisdictions, e.g. the UK, there is a national standard for business accounting which is similar to IAS19, while in other countries a historical approach continues to be used, which can be quite different from IAS19. In Germany, for example, an ABO approach and a fixed interest rate were used for a long time. With recent reforms in 2009, however, the German GAAP is now closer to IAS19, requiring a PBO approach and a time-variant discount rate (which is regularly defined by the Deutsche Bundesbank).

It is important to stress that data reported by corporations for regulatory purposes may use a different basis than company accounting practices. Generally, it should be examined which approach is applied in accounting practices. Preferably, the approaches used for the columns of the supplementary table should be comparable. If e.g. both ABO and PBO data are available, the latter should be used to complete the supplementary table.

c. International Public Sector Accounting Standard (IPSAS)

The international accounting standard for the employer pension schemes of public bodies is set out in International Public Sector Accounting Standard (IPSAS25 – 'Employee Benefits'). This standard is largely based on IAS19, including the use of the projected unit credit method[42]. Yet it diverges from IAS19 in one main respect: there is more leeway concerning the discount rate, as it can be based on the yields of either government or corporate bonds. In this context, the IPSAS Board has concluded that the required rate should reflect the 'time value of money' and that in some jurisdictions the yield on government bonds would be the most appropriate. The new standard will apply to reporting periods commencing on or after 1 January 2011. It should be noted that the IPSAS25 standard does not cover reporting by social security pension schemes.

Where IAS19 or IPSAS25 based accounts are available, they can often be readily used to complete the main parts of the supplementary table. In these accounts, the pension

[41] More specifically, the following changes in benefit costs should be presented separately: 1) service cost — in profit or loss, 2) finance cost (i.e. net interest on the net defined benefit liability) — as part of finance costs in profit or loss and 3) remeasurement — in other comprehensive income. .

[42] Similar to the current legal status of IAS 19, the IPSAS 25 recognises a corridor approach. Presently, there is no information that this approach will be eliminated. For further information on IPSAS 25 see: http://www.ipsas.org/PDF_ipsas_standards_ifac/IPSAS25.pdf .

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

entitlements are measured on an actuarial basis and the assumptions made are usually readily available from the notes to the accounts.

Access to business accounts varies between countries. In some cases, the full data are available through central balance sheet offices or similar central data collections, while in other countries the collection might be based on the largest companies or some other sample-based approach. However, the data available might not be broken down by defined contribution schemes and defined benefit schemes — for this, regulatory data sources may need to be used (see below).

6.2 Regulatory data (rows A through F)

All European countries have a government agency (or possibly several agencies) responsible for the regulation of pension schemes (possibly life insurance, too). This agency will have laid down clear reporting requirements for pension schemes, usually on an annual basis, though in some cases with a limited collection of key quarterly data. National accountants are usually already in touch with this agency, but close cooperation is nevertheless recommended on this point.

While many pension regulators collect data based on business accounts (for example they require the annual accounts of the schemes to be provided), some data requirements relate to quite specific measurement and valuation standards. For example, pension requirements may be reported on an ABO basis while they are recorded on a PBO basis in the business accounts. It will be useful for national accountants to obtain the precise definitions used to compile the regulatory data, usually available as a technical manual. Comparable approaches should be chosen for the columns of the supplementary table. A PBO approach should thus be used if the necessary data are available.

Where regulatory data are published, they will be readily available to national accountants. It is usually helpful to agree on direct data transfer from the pension regulator, possibly subject to safeguards on confidentiality of individual returns.

Additionally, data on pension funds can be obtained from the European Structural Business Statistics. This database — which is collected by Eurostat — includes pension contributions (differentiated by defined contribution, defined benefit and hybrid schemes), pension payments, capital gains and losses as well as liabilities. However, it has to be underlined that the data are provided with a time lag of three years.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

The European Structural Business Statistics are available at:[43]

http://epp.eurostat.ec.europa.eu/portal/page/portal/european_business/data/database

Practical examples of the use of regulatory and accounting pension data for completing the supplementary table are given in Section 8.2.

6.3 Other pension data (columns G and H)

While non-government employer pension schemes are usually recorded on a business accounting basis or subject to reporting requirements for regulatory purposes, this is often not the case for government-managed pension schemes. Especially for social security pension schemes, usually only cash data are available. In government employer schemes as well, regular 'long-term' accounting, e.g. of pension liabilities, is not widely used. Therefore, for these government-managed pension schemes the figures for the supplementary table (in columns H and G) can only be partly derived directly from statistics. Only some rows can be extracted from government finance data. Large parts of the rows in columns H and G need to be estimated with an actuarial model.

6.3.1 Pension data directly obtained from statistics (rows 2.1, 2.3 and 4)

Parts of columns G and H can be derived directly from the administrative data of general government, namely for:

- row 2.1 (employer actual social contributions);
- row 2.3 (household actual social contributions); and
- row 4 (reduction in pension entitlements due to payment of pension benefits).

The pension data should be recorded in gross terms and social assistance schemes should not be included. Table 3 illustrates, for example, the aggregated budget data for Spain's social security pension scheme required to complete rows 2.1, 2.3 and 4.

If pension data cannot be obtained from administrative entities, alternative sources may be used. They are described in Box 7.

[43] Once the link to the European Structural Business Statistics has been opened pension funds data can be found under the following folder 'SBS — services/financial services statistics/ Statistics on pension funds'.

6.3.2 Pension data to be estimated by an actuarial approach (all rows except 2.1, 2.3 and 4)

Most of the rows in columns G and H — namely all rows other than 2.1, 2.3 and 4 — need to be estimated by means of an actuarial model. Different actuarial tools already exist across European countries, ranging from simple dynamic simulation models to comprehensive stochastic micro-simulation models. At national level there are an increasing number of models for individual pension schemes, often developed by the ministries of finance or social security and/or government bodies responsible for pensions. Moreover, various research institutions use pension models for long-term projections of government-managed pension schemes. These models may be used and extended to estimate pension entitlements under social security and government employee pension schemes.

In the course of the AWG exercises, experience has been gained with a unified approach to long-term projections of government-managed pension schemes.[44] However, the concept used in these exercises is an OSL concept which differs from the concept of ADL with respect to the time horizon applied (for more details see Box). Nevertheless, both approaches — the estimation of pension entitlements in national accounts and the projections carried out by the AWG — rest upon similar input data. Therefore, close cooperation and exchange of data sources and underlying assumptions (e.g. employment rates and productivity growth) between the Eurostat/ECB Contact Group dealing with estimations of ADL and the AWG is recommended.[45]

For some pension schemes whose pension entitlements are reflected in columns G and H, actuarial estimates may already exist. These actuarial estimates may be used to fill in the

[44] The AWG publishes an 'Ageing Report' including long term budgetary projections. The last report was published in 2009: http://ec.europa.eu/economy_finance/publications/publication14992_en.pdf .
[45] For an overview of the current national representatives in the AWG see the European Commission (2009), p. 4ff.

supplementary table. However, the concept and approach applied to estimate these figures should be cross-checked against other data in the supplementary table. In particular, it needs to be ascertained whether the ADL approach is always taken.

a) Data inputs for the actuarial estimation of pension entitlements

Generally, pension data for actuarial estimations of social security and government employer pension schemes can be obtained from the institutions responsible for the pension schemes in question. The government entities responsible for a specific pension scheme usually collect (and publish) data on contributors and pensioners on a regular basis.

The necessary pension data include both macro data and micro data:

- Generally, the required **macro data** cover information on total pension expenditure and contributions (also required for rows 2.1, 2.3 and 4) as well as the total number of beneficiaries and contributors differentiated by age and gender in a given base year.
- The required **micro data** relate to individual contribution and benefit levels in a given base year — preferably broken down by age and gender. Additionally, individual accounts stating the contribution history of contributors should be obtained if available. Some countries provide their citizens with periodical information about their accrued pension entitlements. The pension schemes as observable in Sweden, Poland and Austria have introduced individual pension accounts that explicitly show the value of personal entitlements. Such information should be collected and applied in the actuarial calculations if obtainable. However, individual accounts might not always be available. Furthermore, the compilation of these data may turn out to be time-consuming and costly. In such cases, the pension entitlements of contributors can be approximated e.g. on the basis of present pensioners.[46]

The quality of data sources may vary across countries and schemes. For the actuarial estimation, ideally, processed data provided by the institutions responsible for the pension schemes in question should be used. The advantage of these data is that they cover (nearly) all members of the pension scheme and are already processed, e.g. average data per cohort are given. Therefore, they can be more easily used in the calculations.

[46] The PROST model of the Worldbank works on this basis but also the Freiburg model — used for the benchmark calculations of the Contact Group on pensions — uses data of present pensioners to estimate the pension level of future pensioners. For a detailed description see Heidler et al. (2009).

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Apart from publicly available pension data, files provided by the pension scheme administrations may also be used. These data sets provide users with a broader and more detailed picture of the pension scheme. This is thus useful for modelling complex features of pension schemes such as e.g. the development of minimum pensions, which generally requires detailed information on the distribution of entitlements. The application of such data bases may demand knowledge of statistical software and can be relatively time-consuming.

If no pension data can be obtained from the institutions responsible for the pension schemes, alternative data sources may be used as described in Box 7.

Box 7
Additional data sources to compile pension entitlements

Macroeconomic data

ESSPROS

One additional data source based on macroeconomic data is the European System of Social Protection Statistics (ESSPROS) maintained by Eurostat. It contains statistics on the financial flows of social security expenditure and receipts. ESSPROS is based on registers and other administrative sources, surveys, and estimates by EU Member States and is designed to provide a comparable data base for EU countries plus Iceland, Switzerland and Norway. Pension data are categorised by various types of pensions such as old age pension, disability pension or survivor's pension. ESSPROS data are generally available with a time lag of 2–3 years. Similar to the distinction made between social insurance and social assistance pension schemes — the latter are not to be included in the supplementary table (see Section 3) — ESSPROS divides benefits into means-tested benefits and those that are not means-tested. However, ESSPROS should only be used if no other data sources are available because it lacks precision on a number of issues. For example, it provides only limited information on the number of beneficiaries, which is differentiated by gender but not by age. Furthermore, it does not provide aggregated contribution data. Also, no distinction is made between government employee and social security pension schemes.

COFOG

Another macroeconomic data source refers to data based on the Classification of the Functions of Government (COFOG), which is compiled under the ESA transmission programme. It provides a breakdown of general government expenditure by economic function and by type of transaction. Pension data are divided into old age, survivor, and sickness/disability pensions. It should be noted that COFOG data provide only a very rough overview of pension expenditure aggregates. They cannot give a differentiated picture of pensions since they do not distinguish between social insurance and social assistance. Furthermore, no differentiation is made between government employee and social security pension schemes. Also, the category of sickness and disability benefits should ideally be split into two groups — sickness and disability — since only the latter is relevant for the supplementary table. Accordingly, COFOG data should only be used for the supplementary table if no other data source is available.

Microeconomic data

National and EU household surveys

Household surveys focus on the living conditions of representative households and generally cover pensioners too. Household surveys are usually available at national level but also at European level. Since national surveys generally cover a larger sample, it is recommended to use these data sources. If national household surveys are not available, European household surveys should be used.

One major European household survey is the European Union Statistics on Income and Living Conditions (**EU-SILC**), which was launched in 2003 and collects comparable multidimensional micro-data on income, poverty, social exclusion and living conditions on an annual basis. Every year, both cross-sectional data (covering a given time or a certain time period) and longitudinal data (relating to individual-level changes over time, observed periodically over — typically — a four-year period) are collected. EU-SILC covers all EU Member States as well as Iceland and Norway. It differentiates between various pension types, namely old age, survivors, disability and sickness benefits. Furthermore, benefits are distinguished by whether they are paid out by a pension scheme managed by general government or not. The same differentiation applies to contributions. However, EU-SILC does not differentiate between pensions paid out by government employee and social security pension schemes.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Before using household survey data, it has to be examined whether the individuals covered by the household survey are representative of the members of the pension scheme analysed. Generally, these surveys cover a sample characteristic of the overall population. Therefore, household surveys may be a particularly suitable alternative data source for social security pension schemes

b) Further quality issues and benchmarking

While the estimation of pension entitlements should be based on a harmonised approach across Europe, this may not always be feasible in practice. Nonetheless, to ensure accurate estimations, the following general guidelines should be followed:

- Pension data and estimations should be divided by gender; this is necessary since men and women show differences not only in the level of contributions and pensions but also in expected life expectancy, and should therefore be modelled separately.
- Pension data and estimations should be differentiated by age; pension entitlements should ideally be calculated in one-year age groups (i.e. entitlements of a 20-year-old, 21-year-old etc. should be calculated), which can considerably improve the accuracy of results since e.g. pension reforms may affect a cohort born in the year x but not in the year $x - 1$.

It is furthermore recommended to divide participants of a pension scheme into present beneficiaries and future beneficiaries, i.e. present contributors. The latter have accrued pension rights but have not yet received any payment, while present beneficiaries have accrued 'full' entitlements and are receiving payments from the pension scheme. Both groups may also be differently treated due to pension reforms and indexation rules. It is thus reasonable to estimate the pension entitlements of these two groups independently.

Pension models are usually relatively complex — often considered even a 'black box'. Therefore, benchmarks are crucial in order to cross-check the plausibility of the outcomes. This is particularly the case when new pension models are introduced to estimate pension entitlements. Here, the probability of error is generally higher than in frequently used and well-established models. Different generic models can be used for benchmarking and quality assurance. These include the World Bank's pension reform modelling software PROST, although generational accounting models can be used for benchmark exercises too.[47]

[47] For an application of PROST to estimate pension entitlements see e.g. Holzmann et al. (2004) who examined public pension schemes of 35 low and middle income countries. For an application of generational accounting see e.g. Müller et al. (2009) who calculated ADL of government employee and social security pension schemes in 19 EU countries. This model is outlined as a worked example in section 8.1.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

A high level of transparency in the compilation process should be ensured. Countries are therefore encouraged to publish a description of the compilation of the supplementary figures. This may include an outline of the actuarial model used to estimate pension liabilities as well as a description of the external actuarial valuations and data sources used.

7

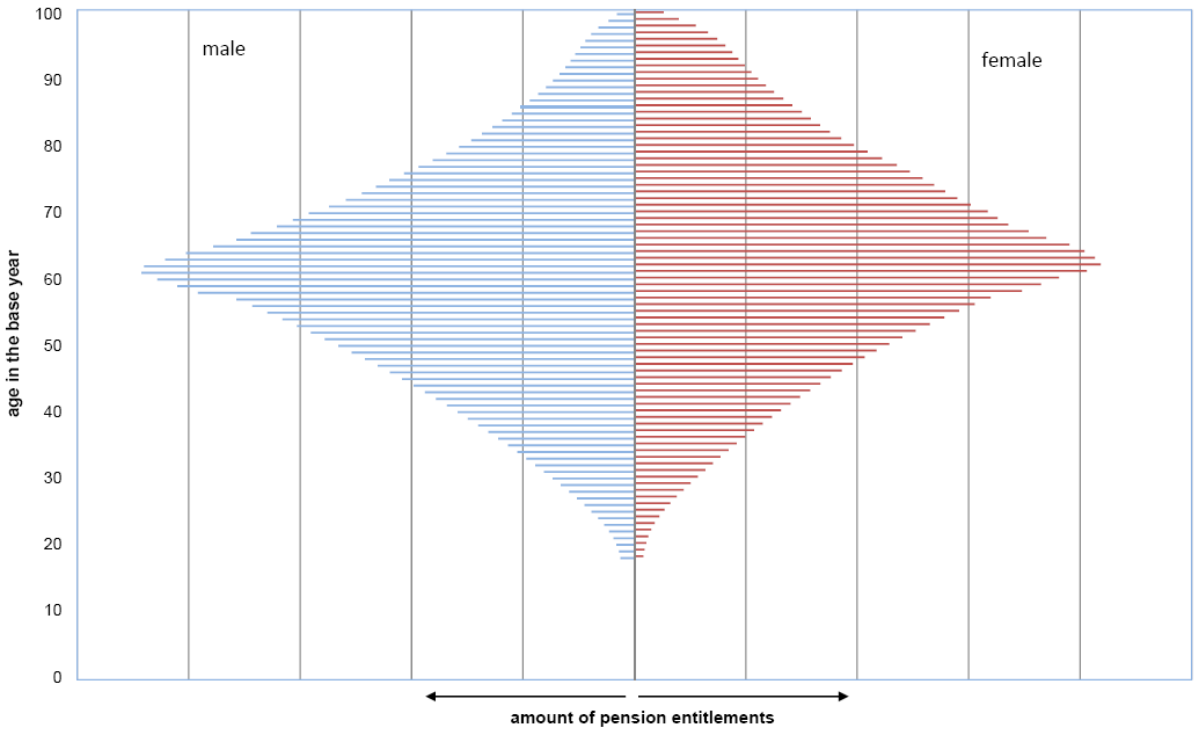
Description of the approach to estimating pension entitlements for government-managed pension schemes

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

7 Description of the approach to estimating pension entitlements for government-managed pension schemes

7.1 Overview

The aim of the following section is to outline step-by-step the procedure to estimate pension entitlements of unfunded public pension schemes. The actuarial approach[48] to estimating these new figures in national accounts is presented in a general way to provide a description which can be applied for a variety of pension schemes. This chapter will address a broad audience, including actuaries, as well as non-actuaries (statisticians, data compilers, etc). Against this background, the calculation procedure is outlined using formal equations as well as various illustrative examples. Furthermore, this section is intended to assist countries which have not yet (fully) built up a model to calculate accrued-to-date pension liabilities.



Before the calculation procedure is outlined, it is useful to state the aim: pension entitlements accrued-to-date of all public unfunded pension schemes in the country concerned. This figure represents the sum of entitlements of each participant in the relevant pension schemes. Of course, individual entitlements differ by age and gender. Figure illustrates the typical distribution of pension entitlements, by age groups as well as by gender. Cohorts at the age of retirement, i.e. around the age of 60, have usually, accrued-to-date comparably high pension entitlements. They have, generally, contributed to a pension scheme over a longer period than younger cohorts, and have therefore accrued higher pension entitlements. Furthermore, cohorts at the age of retirement usually show a higher value of pension rights than older age groups. This is mainly due to the fact that only future pension benefits are taken into account in the calculations. New retirees can look forward to a relatively longer remaining retirement period. Older retirees, on the other hand, have already received some of their pension benefits. Their entitlements are, therefore, accumulated over a shorter remaining pension period.

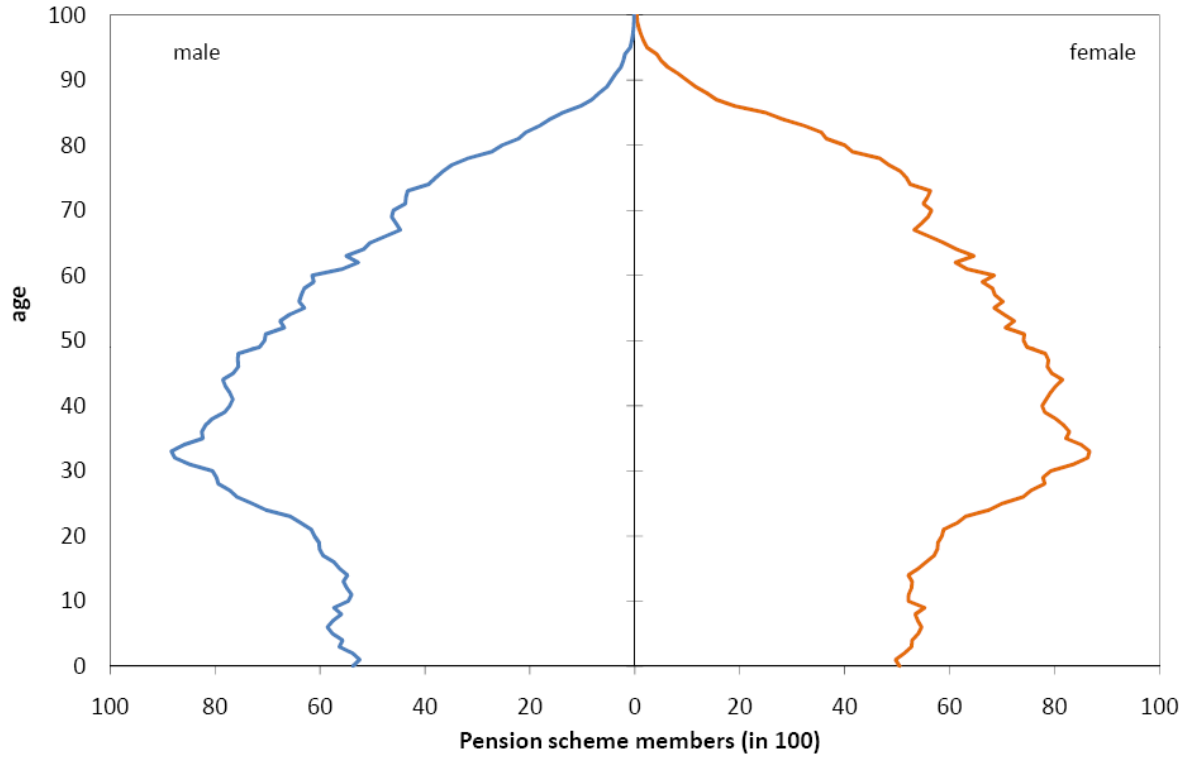
[48] As outlined in section 2 an actuarial calculation bases on a forward looking approach. For the estimation of pension entitlements it is, simply speaking, applied to project pension benefits in the future and to accumulate and discount them finally to the present value of the base year. .

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Figure 10

Example showing distribution of pension entitlements by age and gender

Source: Forschungszentrum Generationenverträge, University of Freiburg.

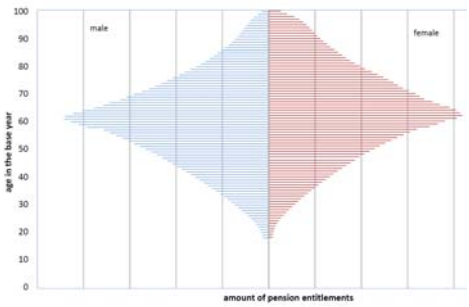


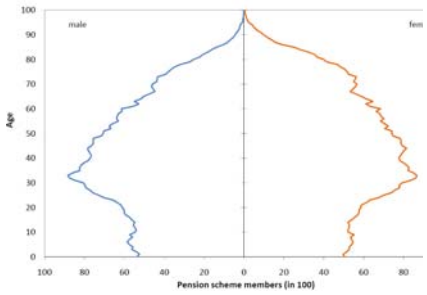
Besides age-specific differences, differences in pension rights between genders are also apparent. As displayed in Figure 10, women have usually accrued lower pension entitlements than men. Such gender differentials may be explained by, for instance, shorter contribution periods, as well as lower average wages for women, which result in comparably lower pension benefits and entitlements. To estimate accrued-to-data liabilities, these age- and gender-specific differences in pension entitlements should be taken into account.

Two major steps are required to estimate accrued-to-date pension liabilities. In the **first step,** average pension entitlements of different age and gender groups are estimated, as illustrated in Figure 10.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Figure 11





Exemplary cohort sizes by age and gender

Source: Forschungszentrum Generationenverträge, University of Freiburg.

In a **second step,** these group-specific pension rights (shown in Figure 10) are multiplied by the respective age- and gender-specific cohort sizes of the pension scheme members (displayed in Figure 11Figure). Step 2 generates the final result: the total value of pension entitlements. To give a general overview, both major steps to calculate pension liabilities are displayed in Figure 12 below.

Figure 12: Overview on the calculation of pension entitlements

Step 1: Estimating age- and gender-specific average pension entitlements		Step 2: Weighting these average pension entitlements by the respective cohort sizes		
	X		=	*Pension entitlements*

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Step 1 (Chapter 7.2 – 7.4) considers the pension entitlements of a single participant. In step 2 (Chapter 7.5), these individual pension rights are aggregated.

7.2 Estimating individual pension entitlements

Pension entitlements represent the sum of all future pension benefits which are accrued-to-date in present-value terms of a base year. The approach to calculating this figure will be demonstrated below. A formal outline will be given first, to provide an introduction, especially for actuaries. Then the estimation approach will be illustrated through various examples.

Formal outline of the estimation approach

Equation 5 presents the general approach to calculating pension entitlements.[49] In the following sections, further extensions of this formula are discussed.

$$(5) \qquad E_{x,g,b} = \sum_{s=x+1}^{D} B_{s,g,f}^{accrued} * p_{s,g,f} * (1+r)^{x-s}$$

where

$E_{x,g,b}$ = the pension entitlements of a representative individual of age x and gender g in the base year b,

$B_{s,g,f}^{accrued}$ = the annual pension benefits accrued-to-date of a representative individual at age s and gender g in a future year f ($f = b + s - x$),

$p_{s,g,f}$ = the probability of a representative individual of gender g of surviving to age s in a future year f ($f = b + s - x$),[50]

D = the maximum life time,

r = the discount rate.

The aim is to calculate pension entitlements E for an average representative of different age groups x and genders g in a given base year b. The variable $B^{accrued}$ denotes the annual

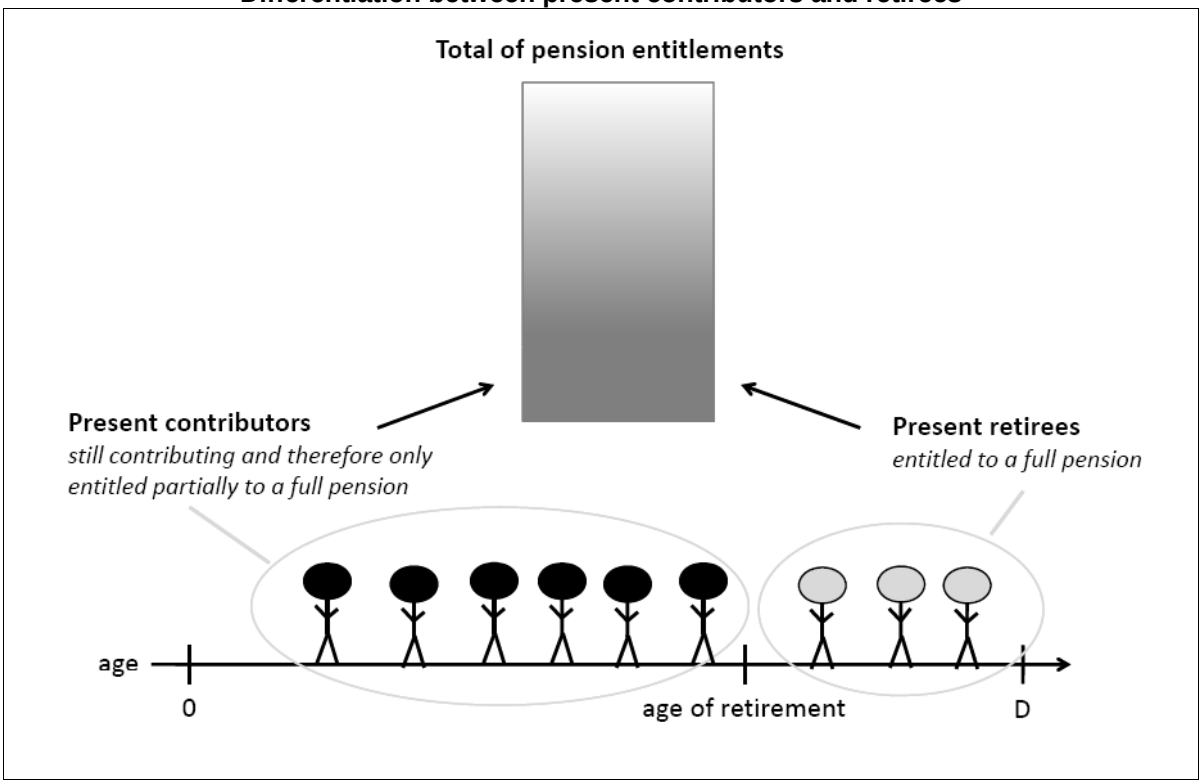
[49] Please note that the following definitions may not be fully applicable for disability, survivors' and early retirement pensions. It should be e.g. taken into account that after the death of a retiree his/her surviving spouses/orphans (if existing) are entitled to a survivors'' pension benefit. For a further description of the differentiation by pension type see section 7.4.4.

[50] These survival rates should reflect the expected increase of the life expectancy according to the newest EUROPOP projections. For a further discussion see section 5.3.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

pension level accrued-to-date. How to derive this pension level accrued-to-date is then discussed in detail. It is important to note that only future pension payments are taken into account for the estimation of pension entitlements. All payments durin g or before the base year are disregarded. Therefore, the control variable s starts with the age $x+1$, i.e. one year after the base year, and ends at the age D. In this context, the variable D denotes the highest maximum life time considered in the calculations. Usually, a level of 100 years is chosen for the variable D. Pension entitlements represent the expected amount of pension payments accrued-to-date. In line with this concept, future survival rates are taken into account for the calculation of entitlements. For this purpose, the variable p $(0 \leq p \leq 1)$ is introduced. It represents the probability of an individual of gender g surviving to a certain age s (in the year $b+s-x$). In accordance with the applied present value concept, all future pension payments are discounted to the base year.

Distinguishing between current retirees and current contributors



For the estimation of pension liabilities, it is important to distinguish between pension entitlements accrued by present retirees, and pension entitlements accrued by current contributors. The former group has its working and contribution period behind it, and is therefore already entitled to full pension benefits.[51] For the estimation of accrued-to-date liabilities, it is important to take into account that current contributors have not yet accrued 100 per cent of their future (expected) full pension benefits upon retirement. They still have an (expected) contribution period ahead of them, whether this is one year (in case of a 59-year-old) or 40 years (in case of a 20-year-old, in our example). It is strongly recommend to distinguish between present retirees, who have already accrued full pension benefits, and present contributors, who have only partially accrued their future full pension benefits. Figure 13 illustrates this important distinction.

[51] Of course, in some pension systems — such as in Germany — it is possible to contribute and accrue further pension rights after receiving a pension benefit. .

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Figure 13

Differentiation between present contributors and retirees

Pension entitlements reflect the present value of all future pension benefits which have been accrued-to-date. Contrary to other figures in national accounts, accrued-to-date liabilities are not calculated solely on the basis of historic data; rather a projection of future pension payments is required. This forward-looking approach will be discussed in further detail below. First, the actuarial method for estimating pension entitlements for current pensioners will be outlined (Chapter 7.3). Then an equivalent description will be provided for present contributors (Chapter 7.4). The following two sections always consider an average representative of a certain age group and gender.

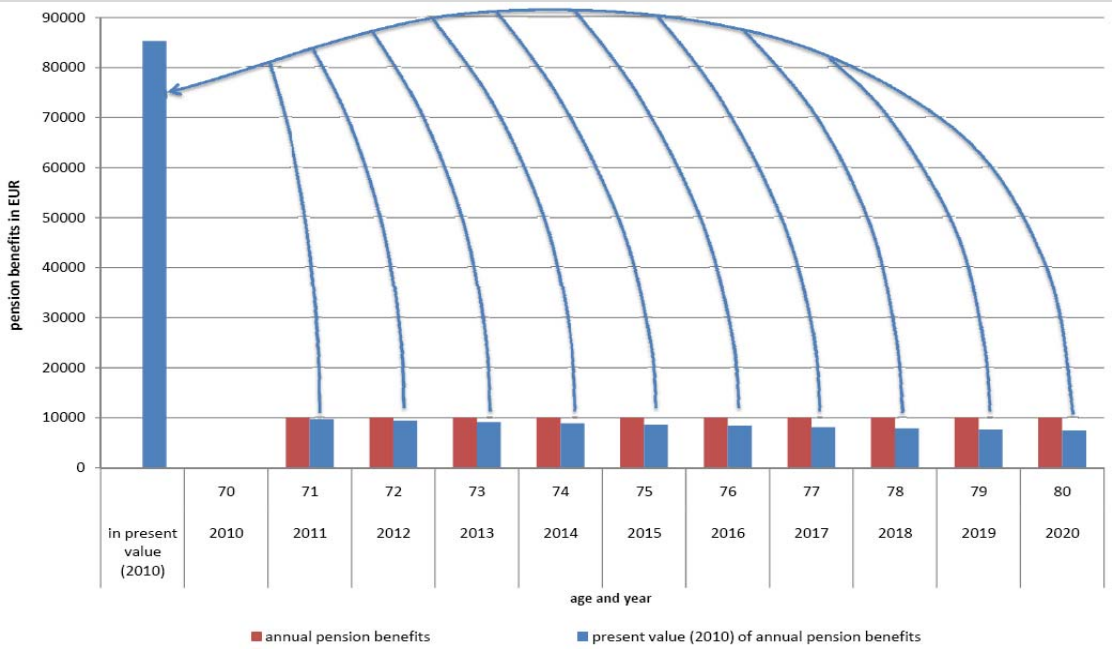
7.3 Estimating individual pension entitlements for current retirees

Current pensioners are entitled to pension benefits on the basis of past accrued pension rights. As outlined above, this group is entitled to full pension benefits. In other words, the benefits they receive in the base year are fully accrued. It is important to note that current pensioners are entitled to pension benefits not just for one year but, in fact, to all future pension payments, usually until they die.[52] To illustrate the estimation approach for current retirees, see the example in Box 8.

[52] In fact, one may furthermore attribute future survivor's benefits — which accumulate after the death of present retirees — to the entitlements of current pensioners. For a further description see Box 18. .

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Box 8



Estimating pension entitlements for current retirees

To outline the estimation approach applied for current retirees, take the example of an average male pensioner, aged 70. His pension entitlements are relatively straightforward to calculate. The current retiree's pension benefit level is projected over his remaining (expected) life span. Generally, the pension data needed for this projection can be obtained from the respective pension scheme institutions, while assumptions on the (contingent) life expectancy should be obtained from Eurostat.[53] For the following example, the representative retiree will receive an annual pension payment of EUR 10,000 in the year 2010. His life expectancy at age 70 is 10 years. In other words, he can expect to receive EUR 10,000 per year over an (expected) period of 10 years, which adds up to EUR 100,000 over the rest of his retirement.

Calculation of the present value of pension entitlements

Pension entitlements represent the aggregated present value of future pension payments. In accordance with this present value concept, pension benefits in the far future are generally considered less valuable than present pension payments. To estimate entitlements, therefore, a discount factor is applied — described in Section 5.1 — to translate future pension benefits into present-value terms. As a consequence, a pension payment of EUR 10,000 in 10 years is, for instance, worth only EUR 7,440 in present-value terms at a discount rate of 3 per cent. The blue bars in Figure 14 represent the respective present values of the future pension payments.

Figure 14
Aggregating annual pension benefits in present value terms

Source: Forschungszentrum Generationenverträge, University of Freiburg.

In the final result, pension entitlements are calculated by summing up all future pension payments in present- value terms. In this example, the total pension entitlements of a 70-year-old pensioner would amount to about EUR 85,000 EUR. From the point of view of the government, this figure represents the accrued-to-date pension liability. In other words, the value of EUR 85,000 reflects the amount of money which has to be set aside today by the government to finance all accrued pension rights of the hypothetical 70-year-old average retiree.

[53] For a further description of the demographic data and assumptions see section 5.3.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Choosing a base year for the calculations

Only future pension benefits over the remaining life cycle of an individual are considered in estimating pension entitlements. All pension benefits received in the past — or more precisely, before the end of a certain base year — are not taken into account. The pension payments considered, therefore, depend on the base year applied. If the base year is 2010, the aim is to estimate the stock of pension entitlements at the end of the year 2010 for inclusion in row 10 of the supplementary table of the base year 2010.[54]

Consideration of pension indexation rules

For the calculation of entitlements, the indexation practice of the respective pension scheme should, possibly, be reflected. Most EU countries, including, for instance, France and Spain, adjust pension benefits annually in accordance with the change in the consumer price index (CPI). This is '*price indexation*'. Several EU countries, for instance, Slovenia or the Netherlands, base annual pension adjustments on general wage growth in the economy. This is referred to as '*wage indexation*'. Other countries have a *mixed indexation* system. In their annual pension indexation changes, they consider the CPI and, to some extent, wage growth.[55] In accordance with the respective pension indexation, an accrued pension benefit ($B^{accrued}$) in year $t+1$ may differ from that in the previous year t (see Equation 6). The variable a denotes the annual adjustment factor, which reflects the indexation rules in the respective country.

$$(6) \qquad B_{t+1}^{accrued} = (1 + a_{t+1}) * B_t^{accrued}$$

Before implementing country-specific indexation rules, it is crucial to decide whether future payments will be calculated in nominal or in real terms. As outlined in Section 5.4.1, the difference between these two approaches concerns the way in which future inflation is considered. A nominal estimation approach takes into account assumptions on future inflation, while a real approach disregards such expectations.[56] The indexation of pensions with prices as well as with wages is illustrated in Box 9

Box , which shows calculating pension entitlements both in nominal and in real terms.

[54] For an overview on the new supplementary table see chapter 4.
[55] For example Finland adjusts pension benefits annually with 80 per cent of CPI changes and with 20 per cent of the growth of the earnings level.
[56] For a further discussion on these two approaches see section 5.4.1.

Box 9
Estimating pension entitlements for current retirees — considering pension indexation rules

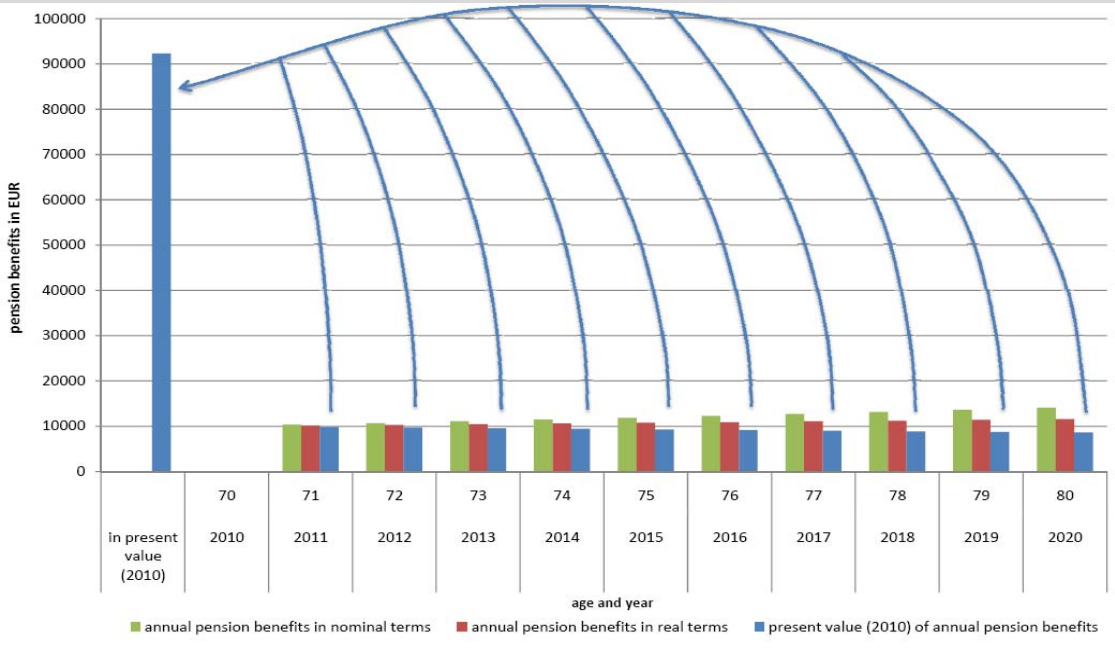
Below are outlines of examples regarding pension indexation rules. The case again is a typical 70-year-old male pensioner, on the same assumptions as in Box 8**Box** . First, the application of a price indexation is described. Under these rules, an expected future price rise of e.g. two per cent would translate into annual pension increases of two per cent — see green bars in Figure 15. If future pensions are projected in real terms, an indexation of the pension in line with prices would imply that pensions stay constant in real terms — see red bars in Figure 15.

Figure 15

Consideration of price indexation in real and in nominal terms

Source: Forschungszentrum Generationenverträge, University of Freiburg.

As outlined in Section 5.4.1, both approaches, a nominal and a real calculation approach, should lead to almost the same level of pension entitlements. It is, however, crucial that the approach used for the pension indexation is also applied to the discount rate. In other words, if the projection is undertaken in real terms, inflation expectations should not be considered in either the discount rate, or the pension indexation.



Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Further assumptions have to be taken in pension schemes which apply wage-growth indexation. To estimate pension entitlements for these schemes appropriately, assumptions on future growth of wages are required. For the sake of simplicity, constant wage growth of 1.5 per cent in real terms is assumed in the following example. This translates into nominal wage growth of 3.5 per cent.[57] Obviously, future pension levels differ if varying pension indexation rules are applied. To take the example of a current pensioner aged 70 again, if pensions are adjusted only according to the CPI, this retiree can expect an increase in his pension benefits from EUR 10,000 currently to EUR 12,200 (EUR 10,000) in nominal (real) terms until the age of 80. Under wage indexation, as observed in the Netherlands or Germany, his pension level would, on the other hand, rise to EUR 14,100 (EUR 11,600) in nominal (real) terms at the age of 80 — see Figure 16.

Indexation rules play an important role in the estimation of pension entitlements, since the effects of indexation accumulate over the entire retirement period. This is also apparent in our example. In the case of price indexation, the pension entitlements of the 70-year-old pensioner add up to about 85 000 EUR. However, they are considerably higher, by 7 000 EUR, if wage indexation is applied to the entitlement.

Figure 16

Consideration of wage indexation in real and in nominal terms

Source: Forschungszentrum Generationenverträge, University of Freiburg.

Consideration of future adjustments in the benefit formula

Besides indexation rules, future pension levels of current retirees might also be altered due to future adjustments in the benefit formula. For example, the German statutory pension scheme has a sustainability factor. With this new element in the benefit formula, pensions are adjusted annually in accordance with demographic and employment changes. Such

[57] The level of 1.5 per cent follows closely the forecasts of the AWG on the labour productivity in EU countries. As discussed in section 5.2, the AWG labour productivity predictions should, possibly, be applied as a basis for the future wage growth. Furthermore, as outlined in chapter 5.4.1 an inflation rate of two per cent should be used in the calculations. This value has also been chosen in the example above.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

future alterations in the benefit formula should if possible be taken into account when projecting future pension benefits of current retirees. The variable b in Equation 7 denotes such changes in the benefit formula.

$$(7) \qquad B_{t+1}^{accrued} = (1+a_{t+1}) * (1+b_{t+1}) * B_t^{accrued}$$

For the estimation of entitlements, it has to be taken into account that in most European countries, future adjustments in the benefit formula affect only future new pensioners, i.e. current (and future) contributors. For example, the future rise in the age of retirement in the United Kingdom, or the gradual change of accrual factors in Portugal, only play a role for future new pensioners. Such changes in the benefit formula will be discussed in Section 7.4 below, which outlines the estimation procedure for future new pensioners.

The conclusion is that data on the annual pension level and life expectancy are required for the estimation of pension entitlements of current pensioners. Furthermore, pension indexation rules as well as future adjustments in the benefit formula of the respective pension scheme should be reflected in the calculation procedure. To obtain the present value of entitlements, a discount rate of, preferably, three (five) per cent in real (nominal) terms should be applied.

7.4 Estimating individual pension entitlements for current contributors

7.4.1 A general overview

The estimation of pension entitlements for current contributors closely follows the approach described in the previous section. However, two further aspects need to be considered when calculating the accrued pension rights of this group. On the one hand, the fact should be taken into account that present contributors are not yet entitled to the full pension[58] they would receive after a complete contribution career. On the other hand, current contributors are not yet retired. Hence, their future pension payment needs to be newly estimated.

Current contributors are, generally, expected to accrue further pension rights in the future. This differentiates them from current retirees. To indicate the extent to which a future full

[58] A full pension is defined as the pension level one receives after the completion of the individual contribution career. The individual contribution career may vary considerably. Some individuals may retire already at the age of 40 due to a disability while others finish their contribution career not until the age of 65 or later. Consequently, also the full pension levels can differ. This aspect is discussed in further detail in the following sections.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

pension B^{full} has been accrued-to-date, the so-called accrual factor λ is introduced (see Equation 8).[59]

$$(8) \qquad E_{x,g,b} = \sum_{s=x+1}^{D} \underbrace{B_{s,g,f}^{full} * \lambda_{x,g,b}}_{B_{s,g,f}^{accrued}} * p_{s,g,f} * (1+r)^{x-s}$$

Equation 8 illustrates the link between the estimation of pension entitlements and other pension projections such as the AWG exercises. While the latter group, generally, takes into account only pensions after a full contribution career (B^{full}), the ADL approach considers only a certain proportion (λ) of such 'full' pensions (in the case of current contributors). In other words, only accrued-to-date pension benefits ($B^{accrued}$) are considered in ADL calculations.

The value of $\lambda (0 \leq \lambda \leq 1)$ may differ by age and gender. For present pensioners, the accrual factors sum by definition to unity, i.e. they are fully entitled to their pensions paid in future years. For current contributors, who are still expected to earn further pension rights in future, the accrual factor, generally, amounts to less than unity.

For present pensioners, the level of pension benefits can be obtained from the institutions responsible for the respective pension scheme. For current contributors, on the contrary, this future retiree income has to be newly estimated. The following two sections describe how to estimate the initial annual pension benefit accrued-to-date ($B_r^{accrued}$) at the point of retirement *r.*

Generally, there are two approaches for calculating the 'starting pension' to which a current contributor is entitled. On the one hand, the estimation may be based on the assumption that all contributors feature *homogeneous contribution careers (homCC)*. With this approach, future pension levels of current contributors are not estimated using past contribution data. In fact, future retirement benefits are approximated on the basis of current pension levels. This approach has the advantage of significantly limiting the input data required for estimations, so data on past contributions can be (partly) disregarded. The homCC approach is, therefore, recommended if no or only limited contribution data are available. Alternatively, *heterogeneous contribution careers (hetCC)* may be considered.

[59] Please note that Equation 8 follows the same notation as Equation 5.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

This approach requires comprehensive data on past contributions. The hetCC approach has the advantage of reflecting cohort-specific employment careers. Its application may therefore lead to more accurate estimations than the homCC approach.

The following sections are structured as follows: first, the estimation of the initial annual pension benefit accrued-to-date ($B_r^{accrued}$) is outlined, applying a homCC approach (Chapter 7.4.2) and a hetCC approach (Chapter 7.4.3); then (in Chapter 7.4.4), these annual pension benefits will be projected over the remaining retirement phase to calculate the final result, namely the pension entitlements of current contributors.

7.4.2 Estimating the initial pension by applying homogeneous contribution careers

With the homCC approach, future accrued-to-date pension benefits ($B_r^{accrued}$) of current contributors are not directly calculated on the basis of past contribution data. In fact, $B_r^{accrued}$ at the future point of retirement *r* is estimated from current pension levels. This small detour helps to limit the required data inputs for estimations, namely to limit the data on past contributions. This procedure, therefore, can be valuable for countries wishing to limit the data input for calculations. A worked example applying the homCC approach is provided in Chapter 8.1.

The estimation under the homCC approach proceeds as follows. In the first step, future full pensions[60] B^{full} of current contributors are estimated using the pension data of current retirees. The second step takes into account the fact that current contributors are only partially entitled to their expected full pension B^{full} which is accounted for with the so-called accrual factor λ. Equation 9 summarises formally the steps for the estimation of $B^{accrued}$.

$$(9) \qquad B^{accrued} = \underbrace{B^{full}}_{Step\ 1} * \underbrace{\lambda}_{Step\ 2}$$

Both steps — 1) the approximation of future full pensions and 2) the estimation of the accrual factor — are outlined in detail below.

[60] As outlined before a full pension is defined as the pension level one receives after the completion of the individual contribution career.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Step 1: Approximation of future full pensions

For the first step, the approximation of future full pensions B^{full} of current contributors, the basis can be the pension data of present retirees. It is assumed that future full pensions of current contributors are equivalent to pension benefits of current new pensioners.[61] All future new retirees are assumed to have the same contribution history as present new pensioners, i.e. using homCC as a basis.[62] As a consequence, future new retirees will receive (almost)[63] the same pension benefit as current pensioners.

In a flat-rate pension scheme, the homCC approach implies that all cohorts are assumed to have the same number of contribution years at the point of retirement as current new pensioners. In an earnings-related pension scheme, this assumption would mean that contributors show not only the same contribution periods but also (almost)[64] the same reference earnings over their contribution career as present pensioners. A formal outline of the procedure to estimate full pensions of future new pensioners is provided below. As a start, the pension benefit B^{full} of a new pensioner in the base year b would be equivalent to the pension of a new retiree in the following year $b+1$, as outlined in Equation 10. Of course, Equation 10 ignores the impact of 1) pension reforms and 2) indexation effects.

$$B_{b+1}^{full} = B_b^{full} \quad (10)$$

Most European countries have implemented profound pension reforms in recent years. Usually, these reforms will lower the level of pensions for future new retirees. Therefore, a deduction factor θ should be applied (defined by a reform or, for instance, inherent in the benefit formula, as in the notional defined contribution scheme).

[61] It is recommended to base on the contribution history of present new pensioners and not all current pensioners. The former group is temporally 'closer' to current contributors. Therefore, their contribution history can be assumed to be, generally, more similar to current contributors. This is e.g. the case when looking on female participation rates. While very old female retirees often show low participation rates, new female retirees feature, usually, a higher labour activity over their contribution history which is more comparable to current female contributors.

[62] It should be stated that such an assumption is only reasonable in pension schemes which are sufficiently matured.

[63] Of course, the pension level of future new retirees might differ from current retirees even if one assumes homogeneous contribution histories. For example pension reforms may lower pension levels of future new retirees. This aspect is considered later in the text.

[64] We will outline later that not exactly the same reference earnings should be assumed. In fact, one should take into account wage growth effects, i.e. one should consider (under the PBO approach) that reference earnings increase yearly with the general wage growth in the economy. .

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

$$(11) \qquad B_{b+1}^{full} = B_b^{full} * \theta_{b+1} * (1+v)$$

Secondly, pre-retirement indexation effects need to be considered. The valorisation of pension rights of current contributors up to the point of retirement should be taken into account. In a number of countries, past entitlements are indexed annually to wage growth. These pre-retirement indexation effects are reflected with the valorisation factor *v*.[65]

In schemes where past pension rights are indexed only to prices, the valorisation factor also comes into play. Here future pensioners have, usually, earned higher reference earnings than present retirees, due to general wage growth in the economy. As a result, they should in earnings-related pension schemes benefit from higher pensions than their present counterparts.[66] This aspect is also taken into account with the valorisation factor *v* in Equation 11.

Step 2: Estimating the proportion of the full pension entitlements accrued-to-date

The second step takes into account the fact that current contributors are not yet fully entitled to their future full pension B^{full} since they are, generally, expected to accrue further pension rights. In fact, current contributors are only entitled to a fraction of B^{full} which is denoted by the so-called accrual factor λ.

The crucial question is the extent to which current contributors are entitled to their future full pensions. The answer depends on the choice between the ABO and the PBO approach, as described in Section 2.2. Generally, the PBO approach should be applied for the estimation of government-managed defined benefit pension schemes.[67] Against this background, the following description of the accrual factor is based on the PBO method.[68] Generally, the

[65] Under the ABO approach *v* would equal to zero in schemes with a wage-indexation.
[66] For an illustration we want to imagine a final earnings scheme where the pension level depends on the last earnings in the year before retirement. We want to compare the initial pension benefit of a 60 year old new retiree in 2010 and a 60 year old new pensioner in 2020. Due to the future general wage growth the last earnings of the new retiree in 2020 are expected to be higher than the last salaries of its '2010-counterpart'. In accordance with the benefit formula, also the initial pension benefit of '2020-retiree' would be greater than the pension payment of the new retiree in 2010. This example outlines that even if past earnings are 'only' indexed to prices, wage increases need to be considered under the homCC approach.
[67] As stated in chapter 17 of the ESA 2010(paragraph 17.177) the PBO approach should be followed where the benefit formula 'includes implicitly or explicitly a factor for wage increases (before or after retirement)'. With the PBO approach reference earnings applied in the pension benefit formula are projected over the entire (remaining) contribution career. In this sense the PBO approach is similar to the projected unit credit method — widely used in the private sector accounting (e.g. in IAS).
[68] It should be noted, that the accrual factor can also be applied — after a few modifications — for the calculation of ABO entitlements.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

accrued proportion of the full pension under the PBO approach depends on contribution periods (see Equation 12).

$$(12) \qquad \lambda = \frac{c^{base\,year}}{c^{retirement}} \approx \frac{x-e}{l-e}$$

Where

$c^{baseyear}$ = the contribution periods of the participant until the base year,

$c^{retirement}$ = the total expected contribution periods of the participant until retirement,[69]

x = the age of the participant in the base year,

e = the age at which the participant entered the pension scheme,

l = the expected retirement age of the pension scheme participant,[70]

As outlined in Equation 12, the level of the accrual factor depends on the ratio of contribution years accrued until the base year ($c^{baseyear}$) to the (expected) total number of contribution years upon retirement ($c^{retirement}$). A longer accrued contribution period automatically translates into higher pension entitlements.

In the absence of data on contribution years accrued until the base year ($c^{baseyear}$), this figure can be approximated by subtracting the age at which the scheme member started paying contributions (e) from the age in the base year (x) — as outlined in Equation 12. The value of total contribution years upon retirement ($c^{retirement}$) is then calculated in the same way. To illustrate the approach to estimating the accrual factor further, some illustrative examples are given in Box 10.

[69] In case of disability pensions $c^{retirement}$ denotes the total contribution periods of the participant when he/she is expected to become disabled while in case of survivors' pensions $c^{retirement}$ represents the total contribution periods at the expected age of death of the pension scheme participant.

[70] Please note that this definition holds for old age and early retirement pensions. In case of disability pensions l denotes the age when an individual is expected to become disabled while for the estimation of survivors' pensions l represents the expected age of death of the pension scheme participant. For a further discussion on a differentiation of the estimations by pension type see section 7.4.4.

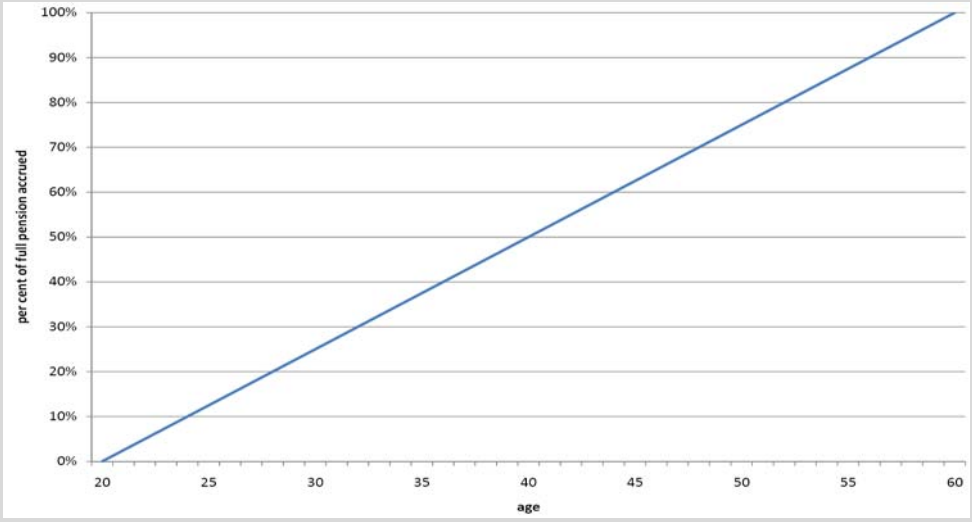
Box 10



Estimating pension entitlements for current contributors — the accrual factor

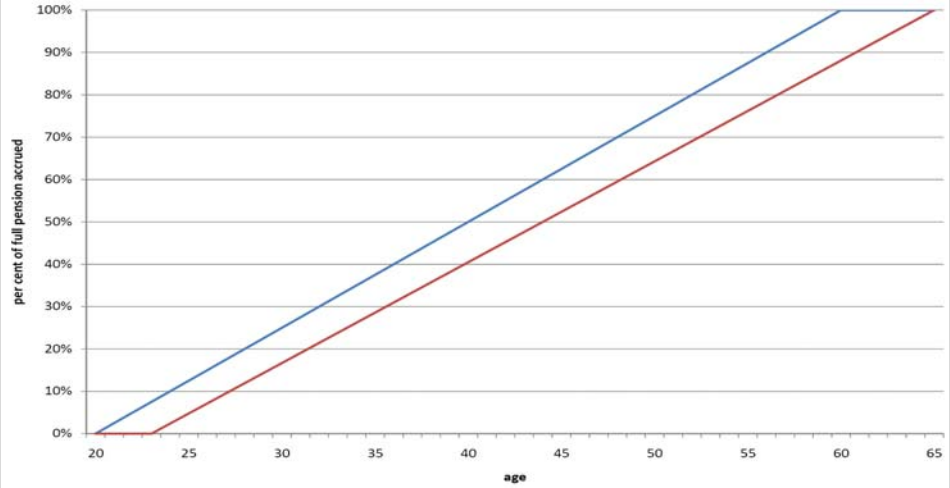
The case of an average contributor, aged 40 in the base year 2010, will provide an example of how to estimate the accrual factor. Selection of a base year always refers to the situation at the end of that year. This case takes a 40-year-old at the end of 2010 with, for simplicity, a birthday at the beginning of 2011. The 40-year-old is assumed to have accrued 20 out of 40 contribution years in a final-earnings pension scheme, and is expected to retire at the age of 61. The accrual rates applied in the benefit formula are constant over the contribution career. Under the PBO approach, this individual is not yet entitled to a full pension. In fact, he/she has accrued 50 per cent of his/her full pension. This value is calculated on the basis of the relative contribution history. The 40-year-old can only look back on 20 contribution years out of 40 (expected) contribution years. For the calculation of entitlements, the accrual factor would, therefore, amount to 0.5.

A 21-year-old contributor who also started to contribute at the age of 21 and who likewise looks forward to retiring at 61 with 40 contribution years is, however, entitled to a considerably lower future pension benefit as of end-2010. At the end of the base year, this individual can look back on just one contribution year out of an expected 40. Due to this relatively short contribution record, this contributor has accrued pension rights amounting to only 2.5 per cent (=1/40) of his/her (expected) full pension. Figure 17 illustrates the relationship between the proportion of the full pension accrued-to-date and the relative contribution history. It displays the accrual factor for each age group. To keep the example simple, it is assumed that one contribution year is accrued in each year of the contribution career.

Figure 17

Proportion of full pension accrued-to-date (PBO approach)

Source: Forschungszentrum Generationenverträge, University of Freiburg.



Of course, the proportion of the full pension accrued-to-date depends on the starting and finishing point of the individual contribution career. A further example is a 40-year-old contributor who started to contribute at the age of 24 and who can be expected to retire at 66. This 40-year-old would not be

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

entitled to 50 per cent of his/her full pension benefit, but only to roughly 38 per cent (=17/42) — see Figure 1.[71]

Figure 18

Proportion of full pension accrued-to-date (PBO approach) — varying contribution behaviour

Source: Forschungszentrum Generationenverträge, University of Freiburg.

The examples outline that the starting point (the age at which contributions are first paid) as well as the finishing point of the contribution career (the expected retirement age) are significant for the estimation of the accrual factor. The choice of these parameters is outlined below.

Choosing the age to pay first contributions

For the estimation of the accrual factor, the number of contribution periods accrued until the base year are required. If such data is not available, one may approximate this figure on the basis of the average age at which contributions are first paid (see Equation 12). Generally, this starting point is usually at the age of 20 across European pension schemes. However, in government employee pension schemes, the age may vary due to specific employment policies in the government sector. The age at which contributions are first paid can be derived from contribution data which is usually obtainable from the institutions responsible for the respective pension scheme. It can differ by birth cohorts and gender.[72]

[71] Of course, it has to be considered that a relatively longer contribution period (in the example 42 instead of 40 years) may also lead to comparably higher full pension levels.

[72] To limit the data input one may base the estimations on one single average age to pay first contributions for all current contributors. For example, it may be assumed that all contributors started their contribution career on the age of 20 years — if this is reflected in the data. Nevertheless, it is recommended to apply a differentiation by birth cohorts and gender.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Choosing the expected retirement age

For the choice of the end of the contribution career, one has to make assumptions regarding future retirement age. One option is to assume a constant retirement behaviour, but a change in retirement behaviour in future may be considered. For further discussion on the choice of retirement age, see Box11 below.

Box 11

Choosing the retirement age

To estimate pension entitlements, various assumptions on future retirement age are possible. There is a choice between constant or changing retirement behaviour, as well as between homogeneous or heterogeneous retirement behaviour. Below, we discuss the appropriate choice of assumptions.

Constant vs. changing retirement behaviour

One option is to assume constant retirement behaviour. We assume that future pensioners will retire at the same age as their current counterparts. Of course, such a scenario is only appropriate if the pension legislation allows current retirement behaviour to be prolonged into the future. In some countries, such as the UK or Malta, the age of retirement will gradually rise in the coming decades. For these countries, a constant retirement approach would not be suitable. The future expected retirement age should always be chosen in accordance with future legal retirement ages (it has to be underlined that only changes of the statutory retirement age which have been legislated until the base year are considered in the estimations).

Alternatively, one may assume changing retirement behaviour on the basis of behavioural forecasts. For some countries, there are authoritative predictions on future retirement choices. Berkel and Börsch-Supan (2004) provide such a forecast for Germany.

It should be noted that the choice between a constant and changing retirement behaviour should have no impact on the level of pension entitlements if the respective pension scheme can be considered actuarially neutral (actuarial neutrality in the context of pension systems means that the present value of accrued pension entitlements does not change due to an earlier or later pension start date. For a detailed description of this concept see Queisser and Whitehouse (2006). As these authors indicate numerous pension systems in the OECD cannot be considered actuarially neutral. A substantial number of countries do subsidise early retirement and penalise late retirement since pension decrements as well as increments are lower than an actuarial neutral rate. In these countries one would overestimate (underestimate) pension entitlements with the constant retirement behaviour assumption if future pensioners will decide to retire later (earlier) than today.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Homogeneous vs. heterogeneous retirement behaviour

When choosing the assumption on future retirement age, the question arises as to whether to consider retirement ages as homogeneous or heterogeneous. Should a single retirement age be assumed for all contributors, or not? As a starting point, it is sufficient to take one retirement age, preferably the average retirement age, as a basis (however, a differentiation between genders is highly recommended since retirement behaviour usually differs considerably between males and females). If possible, however, heterogeneous retirement ages should be taken into account. Box 1 provides a further description of how to include heterogeneous retirement behaviour in the calculation of pension entitlements, under the homCC approach.

Considering pension increments and decrements

For the estimation of pension entitlements, it is important to consider that the level of pension benefits depends on the choice of future retirement age. In most pension schemes, retirement after (before) the legal retirement age leads to an increase (decrease) in annual pension benefits. Such pension increments (decrements) should always be taken into account in the calculations.

Box 12

Taking into account heterogeneous retirement behaviour

Usually, retirement ages vary between males and females. Different retirement behaviour may also be observed within a cohort. Some individuals may choose to work until the age of 65, while others prefer to retire at 60. How should such heterogeneous retirement behaviour be taken into account? To give an illustration, let us return to the example of the average 40-year-old contributor (see). As stated, this contributor can look back on a contribution history of 20 years. For the example with heterogeneous retirement behaviour, let us assume that the probability of this person retiring at the age of 61 is 50 per cent. Furthermore, he/she might retire at 60 (with a probability of 25 %), or at 62 (with a probability of 25 %). Pension entitlements are calculated separately for each of these three retirement paths. In the first path, the 40-year-old individual is assumed to retire at 60, and has therefore accrued-to-date 51 per cent (=20/39) of his/her full pension for that retirement age. According to the second path, he/she is expected to work until the age of 61, and has consequently accrued-to-date 50 per cent (=20/40) of the full pension to which they will be entitled at the age of 61. The third path is calculated analogously, resulting in an accrual factor of 0.49. Of course, it has to be considered that in most pension schemes a later retirement age would result in a higher full pension level. This issue will be discussed below. Finally, the sum of these pension rights, weighted with the respective probabilities, represent the pension entitlements of the 40-year-old female contributor.

Equation 13 provides a formal outline of the procedure to calculate pension entitlements with heterogeneous retirement behaviour under the homCC approach (please note that Equation 13 can be applied for old age

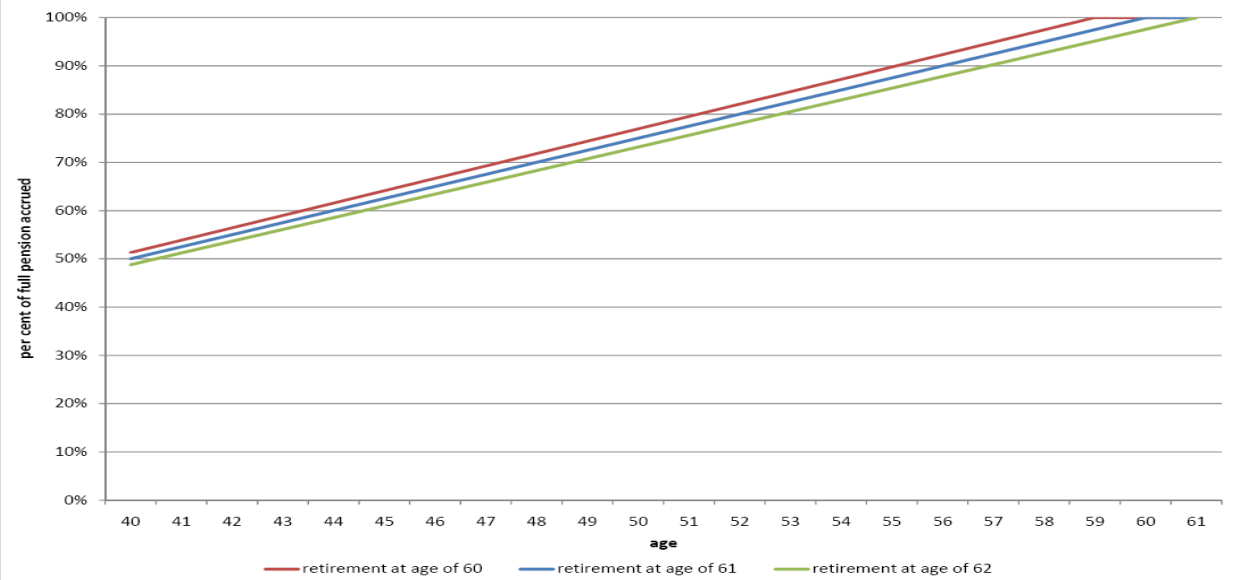
Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

and early retirement pensions). For the consideration of other pension types, such as e.g. disability pensions (see Box 18) In fact, this formula represents an extension of Equation 5. In Equation 13, the final entitlements $E_{x,g,b}$ of a contributor are reflected by the probability-weighted sum of pension entitlements for each possible choice of the retirement age l ($x < l \leq l^{max}$). Furthermore, the accrual factor $\lambda_{x,g,l,b}$ as well as the annual pension benefit $B_{s,g,l,b+s-x}$ depend on the respective choice of the retirement age l.

$$(13) \qquad E_{x,g,b} = \sum_{l=x+1}^{l^{max}} [\lambda_{x,g,l,b} * q_{x,g,l,b} * (\sum_{s=l}^{D} B^{full}_{s,g,l,b+s-x} * p_{s,g,b+s-x} * (1+r)^{x-s})]$$

where

l^{max} = the highest possible retirement age,



$\lambda_{x,g,l,b}$ = the accrual factor for a given retirement age l,

$q_{x,g,l,b}$ = the probability of a x year old in the base year b to retire at age l,

$B^{full}_{s,g,l,b+s-x}$ = the annual full pension benefit of a s year old in the year b+s − x after retirement at age l.

Figure 19

Accrual factors considering different retirement ages

7.4.3 Estimating the initial pension by applying heterogeneous contribution careers

A more detailed approach to estimating pension entitlements represents the consideration of heterogeneous contribution careers (hetCC). This procedure allows the contribution career of a future new retiree to differ from those of current pensioners. For example, due to longer unemployment or education periods for younger age groups, contribution careers

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

may vary considerably between birth cohorts.[73] To consider such hetCC, comprehensive data on the contribution history of current contributors need to be collected. On this basis, the accrued-to-date pension benefit ($B_p^{accrued}$) at the future point of retirement *r* is directly estimated, and later projected over the remaining retirement phase.

The way in which the past contribution career precisely translates into pension entitlements varies from pension scheme to pension scheme and is formulated in the respective benefit formula. Therefore, before describing the required steps to estimate $B_p^{accrued}$ of current contributors, it is useful to classify government-managed employee pension schemes more closely with regard to the benefit formula applied. Across Europe, pension schemes may be distinguished as follows:

1) ***flat-rate pension schemes***
2) ***earnings-related pension schemes***
   - ***final earnings schemes***
   - ***pension account schemes***

In flat-rate pension schemes, the final pension level depends on the individual's number of contribution or residence years, as well as on a certain benchmark pension. In earnings-related pension schemes, on the other hand, the level of benefits depends not only on the number of years during which contributions were made, but also on the amount of reference earnings or contributions during the contribution career. Earnings-related pension schemes can be further differentiated into final earnings types and pension account types. A more detailed classification of pension schemes with respect to the benefit formula is provided in Box 13.

Box 13

Classification of pension schemes with regard to the benefit formula

In all government-managed defined benefit pension schemes covered in the supplementary table, the calculation of pension benefits is based on the past contribution career of scheme participants. How this past contribution career precisely translates into pension benefits and entitlements varies from one pension scheme to another and is formulated in the benefit formula. It is useful to classify these pension schemes with regard to the benefit formula applied. In this context, dividing pension schemes into flat-rate and earnings-related schemes.
Flat-rate pension schemes can be found in the Netherlands or in the UK, for instance. They provide a basic flat-rate pension (in the UK also earnings-related public pension schemes can be found.[74] In these schemes, the final pension level depends on the individual´s number of contribution or residence years (C) as well as a certain benchmark pension (BP), as outlined in Equation 14. The BP is, generally, the highest possible pension one can receive after a certain number of contribution

[73] Such differences are also referred to as *cohort effects*.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

years.

$$(14) \qquad B^{accrued} = benefit\ \ formula(C, BP)$$

Most other European countries — such as France, Poland, Greece and Germany — feature **earnings-related** pension schemes. In these schemes, the level of benefits depends not only on the number of years of contribution, but also on the amount of reference earnings or contributions during the contribution career. All earnings-related pension schemes are based — at least to some extent — on the principle of equivalence. According to this notion, higher reference earnings should result in higher pension benefits. This aspect plays a role and should be reflected in estimates of pension entitlements.

Earnings-related pension schemes can be differentiated further with respect to their benefit formula. Traditionally, benefit formulas across Europe are designed as **final earnings schemes.** In such schemes, the pensions are calculated, as the name implies, on the basis of final earnings (FE) before retirement. These FE may comprise the earnings over the entire contribution career, or over a shorter period, such as the last year or the last 10 years before retirement. Furthermore, benefit formulas of final earnings schemes explicitly take into account the number of past contribution years (C) and generally also a so-called accrual rate (AR).

A formal outline of the calculation for accrued-to-date pension benefits in final earnings benefit formulas is provided in Equation 15. The earnings-related part of social security pensions in the Czech Republic is an example of a final earnings scheme. In this scheme, future pension benefits are calculated by multiplying contribution years by the accrual rate (amounting to 0.015) and the respective reference earnings[75].

$$(15) \qquad B^{accrued} = benefit\ \ formula(FE, C, AR)$$

In recent years, final earnings benefit formulas have been replaced in many countries by **pension account schemes.** The characteristic of such schemes is that individual contributions are directly converted and recorded in an individual pension account (PA). In comparison to final earnings schemes, individual accounts are explicitly considered in the benefit formula — see Equation 16.

$$(16) \qquad B^{accrued} = benefit\ \ formula(PA)$$

Typical examples of such pension account schemes are notional defined contribution (NDC) accounts, as found in Poland, Latvia, Italy or Sweden. In these systems, the amount of yearly individual contributions is directly transformed into an equivalent increase in individual pension accounts. Pension point systems, found in Germany or Slovakia, are also examples of pension account benefit schemes. In these schemes, individual earnings translate into a certain level of pension points, recorded in individual accounts.[76]

The following description distinguishes between flat-rate pension schemes and two types of earnings-related pension schemes, namely final-earnings and pension accounts types.

[74] In the UK also earnings-related public pension schemes can be found.
[75] Currently reference earnings in this scheme cover all earnings since 1985.
[76] Generally, one pension point is accrued by contributors who earn in a certain year the average earnings in the economy. Higher or lower salaries result in increased or diminished pension point values per year.

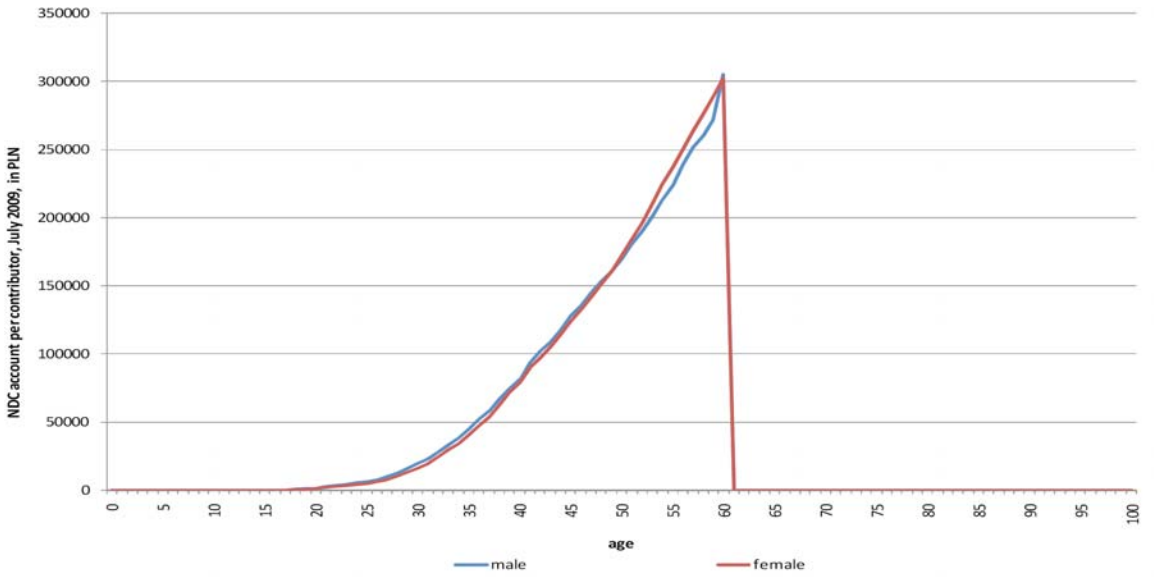
Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Collection of data on the past contribution career

In a first step, data on the contributions of current contributors need to be collected. The extent of data required depends on the benefit formula of the respective pension scheme.

In a flat-rate pension scheme like those found in the Netherlands, the accumulated number of contribution or residence years should be taken into account. It is useful to collect past contribution data broken down by one-year age groups and by gender. This are data for the accumulated contribution years for an average *x* year-old male, an average *x* year-old female, an average *x* +1 year-old male, an average *x* +1 year-old female and so forth.

In earnings-related pension schemes, additionally, past earnings or contributions of current contributors should be considered. This past contribution data depend on the type of earnings-related pension scheme. The following description, therefore, distinguishes further between final earnings and pension accounts schemes.



For pension accounts schemes, past earnings/contributions are, generally, already accumulated in individual pension accounts. These accounts facilitate the collection of contribution data since they also reflect (implicitly) the number of past contribution years. For pension schemes classified as pension accounts, the recommendation is to collect past contribution data broken down by one-year age groups and by gender. An example of such data is presented in Figure 20, which displays the required average notional defined contribution accounts, distinguished by age and gender, in the case of Poland.[77]

[77] Contributors older than 60 years have no NDC account in the Polish general pension system. They are insured according to the old, pre-NCD pension rules. For a description of the pension system and the use of this data to project future pension levels see Jablonowski et al. (2010), p. 26-36.

Figure 20

Value of NDC accounts differentiated by age and gender

Source: Forschungszentrum Generationenverträge, University of Freiburg, based on data provided by the Polish social insurance institution (Zaklad Ubezpieczen Spolecznych, ZUS).

In pension schemes classified as final-earnings types, such as those in Bulgaria or Portugal, past reference earnings and the number of contribution years of current contributors need to be collected, preferably broken down by one-year age groups and by gender, that is, data for past reference earnings and the number of contribution years for an average x year-old male, an average x year-old female, an average x+1 year-old male, an average x+1 year-old female, and so forth.

On the basis of the contribution data, future initial pension levels accrued-to-date can be calculated. Below, this estimation procedure is outlined separately for 1) flat-rate, 2) final earnings and 3) pension account schemes.

I. Estimation of accrued pensions in flat-rate pension schemes

The aim is to estimate the annual accrued-to-date pension benefit $B^{accrued}$ of current contributors at the point of their future (expected) retirement. For flat-rate pension schemes, this calculation is relatively simple. In a first step, the future retirement age of current contributors should be set. A discussion on the appropriate choice of future retirement ages is provided in Box .

As a second step, the information about accumulated contribution or residence years in the base year $C_{base\ year}$ is applied in the respective benefit formula.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

$$(17) \qquad B_r^{accrued} = benefit\ \ formula(C_{base\ year}, BP_r)$$

Furthermore, it is necessary to project in a third step the benchmark pension BP from the base year *b* to the future year of retirement *r*. Here — in accordance with the PBO approach — the annual adjustments of BP starting from the year after the base year *b* until the year of retirement *r* should be considered (see Equation 18). In most flat-rate pension schemes, wage indexation is applied. But other indexation arrangements, such as an adjustment for prices, can also be found. In correspondence with the indexation rules, the level of the BP is adjusted annually by a factor v – as outlined in Equation 18.[78]

$$(18) \qquad BP_r = \prod_{s=b+1}^{r} [1+v_s] * BP_b$$

An example of the procedure to estimate $B^{accrued}$ in flat-rate pension schemes on the basis of the hetCC approach is provided in Box 14.

Box 14

Estimation of accrued pensions in a flat-rate pension scheme

Below is a case study on how to estimate annual accrued-to-date pensions at retirement in a flat-rate pension scheme. The example is an average 50-year-old male contributor who participates in a flat-rate pension scheme, similar to the basic state pension scheme in the United Kingdom.

The final basic pension level received at the point of retirement depends solely on the number of contribution years the individual accumulates. A 'full basic pension'[79] (FBP) — corresponding to the benchmark pension in the general description above — is granted if 30 or more contribution years have been earned. In the example given, the FBP would amount to EUR 5,000 in the base year. Furthermore, it is assumed that the FBP is adjusted annually for wage growth in the economy. The example assumes constant future wage growth of 1.5 % (in real terms). Pensions are reduced if fewer than 30 qualifying years have been accrued. More precisely, the number of qualifying years is compared to the number of years needed for a FBP (30 years). This 'contribution years ratio' is then multiplied by the amount of a FBP (in the retirement year) to estimate the individual pension level at retirement. In the example, the representative 50-year-old male contributor has accumulated on average 23 contribution years. To keep the description simple, it is further assumed that all contributors retire at the age of 65. This representative 50-year-old contributor will retire 15 years after the base year.

The estimation of $B^{accrued}$ of the 50-year-old contributor would be as follows: First, the ratio of contribution years accrued until the base year (23 years) to the number of years needed for a FBP (30 years) is calculated — amounting to about 76 percentage points. Thereafter, in accordance with the PBO approach, the FBP is projected to the year of retirement *r*. Finally, both the contribution years ratio and the projected

[78] Often a time lag of one or two years is set in the benefit formula. In other words pensions are indexed to the wage growth one or two years before the base year. The impact of indexation can be considerably. In the example given in Box 1 the level of a full basic state pension in 15 years — when the current 50 year old will retire — would increase by roughly 25 per cent (in real terms) with a wage indexation in comparison to an indexation with prices.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

FBP are multiplied to estimate $B^{accrued}$ at the point of retirement.

$$(19) \qquad B^{accrued}_{50,male,r} = \frac{23}{30} * [(1.015)^{15} * 5000\,€] \approx 4800\,€$$

As outlined in Equation 19, the 50-year-old male contributor would be entitled to an annual pension benefit of roughly EUR 4, 800 at his (expected) retirement age.

II. Estimating accrued pensions in final earnings schemes

In final earnings schemes, pension levels depend not only on the number of contribution years accumulated until the base year ($C_{base\,year}$), but also on final earnings before the retirement year *r* (FE_r). Moreover, in most final earnings schemes, an accrual rate (AR) is applied. For the estimation of $B_r^{accrued}$ of current contributors, all the factors outlined above should be taken into account (see Equation 20).

$$(20) \qquad B_r^{accrued} = benefit\ \ formula(FE_r, C_b, AR)$$

Most of the above-mentioned input factors can be relatively simply obtained from past contribution data. This includes information about C_b but also about past earnings until the base year *b*. Furthermore, the AR is defined in the respective benefit formula and can therefore be directly applied in the estimations.

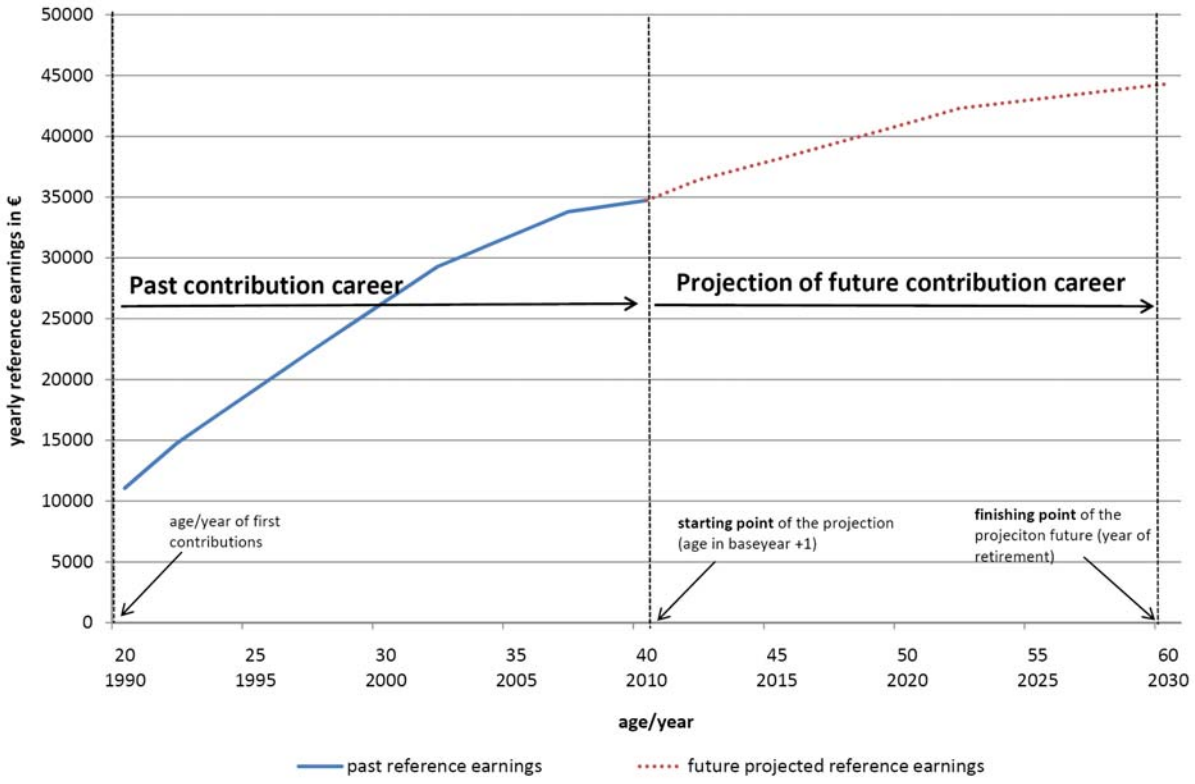
For the estimation of ABO pension entitlements, the above-mentioned input data would be sufficient.[80] However, to estimate pension entitlements with the PBO approach — described in Chapter 2.2 — some further steps need to be taken: future wage increases have to be considered for the estimation of $B_r^{accrued}$. This involves a projection of future earnings periods. The framework and the assumptions of such a projection are outlined below.

Defining the starting and finishing point of the projection

First, it is important to set the starting and finishing point of the required projection. Commonly, the projection of the future contribution career should start after the year for which the latest data on past earnings is available. Since the aim is to estimate pension

[79] A 'full basic pension' should not be mixed up with the term 'full pension'. The latter expression represents a pension benefit received after a full contribution career, while a 'full basic pension' is granted after 30 contribution years. .

[80] Under the ABO approach only reference earnings until the base year are applied for the estimation of $B^{accrued}$. This approach requires no projection of future wage increases.



Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

benefits upon retirement, the natural finishing point of the projection is the year *r* in which the respective contributor is expected to retire. A discussion on the appropriate choice of future retirement ages is provided in Box 11.

The example is an average 40-year-old contributor in base year 2010. He is expected to retire at the age of 60. Data on his past contributions are assumed to be available until the base year 2010.[81] Figure 21 illustrates the required projection period for this example. Data on his past contribution career — reflected by past reference earnings — is obtainable until the base year. For all future years, starting from 2011, until the year 2030,[82] when he is expected to retire, his contribution career needs to be projected.

Figure 21

Projection of the future contribution career under the PBO approach

Source: Forschungszentrum Generationenverträge, University of Freiburg.

Required assumptions for the earnings projection

Generally, the development of individual future earnings depends on two main factors:

[81] Sometimes data on the past contribution may only be available for years before the base year. Of course, in such a case the projection of the future contribution career may begin already in the base year or even in the years before.

[82] To be precise, the projection should finish already at the end of the year 2029 in this example. If the contributor is expected to retire in beginning of 2030 his contribution career finishes at the end of 2029.

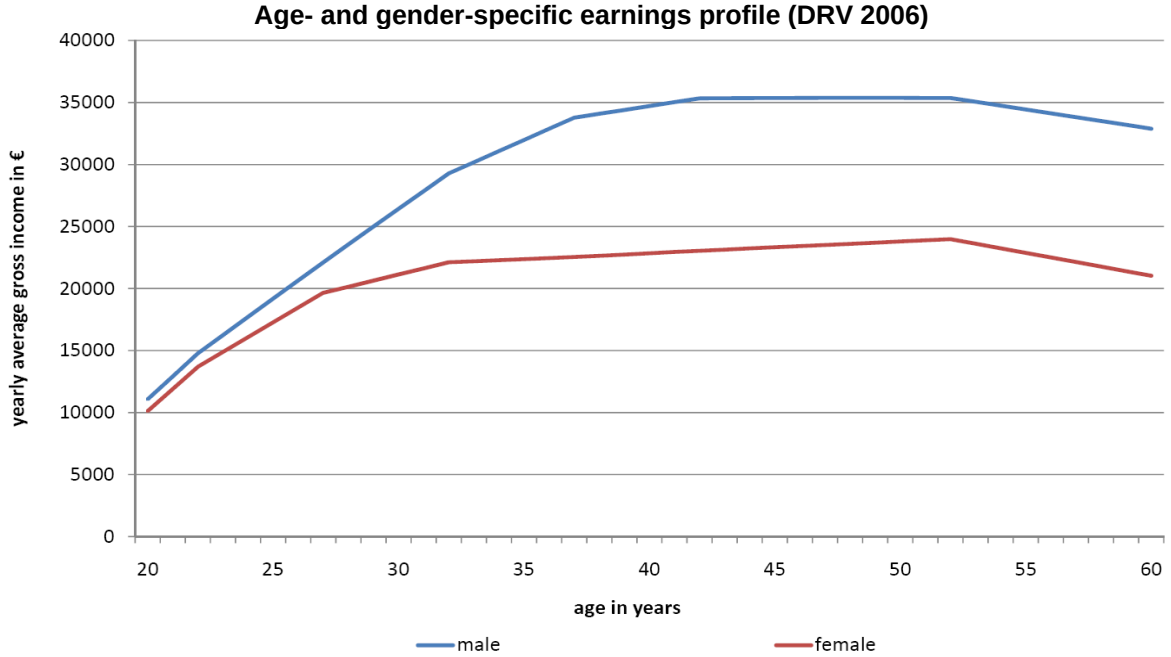
***1) future promotions** and*



2) future general wage growth in the economy

To project future earnings over the (expected) remaining contribution career, assumptions about these two factors need to be taken. The choice and application of these is described in detail below.

As outlined in Chapter 5.2, it is recommended to forecast future promotions on the basis of profiles reflecting the reference earnings or contributions for different age groups and genders. Figure 22 shows such an earnings profile for contributors to the German statutory pension scheme (DRV). The profile reflects a number of factors which might vary by age and gender, such as the average wage paid per hour, the number of hours worked per year, the part-time employment of older (55+) and younger cohorts (20 to 25) and so forth. For the following description, all these factors will be summed up by the term 'promotions'. The picture makes clear that earnings vary over the working career. Generally, salaries increase with age and decline slightly before retirement. In this sense, the profile shown displays the usual hump shape which can be found in many European countries.

Figure 22

Age- and gender-specific earnings profile (DRV 2006)

Source: Forschungszentrum Generationenverträge, University of Freiburg, based on data for 2006 provided by the Deutsche Rentenversicherung (DRV).

For the projection of the future contribution career, it is appropriate to base the calculation on a constant earnings or contribution profile over time. A current average contributor

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

'walks' along this profile over his/her remaining employment life cycle until retirement. Equation 21 provides a formal outline of how to calculate future earnings with this approach.

$$(21) \qquad w_{x,y,m} = w_{y,b} * \prod_{i=b+1}^{m} [(1+\pi_i)*(1+g_i)]$$

where

x = the age of a participant whose future earnings shall be projected,

y = the future age of the participant $(y \geq x)$,

$w_{x,y,m}$ = the projected earnings of the current x year old participant than he/she reaches the age of y in the future year m

m = the future year for which the wage of a current participant is projected $(m = b + (y - x))$,

$w_{y,b}$ = the earnings of a current y year old in the base year b,

π_i = the inflation rate in a future year i $(b + 1 \leq i \leq m)$,

g_i = the general wage growth in a future year i $(b + 1 \leq i \leq m)$.

On the one hand, future earnings are determined by future promotions. According to the formula outlined above, a current pension scheme member aged x can expect to receive the same earnings at age y as a current member aged y. On the other hand, future salaries increase by inflation π and general wage growth in the economy g. Of course, inflation should only be considered if the calculation is carried out in nominal terms.[83]

Data used for earnings profiles can usually be obtained from the institution responsible for the pension scheme. Household surveys can be an alternative data source. For a further discussion on data sources, see Chapter 6.3.2. As outlined in Section 5.2, the AWG assumptions on future labour productivity growth provide a suitable basis for estimating general wage growth in the economy.[84]

With the application of the earnings profile and the assumption on general wage growth and inflation (if required), earnings can be estimated for each year of the individual's future contribution career. For an example showing how to project future earnings, see Box 15.

[83] For a further discussion see section 5.4.1.
[84] For a more detailed discussion on the future wage growth assumption see chapter 5.2.

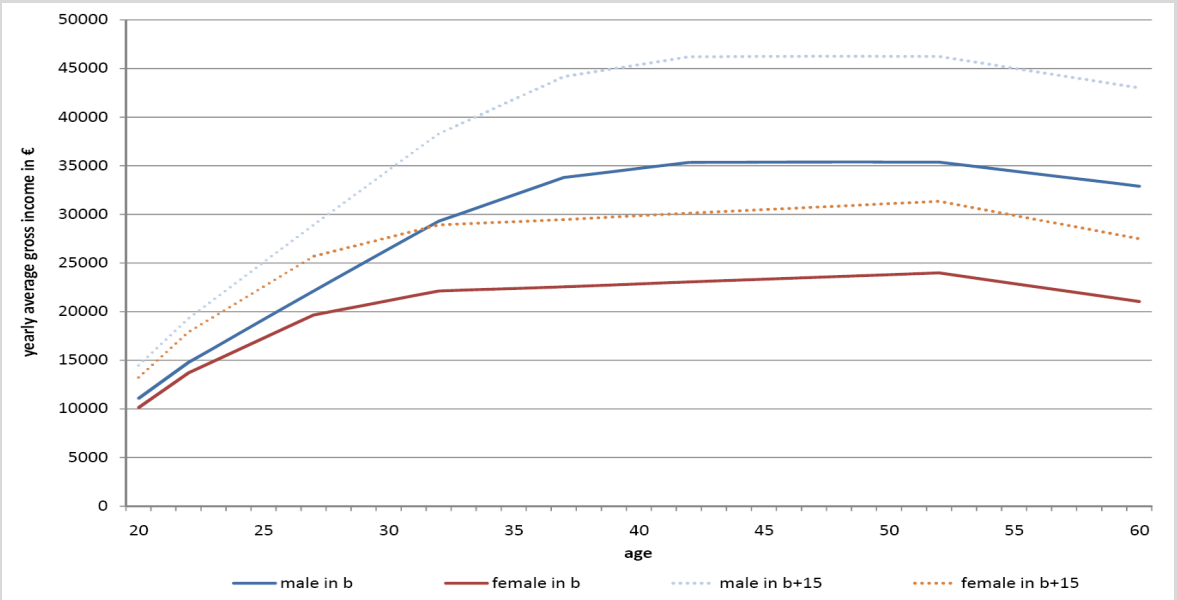
Box 15



Projection of future earnings

The following case study illustrates a projection of future earnings. This example takes the case of a 25-year-old man, an average contributor who is expected to follow the earnings profile shown in Figure . The aim is to calculate his projected earnings at the age of 40. Of course, the same approach can also be applied to other periods of the individual's contribution career.

The projection is carried out in real terms, i.e. inflation is disregarded. In base year *b,* the contributor earns about EUR 20,000 (see Figure 23). Assuming a constant earnings profile over time, he can expect to earn a 75 per cent higher wage at the age of 40 (in 2021), due to career progression. However, there are factors other than promotions to consider for the projection of his future contribution career. The level of future contributions and reference earnings is also affected by general wage growth in the years until 2021. The assumption here is that annual real wage growth in the economy is 1.5 per cent, and that all employees benefit equally. Under these assumptions, the 25-year-old contributor can expect to improve his relative income position in the workforce due to promotions as well as from general wage growth in the economy. In quantitative terms, this implies that in 15 years' time, he will exceed the earnings of a current 40-year-old contributor, about EUR 35, 000 annually. When the 25-year-old reaches the age of 40, he can expect future earnings of about EUR 45, 000 due to general salary growth. The dotted lines in Figure 23 illustrate the increase in the earnings profile due to expected wage growth after 15 years.

Figure 23

Age- and gender-specific earnings profile considering general wage growth (DRV 2006)

Source: Forschungszentrum Generationenverträge, University of Freiburg.

For the estimation of $B_{by}^{accrued}$ a number of further aspects of the benefit formula need to be taken into account, such as the definition and valorisation of final earnings. The most important issues are discussed below.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Defining final earnings

Generally, final earnings reflect the average of annual reference earnings (*RE*)[85] over the last *n* years before retirement (as outlined in Equation 22).

$$FE_r = \frac{\sum_{t=(r-1)-(n-1)}^{r-1} RE_{t,r}}{n} \quad (22)$$

The calculation of final earnings may differ widely from one pension scheme to another. In most pension schemes across Europe, not all contribution periods until retirement age are relevant for the pension calculation. In some schemes, only the earnings in the last three years before retirement matter (e.g. in the German civil servants pension scheme). In other pension schemes, the reference earnings of the best 25 years (e.g. in France) before retirement or even of the entire contribution career (e.g. in Slovakia) are taken into account. The length of the contribution career considered in the benefit formula can have a significant impact on future pension levels.[86] It is important to reflect this aspect in the estimation of $B^{accrued}$. The definition of final earnings should, therefore, always be chosen precisely in accordance with the benefit formula. Furthermore, it has to be considered that these past earnings are usually valorised to the point of retirement *r.* This aspect is described below.

Indexation of past earnings

To estimate future pension levels, the indexation of reference earnings until the point of retirement should be reflected. These adjustments are also referred to as pre-retirement indexation. Most pension schemes across Europe apply indexation to past earnings according to wage growth in the economy.[87] Only a few pension schemes (e.g. in Portugal) choose a lower indexation of past contributions, using the CPI.[88] In accordance with the benefit formula, a past earning *w* in a year *t* is indexed by a factor *v* until the year of retirement *r* (see Equation 23). This valorised past salary represents the reference earning *(RE)* of the year *t* applied in the benefit calculation (see Equation 22).

[85] Reference earnings are defined as the past earnings relevant in the benefit formula.
[86] Generally, an extension of the reference earnings translates into a decrease of pension levels — given the ceteris paribus condition.
[87] In these schemes the AWG assumptions on the future labour productivity growth provide a suitable proxy for the future wage growth. For a further discussion see section 5.2.
[88] In fact, in Portugal reference earnings are indexed to the growth of CPI from 2012 onwards. Before the year 2012 a slightly higher indexation is applied. .

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

$$(23) \qquad RE_{t,r} = w_t * \prod_{i=t+1}^{r} [1+v_i]$$

Considering future adjustments to the benefit formula

Besides the contributions career, future changes to the benefit formula should also be taken into account. For example, alterations to accrual rates (e.g. in Austria or Hungary) as well as extensions of the periods relevant for reference earnings (e.g. in Portugal or Malta) should be considered. In some countries, moreover, demographic factors should be applied when estimating the final pension level upon retirement. These factors, often referred to as sustainability factors, link future pension levels to demographic trends and play a role in, for instance, Germany, Austria or Portugal. It is important to stress that only pension reforms which have already been enacted in the base year for calculations should be taken into account.

Once final earnings have been accurately defined and valorised, $B^{accrued}$ at the point of retirement can be estimated. An example for the estimation of $B^{accrued}$ at the point of retirement in final-earnings pension schemes (applying the hetCC approach) is provided in Box 16.

Box 16

Estimation of accrued pensions in a final-earnings pension scheme

The following case study illustrates how to estimate annual accrued-to-date pensions at retirement in a final-earnings pension scheme. Take the case of a 50-year-old male contributor who is a member of a final-earnings pension scheme. The individual pension received at the point of retirement (P) will depend on the number of contribution years (C), the valorised final earnings of the year before retirement (FE) and on an accrual rate of two percentage points. Equation 24 provides a formal outline of the applied benefit formula.

$$(24) \qquad P = FE * C * 2\%$$

To keep the description simple, it is assumed that all contributors retire at the legal retirement age of 65. Moreover, it is assumed that reference earnings are wage-indexed up to the year of retirement. The example assumes constant future wage growth of 1.5 % (in real terms). In the base year, the representative contributor earned a salary of EUR 20,000. In the case of the ABO approach, this would be applied as FE. However, as pension entitlements will be based on the PBO approach, future wage increases need to be taken into account, requiring an earnings projection. According to this projection the representative contributor will earn an (expected) annual salary of EUR 30,000 (in real terms) in the year before his retirement. Of course, in line with the benefit formula, these final earnings need to be valorised to the year of retirement. Here the valorised FE would amount to EUR 30,450 EUR (= EUR 30,000 * 1.015) in real terms. Furthermore, this contributor has collected 30 contribution years until the base year.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

(25) $B^{accrued}_{50,male,65} = 30{,}450\,€ * 30 * 2\% = 18{,}270\,€$

These inputs yield an estimate of the level of $B_r^{accrued}$ at the future point of retirement *r* — as presented in Equation 25. In this example, the 50-year-old male contributor would be entitled to an annual pension benefit of EUR 18,270 at his (expected) retirement age of 65.

III. Estimation of accrued pensions in pension account schemes

In recent years, final earnings benefit formulas have been replaced in many countries by a pension account scheme. The characteristic of these schemes is that individual contributions are directly converted and recorded in an individual pension account (PA). Individual accounts are explicitly taken into account in the benefit formula — see Equation 26. This aspect distinguishes them from final earnings schemes.

(26) $B_r^{accrued} = benefit\ \ formula(PA)$

In pension account schemes, accrued pension rights are reflected by the value of the PA in the base year. In line with the ADL approach, pension rights accrued in future years are not taken into account. The degree to which the level of the pension accounts translates into future pension payments depends on the pension formula used. Pension account schemes can be divided into: NDC, pension point and other pension schemes (as outlined below).

Pension account schemes — ***NDC pension schemes***; ***Pension point schemes***; ***Other pension account schemes***

The following description of the estimation of $B_r^{accrued}$ distinguishes between these three types of pension account schemes.

NDC pension schemes

NDC schemes are typical examples of pension account schemes such as those in Poland, Latvia, Italy or Sweden. In these systems, the amount of yearly individual contributions is directly transformed into an equal increase in individual pension accounts.[89]

[89] Characteristic for NDC plans is that their benefit formula mimics the build-up of pension accounts in DC plans. Similarly to DC schemes, individual accounts in NDC schemes already reflect to a certain degree the value of individual pension entitlements — at least of old age pensions. Against this background, one may argue that an estimation of pension entitlements based on a projection of future pension payments is not required in case of NDC schemes because pension entitlements should correspond to the value of the NDC account. However, this

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

For the estimation of $B_r^{accrued}$ of current contributors, one has to take into account mainly two factors: 1) the NDC account ($PA_{b,r}$) of the base year *b* valorised to the future retirement age *r* and 2) the average remaining life expectancy LE_r at retirement age *r* (see Equation 27).

$$(27) \qquad B_r^{accrued} = \frac{PA_{b,r}}{LE_r}$$

As a first step, appropriate assumptions about the future retirement age *r* of current contributors are needed.[90] As a second step, the base year NDC account (PA_b) should be valorised until the future retirement age r to reflect future wage growth.

$$(28) \qquad PA_{b,r} = PA_b * \prod_{i=b+1}^{r} (1+v_i)$$

Usually, individual NDC accounts (*PA*) are adjusted annually in accordance with wage bill growth or GDP growth. The indexation rules applied are reflected in the annual valorisation factor v (see Equation 28). On the basis of these two steps, the level of $B_r^{accrued}$ may be estimated – as outlined in Equation 27 above.

Pension point schemes

Pension point systems, such as those in Germany or Slovakia, are also examples of a pension account benefit formula. In these schemes, individual earnings translate into pension points which are recorded on individual accounts.[91] The level of $B_r^{accrued}$ at the future point of retirement depends on 1) the total number of pension points accrued until the base year (TP_b) and 2) the valorised point value in the retirement year ($PV_{b,r}$).

$$(29) \qquad B_r^{accrued} = TP_b * PV_{b,r}$$

'non-projection approach' has a number of shortcomings. First of all, the results would not be comparable to the estimations of other countries which apply a (PBO) projection approach based on harmonised assumptions. With the above described 'non-projection approach' also cases where contributors die before retirement cannot be appropriately reflected. Furthermore, a projection is in most NDC schemes required since survivor's pension benefits are usually linked to old age NDC pensions. Against this background, a projection approach as described in Equation 27 should be applied for the calculation of NDC pension schemes. Only if this approach is not yet realisable for a start a 'non-projection approach may be acceptable for the estimation of current contributors´ entitlements. In other words under such circumstances the sum of individual pension accounts may serve as a proxy of total current contributors´ (old age) pension entitlements.

[90] For a further discussion on the choice of future retirement ages see Box .

[91] Generally, one pension point is accrued by contributors who earn in a certain year the average earnings in the economy. Higher or lower salaries result in increased or diminished pension point values per year.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Generally, the level of PV is adjusted annually to the growth of average earnings in the economy. But other indexation rules are also possible. The valorisation factor *v* reflects the respective indexation rules for the annual adjustments of PV.

$$(30) \qquad PV_{b,r} = PV_b * \prod_{i=b+1}^{r} (1+v_i)$$

To take into account future wage growth, the PV of the base year is valorised until the future point of retirement *r* (see Equation 30).[92] $B_r^{accrued}$ may then be estimated as outlined in Equation 29 above.

Other pension account schemes

In all pension account schemes, accrued pension rights are directly reflected in individual accounts. These accounts are then explicitly considered in the benefit formula. Besides NDC and pension point schemes, there are also other forms of pension account schemes. One example is the UK civil service pension scheme, *Nuvos*. In this scheme, participants pay a certain percentage of pension earnings into a *PA* each year. In other words, the amount of yearly contributions is directly transformed into an equal increase in the individual *PA*. Finally, in the year of retirement *r* the initial annual pension payment equals the level of the *PA*.

$$(31) \qquad B_r^{accrued} = PA_{b,r}$$

For the estimation of $B_r^{accrued}$ it is necessary to valorise the base year pension account to the future point of retirement *r*. This procedure is outlined in Equation 32. In the case of the Nuvos pension scheme, the pension account value of a year *t* is increased in line with inflation to the following year *t+1.* In fact, under such price indexation, no future wage increases need to be taken into account. As a consequence, the results of the PBO estimation approach would equal the ABO outcomes. Of course, other annual adjustment rules, such as wage indexation, are possible. The valorisation factor *v* — in Equation 32 — reflects the indexation rule of the pension scheme analysed.

$$(32) \qquad PA_{b,r} = PA_b * \prod_{i=b+1}^{r} (1+v_i)$$

[92] For a discussion of the choice of the retirement age see Box 11Box .

7.4.4 Estimating pension entitlements

In the sections above, the procedure to estimate the initial annual pension accrued-to-date $B_p^{accrued}$ was outlined — applying both a homogeneous (Chapter 7.4.2) and a heterogeneous contribution careers approach (Chapter 7.4.3). In other words, the calculation of the 'starting pension' of current contributors was described. On this basis, it is relatively straightforward to estimate pension entitlements of present contributors. First, the initial pension level $B_p^{accrued}$ at retirement year *r* is projected over the entire remaining retirement phase. This projection follows the same procedure described for current retirees. For the projection of current contributors´ benefits, (post-retirement) indexation rules also need to be taken into account. and future adjustments in the benefit formula have to be considered. A more detailed description of the projection of pension benefits over the remaining retirement phase is provided in Chapter 7.3.

On the basis of the benefit projection, $f\ (f = b + s - x)$ the annual pension benefit received by a current contributor can be calculated for any future year. To estimate the expected entitlements, future pension payments are weighted in a further step by the respective survival probabilities p. Finally, all future pension payments are summed up and discounted to the base year (see Equation 33 below).[93]

$$(33) \qquad \mathrm{E}_{x,g,b} = \sum_{s=x+1}^{D} B_{s,g,f}^{accrued} * p_{s,g,f} * (1+r)^{x-s}$$

An example of the procedure to estimate pension entitlements for current contributors is provided in Box 17.

Box 17

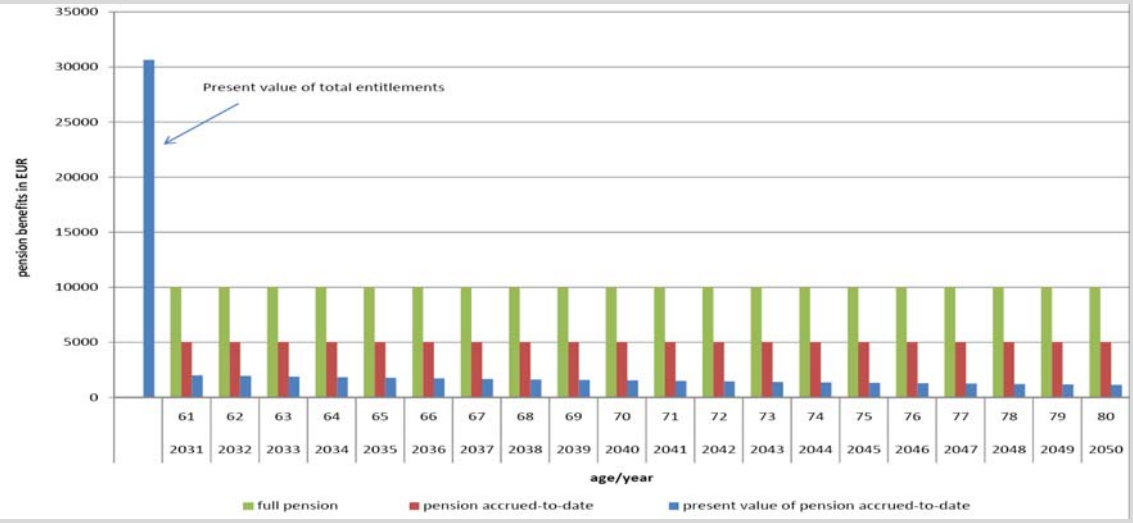
Estimation of pension entitlements of current contributors

This case study outlines the estimation procedure to calculate pension entitlements of current contributors. This example is used to calculate the pension rights of a 40-year-old male contributor, base year 2010. This individual is expected to retire at the age of 61 (in 2031). At the beginning of his retirement he can look forward to receiving a full pension benefit of EUR 10,000 (see first green bar, Figure 24), representing a pension payment after a full contribution career.

For the estimation of pension entitlements, however, only accrued-to-date pension benefits are

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

taken into account. In the example given, the initial annual pension benefit accrued-to-date ($B_{y}^{accrued}$) will amount to EUR 5,000 (see first red bar, Figure 24). In other words, the 40-year-old contributor would be entitled only to half of his future (expected) full pension. This proportion has been estimated on the basis of the homCC approach, described in Chapter 7.4.2.



Pensions are paid until his expected death after the age of 80 (after 2050). To keep the case study simple, all values are calculated in real terms and price indexation is assumed. According to these assumptions, he can expect to receive the value of the initial pension over his entire retirement.

The aim is to calculate pension entitlements in the present value terms of the base year. All future accrued pension payments are therefore discounted. Since these future flows are paid out in the far future, in 20 to 40 years they are heavily discounted (see blue bars in Figure 20). At this stage of the estimation, an important aspect becomes apparent. Younger contributors especially have accrued only relatively little pension entitlement. This can be explained by two factors. First, their future pension payments are paid out in the far future, and are therefore heavily discounted. Secondly, they have accrued only a relatively small proportion of their full pension. Therefore, younger cohorts play only a minor role in the total of pension liabilities. This aspect should be kept in mind when setting up a pension model. It is important to focus especially on the estimation of pension entitlements of present pensioners and older contributors, since they have the largest impact on the total value of pension liabilities.

Finally, all discounted accrued-to-date pension payments are accumulated to obtain the stock of pension entitlements. For the example of the 40-year-old male contributor, these pension rights would amount to about EUR 30, 000 in the base year (see blue bar to the far left). Analogously, for all other age groups, pension rights should be calculated and projected differentiated by gender.[94]

Figure 24

Estimating pension entitlements of current contributors

Source: Forschungszentrum Generationenverträge, University of Freiburg.

[93] Please note that Equation 33 equals Equation 5. For a description of the used parameters and variables see, therefore, Equation 5.

[94] In the given example it was so far assumed that current contributors reach with certainty the age of retirement. This is of course not a realistic presumption since a certain, though, small proportion of contributors is expected to die before they can receive any pension benefits. The aim of the estimations is to calculate the expected pay-out of pension benefits. Therefore, the mortality of current contributors should be taken into account by weighting the final pension with the probability to reach the respective retirement age. This aspect is considered in Box 18 with the probability to die before retirement.

7.4.5 Differentiation by type of pension

As outlined in Box 3, the supplementary table covers various types of pensions. The most significant category for the estimation of entitlements is old age pensions. Generally, the largest amount of pension expenditure and entitlements is determined by this type of pension. However, disability, early retirement, widows' pensions and orphans' pensions should also be considered in this new table of national accounts. As an example Table 4 displays the breakdown of aggregate payments by type of pension for the social security pension scheme in Slovakia.

Table 4

Differentiation of aggregate payments by type of pension — the example of the Slovakian social security pension scheme

Type of pension payments	Pension payments SKK billions, 2007
Total of pension payments	**126.519**
Old age pensions	96.148
Disability pensions	15.380
Survivor pensions	14.991

It is desirable to distinguish among pension types, for two main reasons: the benefit formula and the resulting pension levels may vary considerably between pension types; and the duration for which participants receive a specific benefit may vary significantly by pension type. While old age pensions, for instance, are granted until death, disability benefits are usually paid until the legal retirement age or the death of the beneficiary.[95] Box 18 outlines how to differentiate the calculation procedure by pension type.

In some countries, however, the data and resources to differentiate by pension types in making the calculations may not yet be available. In such cases, it is best to focus on the calculation of old age pension entitlements, due to their relative importance (see Table 4): a detailed estimation of disability and survivors' pension entitlements (for current contributors)[96] may initially be disregarded.[97] Under such circumstances, the final old age pension

[95] Also pension type specific survival rates may represent a reason to differentiate the calculation by pension type. E.g. survival rates of disabled individuals ($p_{x,5}^{disab}$) may deviate from the average survival rates applied for old age. If possible — as outlined already in section 5.3.1 — such pension type-specific survival rates should be taken into account.

[96] For present pensioners the estimation procedure is more straightforward. For this group a differentiation in the course of the calculations by pension type should, possibly, always be applied.

[97] For the development of a pension model it should always be taken into account which factors play the most decisive role for the final results. Generally, about half of pension entitlements are accrued by current

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

entitlements of a current contributor should be rescaled by a factor reflecting the ratio of the total aggregate pension payments and the aggregate of old age pension payments in the base year.[98]

Box 18

Differentiation of estimations for current contributors by pension type

The aim of the calculations is to estimate entitlements for different types of pension: old-age and early retirement, disability and survivors' pensions. The calculation procedure should distinguish between these pension categories. This approach is explained below. The description is provided for a homCC approach. But it is also applicable for a hetCC approach after the consideration of a few minor modifications.[99]

Pension entitlements of current contributors should reflect the fact that these individuals retire with a certain probability q^{old} at age d, but also that they may become disabled or may die with a certain probability at an age d. Their pension rights should represent the probability-weighted sum of entitlements for each of these pension types. Equation 34 provides a formal outline of the estimations differentiating by pension type. The formula reflects heterogeneous retirement ages $d\,(x+1 \le d \le D)$.[100] For every d the accrual factor $\lambda_{x,g,d}$ is calculated. Moreover, the present value of the expected payment stream PV is calculated for each type of pension considering the type-specific survival rates *p* and pension benefits *B*.

$$(34) \qquad E_{x,g,b} = \sum_{d=x+1}^{D} [\lambda_{x,g,d,b} * [q^{old}_{x,g,d,f} * PV^{old} + q^{disab}_{x,g,d,f} * PV^{disab} + q^{surv}_{x,g,d,f} * PV^{surv}]$$

$$PV^{old}_{x,g,d,f} = \sum_{s=d}^{D^{old}} (p^{old}_{s,g,m} * B^{full,old}_{s,g,d,m} * (1+r)^{x-s})$$

$$PV^{disab}_{x,g,d,f} = \sum_{s=d}^{D^{disab}} (p^{disab}_{s,g,m} * B^{full,disab}_{s,g,d,m} * (1+r)^{x-s})$$

$$PV^{surv}_{x,g,d,f} = \sum_{s=d}^{d+D^{surv}} p^{surv}_{s+u^{surv},g^{surv},m} * B^{full,surv}_{s,g,d,m} * (1+r)^{x-s}$$

where

$\lambda_{x,g,d,b}$ = the accrual factor of a participant of age *x* and gender *g* in the base year b who retires/becomes disabled or dies at age d,

$q^{old}_{x,g,d,f}$ = the probability of a x year old to retire at an age d and to receive B^{old} in a future year f $(f = b + d - x)$.[101]

contributors. Of these half about 70 per cent are old age pension entitlements. Old age pensions are therefore rather significant for the final level of pension entitlements while disability and survivors' pensions play a less important role. One may conclude that 'only' about 15 per cent of overall pension entitlements are calculated not in depth when disregarding disability and survivors' pensions of current contributors.

[98] This rescaling approach has been applied e.g. by Holzmann et al. (2004), see p.34. In the Slovakian example shown in Table 4 the rescale factor would amount to about 1.3. In this example it is assumed that only old age pension have been calculated in detail by the actuarial model. Of course, it also imaginable that further types of pensions (besides old age pensions) can be estimated in detail and fewer categories have to be disregarded. In this case the rescale factor would consequently decrease. .

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

$q_{x,g,d,f}^{disab}$ = the probability of a x year old to become disabled at an age d and to receive B^{disab} in a future year f,

$q_{x,g,d,f}^{surv}$ = the probability of a x year old to die at an age d and to have a surviving spouse/orphan who receives B^{surv} in a future year f,

$PV_{x,g,d,f}^{old}$ = the present value of the expected payment stream of old age and early retirement pensions after retirement at age *d* in future year f,

$PV_{x,g,d,f}^{disab}$ = the present value of the expected payment stream of disability pensions,

$PV_{x,g,d,f}^{surv}$ = the present value of the expected payment stream of survivors pensions,

$B_{s,g,d,m}^{full\ old}$ = the annual full old age or early retirement pension benefit at age s in year m after retirement at age d,

$B_{s,g,d,m}^{full\ disab}$ = the annual full disability pension benefit at age s in year m after the participant became disabled at age d.

$B_{s,g,d,m}^{full\ surv}$ = the annual full survivor's pension benefit at age s in year m after a participant died at age d,

m = a future year after retirement/disability/death $(m = b + s - x)$,

D^{old} = the highest possible age to receive B^{old}, i.e. the highest age considered in the calculations,

D^{disab} = the highest possible age to receive B^{disab},

D^{surv} = the number of years a spouse/orphan at age $d + u^{surv}$ can at most receive B^{surv},

$p_{s,g,m}^{old}$ = the probability of an old age pension beneficiary of gender g to survive an age s,

$p_{s,g,m}^{disab}$ = the probability of a disability pension beneficiary of gender g to survive an age s,

$p_{s,g,m}^{surv}$ = the probability of a survivor's pension beneficiary of gender g^{surv} to survive an age $s + u^{surv}$,

u^{surv} = the number of years, positive or negative, that when added to the participant's age (in the year of his death) gives the age of the surviving spouse (in this year).

[99] In case a hetCC approach is applied accrued pension benefits are estimated directly. Therefore, the accrual factor λ would be omitted. Furthermore, annual pension benefits B would reflect not a full pension but accrued-to-date pension payments estimated on the basis of past contribution data — as described in chapter 7.4.3.

[100] In case homogeneous retirement behaviour is assumed it is recommended to choose separately: 1) one average retirement age, 2) one average age to become disabled and 3) one average age to die during the time of contribution. For a further description on heterogeneous and homogeneous behaviour see Box .

[101] In various countries the entitlement of a pension is dependent on a minimum period of membership or contribution in the pension system. For example, in Italy 20 years (for people insured before the year 1996) of contribution are necessary to receive a pension entitlement while in Belgium no minimum period of membership in the pension system is required. The variable q^{old} should possibly reflect the probability to reach the minimum periods of contributions, i.e. to be eligible to a pension benefit.

The approach to calculating pension entitlements for average present pensioners (Section 7.3) and for average current contributors (Section 7.4) has been described). The distribution of pension entitlements for each age group and gender can then be estimated. The last step for estimating the total pension entitlements of a respective pension scheme is relatively simple. As outlined in Equation 35, all average pension entitlements calculated by age and gender in the previous steps need to be multiplied by the respective cohort sizes N in these groups. The sum represents the total of pension entitlements $\{TE\}$ in the respective scheme in present values of the respective base year *b*.

$$(35) \qquad TE_b = \sum_{s=0}^{D} E_{s,b}^{male} * N_{s,b}^{male} + \sum_{s=0}^{D} E_{s,b}^{female} * N_{s,b}^{female}$$

8 Worked examples

In this section worked examples are provided in order to complete the new supplementary table of national accounts. These case studies include the application of an actuarial model to estimate both the pension entitlements of social security pension systems (column H), and those of government employee pension schemes (column G) — see Section 8.1. Additionally, the use of business accounting data and regulatory data to compile the figures in columns A to C is described — see Section 8.2.

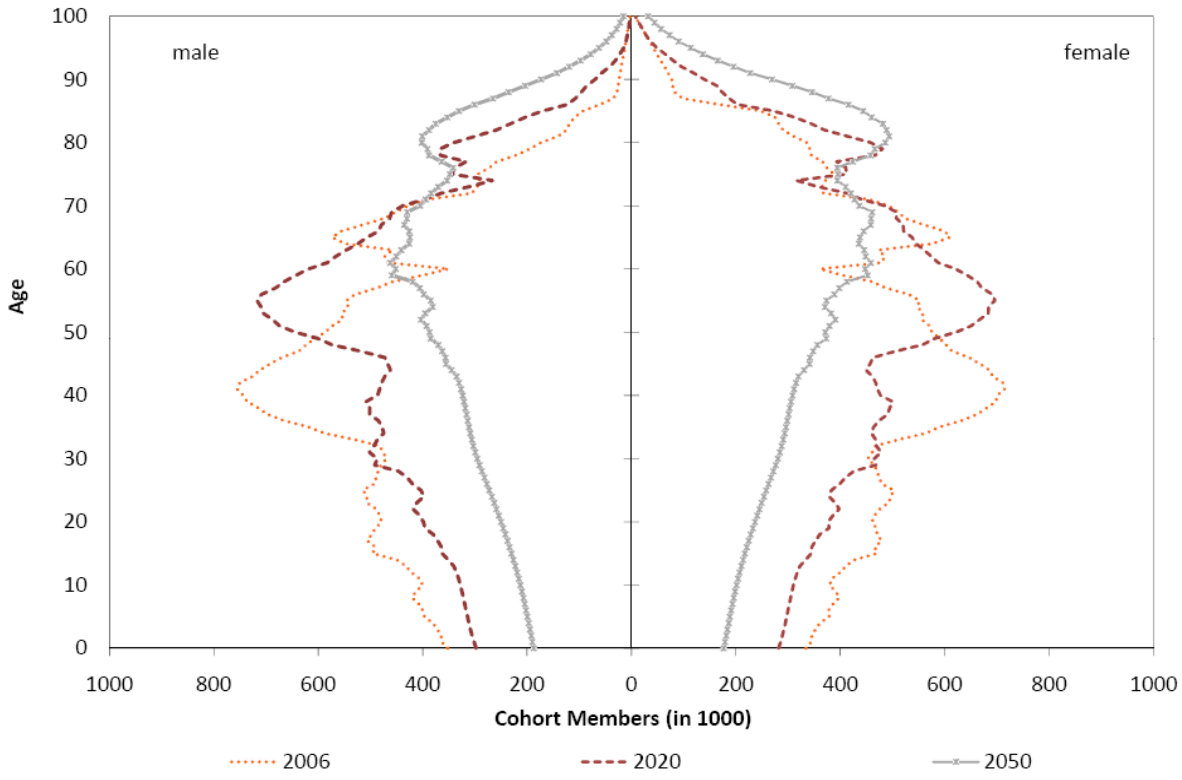
8.1 Using an actuarial approach to fill in columns G and H

The following section provides a worked example for the estimation of pension entitlements recorded in columns G and H. First, the so-called Freiburg model is outlined — which is applied to estimate these new figures in the national accounts. Thereafter, the outcomes of the actuarial approach will be presented using the example of the German supplementary table of 2007.

The Freiburg model has been developed to make benchmark calculations of pension entitlements on behalf of the Eurostat/ ECB Contact Group on Pensions.[102] The starting point for the Freiburg model is the method of generational accounting.[103] This method can be used for a wide variety of purposes. For this project, the method is applied to government-managed pension schemes[104] in isolation and to a group of existing retirees and current contributors (future retirees) only.[105] Additionally, the standard method is modified to account for the amount of benefits accrued to date, instead of considering future pension benefits in total. These calculations include old-age pensions, disability pensions and survivors' pensions. Any kind of means-tested social assistance is excluded wherever feasible. In order to estimate the entitlements of current contributors, the approach is based on the homCC approach described in Chapter 7.4.2. However, the Freiburg model may also be applied to a hetCC approach as outlined in Chapter 7.4.3.

[102] The model has been applied for 19 EU countries. For an outline of the results see Müller et al. (2009).
[103] This method was developed by Auerbach et al. (1991, 1992 and 1994). See Raffelhüschen (1999) and Bonin (2001) for a detailed depiction of theory and application as well as limitations of the method of generational accounting.
[104] The terms 'public pension scheme', 'government pension scheme' and 'pension scheme in general government' are used as synonyms. However, we differentiate between two different types of schemes. The government employer pension scheme indicates a pension scheme for civil servants, whereas a social security pension scheme describes a general pension scheme. For a discussion of the definition of government pension schemes see Eurostat/ ECB Task Force (2008), p. 20 et seq.
[105] For a closer look on the application of generational accounting to public pension schemes see Müller et al. (2010) or Jablonowski et al. (2010) who employed the concept of open-system net liabilities to investigate the sustainability of the German and the Polish statutory pension scheme respectively.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.



The core presumption is a projection of per capita future pension benefits based on those of today's existing retirees: the entire calculation procedure is set out in the five steps described below.

Step 1 — Population projection: Age-sex-specific projections of the base year's population need to be calculated. The demographic model used to generate these projections is based on a discrete and deterministic formulation of the cohort component method.[106]

In general, the three major determinants of future population changes are fertility, mortality and migration. Since ADL only take into account rights accrued by existing and former workers before the base year, the future migration of the base year population is irrelevant. The development of survival rates is examined by adjusting the initial set of survival rates using an exponential adjustment procedure.[107]

Figure 25

Projected German population

Source: Source: Forschungszentrum Generationenverträge, University of Freiburg, based on data provided by Eurostat.

The population data used for the calculation come from Eurostat. Also the assumptions on the future trend in life expectancy are based on data provided by Eurostat, i.e. the

[106] For a detailed description of the demographic model applied see Bonin (2001), p. 245 et seq.
[107] This procedure is suggested by Pflaumer (1988). See also Bonin (2001), p. 248.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Eurostat population projection (EUROPOP). Both declining fertility rates and the ongoing and fairly steep increase in life expectancy have led to a significant ageing process in Germany. As a result, the configuration of the German population pyramid will change considerably in the coming decades. Figure 25 illustrates the outcomes of the population projection for the years 2006, 2020 and 2050 as examples.[108]

Step 2 — Projecting the pensions of existing retirees: The projection starts by estimating the benefits of the average age-sex-specific existing retirees in the base year. As mentioned above, the projection of these pension benefits is the centrepiece of the calculations, the accrued pension benefits of the future new retirees are developed by changing the benefits of the existing retirees. Please note that *future new retirees* include all individuals who retire after the base year, while *existing retirees* are already in retirement in the base year.

It has to be emphasised that these calculations look only at average individuals within the respective age groups, i.e. they are not separated into different income groups. In fact, the calculation of age-sex-specific benefits is separated into existing and future new retirees, assuming that an average representative of an age group is to some extent an existing and a future new retiree in every year of his or her life-cycle.

The example of a 65 year old average representative may make this easier to understand. At this age this representative individual is to a large extent already retired, as he/she is an existing retiree. Nevertheless, with the concept of the representative individual, the fact is also taken into account that — although the probability is low — the 65 year old average representative may not retire until he/she is aged 66 or older. Hence, the average 65 year old taken as an example in the calculations is also to some extent a future new retiree.

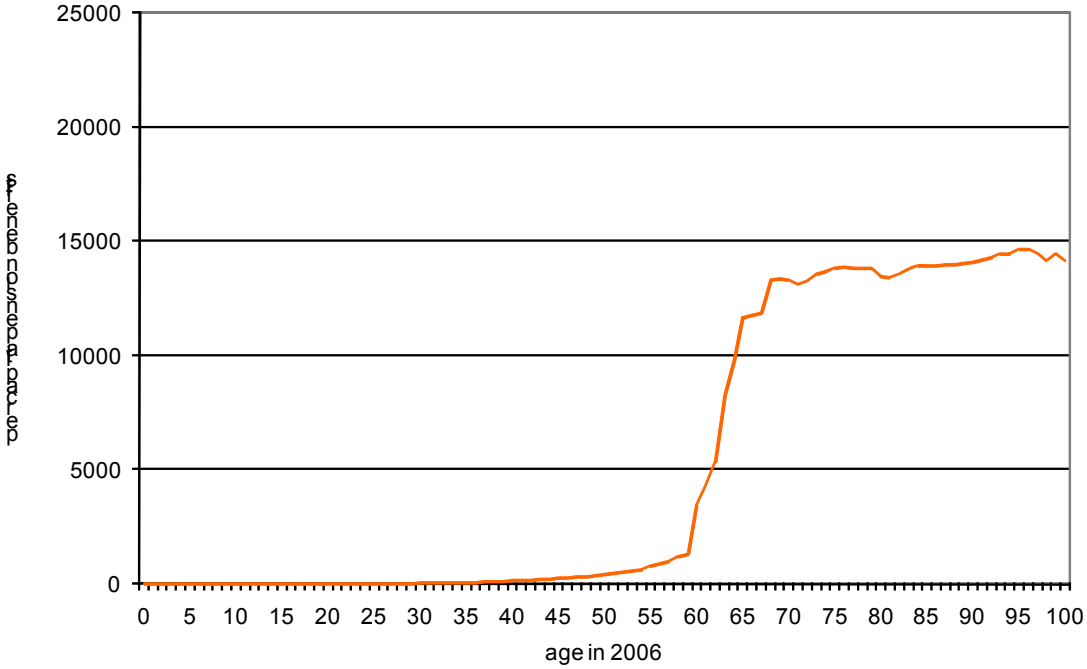
Generating age-specific pension profiles

Before going further into detail, the projection approach for the benefits of existing retirees is outlined here. First of all, the benefits are calculated by distributing the aggregated amount of today's pension expenditure to the different cohorts of retirement age. This procedure creates a cross-section profile of age-sex-specific benefits generated from the budget and micro data of the observed country, in this case Germany.

Figure 26 shows an average rescaled[109] profile of existing retirees' benefits for living male cohorts in the year 2006.[110] This profile reflects heterogeneous retirement behaviour.[111]

[108] In line with the ADL concept future migration is neglected.

[109] The profiles are rescaled in a way that the aggregates based on micro-profiles and population data correspond to the respective government budget aggregates in the base year. This rescaling approach is described in further detail below.



Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Benefits are measured in per capita of the population units. In other words the pension benefits $p_{b,k}$ (in the base year b of the cohort born in k) of a x $(x=b-k)$ year old representative residing in the respective country in a given base year are quantified.[112] Formally (see Equation 35), $p_{b,k}$ is derived by multiplying the average pension benefit of a scheme's retiree $B_{b,k}$ of a certain age x by the number of scheme retirees at this age $M_{b,k}$ and dividing this product by the cohort size of the overall population.

$$(35) \qquad p_{b,k} = \frac{B_{b,k} * M_{b,k}}{C_{b,k}}$$

Figure 26

Rescaled profile of average existing retirees' benefits in 2006 (Social security in Germany, men, EUR)

Source: Forschungszentrum Generationenverträge, University of Freiburg.

Typical of most European pension schemes is the sharp increase in the pension profile around the age of 60. A steep rise of this type can also be observed in the German example (see Figure 26). It mainly reflects an increasing share of pension cases, because

[110] For illustrative reasons we only show here a male profile. For the calculations also a female profile was applied.
[111] For a description of heterogeneous retirement behaviour see Box . Most former surveys apply one constant average retirement age for their calculations instead of an age-sex-specific pension profile. From our point of view, this approach represents a simplification of retirement behaviour and leads to less accurate results.
[112] Since our projection method does not correct aggregates for business cycle effects, base year economic performance is perpetuated indefinitely. This may lead to a bias. Nonetheless this effect seems not as critical in case of considering pension expenditure only since they are for the most part dominated by demography.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

the probabilities of retirement around the age of 60 are relatively high.[113] It should be noted that the profile also reveals other age-specific characteristics, namely the average rate of participation in the respective pension scheme (in per cent of the population) as well as the average pension benefits at a given age ($B_{b,k}$).

The profiles applied include payments in respect of old-age pensions, disability pensions and survivors' pensions.[114]

Rescaling the pension benefits of existing retirees

Formally, the estimation of the existing retirees' benefits is based on the following identity:

$$(36) \qquad P_b = \sum_{k=b-D}^{b} p_{b,k} C_{b,k}$$

This identity states that the sum of age-specific individual pension benefits $p_{b,k}$ (in the base year b of the cohort born in k) weighted by the cohort size $C_{b,k}$ must equal the corresponding overall aggregate pension expenditure, denoted by P_b.[115] The problem of Equation 36 is that it applies only in theory. While macroeconomic data – which are, typically taken from national accounting statistics - are relatively exact, micro data are generally difficult to gather and often inaccurate. To resolve this problem, re-scaled age-sex-specific benefit profiles are estimated in two stages. First, age-sex-specific information regarding per capita pension benefits has to be collected in order to calculate the relative fiscal position of different age groups as accurately as possible. The vector of relative pension benefits by age taken from the statistics, ($\tau_{t,t-D}, \ldots \tau_{t,k}, \ldots, \tau_{t,t}$), is then denoted by $\tau_{t,k}$.[116] This vector is supposed to show only the relative pension position in period t of an individual born in the year k, and thus imposes a lesser restriction on the accuracy and availability of micro data at the absolute level. Second, the estimated relative age distribution is checked against the corresponding aggregate pension benefit P_b by the application of a proportional, non-age-specific benchmarking factor, denoted by φ. The relative distribution of pension payments is re-evaluated according to

$$(37) \qquad p_{b,k}^{rescal} = \varphi \tau_{b,k}$$

for all living generations $b\text{-}D \leq k \leq b$, where φ is defined by

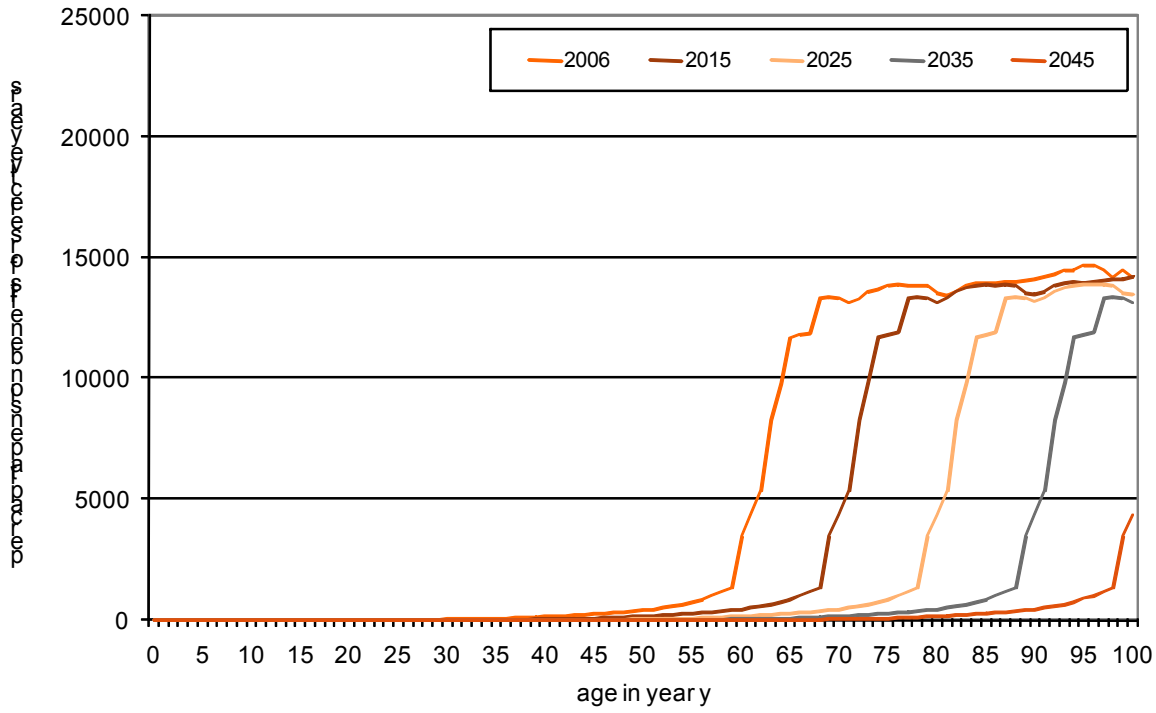
$$(38) \qquad \varphi = \frac{P_b}{\sum_{k=b-D}^{b} \tau_{b,k} C_{b,k}}.$$

[113] At this point it is worth mentioning that we employ age-sex-specific pension data which is broken down into one-year intervals. Most former surveys use five-year interval data which can lead to inaccuracies especially when looking at the cohorts retiring in.
[114] In doing so, we are able to take into account survivor pensions in a rather accurate way, compared to most other surveys dealing with the measurement of pension liabilities.
[115] Please note that D represents the maximum age of an individual which is 100 years by our assumption.
[116] For ease of notation we drop the sex-specific notation as from now on.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Equation 38 ensures that Equation 36 is finally satisfied. On the basis of the rescaling factor φ, it is ensured that the micro pension data match the given macro data.

Projecting the pension benefits of existing retirees



Lastly, the resulting rescaled average age-sex-specific benefits of existing retirees' are projected according to the indexation rules of the respective country:

$$p_{t,k}^{exis} = p_{b,k}^{rescal}(1+g)^{t-b}, \quad (39)$$

for all cohorts $b\text{-}D \leq k \leq b$ living in the base year. This Equation 39 states that an individual already retired in base year b receives the same pension in a specific year t as in the base year b, only corrected by the indexation g of a pension in payment. In the case of the German statutory pension scheme, pensions are adjusted annually to wage growth. For the calculations, a real wage growth rate of 1.5 per cent is applied.

Figure 27

Phasing out the average profile of existing retirees' benefits from 2006 to 2045 (Social security in Germany, men, EUR)

Source: Forschungszentrum Generationenverträge, University of Freiburg.

Equation 39 also involves a 'phasing out' of the stock of existing pension benefits, since it applies only to all living generations. Thus, the pensions of all existing retirees for the base year will have disappeared at the latest when the youngest existing retiree of the base year is dead. To account for this future cohort-specific development of the pension benefits of existing retirees, the rescaled age-sex-specific existing retirees' profile is

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

phased out year-by-year and the pension benefits are indexed according to the benefit formula (see Figure 27). Consequently, the pension benefit of a 65 year old existing retiree in base year 2006, for example, would equal the pension benefit of an 84 year old existing retiree in 2025, disregarding indexation effects.[117] In year 2045 the 65 year old representative in the base year would be 104 years old. However, his benefits in that year would be disregarded, since the calculations do not take account of any payments after the age of 100.

Step 3 — Projecting the pensions of future new retirees: The age-sex-specific pension profile for future new retirees, which is the basis for the estimation of accrued-to-date entitlements, is calculated by manipulating existing retirees' benefits in the base year. This is done in five stages. First, the difference of the existing benefits for consecutive age groups (during the base year) provides the pension benefits for new retirees in the base year.[118] This provides the basis to estimate pension benefits for new retirees in future years. In a third step, pension benefits for new retirees are evaluated for a specific year *t.* Thereafter, if necessary, future new pension benefits are altered by a deduction factor defined, for example, by a pension reform. As a fifth and last step, the cumulated average benefits of future retirees are calculated by totalling year-by-year the benefits of new retirees, which explains why an individual can receive a new retiree benefit on average for any future year *t*.[119] All of these four steps will be described in greater detail below.

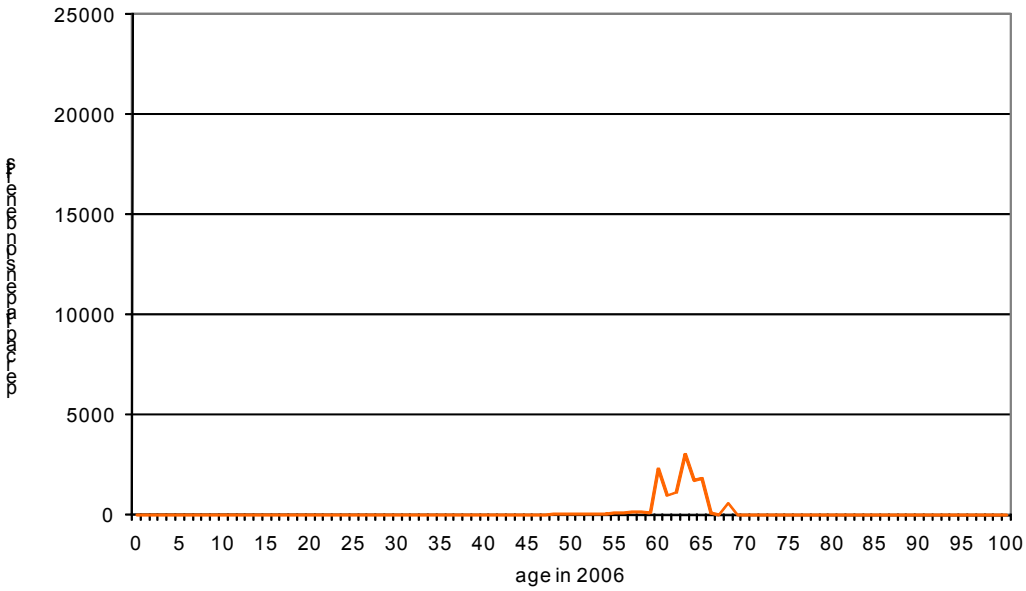
Estimation of pension benefits for new retirees in the base year

First, the pension benefits for new retirees in the base year are estimated. Formally (see Equation 40), the new retirees' benefit $p_{b,k}^{new}$ in the base year *b* for a cohort *k* is generated by calculating the absolute change in existing retirees' benefit $p_{b,k}^{exist}$ of the cohort *k* to the cohort one year younger in the base year, namely *k+1*.[120]

$$p_{b,k}^{new} = \left[p_{b,k}^{exis} - p_{b,k+1}^{exis} \right] \quad (40)$$

This example estimates the average pension benefit of a 60 year-old new retiree in the base year 2006, that is a representative of the cohort born in 1946 (*k=1946*). From the pension data of existing retirees we know that an average male individual of the population

[117] Please note that for illustrative reasons in all figures wage growth rates have been set to zero. Correspondingly, no pension indexation effects can be observed in the figures.
[118] Note that new retirees' benefits represent those benefits that are paid for the first time upon retirement in a specific year *t>b*.
[119] The separation of existing pensions and future new pensions (pensions paid out for the first time after the base year) bears one big advantage: In case of a pension reform which affects only future pensions, only these pensions are changed while existing pensions are held constant.
[120] Changes after the age of 67 years are generally set to zero since new retirees' old-age benefits after the age of 67 are negligible. The only exception from this rule is widow's pensions.



Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

at the age of 59 (i.e. of the cohort *k+1=1947*) received a pension benefit of EUR 1,300[121] in 2006. This figure reflects all pensioners who retired at the age of 59 or earlier. The male cohort that is one year older, i.e. born in 1946 and aged 60, received an average pension of EUR 3,500 per capita. This pensioner aged 60 is assumed to have been to some extent a new pensioner in 2006 and to some extent an existing pensioner — who already retired before the age of 60. So the pension benefit of EUR 1,300 — which reflects pension benefits of pensioners who retired at the age of 59 or earlier — is allocated to existing pensioners. The remaining increase of the average pension from the age of 59 (EUR 1,300) to 60 (EUR 3,500) is accorded to new retirees entering at the age of 60. In line with Equation 40, the benefit received by new retirees at the age of 60 in base year 2006 would amount to EUR 2,200.

Figure 28

Rescaled profile of average new retirees' benefits for 2006

(Social security in Germany, men, EUR)

Source: Forschungszentrum Generationenverträge, University of Freiburg.

The same estimation procedure as for the example of the 60 year old new retiree in the base year is applied to all relevant age groups from the age of 0 to 100.[122] Figure 28

[121] It should be once again underlined that this figure does not represent the average pension benefit of a 59 year old retiree. In fact, it quantifies the amount of pension payments an average male representative of the overall population receives at the age of 59. This representative individual is with a high probability not yet retired — which explains the relatively low average pension benefit of EUR 1,300 per capita.

[122] We consider only differences until the age of 67. After this age, new retirees' benefits are negligible This treatment allows designing maturation effects for future retirees' cohorts and is necessary since the existing retirees' benefit profile after the age of 67 is not a good predictor for future retirees' benefits. This is due to the fact that both average benefits and the share of pension cases vary substantially across existing retirees cohorts reflecting past differences in working careers. Note that this proceeding nonetheless maintains base year economic structures for new retirees indefinitely. In particular, the analysis thus abstracts from changes in labour force participation and unemployment rates for future new retirees' benefits. Please note that this does not count in case the age-sex-specific survivor pensions are available. In this case we consider the difference of the rescaled base year profile until the age of 90 in order to take into account widow's pensions in a more

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

illustrates the resulting profile of average benefits of new (male) retirees for the year 2006. This profile reflects the average pension payment per capita of the population of a male individual at age *x,* who retires in 2006. The shape of this profile is mainly determined by the probability of retiring at age *x*. The kinks at the ages of 60 and 63 indicate that the highest probabilities of retiring can be found at these ages.

Estimation of pension benefits for new retirees in a future year

So far we have estimated the age-specific pension benefits of new retirees in the base year. For future years this profile remains constant, i.e. the base year retirement behaviour continues in the years to come.[123] As a consequence, the pensions of new retirees in future years *t* are estimated in the same way as in the base year (see Equation 41, step 2). Only the notation of the respective cohorts is slightly altered and now linked to the future year *t* and the base year *b*. Accordingly, a new retiree's benefit $p_{t,k}^{new}$ in a specific year *t* of a cohort *k* is developed by calculating the absolute change in the benefit of the existing retirees of the cohort *b-(t-k)* (the cohort with the same age *(t-k)* in the base year *b)* to the cohort one year younger in the base year, namely *b-(t-1-k)*.[124] Equation 41 sums up the calculation of pension benefit for future new retirees in a given future year *t*:

$$(41) \qquad p_{t,k}^{new} = \underbrace{\left[p_{b,b-(t-k)}^{exis} - p_{b,b-(t-1-k)}^{exis} \right]}_{Step\ 2} * \underbrace{(1+v)^{t-b}}_{Step\ 3} * \underbrace{\theta_{t,k}}_{Step\ 4}$$

for all cohorts $b\text{-}D \le k \le b$.

Added value of the pension benefit for a future new retiree

The third step takes into account the fact that past pension rights are re-valued annually according to the benefit formula.[125] As a result, in most pension schemes the pension benefits of new retirees in year t+1 will be higher than in the previous year t. This aspect is reflected by the valorisation rate $(1+v)^{t-b}$ (see Equation 41, step 3). The variable *v* is the valorisation factor calculated according to the benefit formula.[126]

accurate way. After this age, the data usually is non-representative due to small numbers of cases in the age cohorts above 90.

[123] Only in some cases where a future increase of the legal retirement age has been legislated, we alter future retirement behaviour respectively.

[124] Changes after the age of 67 years are generally set to zero since new retirees' old-age benefits after the age of 67 are negligible. The only exception from this rule is widow's pensions.

[125] In some pension schemes past earnings are valorised in other schemes so called pension points during the contribution career are yearly adjusted. In NDC schemes individual accounts are annually valorised. Usually, the valorisation of such past pension rights — whether reflected by reference earnings, NDC accounts or pension points — is linked to wage growth.

[126] Usually, the valorisation rate is linked to the wage growth.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Pension reforms

The majority of European government-managed pension schemes have introduced wide-ranging reforms in recent years which will lower future pension benefits. In a fourth step, the benefits of future new retirees' are therefore reduced accordingly by a deduction factor $\theta_{t,k}$ (see Equation 41, step 4). This factor reflects already implemented pension reforms, such as the raising of the legal retirement age in Germany from 65 to 67.

Estimating the cumulated benefits of future new retirees

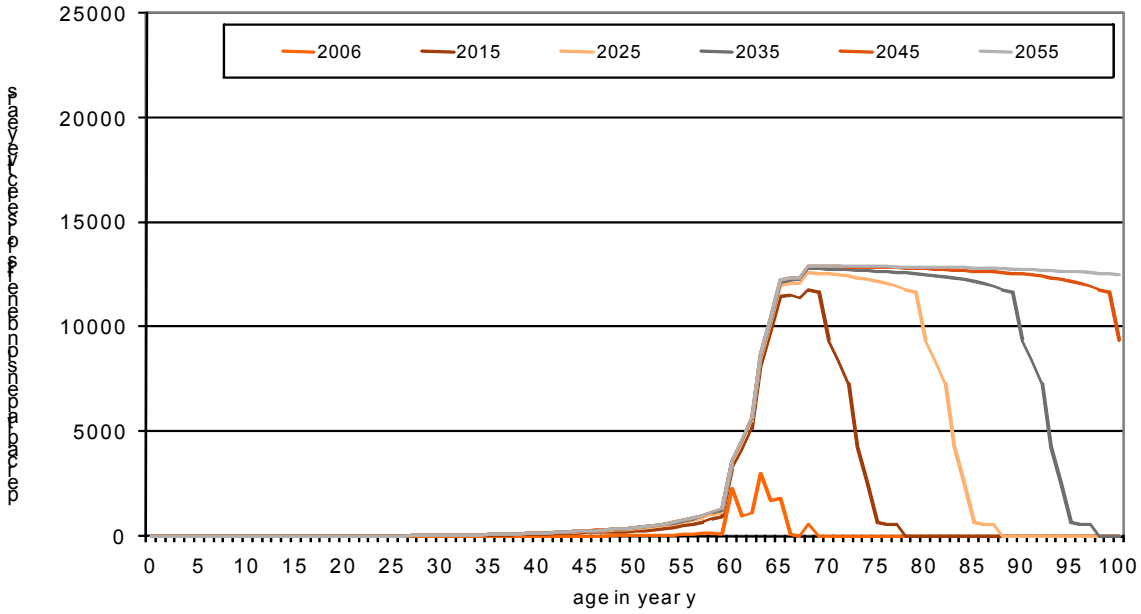
Lastly, the accumulated future benefits of new retirees need to be calculated. This fifth step cumulates year-by-year all future new pension benefits of an *x*-year-old representative (in the base year) during his remaining life cycle. Thus, for example, a 59 year old representative (in the base year) will have a certain probability of retiring at the age of 60, 61 and so on. Formally, this is done by cumulating year-by-year $p_{t,k}^{new}$ according to Equation 42. The accumulated age-sex-specific future pension benefits $p_{t,k}^{fut}$ of a retiree for a specific year *t* of the cohort *k* are defined as follows:

$$p_{t,k}^{fut} = p_{t-1,k}^{fut}(1+g) + p_{t,k}^{new}, \quad (42)$$

From this equation it follows that the average individual born in year *k* receives a future benefit in year *t* (*t*>*b*) which consists of the accumulated pension payment one period earlier (*t-1*) corrected by the pension indexation *g*[127] plus the pensions paid to new retirees in that year. In other words, a future new retiree (i.e. an individual who retired after the base year) in year *t* is to some extent a new retiree in this year *t* — receiving $p_{t,k}^{new}$ – and to some extent an 'old' retiree who has already received a pension benefit in the years before *t-1*. Thus, the age-sex-specific benefit profile for future retirees builds up year-by-year to project the future accumulated benefits of retirees.

Figure 29 shows the development of future retirees' pension benefits for selected years. An example is a 50 year old male future new retiree (in the base year 2006). He is increasingly likely to enter retirement in future years (after the base year). In particular there is a strong probability that he will retire between the ages of 60 and 65, as can be seen by looking at the kinks in the profile for the year 2006. In 2025 — when he is aged 69 — his accumulated future new pension benefits will amount to EUR 12,000. After the age of 69, i.e. after the year 2025, his probability of taking retirement is close to zero. This explains why, in the year 2035 (at the age of 79) or in the year 2045 (at the age of 89), the

[127] The growth rate g reflects the annual indexation of pensions. In Germany pensions are indexed to the wage growth. The impact of the sustainability factor needs also to be taken into account.



Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

amount of the accumulated future new pension benefits of this person is almost unchanged and equal to the level in 2025, which was roughly EUR 12,000.

As Figure 29 shows, after being built up almost completely the right to a full pension (year 2055), in the case of Germany his profile is considerably lower than the profile of existing retirees. This is due to reforms which will considerably lower future pension levels.[128]

Figure 29

Build-up of accumulated future new retirees' pension benefits profile from 2006 to 2055 (Social security in Germany, men, EUR)

Source: Forschungszentrum Generationenverträge, University of Freiburg.

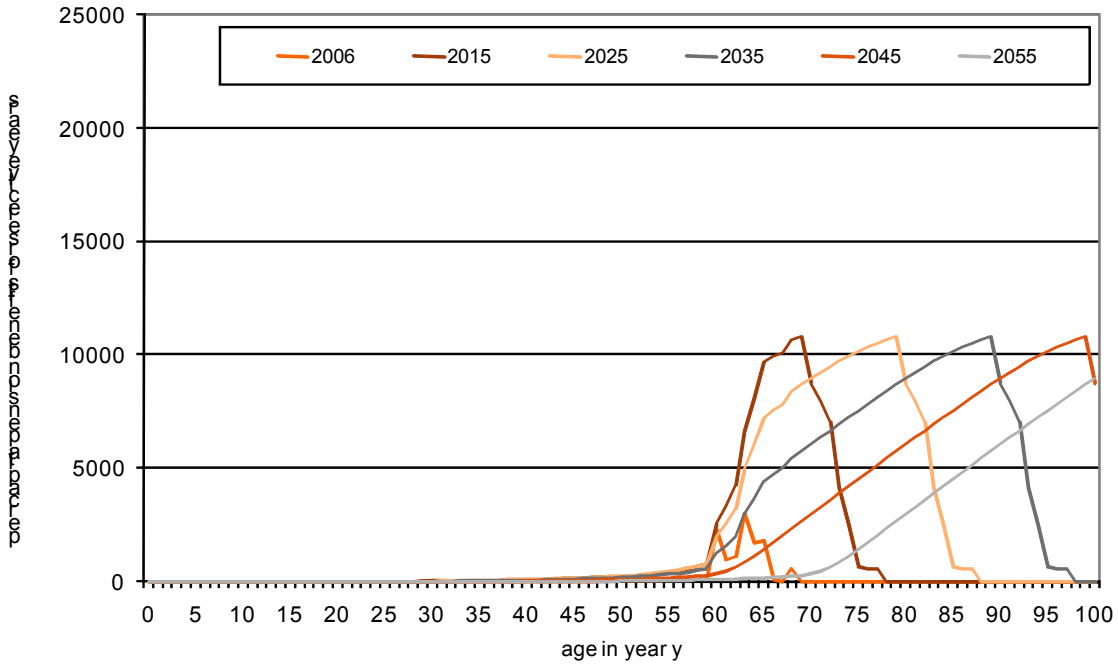
Step 4 — Considering the proportion of full pensions accrued-to-date: Now, in order to meet ADL, only that part of the future pension benefits (of current workers) which is earned until the base year has to be considered. This means in turn that $p_{t,k}^{new}$ must be reduced by a factor $\lambda_{t,k}$ representing the cohort-specific amount of entitlements of current contributors in relation to the full entitlements.[129]

Future pension benefits are thus finally defined by

$$p_{t,k}^{fut} = p_{t-1,k}^{fut}(1+g) + \lambda_{t,k}\, p_{t,k}^{new}, \qquad (43)$$

for all cohorts *b-D* ≤ *k* ≤ *b.*

[128] For an overview of the considered reforms see Müller et al. (2009), p. 51ff.



[129] The calculation of the factor $\lambda_{t,k}$ requires the knowledge of the average age-sex-specific wage distribution. Many other surveys work with one single average wage over the whole career which leads to different results.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

The reduction of future retirees' benefits to account for only the part that is accrued to date is outlined in Figure 30. Given that PBO is applied in this case, the benefits are cut in a linear manner according to the ratio of contribution years until base year to average contribution years until retirement.

Figure 30

Amount of average future retirees' pension benefits accrued to date Profile from 2006 to 2055 (Social security in Germany, men, EUR)

Source: Forschungszentrum Generationenverträge, University of Freiburg.

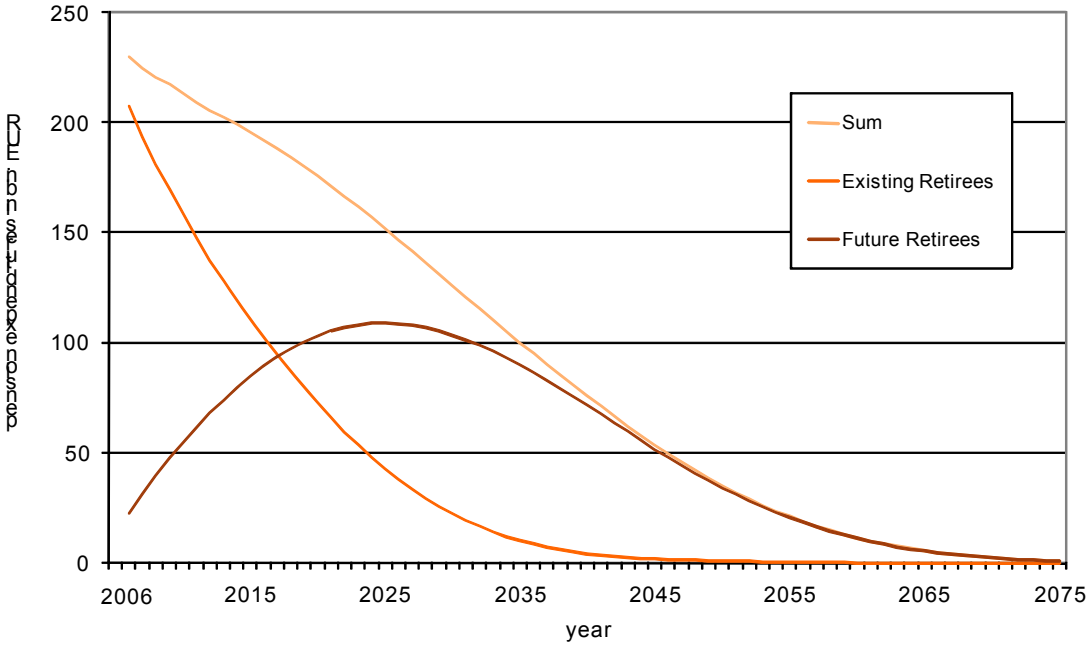
Note that the accrued-to-date concept requires a definition of the valorisation and accruing process for the entitlements. As a matter of principle there are several possibilities that have to be accounted for, including ABO and PBO. These two approaches, which applied in the Freiburg model, are described below.

Step 5 — Aggregating and discounting pension benefits: Finally, the ADL of the pension scheme are calculated by discounting and adding up the above projected pension benefits over the cohorts living in the base year. For the real discount rate, a value of 3 per cent has been applied.

Thus, the ADL_b (accrued-to-date liabilities of the base year b) can be expressed as follows:

$$ADL_b = \sum_{t=b}^{b+D} \sum_{k=b-D}^{b} \frac{(p_{t,k}^{exis} + p_{t,k}^{fut})}{(1+r)^{t-b}} C_{t,k} \quad (44)$$

This means that, in every period t, the pension benefits of the existing retirees ($p_{t,k}^{exis}$) and the pension rights accrued until the base year ($p_{t,k}^{fut}$) — which are both discounted by the factor $(1+r)$ for every future year $(t-b)$ — are multiplied by the number of members of this



Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

age cohort $C_{t,k}$. This is done for each age group, beginning with those born in $k=b-D$, which goes back 100 years prior to the base year.

Figure 31 shows the development of the projected aggregates. The sum of the existing retirees' benefits decreases due to the phasing out of the profiles, i.e. due to the ageing of existing retirees. By contrast, the aggregated benefits of future retirees show an inverse u-shaped pattern, because the future retirees' benefits initially increase as a result of the building up of the profile. However, these benefits are reduced accordingly, since only the accrued-to-date amount is considered.

Implementation of ABO and PBO in the Freiburg model

As described previously in this chapter, pension entitlements are estimated by calculating future pension payments. In layman's terms this is done by projecting present age-sex-specific pension payments into the future, taking into account the indexation of the respective pension scheme plus any pension reforms which have already been decided and which will have an impact on future pensions. In order to receive the ADL of a pension scheme, it is crucial to divide the beneficiaries of future pension payments into two groups: The first group consists of those who are receiving pension payments today. The members of this group enjoy full pension entitlements because they have already retired

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

and are unable to increase their pensions by paying contributions.[130] The pension payments of this group — the 'existing retirees' (or more precisely: persons who are already in retirement in the base year) — are accordingly projected in line with the relevant indexation until the last retiree dies.

The second group consists of persons who do not yet receive pension payments. They have earned some kind of pension entitlements in the past — regardless of whether they took up employment only one year ago or are close to retirement — and they will probably earn more pension entitlements in the future, up to the time when they retire. It follows that this group does not yet enjoy full pension entitlements. The ADL approach includes entitlements earned up to the base year only; therefore the projected future pension payments of a 'future retiree' (or more precisely: a person who will retire after the base year)[131] has to be reduced. This introduces the issue of ABO versus PBO:

New pensioners will enter the pension scheme in every year after the base year. The initial question to be answered is what will be the amount of the first paid benefit in relation to the new pensioners' benefits in the base year. Let the amount of first paid pension — sometimes referred to as the primary insurance amount (PIA) — in the year b be $B(t)$ and the constant per-capita wage growth in real terms be g. When applying the PBO approach, the first paid pension will be defined as follows:

$$B_t = B_t(1+g) \quad (45)$$

Since g is assumed to be constant over time, the first paid pension can also be expressed subject to the base year b.

$$B_{t+1} = B_b(1+g)^{t-b} \quad (46)$$

When changing to the ABO approach, it has to be borne in mind that no allowance is made for future pay increases. In the current case, only general wage growth is observed. It follows that the first paid pension of a future year *t* in the ABO approach changes to:

$$B_t = B_b \quad (47)$$

The difference between Equations 46 and 47 can be explained by the different approaches of ABO and PBO. The latter takes into account general future wage growth,

[130] This counts only for pension schemes which do not allow their beneficiaries to increase their pension after retirement, i.e. by taking up employment, paying contributions and thus augmenting their pension entitlements.
[131] Please note that 'future retirees' involve all individuals that retire after the base year. In contrast to this, 'new retirees' indicate individuals who retire in a certain year x in the future. Those individuals who retire in the year x will in that year enter the group of 'future retirees'. In the year x +1 they will still be 'future retirees' but not 'new retirees' anymore.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

while ABO does not consider any future changes of earnings; the wage level of the base year is kept constant in real terms.[132]

The second difference between ABO and PBO can be observed when reducing the initially calculated full benefits of 'new pensioners' according to the concept of ADL. The full benefits are reduced by a vector — the 'accrued-to-date vector' – which expresses the entitlements earned up to the base year as a share of the amount of entitlements which qualifies for a full pension. This share is given for every projection year. It is straightforward that the share decreases from a value close to one for primary pensions paid out shortly after the base year to a value of close to zero for primary pensions paid out in the distant future. This vector is multiplied by the respective accounts of full pension entitlements and the outcome is the amount of pension entitlements earned up to the base year for every projection year, known as the 'accrued-to-date entitlements'. The difference between ABO and PBO is shown by the different consideration of increases in personal earnings during the person's working life. Generally, the earnings at the beginning of a person's career are less than the average earnings and end up somewhere above average as the person comes closer to retirement. PBO takes this effect into account, ABO does not.

Regarding the accrued-to-date vector in the PBO approach, only the missing amount of contribution years has to be taken into account, given that the full pension primarily calculated by the model includes assumptions for both personal and general wage growth. In summary, the difference between ABO and PBO consists of two parts. The first part is general wage growth, which in most cases is connected to general economic growth. The second part is the development of earnings over the individual's career.[133]

Results of the Freiburg model — the supplementary table of 2007

Table 5 illustrates the results of the actuarial model, the non-core accounts of the supplementary table for Germany in 2007. A distinction is made between social security (column H) and government employee pension schemes (column G). The stocks of pension entitlements in these columns are estimated on the basis of the Freiburg model using the PBO approach.

[132] It is crucial that this only counts for the calculation of the first paid pension or PIA. When projecting a benefit which has already been paid out before, i.e. the indexation of existing benefits, a constant real wage growth is assumed. In this regard the ABO approach displays a schizophrenic world where in one situation future wage growth is considered and in the other it is not. Please note, that there are other interpretations of the ABO approach which do not consider (post-retirement) pension indexations.

[133] For a further description see also section 7.3.

Source: Source: Forschungszentrum Generationenverträge, University of Freiburg, based on data provided by the respective pension schemes.

Starting with the general government employer pension scheme (column G), pension entitlements at the beginning of 2007 total EUR 1129,18 billions (row 1). This figure is calculated on the basis of the Freiburg model. In contrast to social security pension schemes, there are no actual contributions to this scheme, and so zeros are entered in rows 2.1 and 2.3. The imputed social contributions amount to minus EUR 5.41 billions (row 2.2). This row serves as a balancing item. It represents the difference between current benefits and actual contributions payable (by both employers and employees). Supplements to household social contributions account for EUR 56.58 billions. In practice, they are equal to the nominal discount rate (5 per cent in this case) times the pension entitlements at the beginning of the respective base year. The overall increase in pension entitlements due to social contributions (row 2) — reflecting the sum of rows 2.2 and 2.4 — amounts to EUR 51.17 billions. Pension benefits paid out in 2007 reduce the entitlements by EUR 46.52 billions. This figure has been provided by the institutions responsible for government employee pension schemes, namely the general civil servants' scheme and the supplementary pension scheme (VBL).

The change in benefits (row 5) amounted to EUR 4.65 billions in 2007. It is calculated by subtracting row 4 from the total of rows 2 and 3. There were no changes of pension entitlements due to other transactions (row 7) such as legislated pension reforms. Nor has

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

there been a transfer of entitlements between schemes in 2007 (in column G). Furthermore, no changes in entitlements due to revaluation (row 8) or other changes in volume (row 9) need to be considered in 2007. At the end of 2007, pension entitlements (row 10) amount to EUR 1,133.83 billions, which is equal to 46.8 per cent of GDP in 2007. This figure is also estimated using the actuarial model. Unfortunately, no data on financial services —on the cost of running the pension scheme during 2007 — have been provided. Therefore, the letter *L* is entered in the last row 11 — indicating that no data are currently available.

With regard to social security pensions in Germany (column H), the value of the opening stock of pension entitlements was EUR 6,522.94 billions in 2007. Actual contributions paid by households and employers account for EUR 84.89 billions and EUR 78.21 billions respectively. The data needed to complete the rows 2.1 and 2.3 have been provided by the statutory pension insurance scheme as well as the old age insurance for farmers, which is also covered by social security in Germany.

The household contribution supplement comes to EUR 326.17 billions, the residual value (row 3) is minus EUR 75.23 billions. This row reflects the case of actual social contributions that are not actuarially based. In the case of this base year the negative value is due inter alia to the increase in pension contributions from 19.5 to 19.9 per cent in the German statutory pension insurance scheme, without an increase in pension entitlements. Pension benefits in 2007 amount to EUR 234.87 billions, which has led to a difference of EUR 179.17 billions in pension entitlements.

In 2007 Parliament approved a major pension reform of the statutory pension insurance scheme by increasing the legal retirement age gradually from 65 to 67 between 2011 and 2029. Furthermore, a catch-up element was introduced into the pension formula in 2007 which factors in non-implemented deductions from the period 2011 to 2013. According to actuarial estimates this reform lowered the level of pension entitlements by EUR 178.19 billions. — as shown in row 7 (changes in pension entitlements due to other transactions). The final result, is a closing stock of pension entitlements amounting to EUR 6,523.92 billions, which is equivalent to 269.2 per cent of GDP in 2007.

The service fees to run the pension schemes covered under social security are recorded as additional information in row 11. According to the published data, the German statutory insurance scheme service fees amounted to EUR 3.57 billions in 2007.

As the example makes clear, the German data do not enable a differentiation to be made between defined contributions (column A) and defined benefit schemes (column B). Only

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

the total of pension schemes classified in the non-general government sector can be reflected in the supplementary table in column C. Generally, when compiling the supplementary table, countries should make a distinction between defined contribution (column A) and defined benefit schemes (column B).

The total of pension entitlements at the beginning of 2006 (row 1) amounted to EUR 479 billions. This figure is published annually by the Deutsche Bundesbank.[134] It is based on a number of sources. Much of the pension data was provided by the German Federal Financial Supervisory Authority (BAFIN). This public institution is responsible for the supervision of banks and financial services providers. In this context most pension schemes are required to submit frequent reports to this body. However, not all types of pension schemes are covered by the BAFIN in Germany: other institutions such as the German Insurance Association (GDV), which is the umbrella organisation for private insurers in Germany, provide data to complete the data on pension schemes. The data sources consist of both regulatory and accounting data. In cases where the entries did not appropriately reflect the current value of pension entitlements on the market, further conversions have been applied in line with the accounting standards of the ESA. The increase in pension entitlements due to social contributions (row 2) during the year 2006 amounted to EUR 49 billions. This number is made up of employers' actual contributions of EUR 35 billions (row 2.1) plus actual household social contributions (row 2.3) amounting to EUR 14 billions in 2006. These values come from the German Federal Statistical office (Destatis). It should be emphasised that the data used in row 2.1 and row 2.3 are also used in the core accounts.[135] Furthermore, entitlements have been reduced during the year 2006 due to payments of pension benefits (row 4) amounting to EUR 32 billions. This figure was also provided by Destatis and is taken from the core accounts.[136] Altogether, pension entitlements during the year increased due to social contributions and pension benefits (row 5) by EUR 17 billions. The stock of entitlements at the end of 2006 (row 10) amounted to EUR 499 billions. This figure, which is provided by the Deutsche Bundesbank, is based on the same data as the opening balance (row 1).

FOREWORD

The first ECB/Eurostat Workshop on Pensions, which was held in Frankfurt on 29 and 30 April 2009, served to bring together a wide range of experts from national central banks, national statistics institutes, international organisations, and research institutes to reflect on the accounting issues involved in the recording of pension schemes under the System of National Accounts, 2008 (2008 SNA) and also under the European System of Accounts which is currently under revision. At the same time, it provided the opportunity to discuss user's needs and the political messages on this important topic, not least with regard to the sustainability of public finances.

This foreword provides a short overview of the various contributions made by the authors and discussants in the five sessions of the Workshop. Mr. Steven Keuning's welcome speech, given in his capacity as the ECB's Director General Statistics, touched on some key issues of the workshop by referring to the new recording of pension entitlements in the 2008 SNA, in particular in relation to measures of fiscal sustainability.

The issue and discussion papers are presented according to the five sessions of the Workshop: Session I was dedicated to discussing the concept of accrued-to-date pension entitlements from a national accounts perspective. Session II dealt with the experience of pension modellers and accounting standard setters as to how to compile and record pension entitlements. Session III was organised as a panel to illustrate the user's perspective.

Session IV and Session V focused on national experience in compiling accrued-to-date pension entitlements under government schemes. Seven country cases were presented and discussed: the country cases for Spain, Luxembourg, Finland, Canada, the United States, Poland and Germany. In a closing address, Mr. Werner Bier, the ECB's Deputy Director Statistics, Mr. Eduardo Barredo-Capelot, Head of Unit C5 at Eurostat, and Mr. Reimund Mink, a, Senior Adviser at the ECB, concluded the Workshop by focussing on how to communicate the results presented at this Workshop to the public at large.

The content of the e-book is structured by session. Each session contains an introduction with a short overview of the various papers, followed by the issue papers and the discussion papers themselves. The e-book has been compiled and edited by Ms. Marta Rodriguez and Mr. Reimund Mink, both of whom work at the ECB in the Directorate General Statistics.

INTRODUCTION

BY STEVEN KEUNING,
DIRECTOR GENERAL STATISTICS, EUROPEAN CENTRAL BANK

Ladies and gentlemen,

INTRODUCTION

On behalf of Mr Walter Radermacher, Director General of Eurostat, and myself I would like to welcome you to the ECB/Eurostat Workshop on Pensions. I would like to thank all of you who are participating in this Workshop and as well everyone who is involved in organising it. Let me start by saying that I am particularly happy that many of you who have contributed to the successful completion of the System of National Accounts, 2008 (2008 SNA), and specifically of the accounting treatment of pensions that it incorporates, are also present today.

Recently, the UN Statistical Commission has adopted the 2008 SNA as the international statistical standard for national accounts and has encouraged countries to implement it. In the area of balance of payments, the sixth edition of the IMF's Balance of Payments and International Investment Position Manual (BPM6) will be published soon. These two handbooks are seen as constituting the new global international statistical standards. The European System of Accounts (ESA 95) as a counterpart to the SNA is also under revision. For EU countries, its importance goes far beyond that of the SNA, as it is a legal instrument with a very significant impact on key policy decisions in the European Union. Among other effects, it has a direct bearing on the so-called excessive deficit procedure, the contribution to the EU budget, the allocation of regional funds by the European Union and the contributions of Member States to the capital of the ECB.

Considerable attention has obviously been given to the revision of the government accounts and specifically to the impact of the revision on the recording of government deficit and debt. Thus, the new recording of pension entitlements and its impact on these variables is one of the topics of this discussion.

NEW RECORDING OF PENSION ENTITLEMENTS IN THE 2008 SNA

In the discussions from 2004 on how to record pension entitlements in the new SNA the question arose as to whether all or only part of them should be covered within the asset and liability boundary. This question is closely linked to the issue of the extent to which the recording of pension entitlements in the national accounts should be harmonised when the underlying institutional reality differs significantly across countries. For the time being, the institutional differences across countries related to pension schemes (capitalised versus pay-as-you-go) generate significant differences in the accounts, not least because they lead to different economic behaviour. In particular, pension assets (in other words, future pension rights)

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

in countries with mainly capitalised systems are recorded as household wealth, while future pension rights in countries with government-sponsored pay-as-you-go schemes (like France, Germany, Italy or Spain) are not recorded. Of course, the entitlements in the former case are contractually determined.

In essence, there is now consensus in the 2008 SNA on distinguishing pension schemes sponsored by general government, which should be recorded in the core national accounts, from those schemes that should be recorded only in a new supplementary table on pensions (like social security schemes). The updated SNA includes such a table showing the flows and stocks of all pension schemes. For the benefit of users of the accounts, all countries will be expected to produce the new table, and it was suggested that this table would be compulsory for all EU countries under the new ESA regulation.

In 2007, work of the Eurostat/ECB Task Force on Pensions, mandated by the Committee on Monetary, Financial and Balance of Payments statistics (CMFB), concentrated on the design of the supplementary table. The overall aim of the table is to present the opening and closing stocks of pension entitlements for all social insurance pension schemes (including social security), and the transactions and other economic flows during the period that account for the difference between the opening and the closing positions, thus systematically showing pension obligations for all these schemes, and thereby facilitating international comparability. It was clearly indicated in the January 2008 CMFB Report of the Eurostat/ECB Task Force on Pensions, which was presented to the Economic and Financial Committee (EFC), that the pension entitlements derived for government-sponsored pay-as-you-go schemes are not measures of fiscal sustainability which require elaborate modelling simulations. Instead they display the cost of terminating such a pension scheme at the reference date of the accounts.

LONG-TERM SUSTAINABILITY OF PUBLIC FINANCES

In Europe, the Stability and Growth Pact, which was adopted in 1997, strengthened the Treaty provisions on fiscal discipline in the European Union. Government sector accounts as part of the system of national accounts play a key policy role in this field. The new Code of Conduct of the Pact has also incorporated guidelines on the countries' strategies to ensure the sustainability of public finances, especially in view of the economic and budgetary impact of ageing populations.

Timing nicely with the Workshop is the recent release by the European Commission (DG ECFIN) and the Economic Policy Committee's (EPC's) Ageing Working Group (AWG) of the "2009 Ageing Report: Economic and budgetary projections for the EU-27 Member States (2008-2060)". This report is based on the need for the Council to "regularly review the long-term sustainability of public finances, including the expected strains caused by the demographic changes ahead". In 2006, the ECOFIN Council gave a mandate to the EPC to update and further deepen its common exercise of age-related expenditure projections by autumn 2009, on the basis of a new population projection by Eurostat, which was released in April 2008.

ACCRUED-TO-DATE LIABILITIES AND FISCAL SUSTAINABILITY

An advantage of this Workshop is that it brings together national accounts experts who have contributed to developing the concept of accrued-to-date liabilities for measuring government-sponsored pay-as-you-go pension schemes and analysts dealing with fiscal sustainability indicators. Two straightforward questions that need to be answered are whether the data derived for the supplementary table on pensions will be appropriate to serve as an input for the AWG pension projections and what the link is and what the differences are between the approaches of accrued-to-date liabilities and implicit liabilities, in terms of fiscal sustainability indicators?

The data on pension entitlements following the accrued-to-date liabilities approach are compiled ex-post; they are not projections. However, the closed system implicitly used for this approach may be expanded in a consistent way, to derive liabilities for open systems on a gross or even on a net basis, by compiling net open system liabilities following a generational accounting approach.

According to the 2009 Ageing Report, sustainability conditions are defined by comparing current government debt figures with the discounted values of all future primary balances. Sustainability gaps emerge because these discounted values are usually too small to offset current debt. According to the report, age-related government expenditure, as a percentage of GDP, will increase for the European Union as a whole, from 2007 to 2060, by 4.7%, and half of this increase results from the increase in pension expenditure.

The economic and budgetary projections made by the AWG are based on such sustainability indicators. In addition to Eurostat's population projections, the main data source for the report is government finance statistics following ESA 95 principles. In recent years, Eurostat, with the assistance of the CMFB, has taken a number of decisions that have clarified the national accounts for the government sector in Member States and have made them more comparable. There have also been international initiatives to align government accounting practices and international statistical standards. The outcome of this work has been a new chapter on general government and public sector accounts in the 2008 SNA. A similar chapter is under preparation for the new ESA.

FUTURE CHALLENGES

An ageing population raises challenges from an economic point of view. Their seriousness depends on how economies respond and adapt to these changing demographic conditions. Policy-makers need to ensure long-term fiscal sustainability in the face of clearly anticipated risks, as well significant uncertainty. In this context future pension expenditure has to be taken into

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

consideration especially as Europe is in the midst of the deepest recession in decades, which is putting unprecedented stress on economies while also having a major impact on the sustainability of public finances.

I hope that we will continue to enjoy the support that we have received in the past from so many of you. I wish you a stimulating and enjoyable workshop today and tomorrow.

SESSION I

PENSION SCHEMES IN INTERNATIONAL STATISTICAL STANDARDS

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

INTRODUCTION

Session I of the Workshop on pensions deals with the subject of pension schemes in international statistical standards. These standards are the System of National Accounts, 2008 (2008 SNA), the new revision of the European System of Accounts currently under preparation (new ESA). Both, the 2008 SNA and the new ESA deal with pensions and their accounting treatment in separate chapters.

To shed further light on the current work in this area there are three presentations on this topic. John Verrinder's (Eurostat) presentation is on pension schemes in the new ESA and in the 2008 SNA. John starts with a short description of the current recording of pension schemes in the 2003 SNA and in the ESA 95, highlight the incomplete coverage of pension entitlements – specifically those under government schemes. He goes on to describe the long and complicated process of how the new recording of pensions was developed from 2002. It started with an Electronic Discussion Group led by the IMF, continued with the lively discussions at the Advisory Expert Group (AEG) from 2004 to 2007 and was successfully concluded by a compromise solution adopted by the United Nations Statistics Committee (UNSC) in 2008. The major achievement of this work was the design of a supplementary table on pensions in social insurance. Various modelling issues are considered like the valuation of wage increases, the choice of the discount rate, and the treatment of transfers of pension schemes and of pension reforms. Finally, some information is given on the current revision of the ESA 95 in relation to pensions.

Robert Dippelsman (IMF) concentrates in his presentation on the recording of defined benefit pension schemes in macroeconomic statistics. These schemes are defined in such a way that the benefits payable to the employee on retirement are determined by the use of a formula. They are set in contrast to defined contribution pension schemes. Rob clearly indicates that defined benefit pension schemes may be funded or unfunded. Moreover, actuarial methods are required to derive measures of pension obligations based on the pension formula. In a further step, the difference is shown in the treatment of unfunded government employer retirement schemes in the 1993 SNA compared with the Government Finance Statistics Manual (GFSM 2001), in which such obligations are treated as contractual liabilities for a government to its employees. This is in line with the accounting standards applied for the private sector (IAS 19). Finally, the proposed future treatment of pension schemes is described as part of a big picture, namely to recognise defined benefit pension entitlements as financial assets and liabilities, taking into account the higher range of uncertainty than for most other financial instruments due to the application of actuarial methods and the difficulty that social security and government employee benefit elements are often combined.

John Walton deals with the guaranteeing and insuring of defined benefit pension entitlements. He distinguishes between three levels of security for pension entitlements under autonomous and non-autonomous pension schemes as they exist in various countries. He further explores whether funding of the guarantor

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

exists and whether it is independent of government. Accordingly, different levels of cover are distinguished for the different schemes. In this context he thinks that this distinction might not be shown in the supplementary table as there is to be no option to show different degrees of quality of an asset due to guarantees. In a further step, he considers options for how to treat these guarantees – as contingencies or as financial instruments, taking into account the recommendations on the treatment of guarantees in the 2008 SNA.

Gabriele Semeraro (Banca d'Italia) as the discussant of this session provides an overview of the three contributions looking, at the common elements and also some specific issues. All the papers are seen to shed some light on more general properties of pension schemes. While the paper of John Walton focuses on aspects of guarantees (explicitly or implicitly) given to the beneficiary of the entitlements, the presentations of John Verrinder and Robert Dippelsman deal with the new statistics in general as they are presented in the new international statistical standards.

PENSION SCHEMES IN THE INTERNATIONAL STATISTICAL STANDARDS

BY JOHN VERRINDER

1 INTRODUCTION

This article explains the background and main results of the Eurostat/ECB Task Force on pensions.

The System of National Accounts 1993 (SNA93) and its European Equivalent (ESA95) record pension schemes in "social insurance" according to their features:

– *Private funded social insurance schemes* – insurance technical reserves (liabilities/assets), actuarial treatment;

– *Unfunded social insurance schemes operated by employers* – no reserves, actuarial treatment in principle but not in practice;

– *Social Security* – no reserves, no actuarial treatment.

Thus there is a potentially inconsistent treatment of pensions across sectors/ countries depending on administrative set-up. In the lead up to the revision of the SNA93 this was identified as an area of concern and there was an IMF-led Electronic Discussion Group in the period 2002-2004, which culminated in discussions at the SNA Advisory Expert Group (AEG) in the period 2004-2007. The AEG concluded that:

– In principle pension obligations (assets/liabilities) should be recorded on an actuarial basis for all employer schemes (whether funded or unfunded),

– but recording of social security remains unchanged.

2 THE SUPPLEMENTARY TABLE ON PENSION SCHEMES IN SOCIAL INSURANCE

It quickly became apparent that the first of these conclusions raised some important issues in Europe, notably in the difficulty to distinguish unfunded government employer schemes from social security. The following discussions led to a worldwide compromise, which would allow for some flexibility in recording unfunded government employer schemes under clearly defined conditions.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Following these discussions, the SNA 2008 Chapter 17 (part 2 deals specifically with pensions) was adopted by UN Statistical Commission in August 2008, subject to some specific follow-up issues, notably the concept of a sponsor, the criteria for core/non-core accounts treatment pension obligations, and the recording of actuarial gains/losses.

Within Europe, work on pensions started in a Eurostat Task Force on pensions, which explored the difficulties of distinguishing government employer and social security pension schemes. Given the importance of the issue, a Task Force of the Committee on Monetary, Financial and Balance of Payments Statistics (CMFB) was established. This was jointly chaired by ECB/Eurostat, consisted of members from many EU countries plus the OECD and the IMF, and delivered its final report to the CMFB in February 2008 (available on the CMFB website: www.cmfb.org).

A key element of the worldwide compromise was the compulsory production of a *Supplementary Table for pensions*. This is designed to make pensions data more visible and to aid international comparison. It reconciles opening and closing stocks of pension entitlements through rows show transactions and other economic flows, notably:

– Contributions received which lead to entitlements;

– Benefits paid;

– "Changes in pension entitlements" (the net of the above entries);

– Other changes in entitlements (reforms, modelling, etc).

The columns of the table show the types of pension schemes, with "non-core" schemes clearly distinguished in separate columns.

It became clear in designing the table that economic flows would have to be clearly identified – they would have a knock-on effects throughout the national accounts. In general the approach taken was to define what is in the "other economic flows", and many transactions lines, with the "residual" left as imputed employer social contributions (i.e. the remaining part to be met by the employer). Other economic flows obviously include modelling effects which are split between revaluations (discount rate) and other changes in volume (other assumptions).

The measurement of pension entitlements relies heavily on the availability of source data; in general statisticians are not resourced or professionally equipped to model pension schemes. However statisticians need to understand the sources (whether actuarial reports, business accounts, sustainability models…) in order to make appropriate estimations.

For *defined contribution schemes*, the pensions entitlements are inextricably linked to the assets of the scheme (assets = entitlements), which means that the main issue is to obtain estimates of asset values.

For *defined benefit schemes*, given that the eventual pensions are based on a formula, they can only be estimated based on a model applying the formula with given assumptions. SNA 2008 does not seek to impose practical measurement requirements, though it does mention some key assumptions.

Of all the assumptions discussed at the Eurostat/ECB Task Force, *the one which generated the most discussion was the treatment of future wage rises*. Eventual benefits in a defined benefit scheme depend on final or average salary, and the usual career path of an employee involves periodic wage rises due to promotion. There are two ways in which future wage rises could be taken into account:

– Include them as they occur (Accrued Benefit Obligation, or ABO)

– Project them in model (Projected Benefit Obligation, or PBO)

The SNA 2008 describes the issue in detail but does not recommend one or the other approach, leaving the decision to the modeller, who would need to consult carefully the applicable rules for each specific pension scheme.

A few other important points were raised in the drafting of the SNA 2008 chapter:

- The output of pension schemes should be measured for all schemes!

- The notion was established of the "Sponsor" of a pension scheme–a unit which determines the conditions of a defined benefit scheme and possibly has a legal burden to meet shortfalls in pension scheme. Assets and liabilities are to be recorded in the national accounts system to reflect the relationship between the sponsor and the unit administering the scheme.

- Transfers between pension schemes should be recorded as financial transactions, with a pension liability being recorded for government if government assumes responsibility for future payments of a non-government scheme.

- The reform of a pension scheme could be transaction or other economic flow depending on whether or not the reform is negotiated between employer and employees.

- The treatment of "actuarial gains/losses" (if model assumptions do not turn out to be correct) is still a source of debate, since they could be viewed either as transactions or as other economic flows.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Eurostat is developing the revised European System of Accounts (ESA); a draft chapter on pensions has already been made available. The key principles of the revised ESA are fully in line with SNA 2008. However the ESA will contain:

- Stricter criteria on the core/non-core recording of pension entitlements to ensure consistency across EU – in practice this means that entitlements of unfunded government sponsored employment related pension schemes will only be recorded in the Supplementary Table;

- More guidance on key modelling issues, such as:

  – ABO versus PBO;

  – Discount Rate.

There is the intention to draw up a compilers' guide, which will contain further information on practical issues and assumptions.

The Supplementary Table will be a compulsory part of the revised ESA transmission programme, and more emphasis is placed on the Table in the ESA chapter.

3 TIMETABLE FOR THE REVISED ESA

The timetable for the revised ESA envisages:

- Until November 2009: Drafting of chapters and comments of MSs.

- December 2009 – June 2010: Finalisation of the new ESA regulation and adoption of the Commission proposal.

- 2012: Adoption of the ESA regulation by the Council and the European Parliament.

- 2014: Implementation of new ESA and transmission programme (but it is important to note that back-series will be needed, including for pensions).

RECORDING OF DEFINED BENEFIT PENSION SCHEMES IN MACROECONOMIC STATISTICS

BY ROBERT DIPPELSMAN

1 INTRODUCTION

Obligations under defined benefit pension schemes can involve a major future burden for both public and private employers, and a corresponding asset for the beneficiaries. Similarly, the emergence of those pension benefit obligations imply current cost incurred by the employer and income earned by the employee. However, under previous statistical standards, these liabilities (and the corresponding assets) were only recognized to the extent that they were funded. The previous treatment was paradoxical, in that these obligations are most likely to cause problems when no fund had been set up to provide for them.

For economic analysis, it is important to understand these asset and liabilities, because they affect financial position and have liquidity implications for the future. In line with general accrual accounting principles, it is also important costs incurred during the period are measured, including accrual of the rights to pensions to be paid in the future. For the employer, failure to take these expenses and liabilities into account may lead to misunderstanding of actual costs and poor decisions, such as a bias in favor of incurring unrecognized expenses and failure to make proper provision for future cash flow commitments.

This paper provides an overview of the treatment of defined benefits pension schemes in accounting and statistical standards. Because the statistical treatment analyzes the operation of these schemes by breaking them down into several different underlying economic processes, it requires a range of imputations, partitions, and rerouting. Furthermore, defined benefit pension schemes raise additional issues of measurement because the estimation of future benefits is subject to a range of uncertainty.

2 DEFINITIONS

A defined benefits pension scheme is defined in the *2008 SNA* as "… one where the benefits payable to the employee on retirement are determined by the use of a formula, either alone or a minimum amount payable" (paragraph 17.129). The factors taken into account in the formula can include factors such as years of service, final salary or salary over a period, family situation, age at retirement, and options taken by the employee as well as changes in the cost of living.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Defined benefits schemes are contrasted with defined contribution pension schemes, in which the benefits are determined by contributions and the return on funds invested. The two types of scheme have very different ways of bearing of the risk of changes in market performance. With a defined contribution scheme, the variability of market returns is the risk or benefit of the employees, while for a defined benefit scheme, the return is determined by the formula, so is not affected by market conditions (as long as the sponsor of the scheme remains solvent).

The term "pension scheme" can be contrasted with "pension fund." A pension scheme is a set of rules and arrangements for paying pensions, while a pension fund is a designated pool of assets that is used to pay benefits. Defined contribution schemes always have a fund and the issue of underfunding does not arise. Defined benefit schemes sometimes but not always, have a fund. If there is no fund, the employer meets the costs from its own resources, so it is a pay-as-you-go arrangement. If there is a funded defined benefit scheme, it may be fully funded, underfunded, or overfunded. With an underfunded scheme, the funds are inadequate to meet the estimated present value of entitlements that have arisen from labor that has already been provided. In the case of an overfunded scheme, the funds are more than the present value of pension entitlements, as can arise if the fund's returns have exceeded expectations or if there have downward revisions in the estimates of variables such as life expectancy or salary growth. Underfunded and unfunded schemes usually give rise to the greatest economic policy concerns as they generate require additional funding in the future.

The formula used in a defined benefit scheme usually includes at least some items that are not known at the individual level at the time they are accrued. For example, while doing work in the period adds to the length of service by a known amount, the exact benefit may be affected by factors such as departure before vesting, age at retirement, length of life of the employees and their dependents, future general salary increases, and the employee's future promotion path. While individually, these factors can be highly uncertain, the values can be actuarially estimated for a whole group of employees with greater accuracy, based on past behavior and possibly adjusted for trends. Despite the ability to make actuarial estimates, there is still a degree of uncertainty greater than other financial liabilities such as a loan or a bond. Measurement is also much easier for defined contribution schemes, because it is determined on the basis of the assets of the fund.

3 TREATMENT IN THE ACCOUNTING STANDARDS

A. PRIVATE SECTOR

For private sector defined benefit plans, International Accounting Standard (IAS) 19 requires that actuarial techniques be used to estimate the amount of benefits. It requires discounting the future benefits to present value, valuing any assets of the pension scheme at fair value, and recognizing changes in the present value of future benefits resulting from changes in the actuarial assumptions and estimates. Businesses that follow these standards will be able to understand the recognition of pension entitlements and will be able to supply

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

the necessary statistical data. However, the degree of standardization of detailed techniques in practice is possibly an issue, for example on the choice of discount rates, and whether the estimates take into account existing compensation levels (accumulated benefit obligation) or estimated compensation levels that existing employees will have in the future (projected benefit obligation).

The United States General Accepted Accounting Principles (Statement No. 87 and 132) also recognize pension entitlements in expenses and liabilities. However, general accrual principles are qualified by delayed recognition, so that changes in the pension entitlements and changes in the value of assets set aside to meet those entitlements are not recognized as they occur but are recognized systematically and gradually over subsequent periods, although additional disclosure is specified for notes to the balance sheet. As suggested in the text of the statements, it was recognized that the standards involved some compromises from first principles.

B. PUBLIC SECTOR

For the public sector, International Public Sector Accounting Standard (IPSAS) 25 sets out standards which also require recognition of accrued pension entitlements as an expense and liability. (See http://www.ipsas.org/PDF_ipsas_standards_ifac/IPSAS25.pdf). In IN7 the Standard requires an entity to:

(a) Account not only for its legal obligation, but also for any constructive obligation that arises from the entity's practices;

(b) Determine the present value of defined benefit obligations and the fair value of any plan assets...;

(c) Use the Projected Unit Credit Method to measure its obligations and costs;

(d) Attribute benefit to periods of service under the plan's benefit formula, unless an employee's service in later years will lead to a materially higher level of benefit than in earlier years;

(e) Use unbiased and mutually compatible actuarial assumptions about demographic variables (such as employee turnover and mortality) and financial variables (such as future increases in salaries, changes in medical costs and relevant changes in state benefits). Financial assumptions should be based on market expectations, at the reporting date, for the period over which the obligations are to be settled…

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

4 TREATMENT IN THE STATISTICAL STANDARDS

A. SYSTEM OF NATIONAL ACCOUNTS 1993 (1993 SNA) AND EUROPEAN SYSTEM OF ACCOUNTS 1995 (ESA 95)

In the previous standards, funded entitlements were recognized as an instrument:

> Net equity of households on life insurance reserves and on pension funds (AF.61) Reserves held against life insurance and annuity policies by insurance enterprises, whether mutual or incorporated, and by pension funds. These reserves are considered to be assets of the policyholders and not of the institutional units that manage them (*1993 SNA* Chapter 13 Annex).

Since net equity of households in pension funds was limited to reserves held, the obligations of unfunded schemes were not recognized, as was the underfunded amount in the case of underfunded schemes.

The *1993 SNA* gives indications that it realized that this was not an entirely satisfactory treatment. In paragraph 13.88, it was recommended that a memorandum item of the present value of the promises to pay future benefits be shown in the balance sheets of households and employers.[1] For the corresponding income and expense, there is recognition that benefits should be taken into account in principle. The contributions could in principle "be based on the same kind of actuarial considerations that determine the level of premiums charged by insurance enterprises" (paragraph 8.72). However there is also discussion of the practical difficulties in measurement for unfunded schemes. Recognizing the difficulties, it is concluded in paragraph 8.73 that "the benefits actually paid in the current period may nevertheless provide the best available estimates of the contributions and the associated remuneration."

The *1993 SNA* shows an awareness of the issue of unfunded obligations, but fell short of recognizing them in the same way as other liabilities.

B. GOVERNMENT FINANCE STATISTICS MANUAL 2001 (GFSM 2001)

GFSM 2001 generally follows the *1993 SNA* closely in terms of content, although with some presentational changes to meet some particular analytical needs. However, in paragraph 4.35 it is very explicit in stating:

> Contrary to the *1993 SNA*, transactions in unfunded government employer retirement schemes are considered in this manual to involve a contractual liability for a government to its employees.

1 While *ESA 95 is* generally consistent with the *1993 SNA*, the memorandum item is not mentioned.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

This divergence between the *1993 SNA* and *2001 GFSM* reflected the growing concern of policymakers and government finance experts that unfunded obligations of governments were a major and growing issue for some countries. In some cases, the unrecognized obligations were of comparable magnitude to the conventional liabilities in the form of bonds and notes. Off-balance sheet liabilities are a matter of particular concern for analysts.

As a consequence, the pension liability is included in the balance sheet of government and payment of benefits to retirees and their families are regarded as withdrawals from the value of the assets of households, rather than transfers.

C. SYSTEM OF NATIONAL ACCOUNTS 2008 (2008 SNA)

By the time of the update of the *SNA*, the concerns that had been recognized in the text in the 1993 edition were becoming a matter for wider concern. The inconsistency between the treatment of funded schemes and unfunded ones was recognized as being a serious anomaly. The concerns about the extent of off-balance sheet liabilities of government employer schemes that had been recognized in *GFSM 2001* were also relevant to analysis of governments in the *SNA* context. As well, some private employers, such as the US car manufacturers, had suffered weakened balance sheets because of underfunded pensions. Over the same period, there had been increasing recognition of pension entitlements in the accounting community, so that the actual or potential availability of actuarial estimates was much improved since 1993.

As a result of these concerns, the statistical community agreed to move the *2008 SNA* in the direction already taken in the accounting profession and *GFSM 2001*. Nevertheless, it was recognized that the practical implementation would still have some difficulties, especially due to variation in methods of valuation and because many governments had not adopted the international accounting standards for pension schemes. There are also difficulties when government employee pension schemes operate in conjunction with social security. An irony associated with the improved treatment of defined benefit schemes is that such schemes are becoming less common, particularly in the private sector, and many existing schemes have been closed to new staff.

A new instrument "pension entitlements" (AF63) was created to recognize pension obligations, regardless of whether and how the schemes was funded:

> Pension entitlements show the extent of financial claims both existing and future pensioners hold against either their employer or a fund designated by the employer to pay pensions earned as part of a compensation agreement between the employer and employee. The only transaction for pension entitlements recorded in the financial account is the difference between net contributions receivable and benefits payable (paragraph 11.107).

As a consequence of the recognition of the entitlements as being an asset of households, it is necessary to show them as being built up by contributions over the period of employment. For actual contributions by employees it is

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

straightforward. For actual contributions by employers, the contributions are rerouted (from employers through households to the entity that is responsible for the pension scheme's liabilities). The rerouting is necessary to include the contribution in household income and correctly show which party acquires the asset. For unfunded or underfunded amounts, an employer contribution is imputed, and then rerouted through households.

As part of the change from the 1993 to the 2008 treatment, the terminology was amended from "reserves" in the *1993 SNA*, where only funded obligations were recognized, to "entitlements" which also covers entitlements where there are no reserves. "Entitlements" tends to highlight the beneficiaries' viewpoint, while "obligations" tends to emphasize the employer's viewpoint, but national accounting needs to use the same term for both parties. Another implication of the changed treatment is that the income accruing on the pension entitlements in the case of defined benefit schemes is not based on the returns on invested funds, if any, but the increase in entitlements due to the unwinding of the discount factor.

In the *2008 SNA*, there is also a recognition of the possibility of nonpension liabilities, such as for health insurance and other allowances. In countries where employers provide health insurance cover for their retirees at concessional rates, these may be an important issue.

A new instrument "claims of pension funds on pension managers" (AF64) is identified to cover the situation when the scheme is a separate entity from the employer or other sponsor of the scheme. When the sponsor has responsibility for any underfunding, the claim of the pension fund is shown under this heading. Alternatively, if the scheme is overfunded, and the surplus is repayable to the sponsor, the asset is negative.

In addition to changes in the value of pension entitlements arising from employment during the year, the value may also alter due to changes in the plan benefit conditions and actuarial assumptions, which are recorded as other change in volumes. Changes due to price indexation are treated as revaluations, as are promotions (although mainly arising with the accrued benefit obligation method).

The value of pension entitlements are subject to a range of uncertainty. However, this is not a unique situation in accounting or statistics. For example, actuarial estimates are already used in national accounts data for the closely related activities of insurance and annuities. However, statistical compilers cannot be expected to undertake actuarial estimation themselves, so there is a constraint of data available from compilers; or possibly, data as supplied could be adjusted by adjustments to cover gaps or differences in treatment. Countries vary in the extent to which accounting practice recognizes pension entitlements. Although not able to duplicate the work of actuaries, it is important that statistical compilers have some understanding of the methods used so as to identify problems of comparability. As common in statistics, there may be a margin of uncertainty, but omitting the pension entitlements is the equivalent of making an estimate

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

of zero, which is not an uncertain figure, but is certainly wrong. The revision of assumptions underlying actuarial estimates also raises difficult issues. They were subject to different views in the *SNA* revision process as to how they would be recorded, such as whether there should be backward revision of estimates for earlier periods or one-off changes through other changes in volume.

The definition given in paragraph 19 is limited to schemes related to employment, so excludes social security schemes, which resemble defined benefits schemes in some ways, but the requirement to pay benefits is of different nature, more policy-driven and less contractual. Nevertheless, the *2008 SNA* notes that the line between pension and social security schemes is not entirely clear-cut, and arrangements may differ between countries. It shows income and stocks for pension entitlements under social security schemes in a supplementary table (Table 17.10) with different kinds of pension schemes, but does not include them in the core accounts. While not in the core accounts, the data are likely to be of interest to analysts and policymakers. In some countries, social security entitlements are large and helps to address fiscal sustainability issues. Although the *2008 SNA* supplementary table refers to social security pension obligations, health and other obligations may also be relevant in some countries.

D. BALANCE OF PAYMENTS AND INTERNATIONAL INVESTMENT POSITION MANUAL (BPM6)

BPM6 was developed in parallel with the *2008 SNA* and is completely consistent. Its previous edition had given minimal consideration to cross-border pensions, but with globalization of labor markets, the issue has become more important in some cases. For example: multinational companies may have a single pension scheme for employees in different countries; guest workers and other expatriate employees may accrue entitlements in their host country, then return to their home countries; mobile workers can be employed in several different countries during their careers; and people may move to sunnier or cheaper countries after retirement. Depending on the international mobility of its labor force, the issue may be minor for many countries, while in others, it could be economically significant either as a source or recipient of pensions, so statistical compilers need to monitor the situation in their countries.

The principles for measurement are the same as in the *2008 SNA*. For measurement of nonresidents' claims on residents, the residents are pension funds or employers, which are generally capable of reporting data. They usually have some indication of the residence of the beneficiaries, although ratios may be needed to split totals that cover both residents and nonresidents. However, for residents' claims on nonresident employers or pension funds, the data situation is more difficult, because the local parties are a diffuse group of individuals. In those cases, estimation may need to be made with ratios in conjunction with demographic data on retirees from abroad, or data on a pensions from abroad received through the banking system or reported for taxation. When pension recipients change residence to a country, there is an entry for other change in volumes for the pension entitlements.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

E. RECORDING OF 2008 SNA ENTRIES

The recording of defined benefit schemes has a impressively long list statistical complications: It involves entries in the production, generation of income, distribution of primary income, secondary distribution of income, use of income, and financial accounts (but not the capital account). As well, there are complications involving indirectly measured output, rerouting (employer contributions are rerouted through the beneficiary households), and imputations (for unfunded liabilities). There is also a special entry for "adjustment for change in pension entitlements" to reconcile the fact that payment of pension benefits are treated as secondary distribution of income, while at the same time as the withdrawal of a financial asset that has been accumulated over previous years.

These processes can be illustrated from the numerical example (*2008 SNA* Table 17.8, summarized in the Table below). The example covers a defined benefit scheme with a separate fund that is partly funded:

From observed transactions:

Employers make actual contributions of 10.0.
Households make actual contributions of 1.5.
The pension fund generates income on its assets of 2.2.
Benefits are paid to retirees and other beneficiaries of 19.0.

From actuarial estimates:

The underfunding for the year is 4.1, which is therefore the employers' imputed contribution.
The property income payable (due to the discount factor) is 4.0, which is also treated as a pension supplement.

Derived items are:

Pension fund output is 0.6 (difference between total inflows to the fund and total outflows – (10.0+4.1+1.5+4.0-16.0-3.0, i.e., employers' actual contributions plus employers' imputed contributions plus household actual contributions plus household pension contribution supplements less benefits payable less increase in pension entitlements, respectively).

Household pension contributions are 19.0, including actual contributions by households, rerouted actual and imputed contributions by employers. (10.0+4.1+1.5+4.0-0.6, i.e., employers' actual contributions plus employers' imputed contributions plus household actual contributions plus household pension contribution supplements less pension schemes service charges, respectively). (In this way, the contributions, actual and imputed, can be seen as giving rise to the liability).

Change in pension entitlements is 16.0 (19.0-16.0, i.e., contributions less benefits).

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Example – Accounts for Defined Benefit Pension Scheme

	Uses				
	Employer	**Fund**	**Households**	**Other**	**Total**
Production account					
Output					
Generation of income account					
Employers' actual pension contributions	10.0				10.0
Employers' imputed pension contributions	4.1				4.1
Distribution of primary income					
Employers' actual pension contributions					
Employers' imputed pension contributions					
Property income				2.2	2.2
Prop. inc. payable on pension entitlements					
Secondary distribution of income					
Household pension contributions			19.0		19.0
Pension benefits		16.0			16.0
Use of income					
Final consumption expenditure			0.6		0.6
Adj. for change in pension entitlements		3.0			3.0
Saving/net lending/net borrowing	-10.0	-5.3	17.5	-2.2	0.0
	Changes in assets				
Financial account					
Net lending/net borrowing					
Adj. for change in pension entitlements			3.0		3.0
Pension fund claim on sponsor		4.1			4.1
Other financial assets	-10.0	-2.3	14.5	-2.2	0.0
	Resources				
	Employer	**Fund**	**Households**	**Other**	**Total**
Production account					
Output		0.6			0.6
Generation of income account					
Employers' actual pension contributions					
Employers' imputed pension contributions					
Distribution of primary income					
Employers' actual pension contributions			10.0		10.0
Employers' imputed pension contributions			4.1		4.1
Property income		2.2			2.2
Prop. inc. payable on pension entitlements			4.0		4.0
Secondary distribution of income					
Household pension contributions		19.0			19.0
Pension benefits			16.0		16.0
Use of income					
Final consumption expenditure					
Adj. for change in pension entitlements			3.0		3.0
Saving/net lending/net borrowing					
	Changes in liabilities				
Financial account					
Net lending/net borrowing	-14.1	-5.3	17.5	-2.2	0.0
Adj. for change in pension entitlements		3.0			3.0
Pension fund claim on sponsor	4.1				4.1
Other financial assets					

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Saving is the same as net lending/net borrowing in this case because there are no capital account entries. In the *1993 SNA* treatment, all the underfunding would have been omitted (and hence any items where 4.1 was taken into account the above example would be calculated without that amount). As well, the property income payable to the beneficiaries would have been 2.2 instead of 4.0.

5 CONCLUSION

The recognition of defined benefit pension entitlements as assets/liabilities and income/expenses in macroeconomic statistics improves the relevance of the statistics by giving a more complete picture of their economic effect. The treatment is in line with economic principles because these entitlements represent a future benefit/burden that accrues from current activities and will remove the anomalies of ignoring underfunded and unfunded entitlements until they are paid.

Accounting practice increasingly recognizes these entitlements, which will assist in adoption of the methodology. However, it should be taken into account that these changes add some additional burdens in data collection and compilation. It will also be important to keep users informed of the explanation for the change, the methods used, and the size of the effects.

GUARANTEE OR INSURANCE OF DEFINED BENEFIT PENSION ENTITLEMENTS

BY JOHN WALTON [1]

ABSTRACT

In some countries there is a degree of guarantee of the pension entitlements of members of autonomous defined benefit (DB) schemes. Often the guarantor takes over the assets and liabilities of schemes which are in deficit when a sponsoring employer becomes insolvent. The guarantee may be only for a proportion of the entitlements, and may have an upper limit. The UK, USA and the provincial government of Ontario (Canada) are examples.

In other countries, regulation is very tight and such guarantee arrangements have been unnecessary. The Netherlands is the main example.

Likewise, in Germany and some other countries with non-autonomous DB schemes, there is a need for a guarantor. Then the guarantee applies, not just to the deficit of an autonomous scheme with segregated assets, but to the entire entitlements (the "book reserves"), or to a proportion of them.

In this paper I refer to and draw on OECD's summary of an examination of such arrangements and of the desiderata for them. I then consider the treatment of these activities in the national accounts, looking forward to the SNA 2008 basis, and in the Supplementary Table. One approach is to assume – perhaps doubtfully, because of systemic risks – that a guarantor's objective is achievable to have usually a positive level of technical provisions (technical reserves), actuarially sufficient to cover future calls to activate guarantees. There is then a choice between considering the counterpart of these technical provisions – representing the net assets of the guarantor – as either contingent or actual assets of the pension schemes whose members benefit, potentially, from the guarantee.

The SNA 2008 treatments of both standardised and one-off guarantees on *loans* do not attribute, before activation, any excess of the guarantor's assets over its liabilities as assets of the bodies receiving the guarantee. If either treatment is applied to guarantee schemes for autonomous funded *pension schemes*, the amounts paid to a guarantor, as premiums (or levies), would not lead to a result in which the net assets of the guarantor are regarded as part of the level of collective savings for pensions.

1 I have written this paper independently and my views could well diverge from those of the ONS, UK. I am indebted to Gabe de Vries and John Verrinder for helpful comments on a draft, though the opinions in the paper are my own; and to various ex-colleagues for corrections to the country notes.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

An alternative for pension schemes would be to treat the guarantor as a kind of reinsurer of the risks incurred by the pension schemes (who incur investment risk and so can be thought of as similar to direct insurers), located therefore in the same sub-sector. Then the technical provisions of a guarantor with assets exceeding activated claims would be combined with those of pension schemes. Likewise, if the guarantor has net liabilities. Another treatment in which the guarantor is regarded as a specialist insurer in the insurance sub-sector probably lacks this symmetry.

The paper also considers the direct implications of these treatments for the Supplementary Table, including what happens when entitlements are transferred to a guarantor, and some indirect implications. There are country notes for Germany, the Netherlands, UK, USA and Ontario (Canada).

INTRODUCTION

The risks, through insolvency of a sponsor, to the obligations of funded defined benefit (DB) pension schemes are insured or guaranteed in some countries, usually compulsorily. There is a detailed description of these arrangements in *OECD Working Papers on Insurance and Private Pensions*, No. 5, April 2007, which also considers desiderata for them. The paper, by Fiona Stewart, is entitled "Benefit Security Pension Fund Guarantee Schemes". It is available for download at www.oecd.org/daf/fin/wp.

In this note I consider the recording of such insurance or guarantee arrangements in the national accounts and in national and sector balance sheets. I mention the possible implications for the Supplementary Table. Country notes include some updating of the OECD report for Germany, UK and USA and Ontario (Canada), see the Annex. The system in the Netherlands, which has many funded DB schemes, is also considered, as a major example of a country which has avoided the need for a pension insurance or guarantee system through other means;[2] and the Netherlands are also included in the country notes.

2 The OECD Working Paper also covers guarantee schemes in Japan, Sweden and Switzerland.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

First level. Segregation of the assets of the fund, under control independent of the sponsor (by "Trustees", in the UK).

Second level. Regulation, for example of the targeted level of funding and of the speed of recovery when underfunded. Regulation has recently been tightened in the UK and USA.

Third level. Establishment by law of a protection scheme or fund ("pension insurer"), which guarantees all or a large part of the obligations of a pension fund if the sponsor becomes insolvent, and which levies a premium from the active pension funds. The level of the guarantee may be less than the full entitlement, and is often subject to an upper threshold.

All these levels take account of the risks of default, including fraud or bad management as well as insolvency of the sponsor. There is also a risk of default due to changes in the markets for financial investments, which is more difficult to cover by insurance or guarantee, as all funds face the same problem – see "systemic risk", 3 below. Usually these risks faced by DB pension funds are not covered by pension insurers when the sponsor remains solvent, but there is an association between the two types of difficulty.

All three levels of security now exist in UK and USA and Ontario (Canada). With very tight regulation of funding levels, the second level suffices in the Netherlands: the funds are required to maintain assets at 105 per cent of liabilities (measured using current market interest rates for discounting) and to maintain a buffer reserve for fluctuations in the value of investments, interest rates and currencies – leading to an average fully funded level, with 'normal' interest rates, of some 120-130 per cent of liabilities. Once a deficit at the 105 per cent level emerges, the funds are allowed a short recovery period for restoration of the funding levels. Until recently this was three years, but a temporary extension to five years is now being considered, in view of the difficulties caused by the current very low interest rates and the disturbances on the financial markets. Also see the country note on page 42.

A further possibility, which may replace the possible third level of security, is that an autonomous DB fund hands over all or part of its risks (from mortality, survivorship or the return on investments) to a life insurer, or to a consortium of life insurers. In that case, solvency of the fund depends on solvency of the insurer. "Multi-employer" schemes may or may not include such transfer of risks.[3]

It is worth noting that the guaranteed amounts are probably related to entitlements on the accrued benefit obligation (ABO) basis at the time of wind-up after an

3 In the USA, some multi-employer schemes are covered by the Pension Benefit Guarantee Corporation, and pay lower premiums than individual funds.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

insolvency, rather than entitlements on the projected benefit obligation (PBO) basis. See section 9, on page 39 below, first paragraph, for a further discussion.

2 ENTITLEMENTS IN NON-AUTONOMOUS DB SCHEMES

A degree of priority for the claims of the "book reserves", or pension entitlements, is a possibility. But as the assets to support these obligations are not segregated, insurance of the risk of insolvency of the employer is vital. It exists in Germany and in Sweden. In Germany the insurer is established by law as a mutual insurance corporation, and it is the same in Sweden; their income and expenditure accounts follow the pattern usual for non-life insurers.

However, in both countries autonomous funds with segregated assets also exist; in Germany they are quite new (since 2002) and are covered by the pension insurer. Also, some companies with a non-autonomous scheme have segregated investments in a separate legal entity, corresponding to part of their pension obligations. In Germany the premiums payable to the insurer by the non-segregated schemes are much higher than those payable by the segregated schemes, because in the event of failure the insurer has to cover the full level of the pension obligations, not just the amount of any shortfall in segregated assets.

3 DESIDERATA FOR PENSION INSURERS OR GUARANTORS

This is a summary of the full survey in OECD Working Paper on Insurance and Private Pensions, No.5 (pages 11-13), mainly taken from the conclusions of that paper, setting out "principles for the successful operation of a pension benefit guarantee system". Readers are recommended to go to the original source. The excerpts below are shown in quotation marks.

- *Regulation*: "accurate and consistent funding rules: pension benefits should be fully funded and plan sponsor should be required to act swiftly in order to limit losses. Successfully combining a guarantee scheme with funding rules ensures some upside limit to potential claims and makes the guarantee scheme affordable. Consistent and adequate financial measurement and disclosure are required."

  Earlier, the report suggests that, for autonomous schemes with diversified assets "good funding rules can achieve almost all of what a guarantee scheme is striving for, are arguably easier to design and manage and, especially when combined with other measures (such as asset liability matching or priority bankruptcy rights) offer a high level of protection" but points out that, for the non-autonomous schemes, the OECD Guidelines of 2002 say "the establishment of an insolvency guaranty scheme should in general be required for occupational defined benefit plans that are financed through the book reserve system."

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

- *Limited benefit coverage:* such as a ceiling on benefit coverage and exclusion of benefits granted prior to insolvency.

- *Risk based pricing:* so as to avoid *moral hazard* (the adoption by funds of "riskier models of behaviour as an undesirable response to the financial protection provided by the insurance carrier") and *adverse selection* (or cross subsidisation of failing schemes by the viable ones).

- *Prudent asset liability management:* both of pension funds and of "the guarantee fund itself, if it takes over the assets of insolvent schemes".

- *Adequate powers:* "a pension guarantee scheme needs to have adequate powers to avoid moral hazard and prevent plan sponsors using their guarantee as a 'put' for their pension liabilities… Any guarantee scheme needs to operate without undue political influence."

Earlier, the OECD report says that

- *Systemic risk* is an unavoidable disadvantage.

"This stems from the fact that the bankruptcy and underfunding risks of pension plan members are correlated, meaning that the insured risk cannot be spread sufficiently" and goes on to say that insurance cover cannot be provided for systemic risks "such as macroeconomic weakness, which increases the bankruptcy risk of all companies, or sharp equity market and interest rate declines."

The following thoughts occur to me. It is evident that systemic risks also affect the pension funds, to a higher degree when there is no insurance/guarantee body. But funds may be less inclined to limit benefits in the face of systemic risks when there is one.

In my opinion, despite the present crisis, a further difficulty of pension insurance or guarantee is the risk of overfunding of the insurance/guarantee body in the long-term, in view of the difficulty of assessing the systemic risks. There are usually no competing bodies to limit possible overfunding, and, even if there are, on the analogy with mutual life insurers, an over-cautious accumulation of reserves could still result.

4 ACTUAL SITUATION OF PENSION INSURERS OR GUARANTORS

Funding of guarantor		
	Funding objectives Independent of Government?	Risk based Levies?
Germany	Yes	No
UK	Yes	Yes
USA	? No	No
Ontario (Canada)	No	Yes

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Levels of cover		
	Upper limit?	Proportion only?
Autonomous		
UK	Yes	Yes
USA	Yes	?
Ontario (Canada)	Yes	Yes
Non-autonomous		
Germany	Yes (100%)	No

Levels of cover	
	Action after a claim
Autonomous	
UK	Takes over the fund and pays compensation
USA	Takes over the fund and pays compensation
Ontario (Canada)	Pays the unfunded proportion
Non-autonomous	
Germany	Buys annuities

5 POSSIBILITIES FOR TREATMENT IN THE NATIONAL ACCOUNTS

I try to look forward to treatments in SNA 2008 (and in the revised ESA that will follow it) but, in the country notes, the references to current treatments refer, of course, to SNA 1993 and ESA 1995.

There appear to be several options for the treatment of a pension insurer or guarantee body in the national accounts and national and sector balance sheets, associated with the possible risk of default of a DB pension scheme from insolvency of the sponsor or other causes. The situation probably varies between countries, depending on the legal status and *modus operandi* of the insurance/guarantee entity.

A primary distinction is between treatments which treat the net assets of the insurance or guarantee body as *contingent* assets of the insured entities and treatments which regard these net assets as *actual* assets of these entities, attributable to the insured entities – collectively, even if not individually.

- *Contingent assets of the insured entities*

  (i) The insurer/guarantor is classified as an ordinary non-life insurer (on the criterion of 'no certainty of benefit')

  (ii) It is classified as a financial auxiliary (a treatment following ESA 1995, perhaps subject to change in the next ESA)

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

(iii) It is classified as an issuer of guarantees:
(a) One-off (perhaps as a financial auxiliary)
(b) Standardised [4]

- *Actual assets of the insured entities, taken collectively*

(iv) The protection body is classified as a specialist insurer (on the basis that its technical reserves/technical provisions are part of overall saving for pension provision)

(v) In the case of autonomous pension funds, it is regarded as like a reinsurer and is combined with the funds.

(vi) Its activities, if located in Government, are part of unfunded social insurance (perhaps unlikely)

The advantage of treatments as actual collective assets of the insured entities is to portray the feature that the existence of a protection body with net assets improves the 'quality' of individual pension entitlements, by reducing deficits of the funds, when taken collectively. The entitlements, taken collectively, are then seen in direct relation to all the assets supporting them. A treatment as collective assets diversifies risks, by adding the net assets of the protection body to the collectivity of assets available for the funding of pension obligations. As a DB pension fund itself incurs investment risk, and possibly mortality/survivorship risk as well, it is like an insurer, so that the guarantee body could be regarded as like a reinsurer offering "excess of loss" cover.

Protection bodies as issuers of guarantees. It is useful at this point to look at discussions in the AEG for the 2008 SNA about guarantees on loans.[5] The note setting out conclusions on this issue (No. 37) distinguishes between standardised and one-off guarantees. Standardised guarantees on loans are "issued in large numbers, usually for small amounts", and have the characteristic of the pooling of risks, such that the levies or fees paid are expected to cover the predicted risks of default on loans, as with insurance. However, the present value of these predicted risks (similar to technical provisions in insurance) is not regarded as an actual asset of the collectivity of the entities receiving the guarantee, but as a 'stand alone' liability of the guarantor, with no counterpart asset. One-off guarantees are regarded only as contingent assets of the guaranteed entity at the time when issued, and are not recorded in the core accounts until they are activated, with the full amount of premiums or levies being treated as payments for a service.

4 Standardised guarantees on loans are similar to insurance, and in SNA 2008 the treatment in the income and expenditure accounts is the same as for insurance, but I have been advised that in balance sheets there is a difference between the recording of an issuer of standardised guarantees on loans and the recording for an insurer, in regard to the treatment of the counterpart to their technical provisions, see section 5 of this paper. The treatment for loans suggests that any entity, benefitting from standardised guarantees accorded to it, should be treated as having no actual asset in respect of a guarantee until it is activated. However, the case of guarantees relating to pension funds is not mentioned specifically in SNA 2008.

5 See AEG issue paper No.37: and the paper for the fourth meeting of AEG "Granting and Activation of Guarantees in an updated SNA", by Reimund Mink (SNA/MI.06/18).

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Thus both types of guarantees, if similarly applied, in regard to the risk of default of DB pension funds, would exclude attribution to the funds of the technical provisions (net assets) of the guarantor, unlike the treatment under insurance. Likewise, there would be no question of attributing negative technical provisions, if a guarantor has claims exceeding assets.

Protection bodies as specialist insurers. Another possibility would be treatment of a protection body as part of insurance proper. What is at issue here is whether a protection body can have a secure basis on which to make actuarial provision for future claims, like an insurer. That appears to be the intention and the practice in some countries. The difficulty is systemic risk, but it should be noted that the risks being covered are both that a pension fund is in deficit and that the sponsor becomes insolvent – not just that the fund is in deficit, perhaps temporarily because of unusually low interest rates, whilst the sponsor remains solvent.

In the first and fourth cases listed in page 33 and 34 above – treatment as insurance proper – the technical provisions of the insurer would be attributed to the "policy-holders", which are the funds. In these cases, the body accepting the risks of default could be called a "pension insurer".

If it were treated as an ordinary non-life insurer – leaving aside for the moment the proposed substitution of expected claims for actual claims – each year's provision for claims, unlike life insurance, would take account only of events which had occurred in the year, that is, insolvencies giving rise to a call on the guarantee; provisions from current premiums for future claims would not be treated as technical provisions but as second line reserves funded out of operating surplus. (However, the substitution of expected claims blurs the distinction between events that have happened and provision for future events; it would be difficult to estimate statistically the expected claims of a pension protection body.)

In some cases such as health insurance a provision for future events is made (and so it would be, if term insurance were treated as non-life insurance, on the 'no certainty of benefit' criterion). Therefore, if the treatment as a pension insurer includes provision for future events within the insurer's technical provisions, these would include the balance of its reserves held for future claims (somewhat similar to the "life insurance provision" of a life insurer). Thus, these liabilities of the guarantor would be attributed as assets to the pension funds which benefit from the guarantee. But symmetry might require attribution of negative technical provisions, when a pension insurer has claims from actual events exceeding its assets.

If it can be considered that the normal situation is one where the pension insurer has positive net assets, it makes sense to attribute the technical provisions of the guarantor to the pension funds which it covers, because the funds' deficits, in aggregate, would thereby be reduced. This appears to be consistent with

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

the fact that there is an increase in the 'quality' of the given DB entitlements.[6] The pension funding sub-sector is often thought of as being analogous to life insurance, primarily because it shares the savings element of the latter. Therefore the attribution of an insurer's net assets to the pension funds, even if only taken collectively, as cover for risks faced by them as policy-holders, looks at the similarity between pension funding and life insurance through their contributions to collective saving. However, there would be difficulty when a pension insurer is in deficit; in that case there are likely to be variations in national law about what should be done – for, instance higher premiums or levies, lower guarantees or the possibility of bail-out by Government.

6 OTHER FEATURES RELEVANT TO TREATMENT IN THE NATIONAL ACCOUNTS

Activities of a pension fund guarantor after activation. Another feature relevant to the treatment in the national accounts is what happens when there is a default of a pension fund. If the guarantee body takes over the obligations of a failed fund, and pays pensions etc itself, rather than purchasing annuities, it acquires features such as the management of pension payments which are similar to those of a pension fund proper.

Combination of a 'guarantor' with autonomous pension funds. Treatment of the guarantee body as like a reinsurer and its combination with autonomous pension funds, as in the penultimate bullet in the list on page 34, would produce a similar effect to treating them as specialist insurers – that of increasing the 'quality' of the given DB entitlements, through reducing the excess of obligations, taken in aggregate, over the combined assets (assuming a 'normal' situation where the pension insurer has net assets). Transactions between pension funds and a guarantee body would be recorded in the same way as those between direct insurers and reinsurers.

Combination also has the advantage of leaving the sector classification unchanged when a fund is wound up and its assets are transferred to the insurance or guarantee body.[7] Thus it avoids entitlements, covered by insurance, being transferred to a separate sub-sector whenever the insurance is triggered, and avoids some differences of treatment stemming from the possibility of different practices once this happens.[8] It also takes account of the fact that the guarantee body may well get involved in the administration of pensions. A difficulty remains, however: that of possible lack of symmetry of recording if the pension

6 A similar effect, through a different route, is seen in a tightly regulated system such as the Dutch one, where the balances of the individual funds reflect higher requirements for the actual asset holdings of each fund. When pension guarantees are treated as insurance, the net asset holdings of the insurer would be regarded as bolstering the reserves of the funds, when taken collectively.

7 In the USA national accounts, benefits paid by the Pension Benefits Guarantee Corporation are split between those previously funded by failed pension funds (around 60 per cent), which remain in the pensions funding sub-sector, and those funded by premiums, which are public social insurance. See footnote in page 44.

8 In the UK, the Pension Protection Fund takes over insolvent funds after an assessment period, itself invests transferred assets and itself pays the guaranteed element of pensions.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

insurer has a deficit, including differences between countries in law and practice about what should then be done.

Public or private sectors. The guarantee body or insurer could be classified as a publicly controlled corporation or as a private sector corporation, depending on the circumstances. If it depends on money from Government, it could be classified to General Government. It could either be classified as part of funded social insurance, or – less likely – as part of unfunded social insurance, if owned or controlled by Government. Unless it is profit making, its output of services would be represented by its administrative costs, which may be included in the premiums levied, or may be charged separately. These administrative costs become intermediate consumption of the premium payers.

Which treatment is best? Very uncertain. It will depend on law and practice in each country, which may well differ. On both the SNA 2008 bases for the guarantee of loans, the net assets (or net liabilities) of the guaranteeing body would be kept away from the guaranteed entities until such time as a guarantee is activated; and after activation a guarantor may acquire some functions similar to those of the funds themselves.

In a 'normal' situation where a body accepting risks of default of DB pension funds has net assets, there are advantages of:

a) classifying it as a specialist insurer with attribution to policy-holders, or
b) treating it as like a reinsurer and combining it with pension funds in the same sub-sector.

If so, the aggregated level of a deficit of the autonomous funds, attributed to the sponsors, is reduced by the level of the technical provisions of the insurer (if positive), consistently with an increase in the 'quality' of the given entitlements of members of DB schemes due to pension insurance. Or if the aggregated level of the funds is a surplus, it is increased.

Symmetry of recording would also require attribution or combination of any deficit of the 'pension insurer', at least in regard to claims known to exist at its accounting date. On treatment a.), there might be lack of symmetry in the recording of any provisions for future claims – included if positive, not included if negative. On treatment b.), any provisions for future events would be included whether positive or negative.

7 EXISTING CLASSIFICATIONS IN THE NATIONAL ACCOUNTS (ON SNA 1993/ESA 1995 BASIS)

Existing classifications (SNA 1993)	
UK	S.125
USA	Public social insurance (part) and pension funds (part)
Ontario (Canada)	Government, sub-sector provincial Government
Germany	S.125, pension funding sub-sector

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Treatment of levies or premiums. For DB schemes, the Supplementary Table records both opening and closing levels of the actuarially determined entitlements and the factors accounting for changes in these. The actuarial valuation of DB entitlements is not directly affected by pension insurance; but the 'quality' of the entitlements is. There appear to be two options for treatment of the levies payable to a guarantor/insurer in respect of autonomous schemes. Either they could be treated as directly payable by the sponsor, so by-passing the accounts of the pension fund, or they could be regarded as payable by the fund with reimbursement from the sponsor. The latter seems preferable. In the case of non-autonomous schemes, they are paid by the employer. They could be either payments for a service (when contingent assets of the entities receiving the guarantees) or – when actual assets of the entities receiving the guarantees insurance – premiums, consisting of a risk premium (or net premium) matched by a provision for present or future claims, and a smaller charge for a service.

Treatment of lost and relocated entitlements. When a fund is closed whilst in deficit, for whatever reason, presumably the entitlements lost without compensation are "Other Volume Changes". When there is no guarantee or insurance, a fund in deficit may remain active during a run-down period, even though the sponsor is insolvent; there is then a moot question: at what stage are some entitlements lost? Probably it is at the time when the sponsor backs out, unless the participants retain a credible legal claim on the fund for the lost part of their entitlements, whilst the fund remains in being.

If a fund is guaranteed or insured, and a large part of the entitlements is potentially picked up by a guarantor or insurer, the balance lost by individual members still seems to part of "Other Volume Changes". But this could well be the net effect of:

a) what the loss would be if not guaranteed or insured, and
b) a degree of restitution by the guarantor or insurer.

For instance, the funding level of the original scheme might be only 60 per cent and, depending on its rules, this might affect the entitlements of active members more than those of retired members. Leaving this complication aside, the average level of entitlements might be restored by the guarantor/insurer to 90 per cent of their original level. Thus "Other Volume Changes" of the sub-sector pension funding would reduce entitlements by 40 per cent and "Other Volume Changes" of the sector in which the guarantor/insurer is located would increase the entitlements by 30 per cent of their original level.

Thus the entries in row 6 of the Supplementary Table (Transfer of pension entitlements between schemes) would show, in Column B for DB schemes, the loss of 60 per cent of entitlements and this would carry through to Col. I (Total: pension schemes) when the guarantor/insurer is in another sector. However, on Option (v) of the list on page 34 above – combining the guarantor/ insurer with the DB pension funds – there would be no net effect. Likewise, on the USA treatment – see footnote 1 on page 44 – the 60 per cent stays where it is.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

9 INDIRECT IMPLICATIONS FOR THE SUPPLEMENTARY TABLE

There may also be some indirect implications. I can think of three. First, ABO/PBO (accrued benefit obligation / projected benefit obligation). By definition an guarantor/insurer encounters a claim only when there is a failure. Thus, the ABO basis applies. IAS 19, on the other hand, looks at a going concern basis (PBO), coupled with defining a state of being fully funded as that required in a potential wind-up situation. Thus a current market rate of interest is used for discounting estimated future outgoings to the present day. (If the interest rate tallies with that used by annuity providers, a fully funded scheme could purchase annuities sufficient to fund existing and future pensions, with some allowance for expected future increases in real wages.)

The possible existence of guarantee/insurance arrangements does not seem to figure in IAS 19 but arguably, on a going concern basis, the potential claims of funds, taken collectively, on the net assets of the guarantor/insurer should be credited to their balance sheet. (This is based on the idea that the guarantor/insurer's net assets are regarded as part of collective savings for future pensions, and so as *actual* assets of the funds – see options (iv) and (v) on page 34.)

Secondly, the very existence of a guarantor/insurer alleviates day-to-day funding requirements, to some extent, by spreading risks. The levies which it charges will cover the risk of collapse of the sponsor at a time when the relation between market interest rates and longer term investment yields is adverse, as well as the risk of collapse at other times. Thus it may become unnecessary for each fund to seek to cover individually the risk of volatility in the relationship between market interest rates and longer term investment yields – the risk of collapse, due to failure of the sponsor, could be viewed in a longer-term manner. In other words, the discount rate used for valuing liabilities – when making funding decisions – could perhaps be smoothed, as was usual practice in many countries, before IAS 19. In this connection, it is interesting to note the following statement by the UK Pension Protection Fund about the basis on which it determines its aggregate requirement for levies.[9]

"To determine the aggregate levy schemes pay, the Pension Protection Fund uses a long term risk model (LTRM). This ensures that the Pension Protection Fund adjusts for short term volatility and uncertainty by taking a longer term time horizon. The LTRM generates a probability distribution of claims on the Pension Protection Fund on different longer term horizons from five to twenty years, taking into account a very large number of possible economic and financial market outcomes".

9 Source: Note 1 of the Pension Protection Fund's series of monthly updates providing the latest estimated funding position of almost 7,800 predominantly private sector defined benefit (DB) pension schemes in the UK. This does not indicate how the aggregate levy is distributed amongst individual funds; the Pension Protection Fund is responsible for keeping the assumptions used for valuations in line with estimated pricing in the bulk annuity market – see the country note for the UK.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

This appears to suggest that recovery periods from a position of deficit could take account of the impact of such short-term volatility, on the basis that premiums reflect cover.

Thirdly, there may also be an implication for the on-going study of the core/ non-core boundary. A degree of guarantee established by law of the entitlements of members of the DB schemes of *private* sector employers, if it exists, implies that their entitlements are relatively secure at the ABO level. Thus, by implication, it would become politically difficult for *Government* to change the structure of the DB schemes set up for their own employees, in such a way as to reduce, retrospectively, the ABO level of their entitlements (viz., a retrospective change in the accrual rate). On the other hand, restructuring of social security pension schemes involving changes in accrued-to-date entitlements are common. Thus, when a guarantee scheme exists, the case may be strengthened for inclusion in the core accounts of any unfunded entitlements of General Government employees, in schemes which are distinct from social security (Col. G of the Supplementary Table).

10 UPDATED COUNTRY NOTES

At Annex, pages 41-45. Also see the OECD Working Papers on Insurance and Private Pensions, Nos. 5 and 17, for more detail. In the country notes I have drawn extensively on both papers. Paper No.17, issued in April 2008. is entitled "Fund Regulation and Risk Sharing", by Colin Pugh and Juan Yermo.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

ANNEX

A1 GERMANY (BOOK RESERVE SYSTEMS ONLY)

Regulation	
Funding target	Not applicable (book reserve system).
Discounting of obligations	6% fixed,[1] the required basis for corporate taxation.
ABO/PBO	ABO, the required basis for corporate taxation.
Recovery periods	Not applicable.
Remarks	Some autonomous schemes with segregated assets, which started in 2002, are also covered by the insurance and pay much lower premiums.
Guarantee/insurance body	
Name	Pensions Sichererungs-Verein Versicherungsverein auf Gegenseitigkeit (PSVaG).
Classification in the national accounts	S.12502, sub-sector, private pension funds.
Level of compensation:	
A proportion only?	No, 100%
Upper threshold?	7,400 euro per month.
Annuities, or self-financing? [2]	Annuities are purchased through a consortium of life insurance companies.[3] (Consideration, earlier, of introduction of a capitalised system – self investment of premium income and own payment of compensation – is no longer active.)
Investment restrictions	No.
Independence from Government	Yes.
Remarks	Premiums are flat, based only on the level of obligations (book reserves) – 0.18% for 2008, 0.30% for 2007 and, on average, 0.38% in the five years 2002-2006. German companies have generally accepted the fact that viable companies subsidise those companies which fail, as an acceptable ingredient of the book reserve system. A risk-based structure of premiums was considered two years ago (with a lawsuit), but has not led to a decision.

1) The Accounting Law Reform has proposed taking the average of market interest rates over the past seven years.
2) After assuming obligations of failed schemes.
3) For this purpose, when PSVaG purchases annuities from insurance companies, a discount rate of 2.5% is used for valuing the entitlements of previous employees of failed companies.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

A2 NETHERLANDS

Regulation	
Funding target	105% of obligations, plus a buffer reserve for volatility in investments, currencies and interest rates, equal in total to some 120%-130% of obligations on average.
Discounting of obligations	Market based. The central bank publishes each month a yield by duration curve, based on the inter-bank swap market.
ABO/PBO	Mostly PBO, but can exclude inflation proofing of deferred benefits or of pensions in payment.
Recovery periods	105% target: limited to three years, but currently a temporary extension to five years is being considered. Investment buffer reserve: 15 years.
Remarks	No known instance of failure whilst underfunded, to date. The current difficulties (very low interest rates) could lead to a restructuring of benefits of some schemes at a lower level, probably starting with fringe benefits such as inflation proofing of pensions, which is discretionary and is linked to funding levels. The rules of some schemes provide for changes in employee contribution rates when there are funding difficulties.
Insurance/guarantee body	None.

A3 UK

Regulation	
Funding target	The Pensions Act 2004 set up a new Pensions Regulator with substantial powers, but it does not have a prescriptive minimum funding requirement. One measure of adequate funding, perhaps a lower bound (being less than on the ISA 19 basis), is to hold assets matching what would have to be paid to an insurance company to take on payment of compensation at the same (restricted) level as payable by the Pension Protection Fund (the so-called "Section 379 basis"). Obligations include statutory price indexation of deferred benefits and pensions, now capped at 2.5%.
Discounting of obligations	At market rates (implied by the S.379 basis), depending on the bulk annuity market, but there may be some flexibility, on a going concern basis.
ABO/PBO	? (but it is PBO in the UK accounting standard, FRS 17).

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Recovery period	Ten year maximum.
Remarks	The Pensions Regulator identifies 'at risk' funds and establishes a funding target for them and an associated recovery plan. It seeks to 'educate' Trustees.
Guarantee/insurance body	
Name	Pension Protection Fund (PPF).
Classification in the national accounts	S.125.
Level of compensation:	
A proportion only?	90% of entitlements for active members, 100% for pensioners.
Upper threshold?	An annual pension of £28,000, currently.
Annuities, or self-financing?[1)]	Self-financing.
Investment restrictions	No. Stated objective is 70% in bonds (?).
Independence from Government	Yes, the Act requires the PPF to be self-financing, gives it freedom to set levies, subject to an upper limit, and provides some discretion in reducing compensation, should the PPF get into in financial difficulty.
Remarks	After an initial period, 80% of the levy will be risk related, depending both on the degree of underfunding and on an independent assessment of the financial strength of the sponsor.

1) After assuming obligations of failed schemes.

A4 USA

Insurance relates to private corporate schemes; funded DB schemes for State and local government employees are regulated differently and are not insured.

Regulation	
Funding target	Yes. The Pension Protection Act, 2006, establishes minimum funding standards & identifies "at risk" schemes.
Discounting of obligations	Investment grade corporate bonds of the appropriate duration.
ABO/PBO	Generally ABO.
Recovery period	Not more than seven years.
Remarks	No statutory indexation of benefits.
Guarantee/insurance body	
Name	Pension Benefit Guarantee Corporation (PBGC).

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Classification in the national accounts	Split between a part treated as social insurance of Government, national accounts when payments are funded by the pool of premium income, and a part remaining classified as pension funding, when benefits are paid out of the resources of the fund, when taken over.[1)]
Level of compensation:	
A proportion only?	?
Upper threshold?	Yes.
Annuities or self-financing?[2)]	Self-financing.
Investment restrictions	Yes (for premium income).
Independence from Government	No-premiums set by Congress.
Remarks	Also covers multi-employer schemes (lower premiums).

1) Information from BEA:
"The sectoring is a bit complicated. When a plan fails and is taken over by the PBGC, the plan will typically have enough assets to fund a significant proportion of the promised benefits (I'd guess 60 per cent would be typical) Those assets are available to the PBGC to help fund the promised benefits. So we split the benefit payments into a part that is paid for out of plan assets and a part that is paid for out the resources of the PBGC itself (which come from insurance premiums paid by the funds). The benefits that are funded by the resources of the PBGC are classified as social insurance paid by government. As for the plan assets, they are already the property of the plan participants, so the interest and dividends earned by these assets are part of household income and the benefit disbursals funded by earnings on plan assets are just a financial transaction." (Author's Note: that is, these disbursals are not treated as part of household disposable income, "dual recording" not being used).
2) After assuming obligations of failed schemes of unfunded entitlements of schemes in deficit whose sponsor fails.

A5 ONTARIO (CANADA)

Regulation	
Funding target	100% of technical provisions and 100% of going concern liabilities as valued at PBO on projected unit credit method.
Discounting of obligations	Federal bonds of appropriate maturity + 0.5%.
ABO/PBO	Both.
Recovery periods	Five years.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Remarks	The above are mostly Provincial Government regulations. No statutory price indexation.
Guarantee/insurance body	
Name	Pension Benefit Guarantee Fund.
Classification in the national accounts	Consolidated within the Provincial Government subsector, Government sector.
Level of compensation:	
A proportion only?	Yes, based on a share of funding.
Upper threshold?	Yes, lower than USA, at 12,000 Canadian dollars, fixed[1)].
Annuities, or self-financing?[2)]	Annuities.
Investment restrictions	Probably not.
Independence from Government	Sets own premiums, but has had to borrow from Provincial Government.
Remarks	Premiums now are a rising proportion of the degree of under-funding, rising from 0.5% to 1.5% of underfunding as a proportion of total obligations (10%, 10-20% and 30%+). Any indexation of benefits in scheme rules not covered. Mult-employer schemes not covered.

1) The fund will provide for benefits based on a share of funding up to $1000 per month. For example, at the time of bankruptcy of an employer if the pension plan was able to cover 70% of the assets required to fund the benefits payable, the fund would pay $300 in benefits. Any benefits in excess of $1000 per month would not be covered.
2) After assuming obligations of failed schemes.

DISCUSSION ON SESSION I

BY GABRIELE SEMERARO [1]

1 INTRODUCTION

This discussion is based on the papers by John Walton, Robert Dippelsman and John Verrinder, all devoted to the new statistical treatment of pensions in the international standards, from different viewpoints. John Walton chooses to focus on a specific, technical point. But the result looks like a test for the whole picture, able to shed some light on more general properties. Robert Dippelsman discusses the developments of new pension statistics, with specific regard to leading role played by the IMF and the concern of government finance experts. John Verrinder presents the new statistics with more emphasis on European contributions, notably in the field of pension modelling and measurement techniques (ABO/PBO, discount rate, treatment of reforms).

In this discussion, I will focus on three specific points, explicitly or implicitly suggested by the papers: the problems of "quality of assets" reflected in the accounts; the importance of modelling aspects, including the separation between transactions and other economic flows; and the coverage of the new criteria on constructive obligation (where should they stop?).

2 ISSUES ON THE QUALITY OF ENTITLEMENTS

The starting point for John Walton's paper is the existence of a second level protection for pension schemes, observed in many countries. This additional protection is normally imposed by the state or a guarantor, and ranges from simple regulation to taking over the assets and liabilities of schemes in deficit when a sponsoring employer becomes insolvent. The paper's purpose is to identify an appropriate treatment in the "core" national accounts, as well as in the Supplementary Table on pensions foreseen in the new System of National Accounts (SNA 2008). At one extreme there is the possibility of regarding the additional level of insurance as contingent liabilities: this basically means recording *nothing*, at least before activation of the "guarantees". At the opposite extreme there is the possibility of treating the protection body as taking part in the insurance process (by adding its own net assets to the original schemes, and by diversifying risks). The body would then act as a sort of reinsurer of the risks incurred by the pension schemes. This basically means recording *something*, in form of actual assets, fully recognised in the system.

1 Banca d'Italia, Economic and Financial Statistics Department. The views expressed herein are those of the author and are not necessarily endorsed by the Bank of Italy.

One of the conclusions is that several options may be adopted for the treatment of a pension guarantor in the national accounts, and the best treatment may vary between countries, depending on the legal status and the operating rules of the guarantee entity. In addition to the specific points directly raised by Walton, it seems natural to ask ourselves something more general. It seems that cases where recognition of assets is more likely are those where some reserves are built up by the guarantor (may be using premiums). Other forms may be less likely to be recognised in the accounts: for example, where there are no payments that might be thought of as part of a reinsurance scheme; nonetheless, in comparison to the former, those latter forms may provide the same level of security, due to a strong degree of commitment by the guarantor. Are we sure that, in the new SNA, entitlements with the same intrinsic value are measured in a consistent way?

The existence of a protection body causes an improvement in the 'quality' of individual pension entitlements, that should be captured in the system of the accounts. Walton's discussion is more focused on schemes where the guarantee resembles the form of a sort of private scheme and standard actuarial techniques are therefore applicable. A representative example is the case where a protection scheme is established for autonomous DB schemes, levies premiums and builds up net assets, in order to reduce the funding risk of the first level schemes. This latter arises from investment risk incurred by the DB funds, as well as from mortality/survivorship risk, and its relationship with the premiums levied by the protection body could be assessed in a standard way. However, it should be stressed that other cases exist, where the "quality" of individual pension entitlements is "de facto" increased by a guarantor, without the form of an explicit reinsurance scheme. Standard actuarial values would take into account the life expectancy, the expected income and age of retirement, and other information on the side of the insured. Things are more complicate on the side of the insurer. Calculations could be made for the investment risk of the fund. A second level fund (combining financial as well as mortality/survivorship risk) may also be assessed, even though incurring some additional estimation problems (see Walton's comments on the risk of overfunding). However, the level of commitment of a third party, as well as the probability of default of all subjects on the insurer side might prove not easy to measure. Of course, it is easy to write down a formula showing the final value as a function of all relevant probabilities. But unfortunately, tables with tested coefficients are available for the employee side, not for the level of commitment of a public protector. Nonetheless, if entitlements were allowed to be exchanged on an appropriate market, their value would be in principle impacted.

This introduces one key, general issue of the new treatment of pensions in the SNA 2008, that is the different properties of actuarial values versus market values. As a general rule in national accounts, consistency within financial instruments of different "quality" is assured by reference to market evaluation. Bonds with the same nominal value and interest payments may differ in the probability of default, depending on a number of factors, including the behaviour of the issuer. However this difference will be reflected in different market values. Actuarial values are tentative substitutes for market values, but this substitution is not perfect. It would be not fully appropriate to object that non standardised

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

protection would be treated as any other (non standardised) guarantees in the SNA 2008. The value attached to liabilities issued by a corporation would be affected by a guarantee, even though the guarantee itself is not recorded. Whereas in the case of DB pension schemes, if the guarantee does not enter the actuarial formula, it is definitely lost in the accounts. As a consequence, different categories of households may face the same level of expected benefits (and actuarial values), with different levels of protection. The entitlements shown in the national accounts may be the same. However, the economic behaviour of the two groups would likely differ: when planning current and future expenditure, households would reasonably take into account the additional level of security. The national accounts would not capture some significant factor impacting on the economic behaviour. It should be noticed that some problems are not direct consequences of the use of actuarial methods as substitutes for market values. As suggested by Walton in other occasions, they may depend on the specific actuarial approach that has been favoured by the national accountants. The current actuarial method is strictly linked to a break-up basis, expressing the cost of terminating the pension schemes. This method is deemed by the accountants to be closer to the concept of current market value. However, there are cases in the national accounts where the break-up basis may significantly diverge from market values, as defined and used in other cases.

Again, investigation of the topics discussed by John Walton reminds us that actuarial values are useful and necessary in the new SNA; but for the purposes of national accounts, they are still imperfect substitutes for market values.

3 COMPARISON BETWEEN SNA 2008 AND ESA 2010

The presentations by Robert Dippelsman and by John Verrinder have some elements in common, since both of them recall the reasons for changing pre-existing rules and comment on the current solutions. However, the presentation by Dippelsman is focused on the SNA, in relation to the big picture provided by the pre-existing International accounting standards and IMF's Manual on government finance statistics (GFS 2001), as well as the 6th Manual on balance of payments. On the other hand, Verrinder's focus is on the ESA, with specific regard to the European debate and contributions. Verrinder recalls the inputs from the first Eurostat Task Force on pensions, that explored the difficulties of distinguishing government employer and social security pension schemes. Then, a CMFB task force was established, jointly chaired by ECB/Eurostat and collecting members from many EU countries plus OECD and IMF. This task force final report, welcomed by CMFB in February 2008, was strictly related to the Draft revised ESA chapter on "Pensions" (17), summarised and commented by Verrinder. In order to add something to their very clear interventions, I will concentrate more on points where the two presentations, though consistent, show alternative points of view.

It is worth comparing how the two authors deal with the problem of reliability of estimates for pension entitlements. When reviewing the reasons for changing the previous treatment of pensions, Dippelsman recalls the particular concern for

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

the IMF about off-balance sheet liabilities. Omitting unfunded schemes would facilitate incurring unrecorded expenses and accumulation of obligations and would mean that vulnerabilities are not reflected in balance sheets. Following Dippelsman, this explained the original deviation of the GFSM 2001 from the pre-existing SNA. Measurement of pensions depends on the award formula in conjunction with assumptions about life expectancies of employees and dependents, staff turnover, future general salary increases, the employees' future promotion path, etc. This raises statistical concerns on the degree of estimation of actuarial figures and on revision of assumptions. Nevertheless, is the agreeable conclusion implicit in the reasoning, estimates subject to revisions are better than off-balance liabilities.

Verrinder's approach also takes into account the same problems of reliability. However his discussion is more biased toward technical solutions minimizing the effects of assumption revision. This aspect is related to emphasis assigned by Verrinder to modelling issues and accurate separation between transactions and other economic flows. The idea is that accurate modelling prescriptions help to obtain "clean" flows, only explained by underlying economic events, and less dependent on assumption revisions. Those latter revisions would then impact on other economic flows (or OEF, that is: changes in stocks not polluting flows). This diverse approach reflects the different purposes of SNA and ESA: the former is a general guidance for macroeconomic statistics in all countries. Whereas the latter (apart from being used in less countries) is more related to administrative uses, including the Eccessive Deficit Procedure foreseen in the European Stability and Growth Pact. Where the SNA include some solutions, the ESA should foresee one solution (leaving aside non-core liabilities of Government, where flexibility is recommended).

The most important difference may be observed in the case of ABO and PBO recording, that are two alternative ways to model promotions. The usual career path of an employee involves periodic wage rises due to promotion: under ABO treatment, future wage rises are included when they occur, whereas under PBO they are projected in the model and recorded before they occur. SNA 2008 describes the issue but does not recommend one or the other approach. However, a clear preference is expressed on the distinction between flows and OEF:

"The question arises, though, of how to record the impact of promotion on the employee if an ABO recording is used. (...) A simpler and adequate solution is to treat the rise in salary as a price change and record the change in the revaluation account." (SNA2008, 17.185)

This basically means that the impact of promotions, treated as *transactions* in PBO recording, is a *revaluation* if ABO is used. In the long run transactions are not the same. By contrast, comparison with the corresponding articles of the draft updated ESA shows some differences in substance:

"The impact of wage increases should be reflected in transactions, because awarding a wage increase is a conscious economic decision taken by the employer. Moreover, in concept the ABO and PBO approaches lead in the long

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

run to the same transactions recorded, even if the timing of those transactions would differ (...).” (ESA 2010, 17.147 (draft))

This means transaction neutrality over time: the only difference for ABO and PBO measurement approaches is the timing of the recording of transactions and entitlements whereas, as just seen, the SNA would imply that over time the transactions observed under an ABO measurement approach would not be the same as those for a PBO approach.

The preference in the SNA seems to be related to problems of aggregation.[2] In the context of the previous remarks, it is worth noting the origin of the opposite position, which has been preferred in the ESA. It has been discussed by the CMFB task force, when investigating the issue of actual computation of transactions versus other changes. It was discussed the case of summing individual calculations as well as the case of cohorts aggregation (a point mentioned in 17.185). The result was that aggregation does not seem to have strong implications for the split between transactions and other flows. Consider, for example, death before retirement. In the one case it should relate to individual death; in the other case it would relate to a generalised decrease in the life expectancy for some cohort. But exactly the same formula would allow for separating transactions from other changes. More in general, our ability to define and compute other changes seems not impacted by the level of aggregation, under both ABO and PBO approaches.

The second reason for the preference in the ESA is also interesting, since relates to the different use in comparison to the SNA (notably in the context of the EDP). The reason is that, when presenting some simulation for a big European country, it appeared that promotions may account for more than 30% of total entitlements. It appeared unreasonable that such a huge amount could either correspond to “surprise” revaluations, or to transactions impacting deficit and GDP. Leaving to countries the option to record or not record transactions amounting to 30% of total stock, it was argued, might result in a serious loss of credibility of the new statistical rules. The practical solution was recognising ABO and PBO as different techniques for identifying the same transactions. The (allowed) choice between ABO and PBO would then impact just the time of recording.

4 WHAT COMES NEXT?

The presentations by Dippelsman and Verrinder clarify most of the points on which a final agreement has been made. It is natural to ask ourselves which points of their surveys are not yet completely defined and which points are likely to change in the future. One first, obvious point refers to the treatment

2 The rationale is provided in the same article: *“(...) Any version of treating the increase as a form of compensation of employees or investment income falls back into the assumption that the aggregate of entitlements is the sum of the individual entitlements but without looking at other individual impacts on the aggregates such as when someone leaves and looses pension entitlement because not enough time has been served or when someone dies before retirement age. (...)”* (SNA2008, 17.175).

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

of unfunded employer schemes vs. social security. Are there valid reasons for a different treatment? A continuous source of incomprehension and scepticism on this issue relates to the different meaning that the word "pensions" seems to assume, in the USA . Of course, behind the different meaning of words there is a substantial difference in the institutional mechanisms.

On the one hand, it is true that in the USA and other countries social security might be thought of as substantially different from all pension schemes, included those reserved to government employees. On the other hand, in many European countries, liabilities incurred in the context of social security may have the same award formula and financing mechanism as the schemes for government employees. At least in those cases, the argument by Dippelsman on omitted liabilities that may lead to poor decision making, would seem to be true for social security as well. However, the precise borderline between core and non-core pension liabilities, as well as other issues concerning the practical compilation of the Supplementary Table, far from being closed, may deserve further analysis and further attention in the near future.

Another point that is somewhat "borderline" in the current standard, but may deserve further attention in the future, is about health liabilities. Some seminal elements may be found again in the IMF's manual on government finance statistics (GFSM 2001). For example:

"(...) An unfunded scheme can pay pensions and other retirement benefits that generate liabilities or it can pay other types of social benefits, such as health care." (GFSM 2001, A2.24.)

However, in GFSM 6.15-6.18 imputed contributions only refer to retirement benefits:

"Social contributions are payments, actual or imputed, made by general government units to social insurance schemes to obtain entitlement to social benefits for their employees, including pensions and other retirement benefits. (...)"(GFSM 2001, 6.15)

As recalled by Dippelsman, explicit recognition of some health liabilities can be found in Ch.13 of SNA2008.

For the time being, it is not clear what the range of application for health liabilities might be. No revolution seems to be expected by statisticians in this regard, at least in the context of this SNA. What is sure is the increasing concern by economists and government finance experts about the growth of (unfunded) health expenditure to GDP. This is even found in countries with a mainly private health system, like the U.S. (see for example Kotlikoff (2009)). It should be added that many of the arguments for health liabilities resemble those adopted in the past for supporting the notion of pension liabilities. Even though it is not the first item in the agenda of statisticians, this may be the issue deserving more interest in the medium range future.

SESSION II

EXPERIENCE OF ACCOUNTING STANDARD SETTERS AND PENSION MODELLERS

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

INTRODUCTION

Session II deals with the experience of accounting standard setters and pension modellers. Three papers were presented.

Gabe de Vries (Sigma Statistical Consultancy) considers accounting standards for pension schemes.

Matthias Heidler, Christoph Müller and Olaf Weddige (Freiburg University) discuss concepts of modelling pension entitlements. After describing the concept of accrued-to-date liabilities, as applied in national accounts in the context of open-system gross and net liabilities, the paper outlines the main features of the Freiburg model to estimate, on an actuarial basis and with harmonised model assumptions, the pension entitlements of various defined benefit employer pension schemes and social security pension schemes in EU countries. Detailed revenue and expenditure data as well as population data have been made available for the various pension schemes in a comparable format. Some effort has been devoted to the appropriate design of the pension benefit formula. This refers specifically to the type of indexation of pensions as well as to the treatment of reductions due to early retirement. Moreover, recent reforms of the pension schemes have been taken into account, like the change of retirement age or of the wage indexation formula. The impact of such reform measures on the pension entitlements are assessed in some case studies.

Michel Englert (Bureau Fédéral du Plan in Belgium and Member of the Working Group on Ageing) presents the work on pensions by the EPC Working Group on Ageing. Forecasts of future pension expenditure and other age-related public expenditure in each of the 27 EU Member states are used to evaluate the sustainability of public finances in each of those states. This evaluation rests on a concept of implicit liabilities which is very different from the one used in the work currently being carried out in order to introduce the implicit liabilities of pensions into the national accounts. Both this concept of implicit liabilities and AWG's forecasting methods are an integral part of the budgetary surveillance mechanisms that have been installed at the EU level.

Marshall Reinsdorf (US Bureau of Economic Analysis) discusses these three papers.

PENSION ACCOUNTING STANDARDS

BY GABE H. DE VRIES [1]

ABSTRACT

This paper deals with the international and national accounting and reporting standards that are relevant concerning the concept of pensions.

The IAS 19, the preliminary views to revise the IAS 19 and the IPSAS 25 discuss the subject premarily from the employers' position. They see accounting and reporting from the angle of the employers' annual account, the picture that should be produced to ensure that these annual accounts reflect fairly the employer's financial situation, the level of the own reserves and the changes over the accounting year. The developers of the updated System of National Account have to decide to what extent this angle should coincide with the national accounts' perception of pensions.

The definitions and terminology differ between slightly between the corresponding documents. This abstact mainly takes the "Preliminary views" as the starting point.

These accounting standards define post-employment benefit schemes as (see "preliminary views"):

> *Post-employment benefit promises are formal or informal arrangements under which an entity (i.e. the employer, ghdv) is obliged to provide employee benefits (other than termination benefits) payable after the completion of employment.*

This concept is wider than old age pensions only, it includes e.g. post-employment medical care and long-term disablement pensions.

Post-employment benefit schemes are broken down into defined benefit plans/ promises and contribution-based promises. The classification of schemes, according to these three (draft) international accounting standards, is deducted from the scheme's characteristics during the accumulation phase only (the period of employment with the employer).

If a scheme/promise is of a defined benefit nature from the employee's point of view but of a contribution-based nature from the employer's point, the later is decisive. The aspect that after the accounting year no further financial consequences are with the employer, is what matters in classifying a promise as a contribution-based promise.

1 Gabe H. De Vries, Sigma statistical consultancy, Treebord 103, 2811 EA Reeuwijk, Phone: +31-182 399 144, Fax:+31-182 399 145, Mobile: +31-6 2249 7855, E-mail: gh.de.vries@sigmastat.nl

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

An employer should report the annual contribution and possibly the unpaid part thereof in its annual accounts with contribution-based promises. With defined benefit, the difference between the gross entitlements of (former) employees and the corresponding assets should be reported on the employer's balance sheet. Also, the current and past service costs (not yet accounted for in earlier years) plus interest costs and actuarial gains/losses should be reported in the employer's profit and loss account. The gross entitlements should take the past and projected future career with the employer as the reference.

Insurers on the other hand would only include the past career of the employee in the calculation of the gross entitlements. The same would apply to pension funds. A non-autonomous pension scheme, i.e. where the employer is the pension institution, would follow the employer's definition of the gross entitlements.

Consequently, the employer(s) should report the over- or underfunding of the pension fund in its (their) own annual account (only with defined benefit schemes). The supervisory safeguards, applying to the pension institution, are not mentioned in these accounting standards. They, as a consequence, are excluded from the definition and calculation of the employer's claim/liability against the pension scheme.

An exception to the reporting of the position with a defined benefit scheme is where the scheme is with a multi-employer fund that does not account separately the position of each individual employer in the multi-employer scheme. Here only premiums and late/early payment could be reported by the individual employers.

I INTRODUCTION [2]

Pensions have become increasingly important within the economies of the European countries over the recent decades. It is not only from the perspective of the aging of the European population and the need to facilitate the income of the elderly that this issue became important. Other relevant perspectives to look at pensions are:

- The large amount of funds that are available with the life insurers and pension funds who became major players on the European financial markets;
- The amount of premiums/contributions that are paid by the working population;
- The corresponding liabilities of employers and pension institutions;
- The effect thereof on the economic situation and development.

2 This text makes reference to the draft version of the SNA and the latest available draft of the ESA, on several places. These drafts are labelled as SNA and ESA as appropriate for simplicity reasons. In case reference is made to the present official versions this will be indicated explicitly.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

The interest concerning the issue of pension premiums/contributions, claims/ benefits and the amount of the assets associated with the pension schemes rose accordingly in society in general. Parallel, the interest in the accounting world rose also.

Simultaneously, confusion on the concept of 'pensions' can still be observed. One can see that the state pensions and the employment related pensions are mixed up. Also, the old age pension and other classes of pensions, esp. the disablement pension, frequently are not properly distinguished.

This paper deals with the way the various classes of (persons), institutions and corporations report or should report their transactions in the field of pensions. Emphasis will be on the employment related old age pensions. Various sets of new and amended accounting rules were developed over the recent years. These are international rules but national ones as well, either developed independently or as a national version of newly developed international standards.

These rules can be distinguished into private sector and public sector accounting rules. A further breakdown is between accounting rules regarding the business sector in general on the one hand and those dedicated standards applicable to specific branches of industry on the other. With the latter especially the financial sector in general and particularly the insurance and pension industry should be mentioned.

This paper aims at summarising the main features of the international and national accounting and reporting standards as seen from the perspective of the system of national accounts, the SNA and the ESA. From this perspective the main elements within these business accounting and reporting standards are the definition of the concept of 'pension schemes' and 'pension promises', the breakdown into separate classes of benefits/promises and the way the financial consequences of these schemes should enter the business accounts of enterprises and government.

Concerning these main elements, the similarities and differences between the business accounting and reporting standards on the one hand and the national accounts' standards on the other will be discussed below.

1.1 ACTORS IN THE FIELD OF PENSIONS

A series of relevant parties exist in the field of pensions.

a. Private individuals: they could be involved in a pension scheme in their role of an employee or as a former employee with deferred rights or as pensioner. A further role could come from the position as a surviving relative (wife/husband or child) of a former employee who died (either in service or whilst being a pensioner).

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

According to the insurance terminology, especially the following breakdown of the roles that these individual persons have regarding the pension contract is relevant:

- Policyholder: this is the contract partner in the pension contract who is paying the premium/contribution (or the employer is paying on behalf of the policyholder);
- The insured person: this is the person who's life or death is insured on the pension contract;
- The beneficiary: this is the person who (will) receive(s) the pension benefit.

One and the same person could play various roles in this "pension play" during some period. So, the employee will be both the policyholder and the insured person during the employee's active period in many cases. After retirement, this person has the role of the beneficiary as well. In case of death of the (former) employee, the surviving spouse (and the children) will take over these roles.

b. The employer: the employer is (one of) the organiser(s) of the pension scheme. The scheme can be a single employer scheme or a multi employer scheme (e.g. a pension scheme for a branch of industry). The employer(s), normally, is (are) a large contributor(s) or often the sole contributor(s) of the scheme. Employee's contributions into the pension scheme only exist as well.

   With non-autonomous pension funds, the employer also has the role of a pension institution, i.e. all pension entitlements are on the employer's balance sheet as eventually are the corresponding assets (depending whether the scheme is funded or 'not funded or partially funded'). Also, the claims/benefits paid to the beneficiaries are included as expenditures in the employer's profit and loss account with a non-autonomous scheme. Premiums/contributions, both the employer's and the employees' part, are not explicitly mentioned within the employer's accounts in case of non-autonomous pension plans in many cases.

c. Pension institution: this is the entity that runs the scheme or a series of schemes from the same (group of) employer(s) or a random class of employers. Depending on the pension institution's characteristics, dedicated organs with the pension institution could perform specific tasks and have specific responsibilities.

The pension institution could especially be one of the following categories of institutions[3]:

- A (non-)life insurer that offers group (non-)life insurance.[4] This insurer might insure a large number of pension schemes and/or reinsure a series of pension institutions;

3 The list of pension institutions and the corresponding accounting rules will vary by country. Especially, the accounting rules with the (non-) life insurers, banks and investment institutions are largely harmonised within the European Union. Reporting for statistical purposes with these units is also coordinated within the EU.

4 A non-life insurer could take on board only specific classes of pensions, esp. long-term disablement.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

The (non-)life insurer could insure all risks associated with the pension scheme such as the short and long life risk, the investment risk, credit risk etc. It is as well possible that the insurer takes over the responsibility of only some and/or part of these risks.

- A pension fund that insures the pension scheme or schemes of a single employer or of a series of employers. The fund could reinsure part or all of the risks associated with the corresponding pension scheme(s) with a (non-)life insurer; Depending on the scheme's conditions, either the fund itself or the employer is responsible to meet the pension obligations;
- A pension fund insuring the pension scheme or schemes of a series of employers. The fund could reinsure part or all of the risks associated with the corresponding pension scheme(s) with a (non-)life insurer. A distinction exists between the case where the fund has separate accounts with the individual employers – a so-called 'Institution for Occupational Retirement Provisions (IORP)' – and the case without separate accounts. No solidarity between the employers exists with an IORP, implying that depending on the scheme's conditions, either the fund itself or the individual employer is responsible to meet the 'own' pension obligations. With the other multi-employer pension funds the group of participating employers or the pension fund itself – depending on the scheme's conditions – is responsible to meet the scheme's obligations.
- The employer can act as a non-autonomous pension fund[5]; specific risks, including the risk of default of the employer, can be reinsured with a (non-) life insurer or a reinsurer. The employer will be responsible and accountable for any deficit in the scheme in most cases;
- A government institution that is responsible for managing employment related pension scheme(s);
- Banks, investment companies etc. could be responsible for administrating non-autonomous pension schemes. Also, with an autonomous scheme, these institutions could administer the corresponding institution. They could insure or even might be obliged (re)insuring the part of the associated risks of a non-autonomous scheme with a (non-) life insurer or a reinsurer.

d. Government, a government agency or a legally independent institution as supervisory authority in the field of private pension. This entity might also set the relevant accounting rules concerning the various classes of pension institutions as relevant within the country – whether or not co-operating with government (ministry of social affairs, ministry of finance, and ministry of economic affairs) – regarding the pension institutions.

The role of government in the field of employment related pension schemes (in addition to the state pension), therefore, could be one from a series of options. Government could be involved in the pension contract as the employer, as the pension institution (a non-autonomous pension scheme regarding its own employees), as the pension institution regarding own or private sector employees or as the supervisory authority.

5 This category includes the case of a non-autonomous scheme regarding government employees. This scheme is not classified as a social security scheme (S.1314).

Because regarding individual persons no accounting rules exist, a complete and consistent description of their individual pension situation is hardly collectable with private persons directly.[6] The description of a full picture of the country's pension situation, therefore, needs to be solely/largely based on the information receivable from the various pension institutions and the relevant employers. However, the accounting rules and standards vary with the various classes of the institutions that are relevant in the country's full pension landscape. As a consequence, the information received from the various classes of entities needs to be transformed to arrive at uniform national accounts definitions, classifications and accounting standards and they need to be integrated in the national accounts in a second run, to arrive at a coherent picture of the country's economy. This transformation, however, is not an easy task because of differences in the accounting rules and standards and the complexity of the relevant concepts.

1.2 SOME NATIONAL ACCOUNTS TERMINOLOGY

Two pairs of national accounts concepts are important when discussing the accounting rules and standards. These concepts are discussed in this section.

Autonomous and non-autonomous pension entities

A pension entity is said to be an autonomous entity if it constitutes a separate and independent institutional unit. The autonomous pension entity makes it own decisions and is accountable for these decisions.

A non-autonomous pension entity is part of the employer's institutional unit. Decisions are made by the combined unit that is also accountable for these decisions. The term 'book-reserve' is also used for the corresponding pension schemes.

The concept of accountability does not imply that the autonomous or non-autonomous pension entity is responsible for the entity's financial position, independently of the cause of any surplus or deficit. This responsibility and accountability is to be allocated in accordance with the corresponding scheme's arrangements and the relevant legislation in the country.

'Fully funded' and 'not funded or partially funded' pension schemes[7]

Fully funded schemes are schemes where the value of the investments associated with the scheme is intended to be at least equal to the scheme's obligations.

The scheme's obligations should cover the full present value of the future costs of the amount of the entitlements of the scheme's policyholders, including policyholders with deferred entitlements and/or the actual beneficiaries, as existing at the end of the accounting period. This amount should include the corresponding claims / benefits handling costs.

6 Some data from individuals might be collected from the tax authorities. The tax authorities will use specific accounting rules, different from those of employers and the pension institutions. These tax-based accounting rules are not dis-cussed in this paper.

7 SNA uses the term 'unfunded' pension schemes where the ESA uses the term 'not funded or partially funded' pension schemes.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Any temporally shortfall of the scheme's investments compared to its obligations would not disqualify the scheme for being a funded scheme. Only, the scheme conditions and / or national legislation should require to arrive at a surplus within a defined and limited period. Also, the scheme conditions and / or national legislation could require a certain surplus to exist.

The class of 'not funded or partially funded' pension schemes deals with all pension schemes where the intension of a surplus of the scheme's assets over its liabilities does not exist.

These definitions don't refer to legally mandatory of voluntary buffers, additional reserves and corresponding assets to protect the pension rights of the employees. These buffer funds complicate the preceding definitions. The buffer fund as such is part of the (non-technical) reserves of the pension entity whereas the corresponding assets are part of the entity's investments. These assets should be taken on board when deciding whether the scheme is funded or partially funded. On the other hand these buffers should be an ingredient of the pension entity's own funds. They should not constitute a liability against the employer.

2 VARIOUS SYSTEMS OF ACCOUNTING RULES AND STANDARDS REGARDING PENSIONS

The international accounting standards board (IASB) sets the international accounting standards (IAS) and the international financial reporting standards (IFRS) regarding private sector entities. These standards apply to the business sector in general. A series of accounting entries (such as 'compensation of employees', 'intermediate consumption', 'taxes' etc) are relevant and identical with non-financial and financial corporations. Those common rules and standards could be found in the existing standards.

Concerning the pension discussion, the dedicated International Accounting Standard 19 'employee benefits' (IAS 19) is especially relevant. Apart from other elements, it sets the present international standard for accounting and reporting on pensions as an element of the employee benefits.

The international public sector accounting standards board (IPSASB) produces the corresponding international public sector accounting standards (IPSAS) that are relevant with public sector entities. A dedicated standard is developed in the field of employee benefits, the international public sector accounting standard 'employee benefit' (IPSAS 25). This standard is strongly based on IAS 19, the private sector standard concerning employee benefits.

Since the IAS 19 has been published a series of comments has been received. Following these comments the IASB has decided to review IAS 19. The IASB has so far produced a report on preliminary views to amend IAS 19. Views and comments on this report could have been sent in until September 2008.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

The preliminary views especially relate to post-employment benefits as a major component of employees benefits. These possible revisions mainly concern defined contribution schemes (labelled 'contribution-based promises in these 'preliminary views' on revising IAS 19) will be discussed also.

The International Accounting and Reporting Standards discussed so far, are oriented towards either the employer mainly. The accounting standards board ('ASB', the UK standard-setter in business accounting), in collaboration with the European financial reporting advisory group (EFRAG) has led the development of a paper on "the financial reporting of pensions, a PAAinE[8] discussion paper".[9] This paper represents a "fundamental reconsideration, starting from first principles, of the accounting that should be required for pensions".[10] This discussion paper takes a fresh look into the issue whereas the other initiatives as mentioned in the preceding text start from the idea of improving existing standards. ASB, EFRAG and the other participating standard-setters expect a large impact of their discussion paper on the future standard-setting process.

The European accounting and reporting directive concerning non-financial corporations is closely in accordance with the IAS and IFRS. Additionally, separate accounting/reporting directives exist with banks, (life and non-life) insurers and investment companies with the European Union.

National accounting legislation regarding the financial and non-financial corporations is according to these European accounting and reporting directives. Also supervisory accounting information is expected to be largely in line with these European accounting/reporting directives. Only series of supervisory details will – if and where necessary – be added.

No dedicated European accounting/reporting directive regarding pension institutions exists. Only in as far as they belong to classes of institutions to whom other accounting/reporting legislation applies (such as banks, investment companies and (non-) life insurers) pension accounting is according to European accounting/reporting standards. Nevertheless, individual countries might have developed national legislation on the accounting and reporting of the pension institutions. As far as pension funds are concerned, they are expected being fairly similar to the life insurance accounting/reporting standards.

IAS 19 and IPSAS 25 are viewing the accounting and reporting standards regarding pensions from a single perspective, the employers' point of view. Looking at the pension subject from this dedicated employers' angle implies that only/mainly considerations that are relevant with the corresponding employers are

8 PAAinE: Europe's 'Pro-active Accounting Activities in Europe'. This is a partnership between the European Financial Reporting Advisory Group ('EFRAG') and European standard-setters. The Coordinating Group of PAAinE, which comprises representatives of the standard-setters of EFRAG, France, Germany, Italy, The Netherlands, Poland, Spain, Sweden and the United Kingdom.

9 The discussion paper can e.g. be obtained from http://www.efrag.org/projects/detail.asp?id=70

10 See "The financial reporting of pensions", page 2.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

considered in developing these rules and standards. This could have implications concerning the content of these rules and standards that are not relevant with other players in this field.

The effect of this one sided orientation of IAS 19, IPSAS 25 and IFRS could be that dedicated amendments, deletions and/or supplements might be necessary when considering the various rules and standards from the perspective of the other players like government (as a pension institution), pension funds, (non-)life insurers, employers, employees, etc.

The System of National Accounts has such a multi-sector perspective. It takes into consideration the impact of rules and standards with all payers in the field. Nevertheless IAS, IFRS and IPSAS will constitute important ingredients within the total process.

3 IAS 19 'EMPLOYEE BENEFITS'

The IAS 19 on employee benefits is part of the total set of international accounting and reporting standards, concentrating on all types of employee benefits.

The concept 'employee benefits' is defined as:[11]

Employee benefits consist of all forms of consideration given by an entity (i.e. the employer, ghdv) in exchange for services rendered by employees. These benefits are broken down into:

- *Short-term employee benefits, i.e. all employee benefits which fall due wholly within twelve month after the end of the period in which the employees render the related service;*
- *Post-employment benefits, i.e. all employee benefits which are payable after the com-pletion of employment;*
- *Other long-term employee benefits, i.e. all employee benefits (other than post-employment benefits and termination benefits) which do not fall due wholly within twelve month after the end of the period in which the employees render the related service;*
- *Termination benefits, i.e. employee benefits which are payable as a result of either:*
  - *An entity's decision to terminate an employee's employment before the normal retirement date;*
  - *An employee's decision to accept voluntary redundancy in exchange for those benefits.*

11 Source: IAS 19, art. 9.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Within the present context, the post-employment benefits benefits – i.e. those post-employment benefits as meant under the second bullet – are central. IAS 19 distinguishes within this class of employment benefits:[12]

- Retirement benefits, such as pensions;

- Other post-employment benefits, such as post-employment life insurance and post-employment medical care.

It seems worth noting, this second class includes the benefits to (former) employees in case of long-term[13] disablement. This class of post-employment benefits has little explicit attention so far in the System of National Accounts. ESA and SNA seem limiting themselves to old-age pensions when dealing with post-employment benefits. This apparent difference might constitute a source of difference between both the business accounting and reporting standards on the one hand and the System of National Accounts on the other.

Within the category of post-employment benefits plans – applicable to both types of post-employment benefits plans as mentioned in the preceding paragraph – IAS 19 distinguishes two subcategories: defined contribution and defined benefit plans.

IAS 19 defines the defined contribution plans as:[14]

- *The entity's formal or constructive obligation (i.e. the employers' obligation, ghdv) is limited to the amount that it agrees to contribute to the fund. Thus, the amount of the post-employment benefits received by the employee is determined by the amount of contributions paid by an entity (and perhaps also the employee) to a post-employment benefit plan or to an insurance company, together with investment returns arising from the contributions;*

- *In consequence, actuarial risk (that benefits will be less than expected) and invest-ment risk (that assets invested will be insufficient to meet expected benefits) fall on the employee.*

This definition of defined contribution plans implies that further obligations, either formally or informally, do not exist with the employer once the company has paid the annual amount. The benefit is straightforwardly calculated from the agreed and paid amounts and any investment income without a guarantee or whatever on the level of the investment income or the benefit that will be paid at or after retirement (or any other type of termination of employment qualifying for the receipt of post-employment benefits). The risks regarding the level of the investment income, the (change of the) value of investments etc. are fully and solely with the policy-holder/beneficiary.

12 Source: IAS 19, art. 24.
13 Long-term is defined as "a period of one year or more" according to IAS 19 art. 7.
14 Source: IAS 19, art. 25.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

IAS 19 defines the defined benefit plans as:[15]

- *The entity's obligation (i.e. the employers' obligation, ghdv) is to provide the agreed benefits to current and former employees;*

- *Actuarial risk (that benefits will cost more than expected) and investment risk fall, in substance, on the entity. If actuarial or investment experience are worse than expected, the entity's obligation may be increased.*

The main distinguishing factor with the defined contribution plans is that the obligations of the employer haven't come to a final halt after the annual payment has been made. In later years, the employer could be obliged to pay additional amounts into the plan concerning employment services rendered in earlier years.

The breakdown of post-employment benefits plans and the associated definitions according to the IAS are close to those of SNA (see para 7.147 and 7.148) and ESA (see para 4.10) in con-tent. The wording, however, is different. An explicit statement on the identity or on the difference of IAS/IFRS/IPSAS and SNA/ESA seems useful.

An element of potential difference between SNA/ESA and IAS/IFRS/IPSAS is the aspect used as the distinguishing characteristic between defined benefit and defined contribution. SNA/ESA emphasise the fact that the benefit is calculated using a formula with defined benefits. IAS/IFRS/IPSAS on the other hand starts from the idea that the employer is or is not sure having paid the full-required amount concerning any year of service. Whenever the employer – through a formal or an informal obligation – might have to supplement the funds of the pension institution (which supplement corresponds to some or all preceding years of employment) at any time in future, the corresponding scheme is classified as a defined benefit scheme according to IAS/IFRS/IPSAS.[16] If not, these accounting standards classify the scheme as a defined contribution scheme.

The classification of post-employment benefits plans does not vary dependently whether the scheme is a single or a multi-employer plan. Where a multi-employer defined benefit plan has separate accounts by participating employer, the employer shall report its share in the schemes' surplus or deficit under this defined benefit plan. If no separate accounts exist (esp. where all employers are equally responsible to the scheme) the employer could only report the financial consequences of this scheme under its liabilities and expenditure as if it is a defined contribution scheme.[17]

The reporting on state pension plans should be according to the same standards as applicable to multi-employer plans.

15 Source: IAS 19, art. 27.

16 Example. A scheme is promising a pension of €100 a month pro year of employment payable for 15 years at the maximum. After 40 years of service the pension will be €4,000 a month. This scheme should be classified under 'defined benefit' according to the IAS 19. If the scheme would additionally include the condition that the employer, after having paid the required amount concerning the year, no further premiums regarding this year could become due, the scheme should be classified under defined contribution according to the criteria of IAS 19.

17 For more details see IAS 19, art. 29-39.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

If the post-employment benefit plan is insured with a life insurer, the employer shall report this plan as a defined contribution plan – whatever its characteristics as perceived by the (former) employees – unless the employer will have a legal or constructive obligation to either:

- *Pay the employee benefits directly when they fall due;*

- *Pay further amounts if the insurer does not pay all future employee benefits relating to employee service in the current and prior periods.*

If the entity retains such a legal or constructive obligation, the entity shall treat the plan as a defined benefit plan.[18]

From the preceding definitions from the IAS 19 it will be clear that classification and treatment of post-employment benefit plans according to IAS is solely from the employers' point of view. So, an insured defined benefit plan from the (former) employees' point of view (e.g. an average or final pay pension) is classified as a defined contribution plan in case all associated risks are with an insurer. This limitation to a single angle to classify these plans might constitute a source for differences between IAS on the one hand and the national accounts on the other.

Accounting and reporting differs between defined contribution and defined benefit plans according to the IAS 19.

3.1 IAS 19 REPORTING OF DEFINED CONTRIBUTION PLANS[19]

3.1.1 THE BALANCE SHEET AND THE PROFIT AND LOSS ACCOUNT

When an employee has rendered service to an employer during a period, the employer shall recognise the contribution payable to a defined contribution plan in exchange for that service:[20]

- In the balance sheet: as a liability (accrued expense), after deducting any contribution already paid (…);
- In the profit and loss account: as an expense (…).

Defined contribution plans should be funded by nature according to IAS 19 with an external entity; it is a funded autonomous pension scheme according to the national accounts' terminology. So, the contribution is always payable to an external pension institution.

So, according to IAS 19 only contributions and late (or early) payment of these contributions should enter the employers' accounts. The pension entitlements of the (former) employees and the corresponding assets don't enter the employers' accounts.

18 Source: IAS 19, art. 39-42.
19 The following part describes the main features of IAS 19 and the 'preliminary views' from the perspective of the system of national accounts.
20 Source: IAS 19, art. 43-45.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

3.2 IAS 19 REPORTING OF DEFINED BENEFIT PLANS[21]

Defined benefit plans on the other hand might be 'not funded or partially funded' according to IAS 19. In the latter case the contributions might be paid into an external pension institution (an autonomous pension fund) or with the employer (a non-autonomous pension fund) that is responsible for the payment of the benefits. The employer, however, remains liable for supplementing the pension institution's funds in case the institution's assets fall short compared to the scheme's entitlements. This obligation to supplement the pension institution's assets constitutes an important characteristic of this class of benefit plans; the employer has not irrevocably satisfied its obligations on paying the year's contributions into the scheme. In any future year, the (formal or informal) obligation could appear for additional payments relating to earlier years.[22]

The employer should report an entry in its balance sheet and an entry in its profit and loss account to reflect the effect of the defined benefit plan on the employer's profit and the level and composition of its assets and liabilities. These two elements are the subject of the next paragraphs.

IAS 19 limits this reporting requirement of the claim/liability of the employer against the pension institution to the larger corporations, mainly those corporations on the country's stock market. Other corporations might – depending on national legislation – be excluded from this reporting requirement.

3.2.1 THE BALANCE SHEET

The employer's defined benefit liability at the end of the year equals:[23]

The gross defined benefit obligation
Minus
The fair value of the plan's assets.

This net figure could be negative; this means that the employer has a claim against the pension institution (the scheme is overfunded), or positive, a liability of the employer (the scheme is underfunded). The standard does not mention any possible separate treatment of an obligatory overfunding (e.g. as a consequence of the existence of mandatory buffers with the scheme. These mandatory buffers exist only because of supervisory regulations. They don't exist in the accounting standards. As a consequence, the definition and calculation of employer's liability don't take account of these buffers. The buffers remain outside both terms in the definition above (i.e. they aren't part of the gross obligations or of the assets associated with the scheme).

21 More details on the accounting and reporting standards concerning defined benefit plans see IAS 19, art. 46-126.

22 It is well possible that the plan excludes the obligatory supplementing of the plan's funds in cases specified in the plan's conditions.

23 IAS 19 distinguishes two further elements to include in the calculation of the employer's defined benefit obligation. These two elements, i.e. any actuarial gains (less any actuarial losses) and any past service cost not yet recognised, are of a smaller importance within a national account's framework.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

The ESA (see para. 5.100, 5.106) and the SNA (see para. 11.108[24]) acknowledges a claim against the corresponding employer. I.e. the ESA is aware of the possibility of underfunding but not of the opposite possibility. The claim in case of underfunding is classified under 'insurance technical provisions' whereas it is the balance between such a provision (the gross 'provision for pension entitlements') and the available assets with the pension institution.

3.2.2 THE PROFIT AND LOSS ACCOUNT

The employer shall account for an expenditure that equals the net total of:[25]

- Current service cost;
- Interest cost;
- The expected return on any plan assets and on any reimbursement rights;
- Actuarial gains and losses, in accordance with the entity's accounting policy;
- Past service cost.

The current service costs should be calculated using a specific actuarial method, the projected unit credit method. Each year of employment gives rise to an additional unit of benefit entitlement under this method. These are measured separately to build up the final obligation. This calculation should take account of the future increases of the employee's future benefits.[26] Further a series of actuarial assumptions should be made, e.g. on mortality, both during and after employment, the proportion of plan members with dependants eligible for benefits, the discount rate, future salary and benefit levels and the expected rate of return on plan assets.

Interest cost is computed by multiplying the discount rate as determined at the start of the period by the present value of the defined benefit obligation throughout that period, taking account of any material changes in the obligation.

The expected return on plan assets is based on market expectations, at the beginning of the period, for returns over the entire life of the related obligation. The expected return is calculated by multiplying the fair value of the plan's assets during the year (so incorporating changes in this value during the year because of transactions) by the expected rate of return.

4 PRELIMINARY VIEWS ON AMENDMENTS TO IAS 19 EMPLOYEE BENEFIT

As the International Accounting Standards Board (IASB) has received a series of comments on the existing IAS 19, it decided to launch a revision project

24 The SNA acknowledges the possibility that the claim on the employer could become negative because of high investment income (but not mentioning e.g. higher prices of the scheme's assets, actuarial factors or the discount rate). The text seems implying that this negative claim remains classified under assets (with a minus-sign) with the pension institution.

25 Only the most relevant entries as mentioned in IAS 19, art. 61 are listed here.

26 E.g. the case where pension rights are received over the 10 or 40 years of service, more years don't produce a further growth of the post-benefit benefits. These 10 or 40 years should be included in the calculation.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

concerning this standard dedicated to post-employment (benefit) promises.[27] A heavy emphasis is with contribution-based benefit promises, i.e. defining and distinguishing these promises on the one hand and the accounting and reporting of contribution-based benefit promises on the other.

One of the suggested changes deals with the terminology used and the definitions of post-employment benefit promises and its two constituent subcategories.

The "preliminary views on amendments to IAS 19 employee benefits" suggested amending these definitions as follows:

Post-employment benefit promises
Post-employment benefit promises are formal or informal arrangements under which an entity (i.e. the employer, ghdv) is obliged to provide employee benefits (other than termination benefits) payable after the completion of employment.

A defined benefit promise
A defined benefit promise is a post-employment benefit promise that is not a contribution-based promise.

A contribution-based promise
A contribution-based promise is a post-employment benefit promise in which, during the accumulation phase, the benefit can be expressed as:

- The accumulation of actual or notional contributions that for any reporting period would be know at the end of that period, except for the effect of vesting 28 or demographic risk;

- Any promised return on the actual or notional contributions is linked to the return from an asset or a group of assets or an index. A contribution-based promise needs not to include a promised return.

With post-employment benefit plans where the accumulation phase consisting of both a period with a defined benefit promise and a period with a contribution-based promise should, according to the preliminary views of the IASB, be considered as two separate promises.

Also, the IASB in its 'preliminary views' suggest that the classification of post-employment benefit promises should depend solely on the characteristics of these promises during the accumulation phase (the deferment and the pay-out phase are considered as irrelevant for the classification of the promise).

It should be decided whether this classification of pension plans/promises, solely based on the accumulation phase would satisfy the ideas of the system of national accounts.

27 With the "preliminary views on amendments to IAS 19 employee benefit" the IASB has changed its terminology into 'post-employment (benefit) *promises'*, replacing the term 'post-employment *benefits'*. Also, the term '*defined contribution* plans' is replaced by *contribution-based*'.
28 Vested pension promises are those promises that are not conditional on future employment.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

The 'preliminary views' distinguishes three further characteristics that are relevant with the definition of the concept of a 'contribution-based promise':[29]

- *A promised return might exist but (if it exists) only one that is linked to the return from an as-set, group of assets or an index.*

The option of a promised return widens the reach of the 'contribution-based promises' compared to IAS 19 (and consequently reduces the reach of 'defined benefit promises'). Esp. it allows for unfunded promises or for delayed payments.

The linkage with an external rate of return does not imply that the promised return should be equal to this external rate; e.g. the promised return might be ½ this external rate or 100 basis point over/below this external rate.

Therefore, a post-employment benefit promise of 5% of the annual income plus an accumulated return of e.g. 75% of the share total return index satisfies the conditions for a contribution-based promise according to these Preliminary views;

- *The promise might be funded or unfunded 'not funded or partially funded';*
- *The contribution is known at the end of the corresponding period except that this definition is independent of vesting conditions*[30] *and demographic risks.*

The classification of post-employment benefit promises, therefore, would not change dependent on the vesting of these promises and in case of vesting on the relevant conditions.

Neither is the classification dependent on the absence or presence of demographic risks (such as the longevity risk). A fixed conversion rate of the accumulated sum at retirement, therefore, would not withhold the benefit being classified as a contribution-based promise (the longevity risk is with the employer).

According to the 'preliminary views' of the IASB the borderline between contribution-based promises and defined benefit promises has been shifted. This is to say that the class of 'contribution-based promises' has been enlarged whereas the class of 'defined benefit promises' has become smaller.

This change of opinion by the IASB seems decreasing the conformity of the presently proposed SNA/ESA-classification of pension promises with the IASB-classification.

The liability and expense under a contribution-based promise should, according to the 'preliminary views' include as well the contribution as the promised rate of return (if any). Valuation should be at discounted value, discounted against a rate derived from present market conditions. Variations in the liability according to a contribution-based promise would result from changes in the relevant discount rate.

29 Source: 'preliminary views on amendments to IAS 19', art. 5.12 -5.59.

30 Independency of vesting conditions would mean that the classification does not change whether or not the promise is or is not conditional on further prerequisites (such as length of service).

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Valuation of the corresponding liability should take account of various risks that would affect the value of the employees' claim against the employer. The 'preliminary views' mention the risks of variations in the prices of the relevant assets, demographic risks and credit risks (i.e. the risk that the assets of the promise plus the employer's assets are insufficient).

Changes in the liability corresponding to contribution-based promises would follow from the service costs (i.e. the annual contribution) on the one hand and value changes on the other. Within the latter a series of components could be distinguished. No sufficient reasons are recognised by the IASB to report these other element separately according to its 'preliminary views'.

The service costs should be reported in the employer's profit and loss account. Regarding the other fair value changes, the 'preliminary views' do not give final guidelines. Though most probable, the IASB seems preferring the inclusion in the profit and loss account.

5 IPSAS 25 'EMPLOYEE BENEFITS'

IPSAS 25, the dedicated government oriented version of IAS 19, draws heavily on IAS 19. Parallels are numerous, therefore. The main feature they have in common is that both IPSAS 25 and IAS 19 describe the treatment of 'employee benefits' from the employers' perspective. Neither of these accounting standards, therefore, is directly applicable to pension institutions (apart from the accounting for the employment benefits concerning the pension institutions' own employees, see also introduction, art. 1).

As IPSAS 25 is based on IAS 19, it is using the terminology as used in IAS 19, giving no regard to the 'Preliminary views'. The corresponding definitions and classifications are not repeated in this section.

The employer's liability is defined in accordance with IAS 19, as reproduced in para 3.2. As in IAS 19, the defined benefit obligation towards the employees is the present value of the plan's obligations before deducting the plan's assets. However, IPSAS 25 does not reproduce the limitations to this reporting requirement.

The employer's expenditure is defined in accordance with IAS 19. The current service cost with defined benefit obligation should include all future years during which the employee's service will constitute a material higher defined benefit obligation.

One question is whether ESA and SNA in their definition of the asset/liability of the employer against the pension plan and the corresponding expenditure (see para 3.2) would limit this definition to the past period of service only or would include all future years of services with increasing promises. In other words, SNA and ESA should consider whether the projected income over the full career is the starting point or the past period of service only.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

6 INSURANCE ACCOUNTING [31]

The Council Directive on the annual accounts and consolidated accounts of insurance undertakings as amended by Directive 2006/46/EC of the European Parliament and of the Council of 14 June 2006 gives rules for the account of life and non-life insurers.

A first observation is the fact that the word 'pension' only appears once within the accounts themselves (provisions for pensions and similar obligations; item liability e.1). However, it refers to the provision for pensions for the insurer's own employees; this item is not part of the insurance technical provisions of the insurer.

Additionally, the directive obliges that the notes to the accounts shall show separately the funds that the insurer manages on behalf of pension funds (see art. 2.2). Countries may deviate from this article (under further provisions). Additionally, article 10 gives more detailed guidelines concerning the reporting of participation in an investment pool (joint investments).

It follows that contributions, benefits and technical provisions concerning pension plans is combined with the (non-pension insurance related) life insurance premiums, claims and technical provisions.

The directive requires also that the written direct premium should be broken down into individual and group premiums in notes to the accounts. It is questioned whether group insurance is identical to the insurance of pension plans.

Pension insurance with life insurers mainly is in nominal amounts. Where the plan includes the formal employer's obligation for an annual increase of the pension benefits compensating e.g. for the effect of inflation, additional annual premiums/contributions are to be paid by the employer (and the employees). With informal inflation proofing of pensions, additional premium payments are also necessary: here depending on the extent that this informal usage is a constructive obligation.

A core-issue is the measurement of benefits, contributions and the technical provisions. Written premiums/contributions and incurred claims/benefits don't constitute a major problem; the amounts invoiced according to the pension contract should be entered into the accounts, both the business accounts and the national accounts. Consequently, the earned premiums/contributions and paid claims/ benefits are also straightforward. Expectantly, only little difference between the insurer and the employer would exist.

More difficulties are expected to exist regarding the technical provisions. It is reiterated that the employer would report the corresponding expenditure and liability as follows.

31 Council Directive 91/674/EEC of 19 December 1991 on the annual accounts and consolidated accounts of insurance undertakings.

Table I Employer's reporting of pension plan's assets/liabilities and expenditure

	Contribution-based	Defined benefit
Expenditure	Contribution	Change in gross pension entitlements based on projected salaries + interest costs – extern return on assets +/- actuarial gains/losses
Liability	Non-paid contribution	Gross pension entitlements – fair value of assets

Source: Missing.

With pension benefit plans, an insurer would have three entries in its balance sheet:

- Non-paid contribution (see also footnote 32);
- Pension plan assets;
- Gross pension entitlements.

6.1 CONTRIBUTION-BASED PENSION PROMISES

Regarding the non-paid contribution, no difference in accounting exists between the employer and the insurer with contribution-based pension benefit plans. Both the insurer and the employer will account for the corresponding amount. Only, the insurer might be allowed (depending on national legislation) to report this entry under its 'life insurance provision'[32] whereas the employer should report this liability separately according to IAS 19. Also, timing differences might cause a further difference between the employer's reporting and the insurer.

The pension plan assets don't enter the employer's balance sheet by definition in case the plan is with a life insurer. Only, the life insurer does not distinguish these assets separately; they are merged with the other investments of the insurer. Reporting is under 'investments for the benefit of life-assurance policyholders who bear the investment risk'.[33] So, pension plans' assets can't be seen separately from the life insurer's balance sheet.

The pension plan entitlements don't enter the employer's balance sheet by definition in case the plan is with a life insurer. They would enter the employees' balance sheet (in case these balance sheets would exist). Only, the life insurer does not distinguish the corresponding provisions separately; they are merged with the other provisions of the life insurer. Reporting is under 'technical provisions for life-assurance policies where the investment risk is borne by the

32 See 'Council Directive 91/674/EEC of 19 December 1991 on the annual accounts and consolidated accounts of insurance undertakings', art. 25 1st para.

33 See 'Council Directive 91/674/EEC of 19 December 1991 on the annual accounts and consolidated accounts of insurance undertakings', art. 6 asset item D.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

policyholders.[34] So, the pension plans' entitlements can't be seen separately from the life insurer's balance sheet.

Additional problems concerning the provisions and assets can follow from mandatory buffers with the insurer. On the liability side of the insurer's balance sheet these buffers should be reported in a dedicated provision, combined with those concerning other insurance contracts. These buffers, however, by their very nature would affect the insurer's assets also.

6.2 DEFINED BENEFIT PENSION PROMISES

The pension plan assets don't enter the employer's balance sheet by definition in case the plan is with a life insurer. However, the life insurer does not distinguish these assets separately; they are merged with the other investments of the insurer. Reporting is (depending on the type of insurance contract linked, with profit, non-linked) either under 'investments' or under 'investments for the benefit of life-assurance policyholders who bear the investment risk'.[35] So, pension plans' assets can't be seen from the life insurer's balance sheet. They are part of possibly two classes of assets.

The pension plan net entitlements (gross entitlement less the assets' fair value) should enter the employer's balance sheet in case the defined benefit plan is with a life insurer where this life insurer should report the gross entitlements (under the insurer's liabilities) and the corresponding assets (under the insurer's assets) and the employer has kept an ultimate responsibility to honour the claims following from the pension contract.[36] The gross liabilities would also enter the employees' balance sheet (in case these balance sheets would be drawn up). However, the life insurer does not distinguish the corresponding provisions separately; they are merged with the other provisions of the life insurer. Reporting is (depending on the type of insurance contract: linked, with profit, non-linked) under either the 'life-assurance provision' or the 'technical provisions for life-assurance policies where the investment risk is borne by the policyholders'.[37] So, the pension plans' entitlements can't be seen separately from the life insurer's balance sheet.

Regarding the non-paid contribution, no difference in accounting exists with defined benefit pension benefit plans. Both the insurer and the employer will account for the corresponding amount. The employer, however, won't report this entry separately in case the employer has retained an ultimate responsibility to honour the pension contract's entitlements. They will be merged with the net defined benefit pension entitlements (gross value less the assets' value) in this

34 See 'Council Directive 91/674/EEC of 19 December 1991 on the annual accounts and consolidated accounts of insurance undertakings', art. 6 liability item D.
35 See 'Council Directive 91/674/EEC of 19 December 1991 on the annual accounts and consolidated accounts of insurance undertakings', art. 6 asset item D.
36 This requirement might be limited to the country's larger corporations, often those quoted on the country's stock market.
37 See 'Council Directive 91/674/EEC of 19 December 1991 on the annual accounts and consolidated accounts of insurance undertakings', art. 6 liability item D.

case. Also, the insurer might be allowed (depending on national legislation) to report this entry under its 'life insurance provision'.[38] On the other hand, the insurer is reporting both the plans' assets and gross pension entitlements separately.

As with contribution-based promises, further complications could come from timing differences between the employer and the insurer.

6.3 PENSION REPORTING WITH INSURERS AND EMPLOYERS: OVERVIEW OF DIFFERENCES

The table below summarises the differences between insurers' accounting and employers' reporting of pension schemes. As both preceding subchapters, this table distinguishes contribution-based and defined benefit promises.

Table 2 Reporting of pension plan's assets/liabilities

	Contribution-based plan		Defined benefit plan	
	Employer	Insurer	Employer	Insurer
Non-paid contribution	Yes (with 3b)	Yes, (with 3a)	Yes (with 3b)	Yes, (with 3a)
Plan's assets	-	Yes [1)]	-	Yes [3)]
Pension entitlements				
Gross value	-	Yes [2)]	-	Yes [4)]
Net value	No (= 0)	-	Yes	-
Mandatory buffers				
Assets	No	-	No	Included
Liabilities	No	-	No	Separate entry
Valuation of entitlements				
Past carrier only	No	No	No	Yes
Past and future carrier	No	No	Yes	No

1) Part of 'investments for the benefit of life-assurance policyholders who bear the investment risk'.
2) Part of 'technical provisions for life-assurance where the investment risk is borne by the policyholders', possibly including the non-paid contribution.
3) Part of 'investments' and/or 'investments for the benefit of life-assurance policyholders who bear the investment risk'.
4) Part of the 'life insurance provision' and/or the 'technical provisions for life assurance where the investment risk is borne by the policyholders', possibly including the non-paid contribution.

38 See 'Council Directive 91/674/EEC of 19 December 1991 on the annual accounts and consolidated accounts of insurance undertakings', art. 25 1st para. The text of the directive seems to imply that reporting of non-paid premiums/contributions under the life insurance provision should not depend on the type of policy (linked, with profit, non-linked).

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

So, it is rather complicated to link employers' data on the value of the pension entitlements with those of life insurers even in cases where the relevant employers are identifiable uniquely. The corresponding figures with the insurers and the employers (nearly) always are part of a larger entry in their balance sheet. Less difficult is the interrelation concerning the premiums/contributions.

A further question has to be addressed: the valuation of the gross pension entitlements with the insurer. Two observations can be made:

- The insurer has obligations according to the pension promise up to date only; the insurer has no obligations that incorporate future years of service and future increases of salaries.
- The insurer will try to have assets in the contract that at least equal the amount of obligations under the pension contract.[39]

The net obligations of the insurer regarding the pension contract, therefore, will approximately be zero. The insurer's net obligations therefore deviate from the employer's obligations that incorporate also future years of employment with the company.

These valuation differences create an imbalance in the system:

- The employer reports liabilities equal to the net amount of the gross entitlements concerning past and future years of the employees' career with the company less the value of the insurance contract;
- The employer would disregard safety provisions (buffers) with the insurer (an obligatory surplus of the assets over the obligations under the pension contract); whether the employer should account for deficits with the insurer (assets are less than the pension entitlements) depends on the nature of the contract (who is ultimately responsible for the payment of benefits?);
- The insurer reports liabilities equal to the amount of the gross entitlements over the past years of the employees' career with the company;
- The employees have a claim on the insurer equal to the value of the gross entitlements over the past years of the employees' career with the company.

If we would agree on the valuations as described in the preceding points, it is the employer's valuation of the pension entitlements that causes the imbalance in the system.

39 For simplicity reasons, this does not take account of the insurer's obligation for an actuarially based safety margin. A difference between the pension entitlement and the assets might come from the system of financing the contract. A simple example from the field of life insurance might illustrate this. This example deals with a simple risk insurance annexed with a loan. Such a contract will have a constant premium (in most cases) whereas the risk of death of the insured increases over the maturity of the contract (due to the increasing age of the insured). The insurer will, therefore, set aside a (small) technical provision to be built during the first half of the contract and to be used during the second half to accommodate for this increasing risk.

7 PENSION FUNDS' ACCOUNTING

This part of the paper deals with dedicated external pension institutions not being a life insurer. A major group of these institutions concerns the pension funds, a separate institutional unit that insurers the pension promises concerning the employees of a single employer or a group of employers, quite often employers in the same branch of industry. Legislation on pension funds is largely national legislation. Therefore, legislation – including accounting – might differ between the European countries.

The main difference between a pension fund and a life insurer is that the first is dedicated to a single employer or a single group of employers. This implies that the entries with a pension fund concern pension insurance only. No combination of pension with other classes of (life) insurance occurs. Apart from these elements, the characteristics are largely identical: esp. both expectantly operate on an actuarial basis in offering coverage for pension risks. Also, both life insurers and pension funds operate on a funded basis.

An apparent difference could be the insurance of inflation proofing. With pension funds this was rather common (at least in The Netherlands) whilst insurers normally insure nominal obligations only. With both classes of institutions an increase of benefits because of inflation, however, is only feasible with an additional premium/contribution. So, difference is limited in this respect.

The pension fund's accounts will show premiums/contributions earned, claims/ benefits incurred, the technical provisions for pensions and the associated assets. These entries would be reflected in the employer's (and employees') accounts. The main cause for differences concerns valuation differences, which will mainly relate to the pension entitlements. The pension fund will report the amount of the gross entitlements over the past years of the employees' careers with the company in case of defined benefit pension promises. Future years of the employees' ca-reers with the company will not be taken on board. With contribution-based promises the pension entitlement would equal the funds pension related assets, which would also be equal to the employer's obligation.

8 NON-AUTONOMOUS PENSION SCHEMES

With co-called non-autonomous pension schemes, the employer operates as the pension institution, either on a funded or a non-funded basis. This type of pension institution is not allowed in all European countries, mainly from the perspective of safeguarding the pension entitlements of the employees, esp. in case the employer goes bankrupt. Compensation for this aspect of risk could be found in an obligatory insurance with a non-life insurer. With non-pension post employment benefits legislation on the structure might differ or even be absent. So, a separate fond might be mandatory in the field of pension benefits whereas with non-pension benefits (such as health plans, disablement plans and sick leave plans) non-autonomous schemes could exist.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

A non-autonomous pension scheme won't show premiums/contributions received from the corporation's employer. These are consolidated within the corporation's accounts. They will only show claims/benefits to the former employees (and their surviving relatives), the pension enti-tlements and the associated assets (if the scheme is funded).

Here the pension entitlements will incorporate the total amount of the employees' entitlements over the past and future years of the employees' careers with the company (in accordance with IAS 19) that would – with a funded scheme – expectantly be equal to the scheme's assets.

CONCEPTS OF MODELLING PENSION ENTITLEMENTS – THE FREIBURG MODEL

BY MATTHIAS HEIDLER, CHRISTOPH MÜLLER AND OLAF WEDDIGE[1]

1 INTRODUCTION

Demographic developments present a major future risk for the public pension systems of most developed countries. Continuously increasing life expectancy and large age groups of the so-called baby-boomer generation in combination with low fertility rates since the mid-1970s will cause considerable enhancements of the old-age dependency ratio which means that public pension systems organized on a pay-as-you-go (PAYG) principle will be forced to either raise contribution rates or taxes, or shorten future replacement rates. This trend raises some important issues in the context of projecting future pension payments. One of these issues refers to the question of measuring the public pension entitlements of private households until today. From a fiscal perspective, these entitlements are equal to the accrued-to-date liabilities (ADL) of a public pension system.

In this paper we will present ADL for public pension schemes of 19 EU countries. These measurements become increasingly important in the context of the recent update of the 1993 System of National Accounts (SNA93). According to this new legislation – approved by the UN Statistical Commission in February/ March 2007 – (implicit) pension liabilities of social security pension funds have to be recorded in a supplementary table of the National Accounts.[2]

We will proceed as follows: In chapter 2, we provide a basic description of the so-called Freiburg model which has been developed by the Research Center for Generational contracts (RCG) at the Freiburg University in order to estimate the ADL of a pension scheme. Chapter 3 describes the data necessary for the application of the Freiburg model and introduces the basic assumptions. In chapter 4 we present the results of our calculations for 19 EU countries. Chapter 5 contains some limitations and possible extensions of the Freiburg model. The paper finishes with a summary of our findings and a short outlook for future research.

1 Freiburg University.

2 Within the EU, it is also planned to produce a specific section on pensions in the revised 1995 European System of National and Regional Accounts (ESA95) which shall follow the updated SNA93. For a description of the recent steps taken to reform the SNA93 see Mink (2007). For a short portrayal of the reasons to change the SNA93 see Mink and Rother (2007) or Semeraro (2007).

2 THE BASICS OF THE FREIBURG MODEL[3]

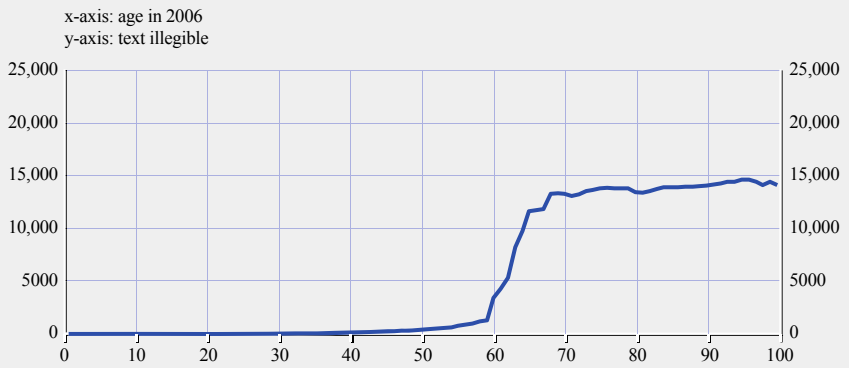
The starting point for the Freiburg model is the method of generational accounting.[4] For this project, the method is applied for public pension schemes[5] in isolation and for the group of existing retirees and current contributors (future retirees) only.[6] The core presumption is a projection of per capita future pension benefits based on today's existing retirees' benefits. We outline below the entire calculation procedure in five steps.

Step 1: Age-sex-specific projections of base year's population need to be calculated. The demographic model used to generate these projections is based on a discrete and deterministic formulation of the cohort component method.[7]

Step 2: The projection of these pension benefits is the centre piece of the calculations since we develop the accrued-to-date claims by modification

3 In this paper we will introduce the Freiburg model in a rather short and non-technical way. For an extensive technical description of the Freiburg model see Heidler et al. (2009). This method was developed by Auerbach et al. (1991, 1992 and 1994). See Raffelhüschen (1999) and Bonin (2001) for a detailed depiction of theory and application as well as limitations of the method of generational accounting.

4 This method was developed by Auerbach et al. (1991, 1992 and 1994). See Raffelhüschen (1999) and Bonin (2001) for a detailed depiction of theory and application as well as limitations of the method of generational accounting.



5 The terms "public pension scheme", "government pension scheme" and "pension scheme in general government" are used as synonyms. However, we differentiate between two different types of schemes. The government employer pension scheme indicates a pension scheme for civil servants, whereas a social security pension scheme describes a general pension scheme. For a discussion of the definition of government pension schemes see Eurostat/ECB Task Force (2008).

6 For a close look on the application of generational accounting to public pension schemes see Ehrentraut (2006) and Heidler (2009) who employed the concept of open-system net liabilities to investigate the sustainability of the German statutory pension scheme.

7 For a detailed description of the demographic model applied see Bonin (2001).

Chart 1 Rescaled profile of average existing retirees' benefits in 2006

(social security Germany; male; in Euro)

Source: Own calculations.

of the existing retirees' benefits. First of all, the benefits are calculated by distributing the aggregated amount of today's pension expenditures to the different cohorts in retirement age. By this procedure we create an age-sex-specific benefits' cross-section profile generated from the budget and micro data of the observed country. For the sake of clarity, in Chart 1 we show the male profile for the German social security pension scheme as an example.

Step 3: The age-sex-specific pension profile for future retirees is calculated by manipulating the base year existing retirees' benefits. An average individual born receives a future benefit in a certain year which is composed of the pension payment one year earlier corrected by the growth rate plus the pensions paid to new retirees in this year. Thus, the age-sex-specific benefit profile for future retirees builds up step by step.

Step 4: Now, in order to meet ADL, only the part of the future pension benefits (of current workers) has to be considered which is earned until the base year. Chart 2 shows how this procedure changes the future retirees profile. Once again, the German social security pension scheme is employed as an example.

Chart 2 Accrued-to-date amount of average future retirees' pension benefits profile from 2006 to 2055

(social security Germany; male; in euro)

Source: Own calculations.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Step 5: Finally, the ADL of the pension scheme are calculated by discounting and summing up the above projected pension benefits over the cohorts living in the base year.

3 DATA AND ASSUMPTIONS

When calculating the ADL of a pension scheme, a comprehensive data set and a number of assumptions are needed. This section aims to introduce both the data (3.1) and the assumptions (3.2) to deploy the Freiburg model.

3.1 NECESSARY DATA

In general, four types of data are needed for the application of the Freiburg model. These types are given by population data, age-sex-specific pension benefits, aggregated pension expenditures for a certain base year and general characteristics of the pension scheme to be examined.

Eurostat provides population projections reaching until 2060. Due to the fact that our calculations reach as much as 100 years into the future, it is necessary to conduct our own projections which prolong official forecasts. However, our projections are based on the baseyear populations and assumptions from Eurostat.

Data regarding age-sex-specific pension benefits is normally taken from micro-data surveys such as the Survey on Household Income and Wealth (SHIW) in Italy or the Socio-Economic Panel Study (SOEP) from the DIW (German Institute for Economic Research) in Berlin, Germany. However, in many cases the administration body of the pension scheme provides age-sex-specific data regarding the recipience of pension payments. As this data encompasses the full category of persons in question instead of a (representative) sample, it is used preferably. In the case of our calculations,[8] age-sex-specific pension benefits were supplied by national central banks or national statistical bodies. Furthermore, data regarding pension expenditures in the base year is generally taken from national accounts' statistics.

The design of a pension scheme represents a crucial point when calculating its ADL. This involves issues like the classification of a pension scheme (DB, NDC, hybrid system), the consideration of past contributions, the indexation of existing pensions or regulations regarding early and late retirement. The sources of these pieces of information are manifold; both international pension surveys[9] and country-specific pension literature contain comprehensive descriptions of the constructions of the various pension schemes. Furthermore, experience shows that the support of national experts is a vital source, too.

8 See Müller et al. (2009).
9 See for example European Commission (2007), MISSOC (2009) or OECD (2007).

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

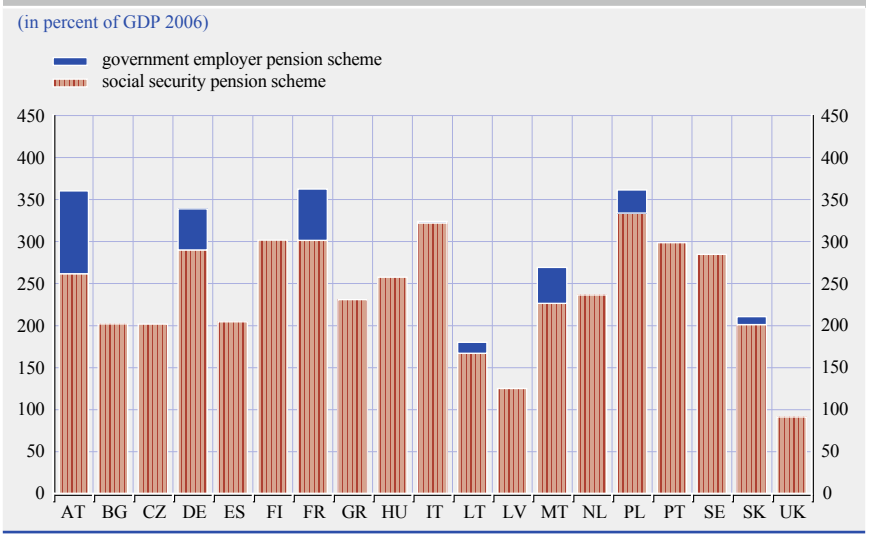
3.2 GENERAL ASSUMPTIONS

As stated above, a whole set of assumptions has to be taken when computing pension liabilities. The possibly strongest assumption states that fiscal policy will not change over time. In other words, the design of the pension scheme to be examined will stay indefinitely constant at the status quo of the base year.

The projection of future age-specific pension benefits demands an assumption regarding the annual rate of wage growth. Since any long-term forecast of future growth must remain arbitrary, we do not make use of sophisticated forecasts. Instead, a supposedly constant rate of wage growth is applied in all future periods. The growth rate is set to approximate the average long-term rate of productivity growth observed in the past. We do not design specific growth patterns for the individual EU member states but rather employ a growth rate of 1.5 per cent per annum in real terms. However, this procedure is open for discussions, and by using varying wage growth paths for different countries one might be able to show the impacts of diverging economic developments on the pension liabilities of the different countries in a more adequate way.

Similar to the growth rate parameter, forecasts regarding the prospective interest rate development are uncertain. Therefore, irrespective of national peculiarities we apply a single uniform discount rate to take all pensions back to the base year. A reasonable range of interest rate assumptions is determined by the fact that public expenditures are significantly more uncertain than non-risky long-term government bonds on the one hand, but not as volatile as the return on risky assets on the other hand. We generally opt for the lower bounds of the discount rate. Thus, we normally choose a standard real discount rate of three per cent per annum, which reflects the ten-year average of Euro area ten-year government bond yields.

At this point it is worth mentioning that the use of a constant discount rate as well as a constant wage growth rate implies a serious simplification. In general, more comprehensive sensitivity analyses could take account for possible variations of these parameters. This also counts for the other key economic parameters (unemployment rates and participation rates respectively), or changes in the behaviour of economic actors.



4 CROSS-COUNTRY COMPARISON OF ADL

In this chapter we will present the results of our calculations.[10] Chart 3 shows the ADL of public pension schemes of 19 EU countries in alphabetical order, expressed in per cent of the corresponding country's GDP.

10 These calculations follow the approach of projected benefit obligations (PBO). For a detailed description of the differences between PBO and accumulated benefit obligations (ABO) see Heidler et al. (2009).

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Chart 3 Cross-country comparison ADL in 2006

Source: Own calculations.

As shown in Chart 3, the largest pension liabilities in per cent of GDP can be found in France (362.2), Poland (361.1) and Austria (359.9), followed by Germany (338.6) and Italy (323.1). It might be a coincidence that all these countries possess a special pension scheme for civil servants but even without these schemes they rank among the highest figures observed. Most of the other countries show pension liabilities in the range of 200 to about 300 per cent of GDP. These are Finland (301.4), Portugal (298.3) and Sweden (284.5) followed by Malta (269.0), Hungary (257.5), the Netherlands (236.2) and Greece (230.7). Slovakia (210.5), Spain (204.2), Bulgaria (201.8) and the Czech Republic (201.4) can be regarded as having a medium level of pension liabilities. The lowest liabilities have been calculated for the United Kingdom (91.2) followed by Latvia (124.8) and Lithuania (179.9).

In a further step we examined the main determining factors for the different results shown above.[11] Table 1 summarizes our findings.

Three points (•••) indicate that the respective factor will considerably increase pension liabilities. One point (•) on the contrary implies the opposite and two points (••) a degree in between. This approach shall be illustrated by an example: Finland shows relatively high (•••) initial pension expenditures as well as a relatively high (•••) increase in the development of elderly people. Furthermore, the Finnish indexation of pensions can be regarded as quite low (•/••) but not very low (•) and it has introduced modest pension reforms (••) in recent years.[12] Overall, Finland features the 6th highest pension liabilities in terms of GDP.

11 For an extensive description of these determining factors see Müller et al. (2009).
12 Since we compare pension liabilities at the end of 2006 only pension reforms legislated up to this point have been considered in Table 1.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Table 1 Main determining factors of pension liabilities in the EU

	Initial level of pension expenditures in % of GDP	Development of elderly persons (60+)	Pension Indexation	Profound (•), Moderate (••), No (•••) recent pension reforms	Ranking of pension liabilities
AT (Austria)	•••	••	•	•	3
BG (Bulgaria)	••	•	••	••	15
CZ (Czech Republic)	••	••	••	•	16
DE (Germany)	•••	••	•••	•/••	4
ES (Spain)	••	••	•	•••	14
FI (Finland)	•••	•••	•/••	••	6
FR (France)	•••	•••	•	••	1
GR (Greece)	••	•/••	•	••	12
HU (Hungary)	••	•	••	••	10
IT (Italy)	•••	••	•	•	5
LT (Lithuania)	•	•	•••	••	17
LV (Latvia)	•	•	•/••	•	18
MT (Malta)	••	•••	•••	•	9
NL (Netherlands)	•	•••	•••	•••	11
PL (Poland)	•••	•••	•/••	•	2
PT (Portugal)	•••	••	•	•/••	7
SE (Sweden)	••	••	•	•	8
SK (Slovakia)	••	•••	••	••	13
UK (United Kingdom)	•	••	•	•/••	19

Hence, it can be stated that the fewer points a country shows in total, the smaller are its pension liabilities in terms of GDP. However, it should be kept in mind in this context that the initial level of pensions apparently is the main determining factor for the level of pension liabilities.

5 LIMITATIONS AND POSSIBLE EXTENSIONS

To understand the outcomes of our model it is essential to grasp the channels which lead to the respective results. In this context it is of interest how the outcomes change if one varies the assumptions taken. Sensitivity analyses which assess the robustness of a model are useful tools for this purpose. They give an indication to which extent the model is driven by the taken assumptions.

Table 2 illustrates the respective sensitivity analysis for the ADL of the German public pension system (base year 2006). Looking at these results a significant limitation of the Freiburg model becomes obvious. Given a small alteration

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Table 2 Sensitivity analysis of the German social security pension scheme (ADL)

(percentages)

Parameters		Amount of ADL (relative deviation to standard scenario)
r	g	
2.0	1.0	9.6
2.0	1.5	21.0
2.0	2.0	34.2
3.0	1.0	-8.5
3.0	**1.5**	**0.0**
3.0	2.0	9.8
4.0	1.0	-22.1
4.0	1.5	-15.6
4.0	2.0	-8.2

Source: Own calculations.

of the assumed interest rate (r) from three to two percent the outcome changes considerably by 21 percent (using the PBO approach). The level of the growth rate (g) also has a considerable impact on the results of the Freiburg model – as shown in Table 2. Since the future is uncertain by nature, this constraint of the model cannot be overcome. Nevertheless, the sensitivity analysis demonstrates once again the importance of choosing appropriate assumptions.

A further limitation to mention is straightforward and counts for every model: the model can only be as accurate as the given input data. This aspect represents a constraint especially for the calculation of pension reforms and of cohort-specific pension levels.[13]

There is also another significant limitation to be mentioned: The introduced model does not take into account future behavioural changes. So far we suppose that future pensioners will take retirement decisions similar to those of their present counterparts.[14] But what happens if future pensioners will change their behaviour and retire significantly later (earlier) than today? The answer to this question depends on the respective pension scheme examined. If the pension increments (decrements) for late (early) retirement can be considered actuarial neutral the behavioural changes should have no impact on our results.[15] However, as Queisser

13 For a detailed description of the limitations and possible extensions of the Freiburg model see Heidler et al. (2009).

14 In addition, in case of pension reforms which lead to an increase of the statutory retirement age we assume that the pension behaviour is unaltered, effective retirement age stays constant and the respective retirees put up with resulting pension decrements. However, an exemption is made when the minimum retirement age is increased within the framework of a pension reform – for example in Austria (with the reforms of 2000 and 2003) or in the UK (with the reform of 2007). In such cases we increase in our calculations also the effective retirement age by the respective years.

15 Actuarial neutrality in the context of pension systems means that the present value of accrued pension benefits does not change due to an earlier or later pension start date. For a detailed description of this concept see Queisser and Whitehouse (2006).

Table 3 Impact of a change in retirement behaviour on ADL (here: German social security pension scheme)

(percentages)

Behavioural change	Amount of ADL (relative deviation to standard scenario)
Postponed retirement by one year	-2.7
Postponed retirement by two years	-5.2

Source: Own calculations.

and Whitehouse (2006) indicate, numerous pension systems in the OECD cannot be considered actuarial neutral. A substantial number of countries does subsidize early retirement and penalize late retirement since pension decrements as well as increments are lower than an actuarial neutral rate. As a consequence, we will overestimate (underestimate) pension liabilities if future pensioners decide to retire later (earlier) than today. In Table 3 we demonstrate the impact of a change in pension behaviour for the case of Germany. As illustrated, a postponement of the retirement by one (two) year(s) lowers the ADL for Germany by 2.7 (5.2) per cent.[16] Consequently, a possible extension of the Freiburg model could take into account predictions of future pension behaviour – similar to Berkel and Börsch-Supan (2004). However, the data basis to forecast pension behaviour within a large cross-country comparison is presently not available.

6 SUMMARY AND OUTLOOK

With the demographic challenges ahead, the calculation of ADL offers a valuable tool to evaluate pension systems under various perspectives. First of all, this approach helps to assess the costs of terminating unfunded public pension schemes. The concept of ADL also represents a useful tool to examine various pension reforms – such as changes in pension indexations or minimum retirement ages – and their impact on pension entitlements. Moreover, measuring ADL can give a further insight when looking on the impact of PAYG pension schemes on national savings. In this context, ADL quantifies the social security wealth which represents a significant determinant on saving rates – as has been pointed out first by Feldstein (1974). With the current revision of the SNA93 and the resulting implementation of ADL in national accounts a further impetus has been given to pay attention to the concept of ADL.

This paper introduces the approach of the Freiburg model to quantify ADL. The presented model has been applied to carry out benchmark calculations of 19 EU member states on behalf of the Eurostat/ECB Contact Group on Pensions. After a short introduction, in chapter 2 we outlined the calculation procedure

16 For the calculation of these figures we assumed that from the year 2010 onwards all future new retirees aged 60 to 67 will postpone their retirement by one (two) year(s). The outcome greatly depends on the country-specific pension regulations – namely the pension increments and decrements – as well as the country-specific life expectancies.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

of the Freiburg model step by step. Chapter 3 gave an overview of the general assumptions and the data supply necessary for the application of the model, while in chapter 4 the main results of our calculations were presented. The following chapter 5 revealed that the Freiburg model entails a large degree of simplification using a limited set of input factors. However, this leads to a major strength of the model: It fits very well when only a limited amount of data can be provided – as it is mostly the case when undertaking large country comparisons.

Several interesting issues could be raised for future research in connection with the Freiburg model. One concerns the field of application. So far the concept of ADL has only been carried out for calculating entitlements of pension systems. But one may argue that entitlements also exist in other fields of unfunded social security systems as for example long term care insurance. Therefore, future research could extend the concept of ADL to other social security systems which are based on a PAYG principle.

IMPLICIT LIABILITIES AND SUSTAINABILITY OF PUBLIC FINANCES IN THE EUROPEAN UNION

BY MICHEL ENGLERT[1]

1 INTRODUCTION

At the end of April 2009, the Economic Policy Committee and the European Commission published a bulky report presenting new long-term projections for public spending in the field of social security [5]. This report is the result of several years of work accomplished by the "Working Group on Ageing" (AWG) of the Economic Policy Committee. This group, chaired by Mr Henri Bogaert, Head of the (Belgian) Federal Planning Bureau, is made up of experts in budgetary forecasts who represent various public offices in the 27 EU Member States, as well as of several international organisations, among which the European Commission, which is in charge of the AWG's technical secretariat.

This paper is of particular interest in the context of the discussions on the implicit liabilities of pensions, as it focuses on a forecast of future pension expenditure in each of the 27 EU Member States, which is then used as a basis to evaluate the sustainability of public finances in each of those States. This evaluation rests on a concept of implicit liabilities which is very different from the one used in the work currently carried out in order to introduce the implicit liabilities of pensions into the national accounts. Both this concept of implicit liabilities and AWG's forecasting methods are an integral part of the budgetary surveillance mechanisms that have been installed at the EU level.

Section 2, which deals with the institutional framework, covers the provisions that have been made in the light of the budgetary surveillance mechanisms and which have led to the creation of the AWG and to the definition of its missions. Section 3 aims at defining both the budgetary cost of ageing and the concept of budgetary sustainability, on the basis of which the AWG's forecasts are converted into operational indicators aimed at evaluating budgetary sustainability. Sections 4 and 5 present a brief summary of the methods and results of the last forecasts, firstly as a whole, and then, more specifically those which are relevant to pensions.

2 INSTITUTIONAL FRAMEWORK

The budgetary surveillance mechanism that was set up at the EU level is an original response to a fundamental inconsistency which is built in the design of responsibilities as regards economic policy within the European Union. This inconsistency is the result of the compromise that lies at the foundation of

1 Bureau Fédéral du Plan (Federal Planning Bureau in Belgium) - Member of the Working Group on Ageing (delegate of Belgium); Federal Planning Bureau Avenue des Arts 47-49 B1000 BRUSSELS – tel. +32 2 507 73 42 – email me@plan.be.

the Economic and Monetary Union, i.e. the coexistence of a monetary policy managed at a supranational level (for the countries which take part in the single currency, i.e. currently 16 out of the 27 Member States) alongside with budgetary policies which have remained a national competence.

The founding texts of this mechanism are article 104c of the Maastricht Treaty (1992) and the Protocol on the excessive deficit procedure, which sets the reference values for budgetary deficit (3% of GDP) and public debt (60% of GDP). These threshold values act as triggers for starting the excessive deficit procedure. However, the actual development of surveillance mechanisms dates from 1997, with the Stability and Growth Pact, which consists of two Council regulations [7] [8]. The first one, which acts as the "preventive arm" of this mechanism [7], sets an obligation for the Member States to draw up yearly stability and convergence programmes (SCP) with medium-term objectives (MTO) to reach a budgetary position "close to balance or in surplus (CTBOIS)". The second one acts as the "corrective arm" [8]: it specifies how to recognize, correct and possibly penalize an excessive deficit situation. This second regulation will not be further discussed in this paper, as it is the first of these two regulations, i.e. the "preventive arm", which lies at the basis of the AWG and of its missions.

The 1997 version of the "preventive arm" in the Stability and Growth Pact basically aims at helping the Member States to progress towards (at least) budgetary balance in order to prevent them from slipping over the fateful deficit threshold (3% of GDP), without having to act against the variations of the budgetary balance due to cyclical fluctuations, while promoting a budgetary position that progressively reduces the load of public debt. No reference was made to the possible future impact of ageing on the deficit and on public debt. However, as soon as the evaluation procedure of the EU Member States' public finances (on the basis of their stability and growth programmes) was set up, the Economic Policy Committee established the Working Group on Ageing Populations (AWG) in order to examine the economic and budgetary consequences of ageing. On the basis of the first age-related public expenditure projections prepared by the AWG in 2001 and 2003, the Commission enriched its evaluation of the budgetary position of the Member States by using these projections in order to assess the long-term sustainability of their public finances.

The 2005 reform of the Stability Pact refined and reinforced its preventive arm via a new version of the former regulation [9][2] by introducing the principle of "differentiated MTO for individual Member States, taking into account the diversity of economic and budgetary positions and developments as well as of fiscal risk to the sustainability of public finances, also in face of prospective demographic changes" (cf. [9], [11]).

A so-called "Code of Conduct" [11] was established in 2005 in order to precisely specify all rules and procedures for both the corrective and the preventive arm of the Stability and Growth Pact. Among other things, this "Code of Conduct" specifies the format and content of the Stability and Convergence Programmes,

2 The "corrective arm" was also revised at the same time [10].

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

which must include the long-term projections carried out by the Working Group on Ageing. The Code of Conduct also states that these projections cover five age-related public expenditure items, namely: pensions, health care, long-term care, education and unemployment benefits. It refers to these projections by stating that the so-called "implicit liabilities" [11] ought to be taken into account in order to set the Member States' medium-term budgetary objectives (MTO).

The current procedure through which these projections are taken into account in the Commission's evaluation of the long-term budgetary sustainability of the Member States is indeed based on this concept of implicit liabilities, which is presented in the next section.

3 IMPLICIT DEBT AND SUSTAINABILITY

The intertemporal budgetary constraint dictates the sustainability condition: the discounted value of the total future primary surpluses should be (at least) equal to the public debt at the starting point (see Box 1).

Now what is happening if the sustainability condition is not satisfied? In that case, it is possible to assess the permanent (and constant) budgetary adjustment required to restore sustainability – a budgetary consolidation effort evenly spread over time. This required adjustment is called the "sustainability gap" (see Box 2).

Of course, ageing implies that the future variations of the primary balance are negative, reflecting the increase in age-related public expenditures if all other public finance items are assumed to be constant in GDP terms. This increase – or budgetary cost of ageing – tends to inflate over time.

Box 1 The sustainability condition

current public debt D_{t_0} + discounted value of all future expenditure = discounted value of all future revenues.

If $revenue_t$ – $primary\ expenditure_t$ = $primary\ balance\ PB_t$

the sustainability condition is

$$D_{t_0} - \sum_{t=t_0+1}^{\infty} \frac{PB_t}{(1+r)^{t-t_0}} = 0 \qquad (i)$$

where all variables are expressed in GDP terms (D, PB in % of GDP; r is the differential between the nominal interest rate i and the nominal GDP growth rate y, *i.e.* $1+r = (1+i)/(1+y)$)

Source: [6], [13].

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Box 2 The sustainability gap

If $\sum_{t=t_0+1}^{\infty} \frac{PB_t}{(1+r)^{t-t_0}}$ is too small to satisfy equation (*i*) – *see box* 1 – to ensure sustainability, by how much (=S_2) should PB_t be permanently increased to restore sustainability?

$$D_{t_0} = \sum_{t=t_0+1}^{\infty} \frac{PB_t + S_2}{(1+r)^{t-t_0}} \qquad (note: \sum_{t=t_0+1}^{\infty} \frac{1}{(1+r)^{t-t_0}} = \frac{1}{r})$$

$$\longrightarrow S_2 = r D_{t_0} - r \sum_{t=t_0+1}^{\infty} \frac{PB_t}{(1+r)^{t+t_0}}$$

$$\longrightarrow S_2 = r D_{t_0} - PB_{t_0} - r \sum_{t=t_0+1}^{\infty} \frac{\Delta PB_t}{(1+r)^{t-t_0}} \quad \text{where } \Delta PB_t = PB_t - PB_{t_0}$$

S_2 is the sustainability gap.

Source: [2], [6], [13].

In this approach, the total discounted value of the future expected increase in age-related expenditures is referred as "implicit liabilities" (see Box 3).

The development presented in Box 2 clearly shows two components of the 'sustainability gap'. The first one represents the required permanent adjustment of the primary surplus, leaving aside the future expected variations in the primary surplus. The second one is the additional permanent adjustment that is required due to the expected deterioration of the primary surplus resulting from the budgetary cost of ageing.

Box 3 Budgetary cost of ageing and implicit liabilities

ΔPB_t is generally negative, reflecting the decrease in the primary balance due to the future increase of age-related expenditure.

– ΔPB_t is the budgetary cost of ageing, assessed on the basis of the impact of ageing on social expenditure (pensions (+) + health care (+) + long-term care (+) + education (-) + unemployment (-)) – assuming constant tax pressure and constant non-age related primary expenditure in GDP terms.

$$-\sum_{t=t_0+1}^{\infty} \frac{\Delta PB_t}{(1+r)^{t-t_0}}$$

is the total discounted value of the contribution of the future expected increase in social expenditure to future deficits, referred to as "implicit liabilities" in EC/ECOFIN Council documents.

Source: [2], [6], [13].

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

It is worth underlining the main specificities of the above-mentioned implicit liabilities.

Firstly, the traditional budgetary principles (unity, universality) apply here to public finances as a whole. In particular, financing public pensions is dealt here in the context of financing total public expenditures using total public revenues, without taking into account the specific financing sources of public pension schemes. This approach either corresponds to a situation where pensions are indeed directly or indirectly financed by the general government budget or translates the fact that even when financing public pension schemes is theoretically clearly specific and independent, the general budget will be, in practice, the financing source in the last resort.

Secondly, the level of economic activity plays a major role for implicit liabilities as indicator for the 'carrying capacity' of an economy to finance public expenditures, in particular social expenditures. In the approach developed here (Boxes 1, 2 and 3), all the aggregates are expressed as a percentage of GDP.

Thirdly and as a consequence, implicit liabilities and the sustainability gap will be influenced by the choice of the scenario concerning future economic growth, population outlooks and social policy. The economic growth will impact the financial weight of future age-related public expenditures; furthermore these expenditures will themselves be influenced by the evolution of employment and incomes as well as by population outlooks (and by the population health which is an important determining factor of acute health care and long-term care expenditures).

Fourthly, the implicit liabilities are estimated without making a distinction between accrued rights at the starting point and future rights. As far as pensions are concerned, such a distinction is not useful to assess the sustainability of public finances. Moreover, it is sometimes difficult to make such a distinction in certain 'Pay As You Go' (PAYG) public defined-benefit (DB) pension schemes where even the 'accrued rights' depend partly on parameters which are influenced by the profile of the whole career or by the situation when retiring.

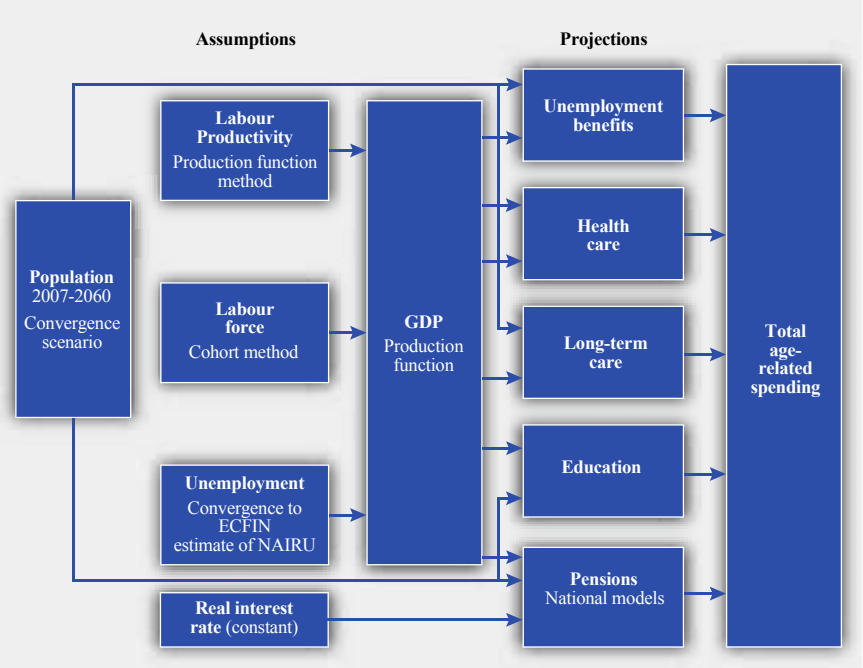
The assumptions and methodologies at the basis of projections of age-related public expenditures therefore play an important role in the calculation of parameters of budgetary sustainability. The present article is not aimed at presenting those assumptions and methodologies in detail. Section 4 describes them briefly. For any further detail, we refer to the related publications (cf. [5], [12]).

Section 4 also presents briefly the results of the last projections of AWG (2009) and hints at the various scenarios selected as sensitivity tests.

4 PROJECTING AGE-RELATED EXPENDITURES

The common methodological framework and assumptions are aimed at producing comparable projections across the 27 Member States (2007-2060) [5]. The preparation phase included a literature survey, the consultation of invited experts, notably via workshops and, of course, the contribution of AWG members

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.



(27 Member States + Norway + ECB + OECD + IMF + Chairman Henri Bogaert from the Belgian Federal Planning Bureau). The demographic projections were prepared by EUROSTAT.

The main features of the demographic and macroeconomic projections can be very roughly summarized as follows [5]:

- a convergence approach for the demographic projection;
- a cohort approach for the participation rates used in the labour force projection;
- an assumption of unchanged structural unemployment rates combined with an assumed fall to the EU15 average for those with initially high structural unemployment rates;
- a production function approach for the potential GDP projection; an assumption of a constant real interest rate.

In practice, calculations are performed by the EC for four out of five age-related expenditure items; for pensions, national models are used (see Section 5). The idea is to capture the detailed specific national pension legislation and retirement behaviours, in given and agreed demographic and macroeconomic scenarios (see Chart 1).

Chart 1 A common methodological framework

Source: [5].

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

The baseline is a no-policy change scenario and therefore should not be interpreted as a forecast, in particular when projected evolutions are clearly unsustainable and will necessary lead to changes in policy, in other words to changes in the legislation. In addition, 26 alternative scenarios have been simulated, from which 6 are policy variants. All the others are sensitivity tests concerning assumptions surrounded by huge uncertainties (see Table 1).

Table 1 Sensitivity tests and policy scenarios

	Demographic variants	Macroeconomic variants	Health care variants
Testing macroeconomic uncertainty (6 (7) variants) and uncertainty of demographic drivers (7 variants)	- higher life expectancy - zero migration	Higher - employment rate - participation rate older workers - labour productivity 3 crisis scenarios (higher interest rate)	3 "health status" scenarios: - pure demographic - constant health - death-related costs
Testing uncertainty of non-demographic drivers for health and long-term care: 6 variants			- income elasticity = 1 - EU 12 cost convergence - labour cost
Testing policy changes: 6 variants			

Table 1 Sensitivity tests and policy scenarios (cont'd)

	Long-term care variants	Education variants
Testing macroeconomic uncertainty (6 (7) variants) and uncertainty of demographic drivers (7 variants)	2 "disability status" scenarios: - pure demographic - constant disability	
Testing uncertainty of non-demographic drivers for health and long-term care: 6 variants	3 cost scenarios: - in line with GDP per capita - fast/slow growth in unit cost	
Testing policy changes: 6 variants	- 3 scenarios with shift from informal to formal care	- higher teacher/students ratio - higher compensation - "Lisbon target" for tertiary level

Source: on the basis of [5].

An example of the baseline results of the 2009 AWG projections is presented in Chart 2 for the EU as a whole and in Table 2 for selected Member States.

The sensitivity tests show that the results are relatively robust. The alternative scenarios give more or less important differences when considering the items separately, but the differences – although significant – are not that impressive compared to the total budgetary cost of ageing in the baseline, except for the zero

migration scenario, and to a much lesser extent for the "high life expectancy" and the "crisis" scenarios (see Table 3).

It should be noted that applying the basic principle of a "no-policy change scenario" is not always straightforward:

– policy changes are well taken into account when they are already enacted; nevertheless, this sometimes raises interpretation problems
– does "no policy change" mean "constant legislation" or are recurrent measures taken into account?

There are obvious discrepancies in the treatment of pension legislation and legislation in the other fields of social protection as far as, for age-related public expenditure other than pensions, the EC relies on standard approaches for the 27 Member States, which makes it impossible to take national legislation and policies into account.

In fact, the focus of the exercise is specifically on pension expenditures, thus on pension policy and pension reforms, but in the context of the possible impact of ageing, on public finances as a whole.

Table 3 Sensitivity tests and policy change scenarios

(2009 AWG projection)

	Change 2007-60, p.p. of GDP, difference from baseline (EU27)			
Macroeconomic variants	Higher productivity (growth rate + 0.25 p.p.)	Higher employment (rate + 1 p.p.)	Higher participation employment older workers (rate + 5 p.p.)	Crisis scenario: permanent shock (maximum impact)
- total cost of ageing	-0.5	-0.4	-0.3	+1.6
- pensions	-0.4	-0.1	-0.1	+1.1
Demographic variants	Higher life expectancy (2060: + 1y.)	Zero migrations	Health status variants	Disability status variants
- total cost of ageing	+1.1	+3.1	-0.4 to +0.6	-0.1 to +0.1

5 PROJECTING PENSION EXPENDITURES

Public pensions in the works carried out by the AWG have a very broad definition[5], including different forms of retirement usually not referred as "pensions" in national administrative practice. In the European System of Accounts (ESA95) and in national accounting, the corresponding schemes belong to the general government sector, namely:
– old-age benefits;
– early retirement benefits;
– disability benefits;
– survivor's benefits (by social security and by other public bodies).

They include earning-related, flat-rate, means-tested pensions. Gross pensions (no deduction of tax and social security contributions on pensions) are considered.

Thus the above-mentioned expenditure items impact the budgetary cost of ageing and the sustainability assessment.

The benefits which are not included in the AWG definition of public pensions are:
– the statutory funded part of old-age pension schemes attached to NDC schemes;
– the private pensions benefiting from a government guarantee (contingent liability);

Member States were free to provide, on a voluntary basis, projections concerning:
– net pensions and tax/social security contributions on public, occupational and private pensions;
– occupational pensions;
– private pensions.

The pension models are quite diverse in nature. All these models have been peer-reviewed in the AWG and documented. Nevertheless, no very clear general picture emerged from this peer-review process, given the heterogeneity of the numerous models: each of the 27 Member States uses its own model and sometimes different models for different pension schemes. Nevertheless, their common feature is their ability to simulate pension expenditures until 2060, within a given demographic and economic context. Most if not all of them are deterministic models (not stochastic). Large differences exist in the level of disaggregation. Some models work with highly aggregated pensioners' categories characterized by one average benefit (in general referred to as semi-aggregated models), whereas others are microsimulation models using large, sometimes very large samples of individual data (see reference [3] for a detailed overview of these models).

The cornerstone of the peer review of the pension projections is the breakdown of the results into four driving forces, namely (see Box 4 and Table 4):
– the demographic factor (ageing);
– the percentage of pensioners in the age group 65 and over;
– the employment rate;
– the benefit ratio.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Source: [5].

Not surprisingly, it appears from Table 4 that the main driver of the increase in the public pension expenditures over the projection period is the demographic factor (summarized by the contribution of the dependency ratio to this increase). The differences across Member States have to do with the differences in the ageing challenge and in the possible – but for most Member States limited – lightening of the budgetary impact of ageing thanks to other factors.

Indeed, the coverage ratio has an important impact in countries where pension reforms tend to increase the effective retirement age significantly. The benefit ratio can also contribute to reducing the budgetary cost of ageing in reforming countries where public pension benefits are, on average, set to decrease (compared to the general living standard) either through parametric reforms affecting the pension formula or the privatization of large components of pension schemes. In both cases, the long-term social sustainability of these developments remains an open question.

DISCUSSION ON SESSION II

BY MARSHALL B. REINSDORF[1]

1 COMMENTS ON "ACCOUNTING STANDARDS FOR PENSION SCHEMES" BY GABE DE VRIES

This paper concerns the actual and proposed accounting standards for pension obligations, which are governed by the international accounting standards board's (IASB) IAS19 in the case of private sector entities and by the international public sector accounting standards board's (IPSASB) ISAS25 in the case of government entities. These standards adopt the point of view of the employer. They distinguish between defined contribution (DC) plans, in which future events cannot affect the employer's obligation arising from employee's service in a given year, and defined benefit (DB) plans, in which future actuarial experience and future investment returns can affect the employer's obligation arising from employee service in a given year. For defined benefit plans, the accounting standards require publicly traded corporations to include the unfunded pension liability (the difference between the gross liability for future benefits and the plan assets) on their balance sheet and the pension expense on their income statement. The pension expense consists of current service cost, interest on the opening benefit liability less expected returns on plan assets, actuarial gains and losses, and other items. The current service cost should be calculated using the *projected unit credit* method. The government accounting standards for pensions (for their own employees) parallel those for the private sector, but the requirement to use the projected unit credit method is replaced by less-specific requirement to use a method that includes effects of future service in calculating current service cost.

The paper also identifies two data problems involving life insurance companies. One of them is that effects of future service are included in the PBO measure of the pension obligation reported by employers, but excluded from the accrued-to-date benefit liability reported by the life insurers who have been contracted to manage the plan and assume its obligations. (Employers sometimes contract with a life insurer to manage their plan and pay the benefits that are due, or they may purchase annuities from a life insurance company when employees retire.) The other problem is the limited availability of information on defined benefit plans that are managed by life insurance companies. Our experience in the US national accounts confirms this latter point: obtaining information on plans managed by life insurers is a problem for us in measuring DB pensions.

Finally, the paper notes that accounting rules and standards vary among the various classes of the institutions that are part of each country's pension landscape. This creates a difficult task for the national income accountant of transforming the information reported by different entities into a common standard to produce a coherent picture for the country as a whole.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

ADDITIONAL DIFFERENCES FROM MEASURES USED IN NATIONAL ACCOUNTS

The paper discusses a proposal to broaden the definition of "contribution-based plans" in IAS19 that would shift some hybrid plans from the DB category to the DC category. If this proposal is implemented, hybrid plans where the contributions are notional rather than actual will still need to stay in the DB category for national accounts purposes. Notional contributions that do not correspond to actual contributions would have to be shown as imputed contributions in national accounts according the 2008 SNA, but imputed contributions from employers can only be shown for DB plans. Moreover, the principle that in a DC plan the employer's pension expense for service during a time period is known with certainty at the end of the period would, in some cases, be violated if hybrid plans were classified as DC plans. For example, some hybrid plans promise a rate of return on notional contributions that depends on a stock market index. A subsequent rise in the index that is not matched by an actual rise in plan assets would increase the employer's obligation. Finally, if hybrids were classified as DC plans in European national accounts, international comparability would suffer. In the US, hybrid plans with notional contributions are considered to be defined benefit plans in labor and tax law, and the US national accounts classify pension plans as DB plans or DC plans based on their legal status.

The second difference between private pension plan accounting and the accounting scheme that has been recommended for national accounts concerns the definition of employer's current pension expense. In the SNA 2008, the employer's pension expense for a DB plan equals the value of the benefit entitlements accrued through service (which is known as "current service cost" in private pension plan reporting):

The imputed contribution by the employer… must be such that the sum of the employer's actual contribution [and] any contribution by the employee [and] the imputed contribution by the employer is equal to the increase in benefit[s] due to current period employment plus the costs of operating the scheme. (SNA 2008, 7.65)

More items are included in the employer's pension expense in private plan accounting. Besides current service cost, this expense includes: cost of interest on the accrued benefit liability minus the expected return on plan assets, actuarial gains and losses, and past service cost. (Past service cost generally arises when employees receive credit for years of service before plan inception or before they entered the plan, and the resulting costs to the plan are amortized.) Some kinds of plan amendments might also be added to this list.

The 2008 SNA does not fully explain how we should account for these pension expense items. It does, of course, cover the current service cost, and its lack of discussion of actuarial gains and losses, plan amendments and past service costs does not seem to be a problem. Various treatments for actuarial gains and losses and plan amendments are possible depending on the circumstances, so it is reasonable to leave the matter up to the discretion of the individual statistical

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

agencies responsible for preparing the national accounts. Also, past service costs should not arise because lump sum credit for extra years of service granted to employees when they enter the plan should count as current compensation.

Yet how to treat the difference between the interest on the accrued benefit liability and the actual property income earned on plan assets is, however, a question that requires a more complete answer than is provided in the 2008 SNA. Plan participants earn imputed interest income on the value of their previously accrued benefit entitlements. The SNA 2008 shows this imputed interest income as payable by the plan to the participating households and as contributed by the households back to the plan under the heading "household pension contribution supplements" (SNA 2008, 17.156). This is entirely appropriate, but it leaves open the question of how the plan obtains the resources to pay this imputed interest income to the households.

The most logical option for avoiding an imbalance between the plan's sources and uses of income would be to record the employer's imputed contributions as amounts that the employer borrows from the pension plan and to let imputed interest charges accrue on these borrowings. (After all, the imputed contributions represent amounts that are due to the plan in the current period but that are going to be paid with interest in some future period.) In principle, the sum of the actual property income that the plan earns on its assets and imputed interest income that the plan earns on loans to the employer arising from past imputed employer contributions should then equal the imputed interest received by households on the value of their pension entitlements. In this way, the pension plan's sources and uses of income will balance.

Nevertheless, national income accountants may prefer to account for the interest due on past imputed contributions in the same way that the private plans do. Under this approach, the difference between the actual property income received by the plan and the imputed interest payable on the households' accrued benefit entitlement would be simply be included in employer's imputed contributions along with the difference between current service cost and employer's actual contributions. Although doing this has the advantage of simplicity, it will change the interpretation of employer's imputed contributions from an item that has to be added to employer's actual contributions to obtain the correct measure of compensation to an item that measures the employer's implicit borrowing from the pension plan. This borrowing will include both a principle component (the unpaid portion of current service cost) and an interest component (the unpaid portion of the interest accruing on past borrowings.)

A third difference between private plan accounting and the SNA is that the private plans can smooth the plan's investment income, but national accounts use actual investment income excluding holding gains. The actual investment income on plan assets will generally not equal the smoothed (and perhaps optimistic) expected returns on assets that are to be reported in business accounts. However, a reasonable option for national accounts would be to include an estimate of expected holding gains on plan assets in their measure of property income, which would bring them closer to the approach of private pension plan accounting.

2 COMMENTS ON "ESTIMATING PENSION LIABILITIES IN THE EUROPEAN UNION: THE FREIBURG MODEL" BY MATTHIAS HEIDLER, CHRISTOPH MÜLLER AND OLAF WEDDIGE

With this paper, the focus changes from pensions provided by the employer to social security (special pension schemes for government employees are also included for countries where they exist). This paper accomplishes the impressive task of estimating *accrued-to-date liabilities* (ADL) of the social security retirement benefit schemes of 19 EU countries. The Freiburg model makes these estimates by simulating the future evolution of each scheme's current benefit payments based on detailed age-sex breakdowns of the current population. For their base case, the authors assume productivity growth of 1.5 percent per year and use a real rate of interest of 3 percent.

The Freiburg model is intended as an approximation that avoids the type of data-intensive detailed calculations that would done by a pension actuary, so the accuracy of the approximation is an important question. Comparisons of the estimates of the ADL (expressed as a percent of GDP) with estimates made by the statistical agencies of Finland and Spain show that the Freiburg model estimates are not far off in these two cases. The Freiburg model is about 10 percent below a comparable estimate from Statistics Finland and about 15 percent below an estimate from INE in Spain, but a difference in assumptions concerning the real wage growth rate appears to account for about 5 percentage points of that gap in the latter case. Thus, the limited empirical evidence at our disposal suggests that the approximations from the Freiburg model are pretty good. One the other hand, the fact that both errors of approximation are negative raises a question about whether the Freiburg model may have a tendency to produce estimates that are a bit low.

The results presented in this paper show that the differences between countries in ratios of the ADL to GDP are remarkably large, ranging from 91.2 percent for the UK to over 300 percent for France and Poland excluding government employee pensions, or about 360 percent for both of these countries if those pensions are included. There are four reasons for the differences in the ADLs: differences in initial level of benefits as a percent of GDP, differences in projected growth of the retirement age population, differences in indexation, and differences in pension reforms. The initial level of benefits relative to GDP is the most important of these.

The ADL is related to another concept used in the generational accounting literature, the closed group liability. The main difference between these concepts lies how the projected value of the benefits that an employee will have accrued at the end of the career is adjusted to account for the part of the career remains to be completed. The closed group liability concept subtracts the present value of the contributions to be made in the future part of the career. The ADL concept in this paper instead assumes that the fraction of the projected length of the career that has already been completed equals the fraction of the projected benefits that have already been accrued. The closed group liability seems to be a better concept for analyzing the effects of social security reforms because the effect of

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

reforms that change the relationship between lifetime contributions and lifetime benefits will be understated by the ADL. At least for the social security schemes of Italy and the US, the closed group liability has become negative at plausible rates of interest for the youngest employees as a result of social security reforms, but their ADL remains positive.[2]

In the past in the US, the average closed group liability at the start of the career was close to zero or positive, so combining the older and younger cohorts that are presently of working age may give a closed group liability for the entire working age population that is not too different from an ADL. The estimate of the closed group liability in the 2009 Trustees Report amounts to 129.5 percent of 2008 GDP based on a long run real interest rate assumption of 2.9 percent and a productivity assumption of 1.7 percent. Social security benefits in the US (including disability insurance benefits) have the same ratio to GDP as state retirement benefits in the UK. Other factors (such as growth of the older population and indexation procedures) are, of course, different, but the effects of these differences may not be too great for a comparison with the US to be interesting. The sensitivity analysis for the Freiburg model implies the assumptions used by the US social security trustees would have raised the Freiburg model estimate of the ratio of the ADL to GDP in the UK to somewhere between 95 and 100 percent of GDP, leaving it roughly 30 percentage points below the closed group liability ratio from the US social security trustees report. Differences in circumstances between the US and the UK may well account for this entire gap, but it is also possible that the Freiburg model estimate for the UK is again a bit on the low side.[3]

An alternative to the closed group liability that is closer to the ADL is the "maximum transition cost" that is calculated by office of the chief actuary of the US social security system.[4] They define this concept as "the cost of meeting the accrued benefit obligations of the old form while continuing the Social Security program in a completely different form, with all payroll taxes for work after the valuation date credited to the new benefit form." It equals the value of accrued benefit obligations less the amount of assets accumulated in the social security trust fund. In 2008 it exceeded the closed group liability by about 16.6 percent of GDP.

I have three suggestions of additional measures that would be useful. First, supplementing the estimates of the ADL with estimates of the closed group

2 Mazzaferro and Toso (*Review of Income and Wealth,* Sept. 2009, p. 788) discuss the Italian case. The social security trustees report at http://www.ssa.gov/OACT/TR/2009/tr09.pdf provides estimates for the US.

3 The paper classifies the indexation procedures used in the UK as a factor holding down the relative cost of their state retirement pensions, but the UK has recently switched from indexation based on price inflation to indexation based on wage inflation. Rising productivity should cause wages to rise more than prices, so the indexation scheme now used in the UK does not seem to be below average in generosity to retirees. Even the past indexation practice was based on a measure of price inflation that tended to rise faster than the harmonized CPI.

4 See Alice Wade, Jason Schultz and Steve Goss, Unfunded Obligation and Transition Cost for the OASDI Program, Actuarial Note No. 2009.1, August 2009. Accessed at: http://www.ssa.gov/OACT/NOTES/ran1/an2009-1.pdf.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

liability for those presently in the social security scheme would be interesting, because it would show the size of the financing gap that has to be filled by assets currently on hand, contributions from future participants in the scheme, or subsidies from general revenues. Second, current year GDP is a flow, but the present value of accrued benefits is a stock. Rather than comparing the ADL to GDP, a more meaningful comparison might be to the present value of future GDP over the same years as are included in the ADL calculation. Third, it would be useful to see a ratio of the ADL to the projected present value of future compensation of employees covered by the social security scheme. The closed group liability for the US social security scheme in 2008 is estimated to be 1.4 percent of the present value of future GDP and 4.2 percent of the present value of future payroll (or 1.2 and 3.7 percent, respectively, after subtracting assets on hand).

3 COMMENTS ON "WORK ON PENSIONS BY THE EPC WORKING GROUP ON AGEING" BY MICHEL ENGLERT

This paper reports on a project by the Aging Working Group (AWG) of the Economic Policy Committee to compile estimates for administrative purposes of effects of population aging on public finances sustainability for 27 EU member countries. The results are discussed in a recent joint report the Economic Policy Committee and the European Commission. The projections of age-related public expenditures cover five items: pensions, health care, long-term care, education and unemployment benefits. (Effects of aging on education and unemployment benefits expenses are negative.) Although it appears from this list that the AWG may have overlooked disability insurance, it was included in the pension component of the study. In other words, the term "pensions" in this paper comprises all the components of what I call "social security" in my paper in this conference volume plus what I call "government employee pensions."

The concept of implicit liabilities used by the AWG is not the same as the implicit pension liabilities to be shown in national accounts. The AWG looked broadly at the financing of total public expenditures using total public revenues without taking into account the specific financing sources of public pension schemes. This means that they included pension schemes that have their owned dedicated source of funding but that are indirectly financed by the general government budget or rely on the general government budget as the financing source of last resort. Furthermore, in their report the implicit liabilities are estimated without making a distinction between accrued rights at the starting point and future rights. For the purpose of measuring sustainability of public sector finances, what matter is the gap between the present value of projected future government outlays and the present value of projected future government revenues.

Each country prepared its own estimates using common methodological framework and assumptions based on literature review, the contributions of experts or Eurostat's demographic projections. This muddies the interpretation and reduces the reliability of the results, but I have no doubt that their general message is correct. The overall cost for EU governments of aging amounts

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

to about 4.7 percent of GDP, including an effect of 2.4 percent of GDP from pensions, an effect of 2.6 percent of GDP from health care and long term care, and a small negative effect from education and unemployment benefits. However, there are enormous differences between countries. These differences show that large challenges await some countries with much higher aging expenses than this overall average, but they also show that some countries have succeeded in making reforms to mitigate the costs of population aging. For example, public pension expenses as a percent of GDP are expected to fall in Italy despite a rise in the proportion of its population over 65.

Even though the concepts in the AWG report are not the same as those used in national accounts, it should be of great interest to national income accounts. Should they occur, large discrepancies between national accounts estimates for pensions and the administrative estimates may indicate a problem that needs to be investigated. For these reasons, I would have liked to have seen results for all the countries, or at least the same 19 countries that have Freiburg model estimates, included in the tables of results in this paper. It would be interesting to compare patterns of projected public pension spending in this paper with the predictions of the Freiburg model. Furthermore, the importance of implicit liabilities for health care expenses in this report suggests that these expenses are a good topic for future research on additions to the information included in national accounts.

SESSION III

PANEL DISCUSSION ON THE USE OF PENSION DATA FOR POLICY-MAKING

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

INTRODUCTION

Session III is organised as a panel discussion on the use of pension data for policy-making. Chaired by Ad van Riet (ECB), contributions are provided by Heikki Oksanen (European Commission, DG for Economic and Financial Affairs), Bernd Raffelhüschen (Freiburg University) and Karsten Wendorff (Deutsche Bundesbank, Chairperson of the ESCB Working Group on Public Finance).

All panellists stress the usefulness of pension entitlement data as estimated on an accrued-to-date basis. Heikki Oksanen refers in his presentation on using pension data for policy to different issues. He indicates the benefits and limitations of this new recording of pension entitlements, saying that some clarifications for using general government deficit and debt data for fiscal surveillance might become necessary, but this can be seen as normal business. New pension data will improve data quality and international comparability. He also refers to a statement from the EU Economic and Financial Committee (EFC) welcoming the cooperation between statisticians, analysts and forecasters by clearly indicating that accrued-to-date measures are useful for economic analysis; but are not per se sustainability indicators as applied in the context of the SGP. On the work ahead, close cooperation between actuaries and statisticians is needed as well as between statisticians and economists making projections and pension reform scenarios.

Bernd Raffelhüschen's paper on the use of pension data for policy making is based on estimations of accrued-to-date pension entitlements for various EU countries carried out for the ECB with the Freiburg pension model. The estimations are based on a rather highly aggregated pension model: Its strengths are its generic character which allows the results to be compared across countries and the fact that it also includes sensitivity analyses of the impact of various measures related to pension reforms. The paper however expands upon the accrued to date pension entitlement approach, moving to an open system by also including the impact of pension contributions. The results are presented for one pension scheme, the social security pension scheme in Germany, by using the accrued-to-date data as a starting point of the analysis. Finally, he uses the concept of open system net liabilities as a measure for the sustainability assessment.

Karsten Wendorff states in his paper that transparent and comparable calculations are required in the area of pension scheme data. This means that a black box should be avoided in terms of model specifications, data and underlying model assumptions. Furthermore, the importance of sensitivity analyses is stressed. The paper also outlines that it might be difficult to find robust EU-wide criteria for the distinction between the core and non-core recording of pension entitlements: However, consistency should be ensured over time. In summary, the work on the estimation of pension entitlements is appreciated as it is useful for policy-making and the analysis of the impact of pension reforms. However, extreme prudence is warranted in the context of international fiscal rules. If the data become a political target (Maastricht criteria), there is a considerable risk of creative accounting and political pressure, which may ultimately lead to a loss in the data's explanatory power, its credibility and that of the fiscal rule itself.

USING PENSION DATA FOR POLICY MAKING – THE CASE OF THE GERMAN PENSION REFORMS

BERND RAFFELHÜSCHEN, CHRISTOPH MÜLLER AND OLAF WEDDIGE[1]

1 INTRODUCTION

In the field of pension policy, data regarding the future development of public pension schemes plays a decisive role. It allows policy makers to realise the implications of certain pension reforms and shows them how the demographic shift in most industrialised countries will influence the future situation of a pension scheme.

The accrued-to-date liabilities (ADL) of a public pension scheme represent an important indicator for the entitlements of private households earned up to a certain point in time. The ADL of a pension scheme are equal to the present value of a capital stock necessary to satisfy the claims accrued-to-date of private households. In that way, policy makers get an idea of the fiscal consequences of a pension scheme's termination. There are many other areas of application for ADL;[2] however, they do not serve as an indicator for fiscal sustainability.

For this reason we will introduce a further indicator for the future development of pension schemes in this paper: open-system net liabilities (OSNL) show if the pension scheme in question can be continued under current rules and settings or if its rules have to be adjusted in order to ensure future fiscal balance. We will apply the indicator of OSNL exemplarily to evaluate the reform process of the German statutory pension scheme in recent years. The paper proceeds as follows:

In chapter 2 we supply a definition for the different types of liabilities. Furthermore, we describe the method and input data necessary to calculate the OSNL of a pension scheme. The outcomes of our calculations are presented in chapter 3. The paper finishes with a short conclusion.

2 ASSESSING FISCAL SUSTAINABILITY – METHOD AND DATA

In the course of the current revision of the 1993 SNA, accrued-to-date liabilities (ADL) of social security pension schemes will be recorded in National Accounts. Against this background the ECB/Eurostat workshop on pensions focused on the calculation and use of these pension entitlements. It has been outlined inter alia that such figures provide valuable information regarding the timing of accumulation of ADL, the impact of pension reforms and explanation of national savings. Pension entitlements, however, are not representing an indicator to evaluate the

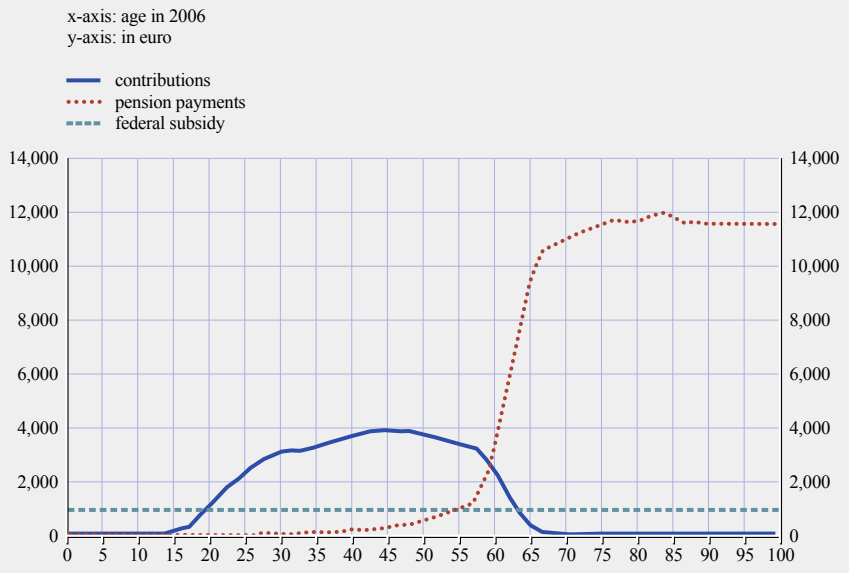
Table I Definition of liabilities

Time horizon	Gross liabilities (including expenditures)	Net liabilities (including expenditures & revenues)
Infinite ⇩	Accrued-to-date liabilities (ADL)	
	Open-system gross liabilities (OSGL)	Open-system net liabilities (OSNL)

fiscal sustainability of pension systems. The following passages will outline how this aim can be achieved by a simple extension of the approach to calculate ADL. First of all the concept of ADL will be defined to illustrate the differences to a fiscal sustainability indicator. Thereafter, the method and data to model a sustainability indicator on the basis of the ADL calculations will be described.

ADL consist of the actual pension payments and the present value of pensions to be paid in the future on the basis of accrued rights. Table 1 makes clear that the concept of ADL has a relatively limited perspective in comparison to other forms of liabilities. In contrast to open-system liabilities future pension rights earned by current and future workers are not included.



Furthermore, revenues are not taken into consideration when applying the ADL approach. By focusing on expenditures only, no statement regarding the sustainability can be made. In other words it is not analyzed to which extent future pensions can be covered by future contributions.

Only two further steps are required to calculate the sustainability of pension systems on the basis of the ADL approach.[3] In a first step the time horizon needs to be extended. While the ADL represent the cost of terminating a PAYG pension scheme, a longer perspective is naturally been taken when assessing sustainability. Therefore, pension entitlements which will be accrued in the future should also be taken into account. Of course, the level of ADL is not connected with any good or bad financial situation of the respective pension system since any financial burden could be balanced by sufficiently high contributions. Therefore, in a second step not only expenditures but also future contributions have to be considered when evaluating fiscal sustainability. As a result one arrives at the OSNL – a valuable indicator to assess fiscal sustainability. It is worth noticing that the instrument to measure this figure is generational accounting. Considering the future demographic development, generational accounting shows which effects a prolongation of a given policy will have on the tax and transfer payments of living and future generations.[4]

3 For an overview on our methodology to measure ADL see Heidler et al. (2009).
4 For a detailed description of generational accounting see Auerbach et al. (1994) or Raffelhüschen (1999).

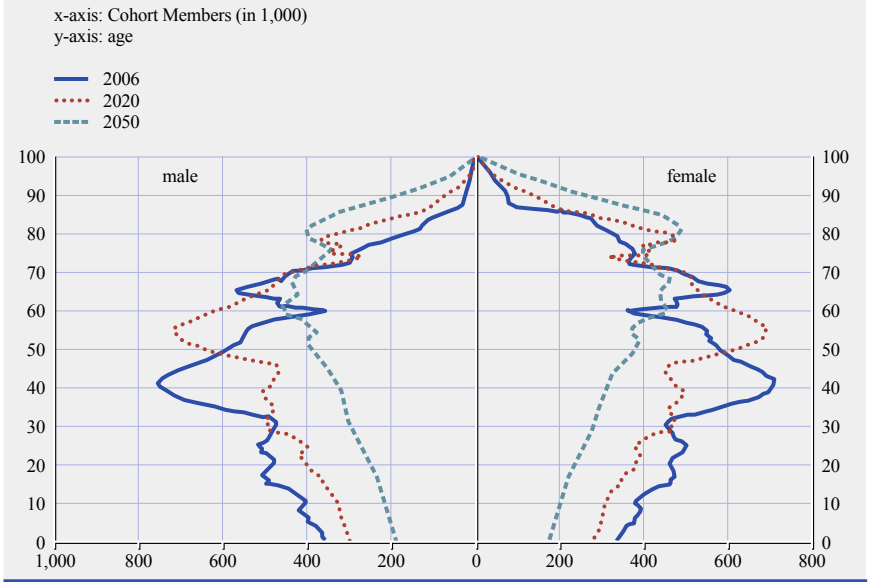
Chart 1 Age-specific payments and contributions of the German statutory pension scheme

Source: Own calculations based on Deutsche Rentenversicherung (2007).

The OSNL approach is based on the same data as the ADL approach: 1) age specific pension expenditure profiles and 2) demographic population projections. In addition, 3) age specific contribution profiles are needed to assess also the revenue side of the respective pension system. Chart 1 illustrates the age-specific payments and contributions for the example of the German statutory pension scheme. It shows the typical picture: While on average contributions are paid at the age of 25 to 60, pension payments are received at the age of 60 and older. Moreover, federal subsidies should not be neglected when analyzing pension systems. Since in the German statutory pension scheme this subsidy cannot be clearly assigned to specific age groups, it is evenly distributed to all cohorts.



Of course, Chart 1 on its own does not provide any information about fiscal sustainability. However, when weighting the age-specific profiles with the respective cohort sizes, one can draw conclusions about the short and long term financial condition of the respective pension scheme. Cohort sizes are taken from population projections which include future age-specific population structures. Chart 2 illustrates the population structure in Germany for 2006, 2020 and 2050.

At first sight it becomes obvious that the German statutory pension scheme – as most European pension systems – will be faced by the challenge of a double aging process. On one hand life expectancy is assumed to rise considerably in the coming decades;[5] on the other hand fertility is expected to stay on its low

5 According to Europop2008 life expectancy of a male (female) born in 2006 will increase from 77.2 (82.4) to 83.6 (88.0) years until 2050. See Eurostat (2009).

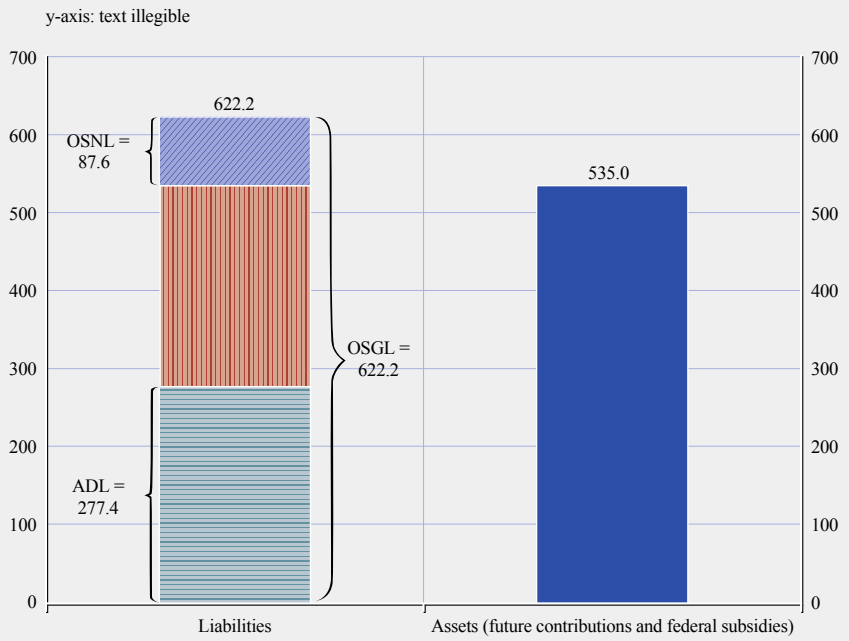
Chart 2 Population structure Germany 2006

Source: Own calculations based on Eurostat (2009).

present level.[6] As a result, the German population pyramid´s appearance will considerably change in the years to come (see Chart 2). In simple terms, this development will lead to a decreasing number of contributors paying for more and more pensioners. The question to which extent the German statutory pension scheme will be prepared to tackle this demographic challenge will be assessed in the following chapter. The German example shall illustrate how policy making can be evaluated and advised applying the indicator of OSNL.

3 THE EVALUATION OF THE PENSION REFORM PROCESS IN GERMANY

We will start by confronting the ADL of the German statutory pension scheme with its OSNL. Chart 3 illustrates our calculations.



As can be seen, the ADL account for nearly half of the open-system gross liabilities (OSGL). The ADL symbolize that part of the OSGL which contributors have been earned up to the base year. The residual part of the OSGL represents the present value of all entitlements which will be earned by present and future contributors after the base year. On the right side of our image we displayed the assets of the German statutory pension scheme. These consist of future contributions and federal subsidies and sum up to a present value of 535 per cent

6 The fertility rate in Germany amounted to a level of about 1.3 in the last years. See Eurostat (2009).

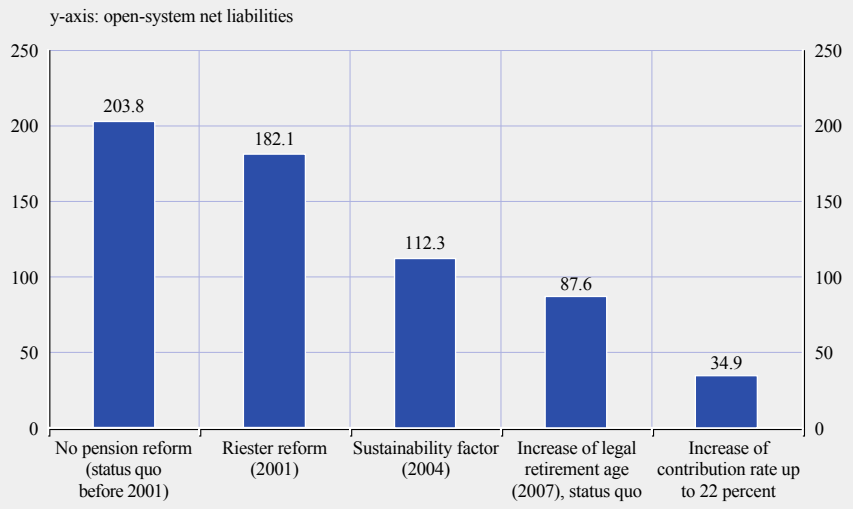
Chart 3 Liabilities and assets of the German statutory pension scheme

(in percent of GDP 2006)

Source: Own calculations.

of German GDP in 2006. The OSNL are now derived by subtracting the assets from the liabilities of the pension scheme. In the case of the German statutory pension scheme, the ONSL amount to a value of 87.6 per cent of GDP. In other words, the sum of all future deficits discounted to the base year equates to ONSL of 87.6 per cent.

In this context it has to be emphasized that the outcome presented above is the result of numerous reforms of the German statutory pension scheme in recent years. In the following part we will briefly sketch out the major reform steps. Furthermore, we will demonstrate the impact of each reform step on the OSNL of the pension scheme.



Beginning with the situation prior to any pension reform (status quo of 2001), the ONSL show a value of more than twice the German GDP of 2006.[7] The so-called Riester reform in 2001 introduced a new pension formula which changed the net wage indexation to the development of gross wages net of pension contributions (both public and private). This reform step reduced the OSNL by

7 Our analysis does not simulate a situation where none of the pension reforms has ever come into force. This is not possible due to the fact that the past impacts of the reforms are implicitly included in the budget of the base year. For this reason, we rather picture a scenario where all pension reforms are abolished in the base year 2006.

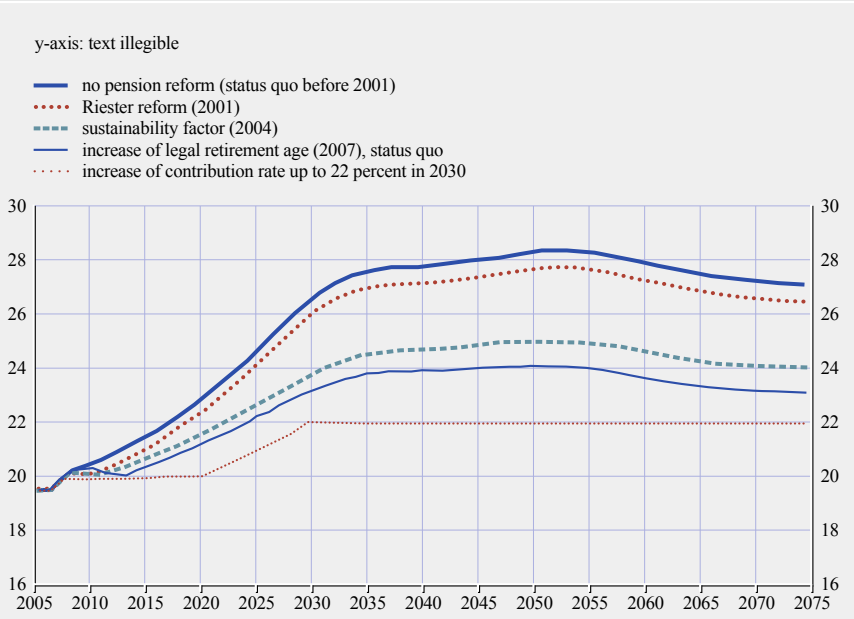
Chart 4 Open-system net liabilities (OSNL) of the German statutory pension scheme

(in percent of GDP 2006)

Source: Own calculations.



nearly 22 percentage points of GDP in 2006. The biggest cutback took place in 2004 when the sustainability factor was implemented in the pension formula. This factor connects the pension level to the development of the ratio of retirees to contributors. It reduced the OSNL by some 70 percentage points of GDP. The last major pension reform in 2007 consisted of the gradual increase of the legal retirement age from 65 to 67, starting in 2011. This reform lessened the OSNL by another 25 percentage points; hence the current status quo amounts to about 88 per cent of GDP. In other words, the sustainability gap of the German pension scheme has been more than halved thanks to numerous pension reform acts since 2001.

It is worth mentioning that the Riester reform from 2001 contains a passage regarding the future development of the contribution rate. Due to this legislation, the German government is supposed to take action in case the contribution rate will exceed a level of 20 per cent until the year 2020 and accordingly 22 per cent until the year 2030. Many pension experts regard this as a paradigm change from a defined benefit (DB) to a defined contribution (DC) scheme.

Our calculations always include the current status quo; hence, we act on the assumption of a constant pension formula and a constant contribution rate (19.5 per cent in 2006). However, Chart 4 shows how the outcome for the OSNL reacts if we assume that the contribution rate linearly increases to 20 per cent in 2020 and 22 per cent in 2030. In this case the pension scheme converges even more to a sustainable situation with OSNL amounting to about 35 per cent of GDP only.

Chart 5 Sustainable future contribution rates of the German statutory pension scheme

Source: Own calculations.

What do we learn from the presentation of OSNL under various reform steps? It has been shown that the calculation of OSNL – one could also call it the sustainability gap of a pension scheme – represents a helpful instrument to assess the impact of certain reform steps in terms of their fiscal sustainability. In this way, ONSL can be a useful tool for policy-makers who are willing to prepare their pension schemes for future challenges. Politicians are given an indicator for the extent to which a pension reform reduces the burden for future generations.

As mentioned before, one of our main assumptions is a constant continuation of current fiscal policy. In the case of the pension sector, this inter alia implies constant contribution rates.[8] We now change this assumption by illustrating what will happen if policy makers immediately adjust the contribution rate in case of an unbalanced budget. Put differently, we calculate endogenous contribution rates which in every period ensure fiscal balance. By doing so, it can be demonstrated how future contributors will be burdened if deficits are financed by contribution boosts instead of taxes. Chart 5 illustrates the course of these contribution rates:

As shown above, the initial scenario (status quo 2001) implies a development of contribution rates up to a value of more than 28 per cent in 2045. The Riester reform slowed down this development by approximately 0.5 percentage points. Again, the

8 This is certainly not a realistic scenario since in a non-balanced situation contribution rates are often subject to change. However, please note that generational accounting is not a forecasting tool. It is rather supposed to unfold hidden debts and shows the consequences of what will happen if policy makers do not react.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

biggest decrease can be traced back to the introduction of the sustainability factor which induced a decline of the sustainable contribution rate by more than two per cent. The increase of the legal retirement age as the last major pension reform further reduced the necessary contribution rate to a value of about 24 per cent from 2035 on. For illustrative purposes, the development of the contribution rate to 20 per cent in 2020 and accordingly 2030 per cent has been included. Overall the results have shown that the recent pension reform process in Germany considerably lowered the burden for future contribution payers.

4 CONCLUSION

This paper aims to introduce an indicator which assesses the fiscal sustainability of a public pension scheme. The open-system net liabilities (OSNL) point out if the settings of a public pension scheme have to be adjusted in order to guarantee future fiscal balance or if no action has to be taken by policy makers against the background of the demographic shifts in industrialised countries.

We demonstrated that the OSNL can be a useful indicator to accompany the reform process of a pension scheme. It is not only possible to assess the consequences of a pension act *ex post* but also *ex ante*. In that way different proposals for pension reforms can be examined in regard to their impact on fiscal sustainability before they are actually enacted. In our paper we described the development of the German pension reform process and the corresponding consequences of each reform step on the ONSL of the pension scheme. As a result of the reform process, the German statutory pension scheme can be regarded as close to sustainable.

Besides the German example, rather distinct reform measures have been taken in member states of the European Union to prepare for the demographic challenges. While some countries such as France modified the pension indexation rules or – like the UK – chose to increase the legal retirement age, other states such as Italy implemented notional defined contribution (NDC) systems.[9] Future research could assess these different reform strategies in Europe using the indicator of OSNL.

USING PENSION DATA FOR POLICY[1]

BY HEIKKI OKSANEN[2]

1 INTRODUCTION

I want to thank the organisers of this workshop for giving me an opportunity to comment on the progress made in revising the national accounting rules for measuring assets and liabilities of pension schemes, as initiated under the auspices of the United Nations Statistical Commission and followed by the work in the Eurostat/ECB Contact Group. Statistics are not produced for their own sake but to provide governments and private sector agents with data for assessing the state of the world and designing responses to various challenges. I will make my comments primarily from the point of view of shaping policies for sound public finances.

The main novelty in the revised national accounting rules will be to record the pension liabilities of general government, taking the *accrued-to-date liability concept* as the appropriate definition, with the aim of estimating this important category of government liabilities and the corresponding assets of the household sector.

This innovation will have major implications for analysis and thus potentially for policy design. There are two main reasons for this: (1) the pension liabilities of governments so defined dwarf conventionally defined public debt in most countries, and (2) these liabilities are in most cases *implicit,* meaning that their amount is not directly measurable but only estimates can be provided, with the consequence that different assumptions can be made and therefore different results can be presented, both on justifiable non-partisan grounds and, potentially, with the aim of steering policies in one or other direction serving specific interests.

However, dealing with non-definitive data is not exceptional. All statistics, not least national accounts, are only estimates, and the conceptual and practical issues involved with public pensions do not bring to the table problems that are qualitatively new, although we might have here an issue that has quantitative implications of a new and huge order of magnitude.

Due to their quantitative importance the new data on public pension liabilities may have drastic implications for monitoring fiscal developments and designing policies to comply with the EU Treaty principle of sound public finances. This is obviously the main issue here, although public pension liabilities are in various ways very significant for private sector agents too. We should also recognise

1 ECB/Eurostat workshop on pensions, 29 and 30 April 2009, Panel discussion

2 Mailing address: Directorate-General for Economic and Financial Affairs, European Commission, BU-1, 5/179, B-1049 Brussels, Belgium, phone: +32.2.2959326, e-mail: Heikki.Oksanen@ec.europa.eu

that any given set of statistical data almost invariably has many users and many potential purposes. Therefore, the advisability of producing such data should probably not depend only on one sphere of application.

The state of preparations for the revised SNA and ESA is currently that *Accrued-to-date pension liabilities* will be part of the new national accounts balance sheets. For private sector employers these will be included in the core accounts, while for government, as far as social security pensions are concerned, they will be recorded in the new supplementary accounts. The treatment of the liabilities of governments vis-à-vis their own employees is still somewhat open, as the solution will depend on drawing the borderline between these and general social security pensions.

As terminology is not yet fully established, *Accrued-to-date pension entitlements* or *Pension entitlements* are here called, for simplicity, *Implicit Pension Liabilities* (IPL), being fully aware that there are alternative definitions of pension liabilities – we will leave the issue aside here.

We will recapitulate in Section 2 some statements made by the EU committees in charge of preparing policies for public finances. Sections 3 and 4 will, respectively, discuss the two arms of the Stability and Growth Pact (SGP), namely the Excessive Deficit Procedure (EDP) and the longer-term issues related to the sustainability of public finances and pension reforms. Section 5 comments on the work ahead and the division of labour between the statisticians and the pension actuaries and economists, and Section 6 draws some conclusions.

2 STATEMENTS BY THE EU COMMITTEES

The EU committees in charge of economic and fiscal developments in the EU commented last year on the plans to include public pension liabilities in the national accounts. The Economic Policy Committee (EPC) stated:

"All indications are that the application of the 2008 SNA rules in Europe (through a revised ESA, with reduced flexibility compared with the updated SNA) will not result in significant changes to general government deficit and debt data used for the purposes of the Excessive Deficit Procedure". It also said: *"Presentation of a broad range of statistical information on pension schemes will allow better international comparability; provide useful information regarding the timing of accumulation of pension entitlements and the impact of pension reforms"* (EPC document of 26/8/2008).

The Economic and Financial Committee stated:

"On pension schemes, the EFC welcomes the work of the Eurostat/ECB Task Force to improve the treatment of pensions in the national accounts. The EFC stresses the importance of an ongoing close cooperation between national accountants, statisticians, and experts preparing pensions projections, notably

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

in the context of the work of the EPC Working Group on Ageing Populations and Sustainability… The EFC underlines that the accrued-to-date measures of pension entitlements are not sustainability indicators. Yet, they will be useful for economic analysis, notably they will provide useful information regarding the timing of accumulation of pension entitlements and the impact of pension reforms. Furthermore, the EFC believes that it is desirable to associate to this exercise the expertise of agencies responsible for public pension schemes" (EFC Statistics document of 25/10/2008).

We can detect a certain ambivalence in these statements. On the one hand, there clearly is some concern that the new data might confuse the Excessive Deficit Procedure (EDP), which is unquestionably the backbone of the fiscal policy rules at EU level. On the other hand, the new data is seen as a useful addition to data for analysing pension policies, which obviously affect public expenditure and thereby fiscal balances in the future, being essentially part of the assessment under the so-called preventive arm of the Stability and Growth Pact (SGP). We will now look in turn into these two dimensions of public finances.

3 EXCESSIVE DEFICIT PROCEDURE (EDP)

The EDP as included in the Maastricht Treaty in 1991 (Treaty establishing the European Community, TEC, which came into force in 2009 and is only slightly modified by the Reform Treaty under ratification in 2009) clearly concerns explicit public debt and deficit under current accounting standards. Its original purpose was to identify gross errors in public finances (Article 104 TEC), and to help comply with the principle of sound public finances (Article 4 TEC). It can be said that the purpose of the EDP was to safeguard against irresponsible policies and to prevent excessive borrowing by any Member State from the common pool to finance fiscal deficits.

To this end it is normally sufficient to look at deficit and debt ceilings as stipulated in the Treaty and under current accounting standards, as they are sufficient to identify gross errors (even though the 3% ceiling is not equally hard for every country).

One potential issue is a situation where there is significant privatisation of the public pension system by creating a mandatory fully funded second pillar providing pensions on the basis of defined contributions – the rule whereby the risk relating to the return on the accumulating assets falls on the employees. As a share of the pension contributions is shifted to the second pillar that is classified in the private sector (due to the risk allocation) and as expenditure from the public pillar falls only gradually over a long period, the 3% ceiling for public deficit may be breached. Note that this problem arises even though assets are correspondingly accumulating in the second pillar.

However, this problem could be dealt with by adding, for the purposes of the EDP, the surplus in the mandatory second pillar to the government budget balance, and deducting the second pillar assets from gross public debt. Note that even though

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

the underlying question here is swapping implicit debt for explicit public debt, this remedy does not necessarily require explicit use of the new IPL data.

Another potential issue is the possible inclusion of IPL related to government employees in the core accounts (the criteria for which are still an open question). This would increase public debt in many cases by 40-60% of GDP, and the corresponding (policy-neutral) effect on the measured government deficit would be 2% of GDP. If it were decided to use such newly defined deficit and debt figures for the EDP, the reference values defined in the Protocol on EDP (3% of GDP for deficit and 60% for public debt) would obviously need to be reviewed, or it should be specifically stipulated that for the purposes of the EDP the old definitions of deficit and debt are used.

Thus, both of these problems could be dealt with – if needed and wanted – by a change to the Protocol on the EDP (by a unanimous Council decision), introducing specific provisions for EDP deficit and debt in this Protocol, and possibly in related documents.

This means that the necessary clarifications could be seen as normal business for specifying what data should be used for each policy-making purpose. Seen in this way, the EDP and the SNA/ESA revision for IPL can live in peace.

4 THE SGP PREVENTIVE ARM, LONG-TERM SUSTAINABILITY, INTERGENERATIONAL EQUITY, PENSION REFORMS

The Committees have rightly stated that an estimate of implicit pension liabilities is not a sustainability indicator. We know that one reason for emphasising this simple fact stems from the need to say that an IPL as large as even 200-300% of GDP, thus a multiple of explicit public debt in most countries, does not necessarily on its own indicate a problem of sustainability of public finances. This is true, and it is confirmed also by the fact that public finances in EU Member States have not collapsed even though the magnitude of IPL is of that order.

It has also been said that when a pure PAYG pension system is established, IPL does not immediately indicate a problem of sustainability. This is also true, but it is only valid for the IPL for the first year or years; a projection for its future value (under various alternative assumptions) would measure the increasing burden (as would also a projection of expenditure) and provide a useful indicator of the possibly looming problem of sustainability.

Let's be clear that no single variable alone is a sustainability indicator. An estimate of the IPL for now gives the starting point for a more comprehensive analysis. It would contain additional information compared to the data on current pension expenditure and a projection for aggregate pension expenditure as it contains the information on the rights accrued up until today.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

The IPL for today would also provide a basis for a *projection* for the IPL. Note, however, that it would not be produced by statistical offices, as it is not their task to make economic forecasts, but should be produced by pension actuaries and economists. Such a projection would always contain more information than a projection for aggregate pension expenditure (or open system pension liabilities) as it contains the information on when the rights are accrued and not only when the pensions are paid out. This, combined with policy rules on the revenue side of the public pension system, would give a useful and necessary basis for looking at issues of who is paying for what, i.e. the question of intergenerational equity could be tackled.

Other arguments for looking at the IPL estimates are as follows:

Implicit and explicit government debt are similar in the sense that both have come about because some groups of beneficiaries of public money cum tax payers have in the past received from the government something more than they paid in (note: this is true for net public debt and excludes borrowing for public investment). Consequently, they are similar also in the sense that current and future generations need to bear the burden of both. The IPL estimate also gives future pensions the same dimension (stock at a given point in time) as for explicit public debt.

It should also be recognised that for many reasons explicit and implicit public debt are not perfect substitutes (normally, one is traded, the other is not). But again, this is not a reason to ignore implicit debt.

Looking at future pensions accrued to date in terms of their present value (=IPL) is useful as this figure gives a basis for looking into its *change* from now onwards. This change can, under population ageing and modest pension reforms, easily be 60-100 percentage points of GDP over 30-50 years, i.e. the same order of magnitude as the current stock of explicit debt in many countries. This induced increased burden is as real as a corresponding increase in explicit public debt: taxes need to be increased or other public expenditures reduced at some stage.

Thus, this set of data helps to spell out the essential question as to when taxes should be increased and for whom. The answer leads to the question of *prefunding* for the projected increase in IPL (or part of it), to keep the total debt burden "tolerable" (in various respects that require assessing public finances at large in the context of macroeconomic developments). "Prefunding" means reduction of explicit public debt, net of assets held by the public sector. This is one essential part of the policy recommendations given by EU finance ministers meeting within the ECOFIN Council.

All this concerns "sustainability of public finances" broadly defined. Understanding the issue requires estimates for IPL for today and the future (under alternative assumptions).

Some people are critical of estimating IPL because it is not backed by explicit well-defined commitments (e.g. indexation assumption) and it is therefore hard

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

to measure. They may also worry that official publication of IPL estimates may give them an explicit character and thereby make it politically more difficult to renege on (presumed and claimed) pension rights.

This is certainly true and an essential part of the problem. However, the differing views on accrued pension rights do not vanish by avoiding making estimates of their magnitude. It is a political assessment whether the pension problem can be tackled more easily with or without more comprehensive data. In this context publication policy can be refined. Publication of IPL estimates can be accompanied by a statement that figures are based on current policies and no legal rights can be derived from the figures. Also, publishing additional projections based on alternative assumptions would give baseline figures a less definitive character.

5 THE WORK AHEAD AND THE DIVISION OF LABOUR

There are many reasons for moving ahead in producing IPL estimates and publishing them in the national accounts. IPL gives data on *"timing of accumulation of pension entitlements and the impact of pension reforms"* as stated by the EFC. Note that here "timing" refers to different generations and cohorts, i.e. IPL gives benchmark data on balancing costs and benefits for each generation (or cohort) expressed as a stock of discounted values.

As governments require businesses to recognise and report their pension obligations it can be asked why the governments themselves should not comply with the same requirements. One can say that there is a difference, as businesses need to generate the required financing from their revenues, while governments have the powers to levy taxes on households and businesses. However, this difference is not necessarily so big, as someone has to bear the burden of pensions anyway. Estimating the IPL can be interesting regardless of who will finally pay for future pensions.

The public and private sectors are linked to each other in many other ways too. Neutrality in comparing the cost of labour in the public vs. the private sector would seem to require that the cost of pension rights accrued as part of the employment contract should be recorded in the same way in all sectors so that a fair comparison can be made of the relative merits in producing services. The imputed pension cost component is part of the cost of labour data for the government sector in the current national accounting rules, but looking more carefully into the estimation methods when producing IPL estimates for government under the new more coherent accounting rules will allow the data on the cost of labour to be refined.

Producing IPL estimates should be seen as producing data on the (recent) past: IPL is a stock at a given date in the past, although it is the capital value of a projected flow in future – this is, however, not unusual for statistics, as every financial stock is related to a flow in future. Thus, the IPL estimates for today should be produced by statisticians with the help of pension actuaries.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Based on these estimates, pension economists and other experts should produce alternative projections for IPL in future to illustrate the effects of possible reforms. These alternative scenarios should also give projections for other key variables (pension expenditure, pension contributions and other taxes collected, assets held by pension schemes, etc.).

6 CONCLUSION

We know that without reforms the public pension systems are heading for crisis. IPL estimates for revised national accounts will greatly help in designing the necessary reforms and experts will have an important role to play in supporting the political processes.

Statisticians and pension actuaries should be highly praised for producing new data on pensions, including the estimated present values for accrued-to-date public pension liabilities.

Thank you for your attention.

THE USE OF PENSION DATA FOR POLICY MAKING

BY KARSTEN WENDORFF[1]

1 INTRODUCTION

Obviously, given their professional background, the participants in the panel discussion on "The use of pension data for policy making" take three different views on and approaches to the topic under consideration. While I am not a distinguished expert on pension data I will take the perspective of a central bank's fiscal expert. Therefore, working for the Deutsche Bundesbank and the ESCB Working Group on Public Finance, I will examine the issue with both a national and an international eye. As a central banker, I am particularly concerned with aspects regarding fiscal sustainability and reliable and binding fiscal rules.

The five main messages I want to convey are as follows:

1. Demographic change will undoubtedly be one of the most important fiscal challenges in the future.

2. Pension data is very important for supporting the respective policy decisions and countering the (implicit) debt illusion in the policy process.

3. In contrast to many other statistics, pension data depends particularly on assumptions and the results may be subject to (public) controversy. This may present a challenge for the credibility of the data and the producers.

4. The transparency of the underlying data input and the models used as well as data availability for analysts, researchers and the general public are very important.

5. Beware of policy makers: If the data becomes a political target (e.g. in the context of the Maastricht criteria), there is a considerable risk of creative accounting and political pressure, which may ultimately lead to a loss in the data's explanatory power, its credibility and that of the fiscal rule itself.

2 TYPOLOGY OF FRAMEWORKS FOR FISCAL ANALYSIS, FISCAL POLICIES AND FISCAL RULES

In general, several frameworks can be distinguished in the context of fiscal rules and the underlying statistical or analytical bases. They differ, inter alia, with regard to their complexity and their need for relying on assumptions to compile the data.

1 *Deutsche Bundesbank Chairperson of the ESCB Working Group on Public Finance*. The views expressed in this contribution are those of the author and do not necessarily reflect the views of Deutsche Bundesbank or the WGPF.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

A very common basis for national fiscal rules and national budgetary legislation are often *cash or budgetary statistics*. They primarily record cash flows and new borrowing. The respective statistical recording is not necessarily internationally harmonised. It is not very complex from the producers' perspective or from a methodological point of view.

National accounts data are (more or less) internationally harmonised (SNA 1993, ESA 1995). They form the core of the European fiscal rules, namely the EU Treaty and the Stability and Growth Pact. The methodology, the "legislation" and the recording are significantly more complex than in the case of the cash statistics. Additional assessment and interpretation by the statistics producers are necessary and the statistical recording is sometimes controversial – as can be observed currently, for example, in the context of the statistical treatment of the public support of financial markets.

In addition to national accounts data, the consideration of *transitory influences on public finances from a medium-term perspective* is an important supplementary aspect of fiscal analysis and the fiscal rules in the EU. Therefore, in a further step, the national accounts data (both budgetary outcome and projection) are adjusted for specific temporary measures and effects as well as for cyclical influences. The methodologies can be very comprehensive and demanding with regard to the data input and model complexity. There are a wide variety of definitions and methodologies which lead, in some cases, to important differences in the results depending on the underlying assumptions and conceptions. However, fiscal surveillance in the EU is based on an agreed methodology which is systematically applied by the EU Commission.

Longer-term influences on public finances and other important aspects such as implicit liabilities are additionally reflected in a broader fiscal assessment and, in some cases, are included in "softer" budgetary rules. One example are the calculations by the Working Group on Ageing, which are expected to be included in the assessment of national medium-term objectives (MTO) in the context of the preventive arm of the Stability and Growth Pact. Other examples include the new pension data, which are the main focus of this Workshop, or results calculated within "Generational Accounting" frameworks. Usually, the consideration of longer-term influences requires relatively complex models based on numerous and important assumptions. As a result, the outcomes can differ considerably and are often controversial. Achieving an international comparison and a harmonised approach is particularly challenging, not least because the national institutional setting is often very complex and varies widely.

All in all, it can be concluded that the increase in scope of the statistical frameworks and the fiscal rules is combined with an increase in complexity and the need for assumptions. The results may become less harmonised, particularly in an international environment, and increasingly controversial in public discussions.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

3 SEVERAL DOUBLE POLES OF PENSION DATA

With regard to pension data in general as well as their design and use, several double poles can be identified.

The information can reflect an *individual or a collective* perspective. The former refers to pension data of an individual and, in particular, to individual's claims against the pension system. The latter refers to aggregated data, e.g. to all participants of a system or to the entire population of a country.

The aggregated framework can be *partial or comprehensive*. It can include, for example, civil servants or the entire population. It may be based on cash statistics, national accounts or generational accounting. The focus can be restricted to public expenditure or also include the revenue side, by considering taxes paid by pensioners.

Moreover, a *national or an international* perspective can be taken. While the national approach may be relatively complex, taking many peculiarities of the system under consideration into account, an international comparison will require more harmonisation, common assumptions and less complexity.

Not least, the intended use of the data is an important aspect. In the context of *academic analysis and research*, complex models and frameworks with various assumptions and sensitivity analysis may be suitable. In the context of *rules and policy*, the frameworks may need to be designed to be more straightforward and simple. The goals of the actors involved are mixed and are not solely focused on increasing academic knowledge. Specific interest groups may play important roles and communication with the general public becomes an important issue. In the context of rules, the potential "creative accounting" tendencies of the various players have to be considered.

All in all, the various pension data sets have their own merits. There is no "one size fits all" data set.

4 THE IMPORTANCE OF PENSION DATA FOR POLICY MAKING AND ANALYSIS

Countries in the EU are facing ageing societies, and the share of old-aged persons in the population will increase considerably in the future. This is an important challenge, not least for fiscal policy analysis and fiscal policy making.

In this context, accrued pension data is of particular relevance as it sheds light on developments which are not reflected in cash flows and are therefore "invisible" in most cases in the budgetary process, which is the main focus of policy makers. Awareness of these "implicit" liabilities is being raised among politicians and

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

voters. The pension data thus works against the "squared fiscal illusion",[2] because the burden on future generations is made transparent and, (backdoor) shifting of the burden is made more difficult. Increasing transparency regarding pension liabilities and their consequences for future generations may lead to reforms or at least discourage attempts to draw them back. Pension reforms may become less unpopular. Transparency may also result in changes in the behaviour of private agents if they recognise, for example, that cuts in implicit liabilities of the state (via reforms of the pension system) will, at the same time, lead to a reduction in their own "implicit" private assets.[3] Private decision making would therefore be based on more rational grounds.

5 TRANSPARENCY AND CAREFUL TREATMENT, ASSESSMENT AND INCLUSION OF NEW PENSION DATA IN POLICY FRAMEWORK IS OF THE UTMOST IMPORTANCE

While pension data is very important for analysis and policy making, its limitations should be borne in mind. For example, the new pension data discussed in this Workshop only partly reflects the aspects of the ageing-related burden and, as stressed by Heikki Oksanen, it is not a sustainability indicator. Due to its nature, it relies relatively strongly on assumptions and the specific methods for its compilation. As a result, international comparability may be limited. Not least, it should not be ignored that implicit liabilities have a different character to explicit liabilities; "defaulting" on implicit liabilities is much easier. The debtor sets the rules and the government can, for example, raise the retirement age or cut the size of individual pensions. Moreover, the government can decide on higher taxation on pensions which, incidentally, would not show up in the new pension data set either.

Against this background, transparency regarding the calculation of the pension data and the underlying (individual national) models is of utmost importance. This concerns, inter alia, the underlying assumptions, national peculiarities and national calculations. The core data and model should be made available for analysis and cross checking and should not be kept in a black box. The "black box issue" is, in my view, also an aspect that affects the calculations of the Working Group on Ageing, which are not explained and published in detail. Full transparency, however, is an important feature for the reliability of any data. It should be a precondition for the use in international comparisons and inclusion in fiscal rules.

2 "Fiscal illusion" usually describes a situation in which, in the public perception, debt financing seems to be "costless", although the burden is (merely) shifted to future generations. Implicit pension liabilities are labelled here as a "squared fiscal illusion" because, in addition to the "debt illusion", the burden does even not show up in the debt data.

3 The comparably high saving ratio in Germany in the past few years may have partly resulted from the fact that the statutory pension bubble burst. After it had become obvious that the statutory pay as you go system would not be as generous in the future as people had estimated (perceived wealth decreased considerably – the pension illusion evaporated) savings increased to partly compensate for these losses. However, the pension claims may currently be underestimated as trust in the functioning of the pension system seems to be particularly low.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

6 BEWARE OF POLICY MAKERS AND INCLUSION IN FISCAL RULES

Particular attention is warranted when statistical data becomes the basis for official fiscal targets or is included in fiscal rules. Inclusion in the policy process, use by policy makers and the potential binding character with regard to concrete fiscal policy decisions risk changing the character of the data – they may lose their "innocence". Therefore, not only will the new data have an impact on the policy makers, the policy makers will also have an impact on the data. Indeed, this is very important in the case of pension data, because the scope for shaping (or even manipulating) the data is relatively large in this context, where several assumptions are needed and the models for the calculations are very complex.

All in all, I would strongly advise against including the new pension data in the core European fiscal rules. This would require a very clear-cut ruling with regard to the calculations – no choices which may otherwise open the floor for strategic behaviour. Moreover, guaranteeing equal treatment in an international environment would be very difficult, but absolutely necessary. I would expect high pressure with regard to creative accounting, which would put the data set and its credibility under enormous stress.

In this context, it is important that the criteria for the distinction between reporting in the core and non-core national accounts should ensure consistency over time. Figures used in the excessive deficit procedure, at least, should be immune to ad-hoc wishes to change the assignment from one year to the next. For example, a country may initially choose to keep a system in the non-core accounts (as it may be at first considered not sufficiently funded), but later on (as the result of an interim accumulation of funds) shift it to the core account when the pensions are paid out and the corresponding reduction in pension claims is not recorded as expenditure (i.e. not above the line) but as redemption of government's pension liabilities. If such choices were possible, this would offer the opportunity to strategically minimise the statistical recording of deficits over time in the national accounts, which should clearly be hindered by the institutional setting.

7 CONCLUDING REMARKS

In conclusion, I very much appreciate the efforts in the statistical domain to calculate and present the new set of pension data. However, the inclusion in national accounts is challenging and the calculations complex. Therefore, a careful approach and communication should be warranted, and transparency with regard to the underlying models and assumptions is of major importance. Extreme prudence is needed regarding inclusion of the new data in international fiscal rules and I, personally, would be sceptical in that respect. The data may influence the behaviour of fiscal policy makers but one should also not underestimate the feedback from the policy process to the statistics.

SESSION IV

COUNTRY EXPERIENCES IN COMPILING PENSION ENTITLEMENTS PART I

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

INTRODUCTION

In Session IV, Lourdes Prado Ureña (Instituto Nacional de Estadística) reports on estimating social security pension entitlements in Spain. In her introduction she describes the two major government schemes in Spain, social security, with 21 million active members and 8 million pensioners and the government employer pension scheme, mainly for civil servants, with 950,000 active members and 500,000 pensioners. In the second part of the paper the modelling for the estimation of pension entitlements is described in terms of model, model assumptions and model outcome. It describes how a working group was set up in Spain in 2006 comprising the Banco de España, the Audit Office, the Ministry of Labour and Social Affairs, the Social Security Treasury, the Ministry of Finance and the Statistical Office (INE). Based on its work, the Ministry of Labour and Social Affairs carried out a pilot exercise, making first estimations of social security pension entitlements in 2007 and the Ministry of Finance made estimates for the government employer pension scheme in 2008. Preliminary results show pension entitlements under social security pension schemes of around 240% of GDP in 2005 to 2007.

Tom Dominique (Inspection Générale de la Sécurité Sociale) reports on the experience in compiling pension entitlements in Luxembourg. He explains that various old age related schemes are in place in Luxembourg: the general pension scheme which is compulsory for all employees, special pension schemes for civil servants, local authorities and public institutions and smaller schemes like supplementary schemes, private pension plans and schemes with a minimum guaranteed income. It is important to mention that the model used to compile accrued-to-date pension entitlements is identical to the model for the pension expenditure projections carried out by the AWG, insofar as the data input, the model specification and assumptions are identical. For the accrued-to-date pension entitlements, estimates show figures of 55-60% for government employer pension schemes and of about 300% for social security pension schemes. In conclusion he states that to ensure consistency it is necessary to keep the approach rather simple and apply the available methodology due to limited human resources.

Paula Koisinen- Jokiniemi (Statistics Finland) presents the main features of the social security pension scheme in Finland. She describes the Finnish pension system in brief, explains the results received for the supplementary table and compares these results with the data of the national model. The Finnish public pension system is made up of two statutory pension schemes (first pillar) and the small voluntary pension insurance sector (second and third pillar). The two statutory schemes are closely linked to each other. They are a combination of a pre-funded system and a pay-as-you-go system. The pension assets of these schemes made up about two thirds of GDP in 2007. As a result of the test exercise it was concluded that the statutory pension schemes are classified as social security pension schemes. Depending on the valuation methods (ABO or PBO) applied in the text exercise the entitlements of the two statutory schemes represent between 235% and 295% of GDP. The 5% discount rate used in the national model is in line with the rate used in the framework of the original Freiburg exercise. The national model deviates from

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

the models used by the AWG and also by Freiburg University. Nevertheless, the results derived for the national model are in between the estimates made by the Freiburg model using an ABO and a PBO valuation method.

Joe Wilkinson (Statistics Canada) outlines the pension satellite account in Canada. He explains how pensions are shown in the national balance sheet, presents preliminary estimates of the pension satellite account and reports on the research agenda. There has clearly been a steady upward trend in employer sponsored pensions. Unfunded pension entitlements are recognised in the core accounts. According to preliminary estimates of the pension satellite account total pension assets exceed $2 trillion CDN in 2007. There is an increasing share of employer sponsored and individual registered plans relative to social security. Compared with most European countries social security pension entitlements are rather negligible.

Ana Almeida (Banco de Portugal) discusses these four papers of Session 4. As the discussant of this session she provides detailed comments on the contributions, highlighting the importance of starting by compiling statistical data on social security for policymakers. On the Spanish experience, the organisational procedure (via a working group) was stressed as well as the development of a national model that accommodates some assumptions from the Spanish Social Security scheme. Some questions on the interpretation of the model were raised. On Luxembourg's participation, the main point addressed was the need for statistical consistency in the national model across different institutions and data sources and the importance of detailed methodology and assumptions in national models. The Finnish experience presents the results of the national model which differ from the Freiburg results. Hence, questions regarding the assumptions and methodology used in the national model were raised. Finally, on the Canadian experience the provision of long time series was highlighted for its usefulness for analytical purposes. Some questions were raised on the interpretation of the results, the methodology and the sources used for compilation.

ESTIMATING SOCIAL SECURITY PENSION ENTITLEMENTS IN SPAIN

BY LOURDES PRADO UREÑA

I INTRODUCTION

The Eurostat/ECB Task Force on the statistical measurement of the assets and liabilities of pension schemes in general government developed its activity between mid 2006 (mandate agreed in CMFB meeting in June) and early 2008 (Final report presented in CMFB meeting in January).

The Task Force met six times during this period. The main tasks carried out were:

i) The design and the description of a supplementary table on pension schemes in social insurance to be part of the pension section in the updated SNA.

ii) The specification and definition of concepts related to the institutional units involved and to the stocks, transactions and other flows shown in the table.

iii) The selection and assessment of criteria to distinguish between defined-benefit government-sponsored employer pension schemes to be recorded in the core accounts or only in the table.

iv) The stock-taking of the features of all government-sponsored employer pension schemes and social security pension schemes in the EU Member States based on a questionnaire.

v) The alternative estimation of pension entitlements by using national models and generic models as provided by consultants of the Research Centre for Generational Contracts of the Freiburg University and of the World Bank.

vi) The presentation of the Task Force work to the CMFB in January 2008 and to the Eurostat Working Groups on National Accounts and Financial Accounts. The EPC – via the CMFB – and its Ageing Working Group has also been informed about the outcome of the Task Force. Finally, a Workshop on Pensions is to be held in Frankfurt in April 2009.

As a member of the Task Force, Spain has taken active part in the above mentioned tasks. In particular, a specific methodology was developed for the calculations of the supplementary table.

A working group made of different institutions involved in Spanish National Accounts and pensions was set up (see section 4). The first step was to estimate the stock of pension entitlements at the beginning and the end of each year (opening and closing lines of the supplementary table). Once this was achieved,

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

both stocks had to be reconciled using a set of different flows which constitute the rows of the table.

Efforts were stepped up and during 2007 a sound methodology was established for Social Security Schemes calculations firstly and for Government Employer Pension Scheme's later. This methodology has been used for the calculations of years 2005, 2006 and 2007.

The present document tries to describe the methodology followed for the estimation of Social Security pension entitlements in Spain. It is focused in Social Security calculations, as it covers a much larger group than the Government Employer pension scheme and both methods are quite similar. Anyway, a couple of lines about the estimations for the Government Employer pension scheme will be included to try to illustrate briefly its main aspects.

The document starts analysing the similarity between both schemes in Spain, as this issue was widely discussed during the different meetings of the TF. Due to this similarity, the Government Employer pension scheme is placed just in the supplementary table and not in the core accounts. In a second part, the text tackles directly the methodology mentioned in the previous paragraph.

It is worth mentioning that the concepts, definitions and methodology related to pensions are rather complex. Thus, the document tries to describe the process followed trying to keep the terminology as simple and clear as possible but without loosing its essence.

2 PENSION SCHEMES SPONSORED BY GENERAL GOVERNMENT IN SPAIN

In Spain there are two main schemes sponsored by General Government:
- The Social Security pension scheme (column H of the supplementary table).
- The Government Employer pension scheme (column G of the supplementary table).

The compromise adopted at the beginning of the Task Force was made of six principles. One of them was to keep Social Security schemes out of the core accounts; they would just be reflected in the supplementary table. For other schemes such as those Government Employer sponsored, the floor was open. The Task Force agreed on a set of criteria that would decide on these last schemes. One of these criterion was to include them in the core/non-core accounts according to their proximity to Social Security schemes.

Therefore, the similarity of this two schemes has been one of the most important points of the Task Force, as it determines the obligation of a scheme to form part of the core accounts or on the other hand, the option of appearing just in the supplementary table. This is the reason why the section Social Security versus Government Employer pension scheme has been included as part of the document.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

In the case of Spain, both schemes are almost the same. Population is obliged by law to participate and duplicity cannot exist. This means that whenever pension entitlements have been accumulated for both schemes, just one of them has to be chosen.

Both schemes are extremely close in terms of risk exposure (borne by the Government in both cases), legal framework, funding (both are unfunded) and ability of General Government to change the benefit formula (in both cases the Government has the discretion to change unilaterally the benefit formula at any point in time and thereby partially default on its pension obligations). Therefore, the modelling for estimating pension entitlements in both schemes is rather similar.

On the other hand, Social Security covers a larger group by far. It is responsible for 95% of the population, whereas the Government Employer pension scheme covers the 5%. This second scheme covers mainly civil servants (from Central Government, the Army, Justice and Law Courts, Public Universities related to the State, etc.). It also covers those civil servants that used to work for the Central Government and are currently working for the State Government after powers have been transferred (equation, health). Finally it also includes another group integrated by Ex Presidents, Vice Presidents, Ministers and others. Social Security covers some civil servants as well (those from the State Government and Local Government), but it is mainly integrated by all kind of employees (those with a contract, grants or in a training period), self-employed people, students and partners in cooperatives.

The next step is to describe the modelling of these schemes. The methodology for Social Security will be explained in detail. Due to the similarity of the two schemes, the modelling for Government Employer pension schemes will be briefly commented, and its main features will be outlined.

3 MODELLING FOR THE ESTIMATION OF FUTURE PENSION ENTITLEMENTS IN SOCIAL SECURITY

BACKGROUND

In 2006, after the first meeting of the Task Force, a working group was set up in Spain in order to fulfil the pension requirements and carry out the modelling for the estimation of pension entitlements. This group was leaded by the INE and integrated by the following institutions:

– Spanish Central Bank (Banco de España);
– Audit Office of the Ministry of Finance (IGAE);
– Ministry of Labour and Social Affairs;
– Social Security Treasury;
– Ministry of Finance;
– Statistical Office (INE).

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Two delegates, one from the Central Bank and another from the INE attended the TF meetings.

The working group met several times in the period 2006-2008, in parallel and after the TF meetings. It discussed widely about the estimation of pension entitlements and agreed on some guidelines about the modelling and assumptions to be used.

During 2007, the Ministry of Labour and Social Affairs carried out a pilot exercise; the first estimations of Social Security pension entitlements. Two experts were hired expressly for this task and worked closely to an expert from the Ministry. Following these steps, in 2008, the Ministry of Finance made the estimations for the Government Employer pension scheme. Once the estimations were ready, the flows that reconcile the stock of pensions entitlements at the beginning and the end of each period were completed. This way, Spain was able to provide data for columns G and H of the supplementary table for the first time.

MODEL

For the time being, the estimations have already been carried out for years 2005, 2006 and 2007.

It is important to underline that this calculations are related exclusively to contributory pensions. Non-contributory pensions are kept out of the modelling despite they exist in the framework of Social Security (in Spain they account for 2.7% of the total).

We talk about contributory pensions when benefits are related to contributions paid in the past. In this group the following pensions have been considered:

- Retirement pension;
- Disability allowance;
- Widow's pension;
- Orphan's pension.

On the other hand, we refer to non-contributory pensions when benefits are provided to people even if they have made no contributions at all.

In line with the Freiburg Model, the individuals considered are divided into two groups: current pensioners and current workers (active population, individuals who already pay contributions but have not generated a pension yet). Those included in the latter have not generated a pension yet, thus the estimations relate to the pension that they will generate in the future provided that the law does not change and that those who worked in the reference year will continue to do so until they generate the pension. Anyway the estimated amount for this second group does not refer to the total pension to be generated, but to that part that matches with the contributions already paid. In the Spanish system there is no direct correspondence between the contributions paid and the pension that will be generated, therefore the percentage of the future pension that correspond to

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

the contributions paid has been imputed using the Unit Credit Method that will be mentioned later.

As individuals have been classified in two groups, the total pension entitlements will be the sum of the entitlements calculated for each group.

Future pension entitlements = Already existing pensions+ Future pensions of active population

In both cases, the procedure to calculate the pension entitlements is similar. Pension entitlements are obtained starting off from some preliminary data and applying actuarial techniques taking into account a bundle of assumptions. This assumptions make reference to the discount rate, revaluations, life expectancy and others and will be described later in the document. Whereas this assumptions and the actuarial techniques keep mainly the same for both groups, the starting up information varies considerably from one group to the other. The case of current pensioners is rather simple, whereas the calculations for the active population become more complicated. Lets describe how to obtain these preliminary data for each case.

Already existing pensions

For already existing pensions the starting point is the figure obtained by multiplying the average amount of contributory pensions (which exist the 31st of December of each year and classified by type of pension, sex and year of birth of the pensioner) by the number of pensions. It is important to point out that future entitlements of pensions have been calculated using the life expectancy of the holder and not until year 2050 (as done in other models).

Future pensions of active population

On the other hand, for future pensions of active population, the starting point should be the pensions generated by the whole active population (individuals who have paid contributions at any time of the year considered) classified by age and sex. This calculation entails difficulties, as the active population is such a huge group that it is impossible to go case by case. Therefore, it was agreed to use a sample of working lives and estimate the pension to be generated by each individual in the sample. The pensions that would be generated by the whole active population will then be obtained using grossing-up factors by age and sex.

As the process above is rather complex it is worth describing both the sample and the technical aspects of the procedure itself in detail. The sample of working lives constitutes a representative sample of all the people related to Social Security in a given year. It is a set of anonymous microdata obtained from different registers: Social Security, Electoral Registers/Census and Tax Agency. It refers to approximately 1 million people, which represent 4% of the population. It is updated every year, the sampling used is random simple with no stratification and the grossing up factor used is 25.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

For each individual in the sample it is necessary to establish two pieces of information in the reference year:

– The number of days paying contributions to Social Security
– The average contribution's base (salaries)

With this information a simulation process is carried out, using stochastic methods and a set of assumptions, to obtain the type, date and amount of the pension that will be generated by each individual in the sample. Some of the assumptions used in the simulation process have been the following:

– The assumptions used for future salaries are in line with the PBO method. Thus, a rate of 1.8% annual increase in real terms over the working life has been considered.
– The frequency of death, invalidity and retirement is estimated by age and gender and it is assumed to remain constant in the future.
– The Unit Credit Method is used to impute for each individual in the sample the percentage of future pension that corresponds to the contributions paid in the reference year. The value of the future pension is multiplied by a coefficient obtained as the quotient of the time the individual has paid contributions and the total expected working life of the individual.

ASSUMPTIONS

Once preliminary data for already existing pensions and future pensions of active population have been calculated, the assumptions applied are the same for both groups.

Assumptions can be divided into two groups: those related to the benefits guaranteed and those related to the financial and demographic variables used for the valuation.

Assumptions related to the benefits

– Retirement: It has been assumed that there are no retirement pensioners under the age of 50. Thus, those under this age are considered as if they were 50.
– Disability: It is supposed that disability pensioners under 16 do not exist. Thus, the cases under this age are treated as if they were 16.
– Widowhood: It is supposed that widowhood pensioners under 16 do not exist. Thus, the cases under this age are treated as if they were 16.
– Orphanage: It has been assumed that orphans ranging from cero to 21 years old are included in this group and they receive the pension until they go over this age.

Assumptions related to the valuation

– The demographic tables used have been provided by the INE (men, women and total population) and Social Security Records (invalidity pensioners).
– Assumptions related to the discount rate, salary increase and inflation (revaluations) have been provided by the Ministry of Finance and are in line with those use in the Ageing Working Group (AWG).
– The discount rate considered is 3% in real terms. The inflation rate has been assumed to be 2%.
– The salary increase considered has been 1.8% in real terms.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

– The PBO method has been followed.
– The age difference between married couples considered is 3 years.
– The marriage rate of pensioners is 92%.
– Instalments are made in 12 payments.
– The reversion in case of widowhood is considered to be 60% of the retirement pension.
– In this model, estimations have been calculated using the life expectancy of the holder and not until year 2050.

OUTCOME

The estimations made for Social Security pension entitlements account for approximately 2.4 times GDP in each of the three years (2005, 2006 and 2007).

In parallel, the same estimations carried out for the Government Employer pension scheme, mean approximately 20% of GDP also for the three mentioned years. Adding up both results the ratio of future pension entitlements in Spain will be 2.6 times GDP per year.

4 MODELLING FOR THE ESTIMATION OF FUTURE PENSION ENTITLEMENTS IN THE GOVERNMENT EMPLOYER PENSION SCHEME

Following the steps of the Social Security scheme, the Directorate for staff expenditure and public pensions of the Ministry of Finance developed the estimations for the Government Employer pension scheme. In Spain, this scheme is called Clases Pasivas.

As both models are quite similar and the methodology for Social Security has been described in detail, for Clases Pasivas the document will just underline its main features.

Actuarial projections of public pensions consist of a demographic projection and a financial projection. In both cases three different projections should be considered:
– Projection of current active contributors and pensions derived;
– Projection of new generations of active contributors that will occur in the future and pensions derived (not considered in this study);
– Projection of current pensioners and the way the disappear progressively.

As in the previous scheme, the first projection (current active contributors) is the most relevant for the calculation of future pension entitlements.

The assessment of pension entitlements in the *Régimen de Clases Pasivas* has been done according to the PBO method.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

The demographic tables used have been a combination of those considered most appropriate by the experience of Clases Pasivas and a collection of Swiss tables for pensioners. The following tables have been used:

– Mortality and survival tables for pensioners for the period 1997-1998;
– For active population, Swiss tables EVK-95 (Eidgenossische Versicherung Kasse 95). INE tables for 2004-2005 have been used also.

The discount rate used has been 3% in real terms and the revaluation rate 2%.

Based on the own experience, the incapacity rate chosen has been the same that was used in the Social Security modelling, corrected with different factors for civil servants and military personnel. For biometrical survival functions, the Swiss EVK-80 tables have been used adding some corrections for the average number of children for civil servants and military personnel.

The modelling used is based in different actuarial projections of the ILO, ranging from a first version of J-P. Tullen to the current ILOPENS model.

The basic model starts from the formulas of J-P. Picard and J-P. Tullen with some variations as:

– the use of average ages of spouses and children instead of age distribution matrixes;
– the use of average estimated pensions instead of theoretical percentages for attributing pensions;
– values of actuarial income for life have been used for current pensions, for pensions derived and for active workers' pensions.

EXPERIENCES IN COMPILING PENSION ENTITLEMENTS IN LUXEMBOURG

TOM DOMINIQUE[1]

1 CONTEXT

The paper illustrates the methodology applied to the Luxembourg old age related schemes in order to compute implicit liabilities as defined by the European Central Bank/Eurostat Task Force of the Committee on Monetary, Financial and Balance of Payments Statistics[2] (CMFP). Special emphasizes is given on consistency matters regarding the computation of the pension entitlements with common available data and applied methodology in other fields of social protection and social budgeting.

A first section gives an overview of old age social protection schemes in Luxembourg. A second section explains the methodology used to compute implicit liabilities. A third section provides the modelling results and a final section presents concluding remarks.

2 OLD AGE RELATED SCHEMES

In Luxembourg several instruments are into place to ensure that elder people continue to receive an income.[3]

THE GENERAL PENSION SCHEME OF THE PRIVATE SECTOR

The general pension scheme is a mandatory scheme and each person having a gainful occupation in the private sector has to be affiliated to the general pension scheme. It can be characterised as a defined benefit scheme, the pension being based on a formula linked to members' wages or salaries and the length of employment. It is a contributory scheme where both the employers and the members have to pay into the scheme.

Apart from civil servants and other statutory employees of general government and two public companies (post/telecom and national railways) with statutory special schemes, all those who are covered by pension insurance in Luxembourg

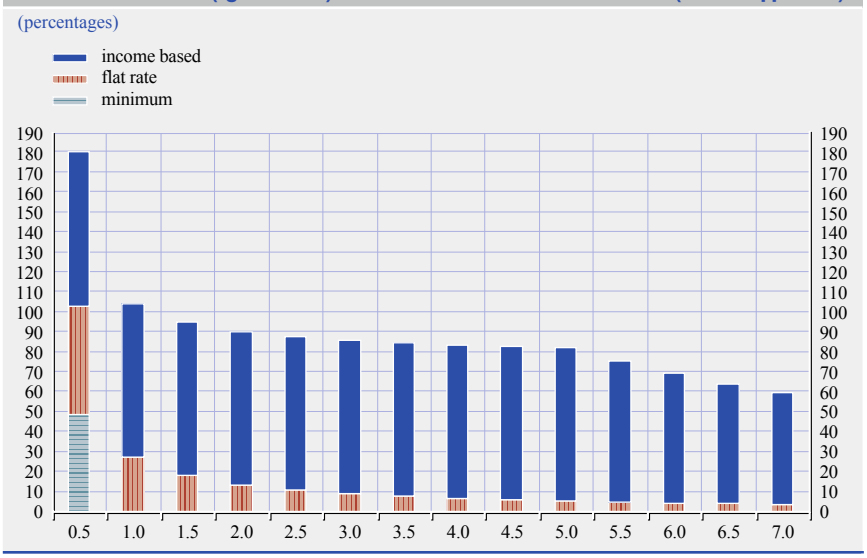
belong to the general pension scheme. Those people who belong to a pension scheme by virtue of working for an international body are not subject to the national scheme.

The general pension scheme in Luxembourg comprises invalidity, retirement and surviving dependants' pensions. The length of time an individual earns rights to the pension benefit is formed by two types of service periods: periods during which contributions are paid (gainful occupation, periods of compensation benefits or voluntary contributions) and additional periods (mainly related to apprenticeship, educational training or child education) for which no contributions are paid. The entire service period is referred to as "total career length" (TCL) whereas the part of the career length related to contributions is referred to as "effective career length" (ECL).

The old age pension formula consists of several components: a flat rate component, an accrual rate component, a staggered accrual rate increase and an "end of the year allowance". Flat rate related benefits are based on the total career length and are not affected by earnings. After 40 years of membership, they are equal to 23.5% of a reference amount (RA). The reference amount corresponds to 100% of the legal social minimum income from work. Flat rate benefits are reduced by 1/40 for every year of difference between 40 and the total career length. The number of years taken into account cannot exceed 40. Accrual rate related benefits (income based) are exclusively associated to the effective career length and are equal to one twelfth of 1.85% of the sum of all income from work (TIC), adjusted to price and wage evolution. Staggered accrual rate increases depend on the age and the contribution history of the beneficiary, beginning at the age of 55 with a contribution history of 38 years. Each additional unit (one per year of age and one per year of contribution) raises the accrual rate by 0.01 up to a maximum limit of 2.05. The "end of the year allowance" (EA) represents an additional flat rate component. This allowance is reduced by 1/40 for every year of difference between 40 and the total career length. The number of years taken into account cannot exceed 40.

The monthly pension formula becomes:



$$P = (0.235 \times RA + EA/12) \times \min[1,TCL/40] + \{0.00185 + 0.0001 \times (age - 55 + \max[38,ECL] - 38\} \times TIC/12$$

Every beneficiary is entitled to an old age pension at the age of 65, provided he has an effective career length of at least 10 years. A beneficiary is entitled to an early old age pension at the age of 60 if he has a total career length of at least 40 years. An early old age pension at the age of 57 years is granted to beneficiaries with an effective career length of at least 40 years.

Invalidity pensions are calculated in the same way as old age pensions. In order to ensure that recipients of invalidity pensions receive an adequate income, however, the period taken into account for the income based enhancement is extended to the age of 55 (special income based enhancement), the amount of the enhancement being derived from a notional salary corresponding to the average of the monthly salaries on which actual contributions have been paid.

Chart I Gross replacement rate of pension system for a typical career of 40 years of contributions (age 20 to 59) as function of social minimum income (SPC-ISG approach[1])

1) Current and prospective theoretical pension replacement rates: Report by the Indicators Sub-Group (ISG) of the Social Protection Committee (SPC), European Commission, 2006. http://ec.europa.eu/employment_social/spsi/docs/social_protection/isg_repl_rates_en.pdf

The period on which the flat rate enhancement is based is notionally extended to the recipient's 65th birthday (special flat rate enhancement).

The surviving spouse's pension comprises three quarters of the income based enhancement, including any incremental or special enhancement, the entire flat-rate enhancement, including any special enhancement, and the entire end of year allowance to which the insured was or would have been entitled. Abatement provisions apply if the surviving spouse's total income exceeds a fixed ceiling.

The surviving child's pension comprises one quarter of the income based enhancement, including any incremental or special enhancement, one third of the flat-rate enhancement, including any special enhancement, and one third of the end-of-year allowance.

The general pension scheme guarantees its members a minimum personal pension equal to 90% of the reference amount provided that they have belonged to the scheme for at least 40 years (total career length). It is reduced by one fortieth of the amount of the personal pension for each missing year, down to an eligibility threshold of 20 years.

SPECIAL PENSION SCHEMES FOR CIVIL SERVANTS AND STATUTORY EMPLOYEES

Special schemes comprise the civil servants and other statutory employees of central government, local government, social security funds and two public non

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

financial companies (post/telecom and national railways) that differ from the general scheme as defined in the Social Insurance Code. Non statutory employees of general government however are included in the general pension scheme.

Special schemes have two distinct pension regimes: the original regime, now known as the transitional special pension scheme, which has undergone numerous amendments, and the new special pension scheme, which, apart from a few specific procedural and funding features, essentially corresponds to the general pension scheme.

In the transitional scheme for civil servants and persons treated as such who were in post on 31 December 1998 or had been appointed by that date, the features of the old scheme have been preserved. In other words, the pension is calculated on the basis of the final salary earned by the public servant (gross replacement rate equal to 83.33%). For years of service after 1 January 1999, the reference replacement rate is lowered in stages from 83.33% to 72%. However, public servants who have completed a full service career of 35 or 40 years when they become eligible for early retirement at the age of 55 or 60 can enhance the value of their pension by 2.31% of their pensionable pay for each year of service beyond that age. In this way, they can obtain, at the age of 60 or 65 as appropriate, a pension corresponding to the maximum pension available under the old scheme.

Applying to civil servants and other statutory employees who entered the public service after 31 December 1998, the new scheme retains the status of a special scheme, but it is based on the same principles as the general pension scheme, with the exception of the income ceiling for the assessment of contributions.

INDEXATION OF PENSIONS

Pensions are automatically adjusted to price evolution each time prices increase by more than 2.5%. In addition, pensions are adjusted every two years to the real wage evolution. Whereas price indexation is automatic, the decision on indexing pensions to wage evolution is the responsibility of government and has to be approved by the parliament.

3 MODEL APPROACH

MODEL DESCRIPTION

A data-processing tool (SOBULUX, Social budget simulating software for Luxembourg) was implemented by the General inspectorate of social security (Inspection Générale de la Sécurité Sociale, IGSS) in order to perform long term financial projections of receipts and expenditures of the pension system. SOBULUX is a cohort-based standard simulation model, based on previous International Labour Organisation (ILO) macro projections.[4] The model covers

4 *Évaluation actuarielle et financière du régime général d'assurance pension du Grand-Duché de Luxembourg*, BIT, 2001. http://www.ilo.org/public/english/protection/socsec/tc/luxemb/lureport.htm

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

the general pension scheme of the private sector and the special statutory pension schemes. A detailed description of the model structure is given on the web site of the national statistical institute.[5]

Basic dimensions of the model are age, sex and origin. Additional dimensions allow differentiating employment status (blue collar, white collar or civil servants) and pension type (disability, old age, early old age or survivor pension). In order to take account of peculiarities of the Luxembourg labour market (high proportion of migrant and cross border workers), the instrument was designed to include dimension of residency.

Pension expenditure is calculated on the basis of average pension (differentiated by sex, age, origin, employment status and pension type). New pensions to be granted are computed on the basis of the available career elements and the pension formula. The model applies a specific module to compute the acquisition of pension accruals. Cohort career elements (aggregate life time salary and aggregate compulsory insurance periods) are established from data available in the IGSS Data Warehouse for the reference year (2002). The model is calibrated in order to reproduce observed figures over the period 2003-2007.

Survivor pension are computed in several steps. In a first step the number of eligible survivors is computed on the basis of known information of married couples. In a second step, survivor age is determined by applying an average age difference between married partners. In a last step the average survivor pension is computed on the basis of legal dispositions.

Pension entitlements are computed on an accrued to date pension liabilities basis. Only the current values of entitlements, arising from the already accrued pension rights, are compiled. Ex-post pension entitlements rely on a number of assumptions which are taken in line with the Economic Policy Committee agreed common set of assumptions and methodologies on long term old age expenditure projections (see section below).

The model applies the accumulated benefit obligation approach so that it does not need to introduce assumptions on future evolution of individual wages over the life cycle in regard of expected promotions and other nominal wage growth factors. Pension elements are determined on the basis of actually known wage histories of the scheme members and pension benefits are adjusted to the global wage growth in the economy.

COVERAGE OF OLD AGE PROVISION

Pension projections include pension provisions from the general pension scheme of the private sector and from special statutory schemes. Expenditure items include all types of old age benefit granted by the schemes, including disability and

5 The Luxembourg pension model – Pension projection exercise: Peer review on pension models and results, IGSS, 2005. http://www.statec.public.lu/fr/agenda/2009/20090220/modele/LuxPension_IGSS/01Luxembourgpensionmodel.pdf

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

survivor pensions for people aged less than 65. In addition, projections do include minimum pension provision guaranteed in the context the pension schemes.

The high level of pension provision from public pensions leaves only a limited need for supplementary schemes. In addition, until now, no detailed information is available not on occupational (0.6% GDP as provisions) pension schemes, nor on individual private pensions (0.2% of GDP as provisions). For both reasons supplementary pensions are excluded from the projections. Social assistance expenditure to people in retirement age (0.055% of GDP in 2007) is not included in the projections.

The coverage of the pension projection model is close to 100%. A detailed list of the schemes include in the projection, based on the standardized classification framework of the European System of integrated Social PROtection Statistics[6] (ESSPROS), is given in the table below. Qualitative information on the schemes is available at the European Commission web site.[7]

In the context of the possible criteria for core or non-core recording as outlined in the report to the CMFB, all schemes are unfunded general government pension schemes and only recorded in the supplementary table as foreseen in the international compromise on the treatment of pension schemes in the updated System of National Accounts (SNA). Scheme 3 is classified as social security pension scheme (column I of the questionnaire on the statistical measurement of the assets and liabilities of pension schemes in general government of EU countries by the contact group on the statistical measurement of the assets and liabilities of pension schemes in general government) whereas

Table I Classification of pension schemes applying Esspros methodology

Scheme 3	Pension scheme (Assurance pension)
Scheme 17	Special pension scheme – civil servants and assimilated employees of central government (Pensions statutaires – Administration centrale)
Scheme 18	Special pension scheme – civil servants and assimilated employees of local government (Pensions statutaires – Administrations locales)
Scheme 19	Special pension scheme – civil servants and assimilated employees of social security funds (Pensions statutaires – Administrations de Sécurité Sociale)
Scheme 20	Special pension scheme – civile servants and statutary employees of 2 public corporations, i.e. the public postage and telecommunication company and the national railway company (Pensions statutaires – Sociétés publiques)

6 ESSPROS manual, European Commission, 2008 http://epp.eurostat.ec.europa.eu/cache/ITY_OFFPUB/KS-RA-07-027/EN/KS-RA-07-027-EN.PDF

7 EUROSTAT – ESSPROS database, qualitative information by scheme http://circa.europa.eu/Public/irc/dsis/esspros/info/data/esspros_public_data/Qualitative/base_qualitative.htm

schemes 17 to 20 are classified as defined benefit schemes for general government employees classified in general government (column H in the questionnaire).

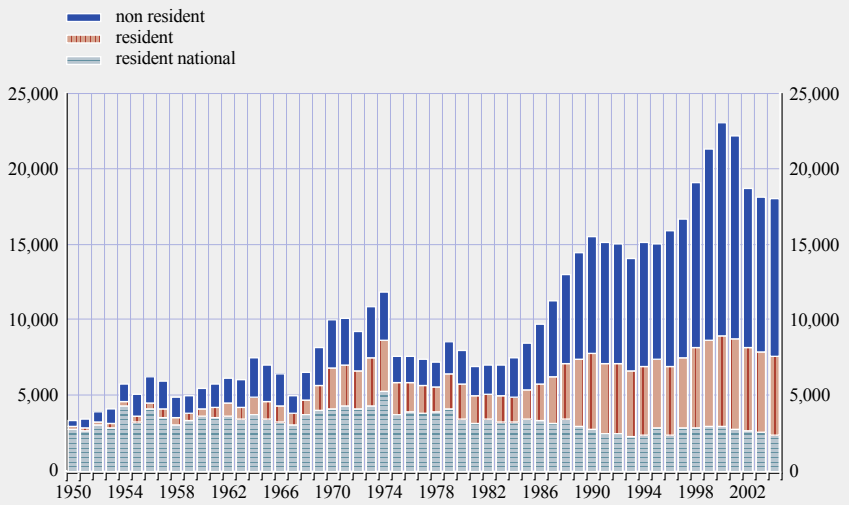
The model does not make a distinction between the special pension schemes 17, 18, 19 and 20 and for the purpose of the projection these schemes are grouped to an overarching special scheme so that some minor classification differences arise in comparison to the classification in the SNA. Scheme 18 is classified as social security pension scheme in the SNA as it is organised by a pension fund classified in social security and financed mostly by employer's actual social contributions. Scheme 20 is classified in the sector of public non financial companies in the SNA as the correspondent companies are classified in the sector of public non financial companies.

ECONOMIC POLICY COMMITTEE AGREED COMMON SET OF ASSUMPTIONS AND METHODOLOGIES ON LONG TERM OLD AGE EXPENDITURE

In 2006, the ECOFIN Council gave a mandate to the Economic Policy Committee (EPC) to update and further deepen its common exercise of age related expenditure projections. The work has been carried out by the EPC Working Group on Ageing Populations (AWG) gathering experts from 27 Member States and Norway and the European Commission (represented by the Directorate-General for Economic and Financial Affairs). The starting point is the population projection EUROPOP2008, produced by Eurostat. In a next step, the EPC agreed a common set of assumptions and methodologies to make projections for exogenous macroeconomic assumptions: the labour force (participation, employment and unemployment rates), labour productivity and the real interest rate. GDP is calculated combining these assumptions. On this basis of these common assumptions, Member States run the projections for pensions using their own national models. A peer review process validated the national pension model on the compliance with agreed assumptions and methodology. A report on the EPC projection procedure is available on the European Commission web site.[8]

Pension entitlements in the case of Luxembourg are computed using the same projection method as used in the context of the EPC projections so that assumptions and methodology applied in EPC and CMPF computations are compliant.

COMPLIANCE OF THE MODEL WITH AWG COMMON ASSUMPTIONS



A constant policy scenario is strictly applied. Indexation of pension is fully aligned to price and wage evolutions.

Fertility rate, life expectancy and migration are in line with EUROPOP2008 base scenario (AWG baseline).

Chart 2 Absolute number of new members of the general pension scheme as a function of residency over the period 1960-2004

Source: IGSS.

Labour force participation rates are computed by applying entry probabilities to inactive population or exit probabilities to active population. In the long run it is assumed that exit probabilities of the various socio-economic agents converge to those currently observed for the resident male white collar workers by the year 2060. Exit probabilities are calibrated in order to proxy the AWG assumptions on labour force participation rates.

AWG employment growth assumptions are used for the projections. Due to the specific situation of the composition of the labour market characterised by a high participation of non resident labour force, labour supply cannot be proxied by applying participation rates to resident population.

The approach used by the Commission to compute cross border employment growth is based on a comprehensive approach. It focuses on the peculiarity specific to Luxembourg – that of a huge number of cross border workers – rather than on the 'top-down' approach to make GDP projections – first fixing GDP on the demand side and subsequently 'filling the gap' with the required labour input externally – in order to exclusively address the Luxembourg-specific situation. The Commission methodology involves the following steps:

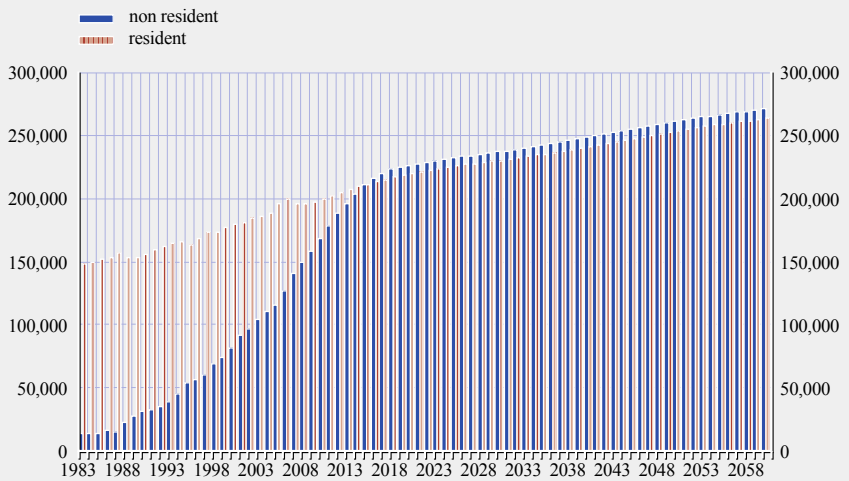
– Cross border workers are proxied by the difference between the total number of persons employed according to the National accounts and the total number of employed persons according to the Labour force survey.

– The ratio of cross border workers to total employment ('foreigner ratio') has risen over time, but the growth rate of this ratio has been on a downward trend over time.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

– A regression function of the growth rate of the foreigner ratio, using a constant and a linear time-trend as explanatory variables (over the full period available: 1983-2007) is estimated.

– The trend (slope) was extrapolated linearly from 2008 onwards and hence the foreigner ratio was allowed to increase until the growth rate would turn negative; at this point, we fixed the foreigner ratio (at about 0.5).



– This would result in an excess growth of cross border workers (over the growth of domestic employment) until 2018 and from then onwards, both cross border workers and resident workers evolve at the same pace.

Standard exit probabilities as observed for residents are applied to non resident pension scheme members. In addition, global life expectancy as for residents is applied to cross border workers.

The total number of civil servants is supposed to increase at the rate of 0.5% per year. Due to the fact that civil servants schemes apply the same pension formula as the general pension scheme from 1999 onwards, the relative share of civil servants within the employed does not have a major impact on pension expenditure in the medium and long run.

Age specific earning profiles are used to compute total economic wage levels. AWG labour productivity assumptions are applied to model real wage growth.

Chart 3 Historical and projected number of contributors to the pension system by residency between 1980 and 2060

Source: IGSS.

COMPARISON OF MAIN INPUT DATA FOR THE MODEL WITH AVAILABLE DATA SOURCES

The statistical Data Warehouse (DWH) implemented by the IGSS centralizes all relevant statistical data in the framework of social protection in an exploitable form. During the past years the IGSS put huge resources in developing the DWH project. Systematic identification procedures concerning administrative data sources at the level of social security institutions and rigorous documentation of procedures on transformation and migration of administrative data from the operational files to the statistical data files in the DWH are now available. Before being integrated in the DWH, raw individual data is checked on quality consistency. In addition, a harmonization procedure is applied in order to ensure a correct and comprehensible labelling of variables.

Today, the DWH constitutes the starting point of different research projects and is used to analyze the joint effects of direct redistribution policies by social transfers and indirect impacts of taxation and contributions on the disposable income of a household or an individual. In particular, the DWH represents the reference database for generating the input data for the pension projections in the context of the SOBULUX model. In addition, the DWH includes all relevant data for establishing national and international statistics on social protection.

CONTRIBUTORS TO THE PENSION SYSTEM

The present section compares the number of contributors to the pension system as used in the model to available data in the DWH for the month of December and in the SNA for the last quarter[9] over the period 2005-2007.

Table 2 Ratio of the number of contributors to the pension system as used in the model to available data in the DWH for the month of December and in the SNA for last quarter

(percentage)

	DWH	SNA
2005	100.6	102.2
2006	101.5	102.9
2007	99.2	100.7

The number of contributors to the pension system is close to the number of contributors as registered in the DWH. Differences are mainly due to the fact that model contributors are projected over the period 2005 to 2007, using 2002 data as base year. In general the model computes slightly more scheme contributors as are reported in the SNA. Reasons for this small discrepancy are multiple. Model reference data is based on December whereas SNA figures refer to the last

9 EUROSTAT – SNA database http://epp.eurostat.ec.europa.eu/portal/page/portal/national_accounts/data/database

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

quarter. In addition pension system contributors include individuals which are not considered as employed in the SNA (e.g. unemployed, preretirement, …).

EMPLOYEE AND EMPLOYER CONTRIBUTIONS

In the context of the pension entitlement computation exercise, model aggregate figures to be reported in the supplementary table as foreseen in the international compromise on the treatment of pension schemes are calibrated to SNA figures [10] whereas in the context of the AWG projection exercise aggregate figures are calibrated to ESSPROS data.[11]

Table 3 Ratio of employee and employer contributions in the SNA to figures reported in ESSPROS

(percentage)

	SNA
2005	100.2
2006	100.5
2007	100.4

The comparison of employee and employer contributions in both datasets shows that differences in contribution recording are insignificant over the period 2005-2007.

SYSTEM BENEFITS

The pension model computes pension benefits on the basis of the observed figures for the reference year 2002. The present section compares the computed benefits by the model to available data in ESSPROS-Pension beneficiaries' module [12] and the DWH over the period 2005-2007.

Table 4 Ratio of the number of benefits computed by the model

(percentages)

	ESSPROS no doublecount	ESSPROS doublecount	DWH
2005	107.7	102.1	101.5
2006	108.5	101.9	102.2
2007	108.1	101.5	101.8

The model overestimates to some minor extent the number of benefits in comparison to the data available in the DWH and in ESSPROS. It has though to be reminded that the model computes pension benefits and not pension

10 Portail des statistiques du Luxembourg – Comptes nationaux http://www.statistiques.public.lu/stat/ReportFolders/ReportFolder.aspx?IF_Language=fra&MainTheme=4&FldrName=2

11 EUROSTAT – ESSPROS database, Receipts http://circa.europa.eu/Public/irc/dsis/esspros/info/data/esspros_public_data/publication/receipts.htm

12 EUROSTAT – ESSPROS database, Pension beneficiaries' module http://circa.europa.eu/Public/irc/dsis/esspros/info/data/esspros_public_data/PB/pension_beneficiaries.htm

beneficiaries, so that the model dos not separate double counting of beneficiaries with benefits from several pension schemes.

SYSTEM EXPENDITURE

As in the case of pension system receipts, model aggregate expenditure figures are calibrated to the SNA in the CMFP projection exercise whereas in the context of the EPC projections aggregate figures are adjusted to ESSPROS [13] data.

Table 5 Ratio of system expenditure in the SNA to figures reported in ESSPROS

(percentages)

	SNA
2005	98.6
2006	98.8
2007	99.0

As for the comparison regarding the receipts of the pension system, differences on benefit expenditures are insignificant between figures reported in both databases.

PROJECTION RESULTS

Model results show that the actual pension entitlements (accrued to date pension liabilities) are close to 300% of GDP over the period 2005 to 2007.

Table 6 Projected pension entitlements[1)]

(percentage of GDP)

	2005		2006		2007	
Column	H	I	H	I	H	I
Pension entitlements	60.8	307.4	56.8	296.7	55.4	299.4

1) Column H: Defined benefit schemes for general government employees classified in general government; Column I: Social security pension schemes.

Pension entitlements computed in the context of the CMFP are not an indicator of long-term sustainability of pension systems or of public finance. Pension liabilities give an indication on the cost of closing the pension system but the figures give no indication on the sustainability of the pension system because they do not include projections, neither on new contributors, nor on expected total individual pension expenditure at the moment of retirement. For this purpose an open system approach, as it is applied in the context of long term old age expenditure projections of the EPC, has to be considered.

13 EUROSTAT – ESSPROS database, Expenditureshttp://circa.europa.eu/Public/irc/dsis/esspros/info/data/esspros_public_data/publication/expenditure.htm

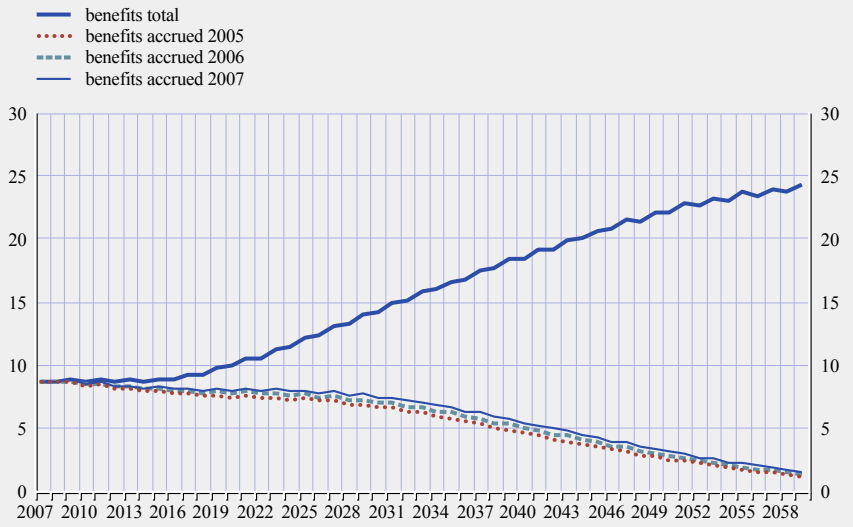
Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

EPC based methodology expenditure projections expect the development of total social security pensions spending to GDP to increase sharply between 2007 and 2060.[14] By 2060 pension expenditure will be around 24% of GDP.

Table 7 Projected gross pension spending

(percentages of GDP)

	2000	2007	2020	2030	2040	2050	2060
Social security pensions	9.1	8.7	9.9	14.2	18.4	22.1	23.9
Old-age and early pensions	5.6	5.8	7.0	10.9	14.9	18.3	20.1
Other pensions	3.5	2.9	2.9	3.3	3.6	3.8	3.9



Both concepts, accrued to date liabilities and total pension expenditure, do not provide a complete picture on the sustainability of the pension system as actual assets and assumed future receipts of the system are not considered. The total expenditure approach although has the advantage of isolating future pressure on pension scheme by providing a quantified estimate of annual financial burdens to be expected over the projection period.

In Luxembourg, the pressure on public pension spending comes from changes in dependency ratio of the pension system. Over the projection period the number of

14 2009 Ageing Report: Economic and budgetary projections for the EU-27 Member States (2008-2060), European Commission, 2009 http://ec.europa.eu/economy_finance/publications/publication14992_en.pdf

Chart 4 Annual pension benefit expenditure accrued to the years 2005-2007 and annual total benefit expenditure over the period 2007-2060

(as percentage of GDP)

Source:

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

contributors per pensioner is sharply decreasing so that less and less contributors have to support more and more pensioners. In addition, due to the fact that the average compulsory contribution period is supposed to increase for all socio-economic agents due to complete careers of migrant and cross border in the long run and increasing participation rates of resident females, the benefit ratio is supposed to amplify in the long run.

4. CONCLUDING REMARKS

The method applied in the case of Luxembourg for computing pension entitlements is fully compliant to old age related benefit projections by the EPC. A single model is used to compile total expenditure figures as well as accrued to date liabilities for the pension system, based on equivalent input datasets, assumptions and methodology. In this way full consistency is ensured in the calculation of projected pension elements within the two different concepts. The methodology is in line with existing frameworks already developed and applied in other fields, especially regarding ESSPROS statistics and the Open Method of Coordination [15] (OMC).

A close collaboration in the context of pension expenditure projections for Luxembourg between national public authorities (national statistical institute STATEC, Ministry of Finance, Ministry of Social Security) ensures an adequate application of concepts at the national level. This strategic approach allows a comprehensive communication of the results, without running the risk of publishing divergent figures and distinct statements.

Accrued to date liabilities and total benefit expenditures are crucially depending on projection models. In order to avoid misinterpretation and to endorse the projection results, it should be made certain that statistics in the area of old age related expenditure projections produced by public authorities at national and international level are based on the similar principals, identical assumptions and harmonized methodologies.

THE SOCIAL SECURITY PENSION SCHEME IN FINLAND

BY PAULA KOISTINEN-JOKINIEMI [1]

This is a background document to the Finnish presentation given in the ECB/ Eurostat Workshop on Pensions in Frankfurt, 30 April 2009.

The main focus of the presentation is to summarise the first experiences of Statistics Finland in exploiting the new Supplementary Table on pension schemes outlined for the updated SNA93 and the revised ESA95. Our comments concentrate mainly on the technical implementation of the Table without trying to explain the background of the Finnish pension entitlement estimates.

1 FINNISH PENSION SYSTEM IN BRIEF

The Finnish public pension system is made up of two statutory pension schemes: the national pension scheme guaranteeing a minimum pension to all residents, and the employment-based, earnings-related pension scheme which is an insurance against loss of salaried income. Payments in statutory pensions amounted to approximately 11 per cent of GDP in 2008, of which the employment based earnings-related pensions accounted for around four fifths and the basic national pensions for the rest, though the role of the latter is diminishing.

Voluntary pension insurance has so far played a minor role in Finland due to the relatively high net replacement ratio of public pensions, the lack of pension ceilings and the full coverage of the statutory systems. The share of the voluntary pension provision of the total pension expenditure is only around five per cent.

In pension terminology pensions are generally divided into three categories, which are referred to as 'pillars'. In Finland there are two complementary first-pillar pension schemes: the national pension scheme, and the earnings-related pension scheme. Both of these are statutory schemes, which makes them both part of the country's social security system. This situation is unique in Europe, as most of the earnings-related pension schemes in other European Union countries belong to the second pillar.

The two statutory pension schemes are closely linked together, with the amount of national pension depending on the size of the earnings-related pension benefits. Increases in the earnings-related pension reduce the national pension by 50 per cent. If the earnings-related pension is above a specified level, the national pension is not paid at all.

1 Statistics Finland.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

The statutory earnings-related pension scheme covers all gainfully employed persons. It comprises different acts for private sector employees, seamen, farmers and entrepreneurs, as well as separate acts for central and local governments, the Finnish Evangelical-Lutheran Church and for some other public institutions. In the 2005 reform the pensions benefits under the different acts – both private and public – were harmonised to a large extent and the benefit and accrual rules are nowadays identical (even if their financing arrangements differ), so that the system can be considered as a collective social security system as a whole. Despite the nature of the system, the administration is decentralised and the pensions are managed by several pension institutions (private pension companies, pension funds and pension foundations, public institutions).

The financing arrangements vary from pure pay-as-you-go (PAYG) schemes to partly funding schemes, but as a general rule the financing of earnings-related pensions is a combination of a pre-funding and a pay-as-you-go system based on insurance contributions from both employers and employees. The pre-funding schemes cover approximately one quarter of corresponding pension outlays, and the rest is financed through the PAYG system.

Despite the pre-funding system in pensions, Finland's earnings-related pension scheme is entirely of defined-benefit type. The pre-funding is collective in the sense that it has no effect on the size of the pension. The sole purpose of the pre-funding is to cut the peak of pension contributions in the coming years. The financial position in the earnings-related pension schemes is fairly good; the system is running on surpluses. The annual surplus has in recent years been some three per cent in relation to GDP. The market value of the pension assets make up about two thirds of GDP (in 2007).

For more information (pension acts etc.), see the website of the Finnish Centre for Pensions at: www.etk.fi

2 SUPPLEMENTARY TABLE ON PENSIONS: FINNISH TEST EXERCISE

The following chapter of the document refers to the draft Supplementary Table on pension schemes, as included in the report of the Eurostat/ECB Contact Group on pensions to the CMFB meeting in February 2009.[2] The Table has been outlined for the updated SNA93 and the revised ESA95.

Among other countries, Finland took part into the test exercise organised by the Eurostat/ECB Contact Group on pensions in order to estimate the benchmark pension entitlements based on the pension model and on harmonised model assumptions as specified by the Research Center for Generational Contracts of the University of Freiburg. For Finnish part the exercise was assisted by Statistics Finland with the help of experts of the Finnish Centre for Pensions. The Finnish

2 Report of the Eurostat/ECB Contact Group on the statistical measurement of the assets and liabilities of pensions schemes in general government to the CMFB meeting, 5-6 February 2009

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

estimations were made for the years 2006 and 2007. The required input data were mainly obtained from the employment and pension registers of the Finnish Centre for Pensions covering all relevant schemes (including civil servant schemes).

The old-age, disability, unemployment, part-time, old-age and survivors' pensions form an integrated part of the pension benefits/entitlements based on Finnish pension laws, so they were also covered by the benchmark estimates. During the exercise there was some debate on whether the national pensions should also be included in the entitlements due to the close linkage between the Finnish earnings-related pension and the national pension (as noted above). However, we concluded that the national pensions should be excluded because of two arguments. First, because no social contributions are payable in the national pension scheme, it can be seen more as a social assistance and not as a social insurance scheme. In the second place, our understanding is that because there is no proper annual pension accrual in the national pension scheme, no reasonable pension entitlement could be compiled either.

The Freiburg University's country studies in the framework of the new Supplementary Table were introduced in the CMFB February report, Finnish social security pension entitlements being shown as total (pages 87-89). Since then the Finnish version of the Supplementary Table has been further elaborated by the experts of Statistics Finland to show the split between private and public pension schemes. This split was done by making use of the separate pension entitlement estimates for the private and public schemes compiled by the Freiburg University. The table was then completed using the same patterns and totals as in the initial Freiburg calculations. To compile the so called 'Household social contribution supplement' the initial assumed five per cent discount/interest rate (in real terms) was also used – the rate being higher than in many other countries' benchmark compilations.

The completed version of the Finnish Supplementary Table for 2007 is shown in table 1 of the Finnish presentation in the Workshop.

SOME CLASSIFICATION ISSUES

At the moment all Finnish statutory earnings-related schemes – both private and public – are classified as social security schemes in ESA95 National Accounts. Our conclusion was that in the new Supplementary Table on pensions they should be shown under column 'Social security pension schemes' (column H). The public sector employer schemes (schemes for government employees) should also be reported under the same category based on the following arguments.

As noted in the previous chapter, the Finnish public sector employer schemes are very close to the nature of social security, and the statutory pension system as a whole can be seen as applicable to the population at large. From the ESA95 point of view this supports the recording of the public sector employer schemes together with other social security schemes in the Supplementary Table.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

From the standpoint of users of statistics this is probably not so obvious. On the contrary, there is clearly a need to have separate data on the public sector's own employer entitlements, even if the public schemes were classified as social security schemes in the statistics. Of course the split to private and public sector entitlements can be added for national purposes – as we have done in the test table – but we think that this kind of information should be clearly available for all users in the forthcoming Supplementary Table.

INTERPRETATION OF THE RESULTS

The representation of the annual change of pension entitlement in the Supplementary Table partly differs from the Finnish national representation. In the reports of the Finnish Centre for Pensions this change is normally comprised of three factors: annual pension accrual, annual pension benefits and a certain interest component. In the Supplementary Table the annual pension accrual is replaced by annual social contributions, and a special row called 'Other (actuarial) increase of pension entitlements' (Item 3 in case of social security scheme) is used to 'match' the change in the pension entitlement. However, in the Finnish system the employer's or employee's actual contributions are not relevant to the annual pension accrual, whereby the interpretation of the information in the Supplementary Table may be somewhat challenging to the users.[3]

The outlined Table contains a separate 'non-core' column for those public sector employer schemes that are not social security schemes (column G). The corresponding 'matching' item in column G is 'Employer imputed contributions' (Item 2.2). This item will also be shown in the 'core' national accounts but there is some concern of whether it should be recorded using the same valuation as in the Supplementary Table.

We think that there are strong reasons for not using the same valuation in the 'core' accounts. In practice the 'Employer imputed contributions' (as well as Item 3) will probably be compiled as a residual item in the Table whereby it may significantly vary from one year to another. If the same valuation were to be used also in the 'core' national accounts, this imputed item would have quite a significant and volatile impact on GDP.

3 LONG-TERM PLANNING MODEL OF THE FINNISH CENTRE FOR PENSIONS

National estimates of pension entitlements are compiled by the Finnish Centre for Pensions (FCP) and included in their public reports. The estimates are produced with the long-term planning model developed by the Centre to meet the

3 In Finnish earnings-related schemes the pension accrues based on a certain accrual rate, whilst the confirmed annual contribution rate may vary below or above the annual pension accrual. After the 2005 pension reform, the pension accrues also during some earnings-related social benefit periods when no contributions are payable (such as parenthood allowance, earnings-related unemployment benefits or periods of childhood and study).

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

planning and forecasting needs of the Finnish pension system. It is an actuarial projection model by nature and there is only little economic theory built in to the model. The model simulates the operation of the pension scheme studying each pension act separately. The existing pension legislation and other stipulations are normally assumed to remain unchanged until the end of the projection period. The projections are based on an average technique by age and gender.

The core assumptions of the latest projection published by FCP are: [4]

1. Population according to 2007 forecast by Statistics Finland
2. Employment rate + 3 percentage points by 2050
3. Effective retirement age + 2.4 years from current level by 2050
4. Actual growth in earnings level 1.75% per year
5. Actual growth of return on pension assets 4.0% per year

The interest rate as such is not critical in the model, but deciding factor is the estimated actual rate of return of the pension assets. As regards the assumptions, the employment rate and the effective retirement age are near the Aging Working Group (AWG) assumptions for Finland. The others slightly differ from those used in the AWG or Freiburg benchmark estimates.

In order to compare the national pension entitlement estimates to the benchmark compilations based on the 'Freiburg' model, a test compilation was carried out by the experts of the Finnish Centre for Pensions using their national long-term projection model but changing the discount rate to 3 per cent and the growth in earnings level to 1.5 per cent, as in the Freiburg exercise. The pension entitlements were compiled separately for the private and public schemes for the years 2006 and 2007. The first results of this test compilation, as well as the 'Freiburg' benchmark estimates are shown in Tables 3 and 4 of the Finnish presentation in the Workshop.

The very first results indicate that the national (FCP) estimates for the total pension entitlement, as well as for the private schemes fall in the middle of the results based on the two 'Freiburg' methods (ABO and PBO) in both years. For example in 2007, the share of total pension entitlement of GDP was 268 per cent using the national model, while the ABO-method resulted in 235 per cent and the PBO-method in 295 per cent. Concerning the public sector schemes, in both years the national estimate was very close to the estimate based on the ABO-method. One presumption about the latter is that perhaps the model does not completely reflect the fact that the accruals of the public pension schemes were better in the history until they started to be harmonised with the private ones, starting from the year 1995. Unfortunately there has not yet been any further investigation of the results to be able to confirm this or to comment on the results any further.

However, we consider the results of this comparison as very encouraging, taking into account the deviating model, as well as somewhat differing assumptions. In that sense they can serve as a good starting point to the future work to develop the statistical measurement of pension liabilities in Finnish national accounts.

THE PENSION SATELLITE ACCOUNT IN CANADA

BY JOE WILKINSON, STATISTICS CANADA

1 BACKGROUND

Demographic projections for Canada are characterized by an aging population. This demographic trend has generated interest regarding the impact of this trend on the economy, particularly the funding of pensions. To better understand the impact of pension stocks and flows on both economic behaviour and on the economy as a whole, both currently, and in future years, a satellite account for pensions has been constructed. This account was first envisioned by national accountants in Canada in the mid-1990s. This note summarizes progress on this initiative. The note first describes the pension system in Canada. It then moves to articulate the need for a pension satellite account. This is followed by an explanation of how pensions are treated in the Canadian System of National Accounts (CSNA). Finally the structure and data sources used in creating the Pension Satellite Account (PSA) are discussed.

2 THE PENSION SYSTEM IN CANADA

In Canada there is a range of savings vehicles and social programs designed to provide funds to retired or aged citizens – including individual plans, employer-sponsored plans and social security schemes. Individual schemes are tax-sheltered saving plans that are designed to encourage citizens to accumulate assets earmarked for use as primary or secondary sources of retirement funds. Employer-sponsored plans cover a variety of arrangements, including retirement defined-benefit and defined-contribution plans in both the public and private sectors. Social security encompasses both employee/employer funded government-sponsored saving plans and non-saving plans where disbursements are financed out of current tax revenue.

Employer sponsored schemes hold a large proportion of assets.

For the most part, the pension system as it exists today is a function of post-war developments in the economy. In Canada, the union movements of the 1950s saw the establishment of large employer sponsored defined benefit plans. In the 1960s a large pay-as-you-go plan managed by the federal government was

Table 1 Distribution of pension assets by type of scheme

established to provide a pension plan for employees across the labour market. In the 1970s provisions were made in the income tax legislation to create individual tax sheltered pension savings vehicles. As the large employer sponsored pensions began to accumulate vast pools of funds, and legal issues arose as to "ownership" of the funds, pension legislation was introduced to regulate large pension plans (some time in the late 1970s and early 1980s). The legislation involved regulation on nomination of trustees, required levels of funding and actuarial evaluation. Subsequently, large pension plans previously in place changed structurally as a result of the legislative environment – including migration of many previously "unfunded" plans to a fully funded status. Finally, a pure social security program has existed throughout the last 50 years funded out of general tax revenues. While the "old age security" program is universal, there is a "claw back" provision in the income tax system above certain income thresholds and an income supplement for lower income individuals.

EMPLOYER-SPONSORED PENSION PLANS (ESPP)

Employer-sponsored pension plans are typically group plans, and, to a very large extent, are funded based on the invested assets criterion. As noted above, these cover both public and private sector plans.

Employer-sponsored plans in Canada are established by either employers or unions to provide retirement income to employees. These plans are registered with the federal tax department and usually a regulatory authority. Autonomous trusteed pension plans, representing employees in both the private and public sectors, hold the majority of the assets in these plans in Canada.[1]

The large defined benefit plans fall under legislation requiring that the fund be managed by an independent trustee and that actuarial evaluations are done regularly. If the pension is sponsored by the employer, actuarial surpluses are generally run down by contribution holidays for the employer while deficits are made up by large lump sum contributions to the plan. All contributions by employees are income tax deductible and no tax accrues on the pension plan investment income or capital gains. The tax accrues only when pension benefits are paid.

Defined benefit plans hold a significantly larger share of the assets of Canadian employer sponsored plans than their share of employees who are members of all pension plans in Canada. The defined benefit plans are actuarially evaluated and surpluses (over-funded plans) or deficits (under-funded plans) are identified and recorded. Recently the valuations of these plans, impacted by stock market fluctuations, have registered significant deficits. In order to restore these plans to sound financial positions, employer's additional/special contributions (which are fall under government regulation) have increased dramatically in some cases. These special contributions have notable impact on corporate cash reserves and, as a result, there has been a significant migration by employers towards defined

1 Insurance companies' contracts account for the bulk of the remainder.

contribution plans in recent years.[2] Conversely, defined contribution plans hold a smaller share of the assets of Canadian employer sponsored plans relative to their share of employees who participate in Canadian pension plans.[3]

GOVERNMENT UNFUNDED-EMPLOYER-SPONSORED PLANS

SNA93 considers unfunded plans as those with no invested assets and are typically viewed as *pay-as-you-go* (PAYG) plans. Such plans may or may not record liabilities, but if they do SNA93 recommends that these (and the corresponding household sector assets) be treated as a memo item. CSNA goes beyond SNA93 in this regard, and has opted for one general approach for all employer-sponsored plans. The basic justification for this approach is that the obligations of the employers are the same under funded and unfunded plans, and that the economic behaviour of households is largely invariant to whether their employer-sponsored plans are funded or unfunded.

Legislation permits unfunded pension plans only in the government sector in Canada. These plans are viewed as non-autonomous, and cover the federal government as well as certain provincial government administrations.[4] Non-autonomous government plans record a pension liability (typically, at both accumulated and actuarial value) and, book interest on these liabilities. As a result, the term "unfunded" may not be the best way to describe these plans. Over time, a number of government plans have been converted from unfunded non-autonomous plans to funded autonomous plans.

INDIVIDUAL RETIREMENT PLANS

There are a number of different vehicles for retirement saving by individuals in Canada, but by far the most important is the registered retirement savings plan. Based on a percentage of their earned income in a year, Canadians are allotted an amount up to which they can contribute into their registered retirement savings plan in the subsequent year. These allotted contributions are linked to the large employer-sponsored plans such that the total allotment includes those contribution made to the large employer-sponsored funds and these individuals have less "room" to contribute to individual savings plans than those who do not participate in larger registered schemes. This contribution reduces their taxable income in the subsequent year and contributors receive a refund of tax based on the size of the contribution and their marginal tax rate. Taxpayers who do not make this contribution can carry forward their allotment to subsequent years. In 2007, 31% of eligible tax filers made contributions. Withdrawals from these plans are taxable.

2 This way employers can avoid the risk related to actuarial evaluations of their employer-sponsored pension plans.
3 Policy analysts within the Canadian government have identified the migration towards these plans as a significant risk to the financial preparedness of Canadians for retirement if the level of funding of these plans remains at their current levels.
4 Except for one province, these plans are all defined-benefit schemes.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Contributions to individual savings plans relative to employee contributions to employer sponsored plans have increased dramatically over the past 10 years. These gains have been impacted by the substantial effects caused by the migration of employers to defined contribution plans where contributions are smaller. Increased payments to individual plans by Canada's aging population have also paid a role.

SOCIAL SECURITY

Canada and Quebec Pension Plans

The Canada Pension Plan (CPP) and the Quebec Pension Plan (QPP) are government-sponsored pension plans, and comprise one component of social security in Canada. Employers and employees contribute to these plans, initiated in the late 1960's as a social policy initiative. CPP and QPP are defined benefit plans in nature; however, employers do not bear risks related to the availability of funds for withdrawals under these plans. These government-established plans are based on a relationship between the workforce and the government, and the intention is to provide workers and their families with limited retirement earnings as well as some protection against disability and death.

Since the late 1990's, when concern was expressed about declining balances in these funds, contribution rates have been increased and more funds have been set aside in these funds which operate at arm's length from government consolidated accounts. As a result of this, and combined with increased investments in marketable securities and real estate, a significant reserve has been built up. However, these funds still do not provide for the benefits and administration of the account in its entirety and certain components of these plans continue to operate on a pay as you go basis.

Old Age Security

Old age security is the second component to social security programs in Canada. Unlike the CPP and QPP programs described above, it has no connection to employment. There are no contributions made into the plan and no reserves set aside, and benefits payments are charged to federal government expenditure. In this sense it is a pure PAYG plan. Payments under this program begin after pensioners reach the age of 65 and the program is meant to guarantee a minimal level of income.

3 THE NEED FOR A PENSION SATELLITE ACCOUNT

A satellite account is an extension of the core System of National Accounts (SNA). It is based on the accounting principles and the established framework of the SNA, thereby aiding analysis. A significant amount of pension information is currently embedded in the core SNA sector accounts; however, only a limited amount of this information is visible in these accounts. The goal of the PSA project is to articulate pension details within the accounts and present them using the structure of the SNA. In addition, the PSA includes estimates for missing pension detail such as items which are implicit with SNA aggregates.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

The need for the PSA arises out of the fact that within the current structure of the SNA it is very difficult to answer the range of policy related topics surrounding the aging of the Canadian population. These topics include, but are not limited to the following:

PERSONAL SAVING AND WEALTH EVOLUTION

The personal saving rate has been declining over the last few decades in Canada. Up to 1990, the decline was considered a return to a normal level, after having peaked at over 20% in 1981. Thereafter, the decline, which continued through the 1990s and into the current decade, has generated more interest. Despite the downward trend in personal saving since 1990, household wealth has continued to accumulate by essentially replacing saving out of current income with capital gains (price appreciation of assets). Pension saving has also been growing, taking up a sharply increasing share of the downward trending personal saving. Concurrently, pension wealth has been a significant contributor to the growth in household net worth. What remains to be understood is the impact of the increasing pension payments/withdrawals, going forward in time, on household financial positions.

FORECASTING THE ECONOMY

Personal expenditure accounts for about 60% of GDP. The ability to estimate its future growth is essential for central banks, policy-makers and analysts. As population ages, there are increasing sources of funds from other than income arising from production and transfers. Pension benefit payments and individual retirement saving plan withdrawals – dis-saving – will soon be key variables to any forecasts of personal expenditure. The PSA indicates that the propensity to spend is quite high out of retirement dis-saving.

PROJECTING TAX REVENUE

There is already a gap between reported SNA income and income taxes paid, largely because realized capital gains are excluded from SNA income, which is of concern to some analysts. Increasingly, taxes will be generated out of pension benefit payments and individual retirement plan withdrawals. The need to project tax revenues from pension dis-saving for fiscal planning purposes is clear, and the federal finance department has expressed interest in this detail of the PSA.

IMPACT ON CAPITAL MARKETS

The accumulated investments in Employee Sponsored Pension Plans (ESPP), social security and individual saving plans are a significant part of economy-wide assets. As assets in these funds grew sharply beginning in the late 1980s and continuing into the 1990s, they have had a substantial influence on capital markets – with respect to both growth and fluctuations. However, as these funds are drawn down by retirees over the years to come, the impact on these markets and on the economy is unclear. The PSA will be able to shed some light on the impact of these trends on the economy.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

SUSTAINABILITY ISSUES

This is the fundamental question of: Is there enough accumulated pension saving – by type, by composition – to meet the needs of increasing number of baby-boomer retirees over the next several years? If not, there are clear implications for the standard of living and likely also for government fiscal balances. Notably, there is a need to understand the age-income class distributions of this accumulated pension saving in order to fully address this issue. (Can we say) The actuarial requirements of this analysis go beyond the structure of the SNA but could be contained within (or based on) a satellite account structure of the PSA.

PENSION SYSTEM RISKS

There is a series of risks associated with the pension system that feedback on the sustainability question. The overall burden of pension saving has gradually shifted from government to employers and to individuals. For defined-benefit ESPP, there are financial risks for employers associated with fluctuating values for invested pension assets. A market correction implies increased business costs as any subsequent actuarial deficits must be eliminated. Clearly, significant market corrections, risky investments or sustained poor returns on pension investments can translate into an overall cost to the economy.

Partly to counteract these vulnerabilities, employers have been moving away from defined benefit schemes in favour of defined contribution schemes. This is a disadvantage for employees covered by these plans, as known benefit streams provide income security.

A further risk to households' future income security relates to the significant amounts invested in individual retirement saving plans. Increasingly, these investments have shifted from fixed income into equities. If returns are not adequate or capital loses are registered, future incomes can be eroded. With the significant amount of funds invested in pensions, it could be argued that the financial position of households is considerably more sensitive to market risk (both asset price and interest rate fluctuations) now than it was years ago, with potential impacts on the economy.

The PSA will help access this level of risk.

4 PENSION TREATMENT WITHIN THE CANADIAN SYSTEM OF NATIONAL ACCOUNTS

The CSNA has two basic architectures: The production-oriented industry-based architecture of the detailed input output tables and the current monthly measures of output by industry; and, the sector-based accounts designed to articulate economic behaviour. This latter set of accounts includes the quarterly measures of income arising and final expenditure on GDP and the underlying and detailed sequence of sector accounts. The sector accounts include: the income and outlay account; the capital account, the financial account and the balance sheet account

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

(including the other changes in assets). The PSA is an articulation and extension of the stock-flow dimension to the sector accounts.

It is useful to clarify two features of the CSNA treatment of pensions that are different from a number of other countries. First, all household pension plans have a similar treatment with respect to their impact on personal saving and wealth. Whether a government ESPP is funded or unfunded (no invested assets), it is treated as a household sector asset, with corresponding saving flows. This treatment is used because the asset is recognized as a liability by the government (or the funding sector?). Second, Canada has a treatment for all ESPP that does not require the D8[5] adjustment described in SNA93 to bring personal saving and personal disposable income into line. Essentially, the incomes and outlay of pension funds are consolidated in the household sector.[6]

One challenge in the Canadian System of National Accounts (CSNA) has been to provide a consistent treatment of saving, net lending and net worth of the institutional sectors over time as the pension saving system evolved. While most of the changes in the pension system over time have either represented incentives to save for retirement or brought about mandatory participation in a pension saving plan, some of the changes have been regulatory in nature. These latter changes were intended to protect previous and future investments and not alter saving behaviour. In these cases, it has been difficult to determine the most appropriate treatment in the CSNA with respect to the SNA standard and international comparability.

INDIVIDUAL PLANS

In the CSNA, contributions to individual plans are made out of current gross income, usually originating from wages and salaries. Contributions are not explicitly recorded in the system as part of current outlays,[7] so that they are implicitly included in estimates of personal saving. Investment income, earned in the current period from these plans, also contributes to personal saving. This reconciles well with the *Financial Account*, where contributions and income earned are included in financial asset investment flows of households. Withdrawals (after tax) that are spent are also only a *Financial Account* item as they are not included in current income, and are a source of funds for expenditure. Withdrawals that are used as a source of funds for personal consumption expenditure are recorded as expenditure and thus serve to reduce personal saving in that period (i.e., represent dis-saving). Total withdrawals are taxable and as a

5 See SNA 93 section 9.16.

6 These are treated as a form of collective investment schemes. Employee contributions are in wages and salaries and employee contributions in supplementary labour income; investment income of the pension funds (excluding gains and losses are in household investment income; benefit payments to pensioners are part of dis-saving in the financial account, such that the net flows in the financial account reflect the major items contributions plus investment income less withdrawals.

7 In contrast, individual saving plan contributions are typically treated as current outlays in the Statistics Canada (?) household income and expenditure survey.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

result, create an incongruity between taxes paid and national accounts' income.[8] Household *Balance Sheet Account* estimates include both the accumulated net inflows (contributions less withdrawals plus investment income) as well as the capital gains on the investments. (and therefore provide a more complete picture of personal saving)

EMPLOYER-SPONSORED PLANS

Tax-deductible employee contributions to employer-sponsored plans are implicit, but are included in wages and salaries.[9] Employer contributions are treated as a labour cost and included in supplementary labour income of households. Autonomous pension plans are treated as collective investment schemes that are consolidated in the current account items of household sector. As a consequence, total contributions remain in the personal sector and investment income booked on the assets is counted in household income, and both are reflected in personal saving.[10] Withdrawals, while taxable,[11] are not treated as income but rather as financial flows that are mirrored in personal saving. In the *Financial* and *Balance Sheet Accounts*, the net asset flows and positions are included in a net pension asset of households. The autonomous funds themselves are included in the financial institutions' sectors, where the invested assets' detail is articulated. The net liability of the autonomous plans is the corresponding net pension asset of households.[12] Household *Balance Sheet Account* estimates include both the accumulated net inflows (contributions less withdrawals plus investment income) as well as the capital gains on the investments.

For defined-benefit plans, actuarial deficits are recorded as liabilities of employers.[13] Special employer contributions to eradicate actuarial deficits are not expensed by business. Rather they are adjustments to an off-balance sheet account. However, these are currently treated as supplementary labour income of households, and a business expense must be imputed (and corporate surplus lowered) when these expenses are incurred.[14] Employer actuarial deficit liabilities are treated as "other liabilities" of businesses and as "other assets" of households;

8 Since the SNA treatment of income and tax policy are not always the same, income arising from production does not always tie in fully with tax payments/receipt flows. This is a similar issue as the SNA treatment of taxable capital gains.

9 Not all employer-sponsored plans require employee contributions.

10 This avoids the SNA93 *D8 adjustment* that is required for saving rate analysis as well as for continuity of household income-saving with the *Financial Account* and *Balance Sheet Account*.

11 Like with withdrawals on individual plans (discussed above) this also drive a bit of a wedge between taxes paid and national accounts' income as there are taxes on the withdrawals which are not included in current SNA income.

12 This is seen by some as an anomaly. However, it must be understood that income arising from production does not tie in fully with tax payments/receipt flows. Of course, this is the similar issue for some as with the SNA treatment of taxable capital gains.

13 Actuarial surpluses are treated as "other assets" of employers, and are eliminated by taking contribution holidays.

14 This is not the case for actuarial surpluses, where employers take contribution holidays by reducing their regular contributions. The current CSNA treatment for actuarial deficits and surpluses is reasonably consistent.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

these are subsequently allocated to pension asset of households, when the actual funds are disbursed to the autonomous plans.[15]

The federal government unfunded employer-sponsored pension plan has been running a surplus for some time. The treatment in this case is different that in funded autonomous plans. Essentially, there is no contribution holiday booked, but the surplus is reduced in each period by way of a special adjustment. This special adjustment (i.e., the repatriation of the surplus) is treated as a capital transfer from households to government. This approach has a certain amount of appeal. (explain pros (and cons) of this approach).

SOCIAL SECURITY

For the CPP and QPP, employee contributions are reflected in wages and salaries and employer contributions in supplementary labour income of households. However, these do not figure into personal saving as both employee and employer contributions are remitted to government as part of current transfers to government from households. Investment income on the plans is part of government revenue, and the plans contribute to overall government saving and surplus/deficit. Benefit payments are treated as part of current transfers from government to households. Financial transactions and positions related to plan assets are articulated in the government sector *Financial Account* and *Balance Sheet Accounts*, respectively.

For the Old Age Security plan, benefit payments are treated as current transfers from government to households. There are no other explicit entries.

5 STRUCTURE OF THE PENSION SATELLITE ACCOUNT

While pension flows and stocks are fully accounted for within the CSNA, they are not fully articulated. This detail is at the heart of the pension satellite account. The Pension Satellite Account explicitly identifies how pension monies are treated in the CSNA; and expands the CSNA database to add specific detail on certain types of retirement saving instruments.

Many aspects of pension schemes are incorporated in the framework of the PSA, such as:
– wealth change;
– contributions;
– investment income and withdrawals;
– realized and unrealized gains and losses.

The PSA is an integrated conventional stock-flow matrix framework with data on both a book and market value basis.

15 Employer actuarial surplus assets actually decrease household sector “other assets”.

Table 2 Basic structure of the Pension Satellite Account (condensed version)

	Opening wealth position	Inflows: contributions, Investment-income	Outlays: Withdrawals, Administration-cost	Other changes: Capital gains/losses	Closing wealth position
Individual saving plans					
Employer-sponsored saving plans					
Social security plans					

The PSA begins with an opening wealth position for a given pension regime. It then quantifies the inflows, outflows and other changes in value due to capital gains or losses to arrive at a closing wealth position.

The PSA examines the whole universe of the pension system in Canada. It reflects the diverse structure of retirement schemes such as private and public employer-sponsored plans, individual savings plans and social security schemes. These schemes generally all have institutional investors-investments dimensions to them, with the net assets of pension wealth and saving belonging in the personal sector while also representing both investments and liabilities in the other sectors of the economy.

Data for the PSA comes from a variety of sources such as:

Pension Plan Survey Data

- The Pension Plans in Canada program is an annual census of all registered pension plans (RPPs) in Canada. Information is collected on pension plan characteristics such as; the plan type (e.g. defined benefit vs defined contribution), number of members, the terms and conditions of membership, contributions made by and on behalf of members and the jurisdiction of the plan. The program is based on regulatory information compiled and standardized from provincial and federal pension supervisory authorities, in a cooperative arrangement with Statistics Canada.

- Trusteed Pension Fund surveys gather financial information on trusteed pension funds representing about 40% of all registered pension plans in Canada and covering about 70% of its members. The surveys measure the investment mix of assets over time (book and market value), rates of return and sources of income and expenditure. The Trusteed program includes a quarterly survey of the largest funds (representing 85% of fund assets) and a biennial Census.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Household Survey Data

- The Survey of Financial Security is a household survey that collects information on the assets and debts of families and individuals in Canada. The survey provides information on the Canadian wealth distribution, including a wealth value of employer pension plans, individual retirement savings plans (RRSPs, RRIFs) and all other asset and debt instruments in the context of overall net worth at the family level.

Tax Data

- Contributions to individual savings plans are generally tax deductible and reduce the taxable income of the contributor. As a result, contributions can be aggregated from tax sources and an annual total can be calculated. Similarly, withdrawals from tax sheltered individual savings plans are subject to tax and become part of taxable income in the year of withdrawal. These withdrawals are aggregated to tabulate total annual withdrawals from plans.

Government public accounts and other administrative data

- Reporting for social security programs such as old age security and the Canada and Quebec Pension Plans are part of the regular reporting for Government through the Public Accounts. In addition, aspects of these programs represent transfers within the CSNA and these series are followed closely. The unfunded pension liabilities of government bodies are disclosed in the Public Accounts.

Surveys of financial institutions (insurance, banks and other financial intermediaries)

- Some details of pension related assets of the household sector are available from the survey sources for various financial institutions. For example, tax sheltered deposit liabilities are reported by the financial institutions as a detailed component of their overall deposit liabilities. These deposits represent part of the assets of household's individual savings plans.

Other sources

- Various associations of financial intermediaries as well as private sector data providers present components of the data used in the PSA.

- Some degree of modelling and derived data.

6 SUMMARY

The System of National Accounts provides the opportunity to present pension-related flows in a coherent framework. The PSA will provide the tools required to better analyze household consumption behaviour in light of a significant shift in the source of funds from current income to dis-saving taking the form of pension benefits or withdrawals from other pension assets such as individual savings plans. It will allow a deeper understanding of personal wealth and its distribution.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

The PSA covers the entire universe of retirement regimes in Canada which includes government sponsored social security plans, employer sponsored pension plans and voluntary individual retirement saving plans. For each of these three pillars of the Canadian pension system, the PSA provides an articulation of the stocks and flows as related to the sector accounts (i.e. the income and outlay accounts, the capital account, the financial account and the balance sheet). Total assets of the pension programs account for about $2.1 trillion at year end 2007.

DISCUSSION ON SESSION IV

BY ANA ALMEIDA [1]

1 INTRODUCTION

In the context of the revision of the European System of National and Regional Accounts 1995 (ESA95), the compilation of pension entitlements entails a specific and growing interest as European countries face serious challenges due to Social Security deficits. The importance of these issues becomes visible in the revised ESA with the inclusion of a new chapter - chapter XVII - dedicated entirely to the recording of pension schemes. The creation of a new Supplementary Table, to be compiled on a mandatory basis, is one of the most relevant changes within the framework of the ESA95 revision. This table, which aims to record all the transactions and other economic flows, pretends to have a full coverage of pension schemes data included as social insurance.

In order to accommodate Supplementary Table proceedings and modelling pension entitlements, European and also some non-European countries were invited to give their contributions in a conference organized jointly by the ECB and Eurostat: *ECB / Eurostat workshop on pensions*, which took place on 29th – 30th April 2009.

Banco de Portugal [2] was invited as a discussant in the 4th Session of the conference: "*Country experiences in compiling pension entitlements*". The session aimed to discuss and point out the main concerns, difficulties and improvements that can be made in order to harmonize and make more effective the compilation of pension entitlements. Four countries, with very different experiences, gave their contributions during this session: Spain, Luxembourg, Finland and Canada.

This paper designs the main features and discussion issues prepared by *Banco de Portugal* in the referred workshop on pensions, reflecting the experiences of the participant countries mentioned above. It is organized as follows: section two provides an overview of the Social Security's current issues. In section three, some aspects of country experiences in the compilation of pension entitlements data are summarized and discussed. Further general issues / final remarks and future developments of recording pension entitlements are presented in section four.

2 SOCIAL SECURITY – AN OVERVIEW

Social Security has been an active area of economic and statistics research in the last years, due to the highly concern on the financial sustainability of the

1 Ana Almeida, Sérgio Branco, João Falcão, Banco de Portugal, Statistics Department.
2 Ana Almeida.

system. The ageing of population and the corresponding demographic changes are the main causes to this issue. In fact, the increase of life expectancy and the downward trend in fertility rates lead to changes of the population structure in such a way that older people outnumber younger ones. This situation creates intergenerational imbalances with increasing costs for caring for the older generations and consequently Social Security growing expenditures. The following chart plots age dependency ratio and clearly indicates the expected increase number of people aged beyond 65 years, from 25 per cent of the working age population (from 15 to 64 years old) in 2008 to 50 per cent in 2060.

The change in demographic trend jointly with the immigration phenomena turns out to be a problem to the European countries, as public expenditure on pension schemes increases. This situation pressures active workers, through the increase in contributions, especially when they belong to a pay-as-you-go system, the most common Social Security scheme in Europe.

Under this situation, policy makers have to be aware of the problems that may arise. It becomes urgent to ensure long term fiscal sustainability to avoid uncertainty and the risks associated under this scenario. In order to guarantee future benefits to active workers during their retirement period and to ensure reasonable living standards, many countries made some reforms in their Social Security regimes.

The main implemented reforms can be summarized by the following vectors: increase of pension benefits to workers that remain working beyond the retirement age (as in Spain); penalties to early retirements, with an actuarial reduction of pension benefits when the retirement is earlier than the standard legal age (as in Finland); and, finally, the increase of the second and third pillars (privately managed pensions and voluntary schemes) (as in Luxembourg and Canada).

Old age dependency ratio

Statistical data can provide several contributions by shedding some light on the specific areas of Social Security where policy makers may intervene. If at a micro level, accounting practice recognizes pension liabilities of employers and pension funds, national accounts should also be important to raise, at a macro level, the main specific areas where Social Security problems exist and which can be improved. The possibility of making realistic economic projections will also become more effective with a good compilation procedure of the statistical data. Finally, statistical data have other important advantages like, for instance, allowing for cross section analysis. This is the case of the Supplementary Table, as it provides the basis for compiling comparable stock and flow data of all pension entitlements from a debtor/creditor point of view across countries.

3 COUNTRY EXPERIENCES

3.1 SPAIN

Statistics Spain[3] described the Spanish experience on the subject, in the paper *"Estimating Social Security Pension Entitlements in Spain"*.

As we can infer from this presentation, Spain is an example of a country that made some efforts to prepare the measurement of pension entitlements under the Supplementary Table. There are three interesting aspects in the presentation that we would like to focus on.

The organizational procedure, with the creation of a working group composed by the national institutions concerned and the definition of the responsibilities for the compilation, is clearly a good starting point to this exercise. Another main aspect of the Spanish Social Security system is the existence of two parallel pension schemes sponsored by General government: the Social Security and the Government employer pension schemes. A third important and interesting feature from this presentation is the development of a national model that accommodates specific assumptions of the Spanish Social Security scheme. In fact, this model can be used as a benchmark for future comparisons with the model from the University of Freiburg.

Some issues can, however, raise a deeper discussion on the presentation made by this country.

One question that can be brought up deals with the interpretation of the "total amount of contributions" estimated by the national model. As it was mentioned before there exists a breakdown between Social Security and the General government employer pension schemes but, apparently, no distinction in the final estimates is done. How can we split pension entitlements between these two regimes?

The description of the national model would also gain with the identification of certain assumptions. It would be very useful to have a better clarification of the

3 Lourdes Prado.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

sources of data and on the methodology definition and sample criteria used in the estimation of future pensions of active population.

A final remark concerns the interpretation and comparison between the national model estimates and the University of Freiburg model. Pension entitlements under the Freiburg model represent 204 per cent and 207 per cent of GDP in 2006 and 2007, respectively (according to the Contact Group on Pensions Report, CMFB, 2009), whereas, in the national model, pensions entitlements are 240 per cent and 242 per cent of the GDP in the same years. Can we interpret these differences solely due to the different wage growth rate assumptions, or are there any other reasons that explain these differences?

3.2 LUXEMBOURG

Luxembourg's participation was made by *Inspection Générale de la Securité Sociale*[4] through the paper "*Experiences in compiling pension entitlements in Luxembourg: 'Ensuring consistency*'", which focuses the main concerns that arise from the compilation of pension entitlements data in Luxembourg. The main aspect addressed by Luxembourg relates to the consistency that needs to be ensured in national data among different institutions and data sources. Other difficulties mentioned by this country rely on the heterogeneous definitions of benefit schemes and Social Security regimes across countries. An additional issue is also referred by Luxembourg: the problems that are raised by the existence of different data sources.

The presentation provides the estimates of a national model that was developed by Luxembourg. However, we are not able to compare them with the estimates provided by the Freiburg model, as this country did not compile data for the fulfilment of the Supplementary Table.

The first issue we would like to bring up into the discussion is the importance of having a more detailed methodology and assumptions used in the national model. This could facilitate the interpretation of the estimations, for example, the motion of pension entitlements in percentage of GDP and replacement rate, both decreasing until 2007.

The chart "Entitlements and expenditure" deserves also, in our opinion, a better clarification, namely the path of differences between "percentage of GDP all" and "percentage of GDP by years".

Finally, difficulties stressed by Luxembourg concerning the statistical consistency and harmonization to be ensured across countries that experience different and complex structures of pension schemes and retirement regimes, motivate also a discussion on this topic. It would be useful to have the participant's opinion on how this process could be improved.

4 Tom Dominique.

3.3 FINLAND

The paper *"The social security pension scheme in Finland"* presented by Statistics Finland[5] provides a very good overview of the Finnish pension system. One of the main features of this system is the fact that it is a three-pillar pension regime. It includes two statutory pension schemes (first pillar) and voluntary pension insurance (second and third pillars). An explanation for this classification should be given since, according to the multi-pillar approach (World Bank), the second pillar is mandatory and not voluntary as it is stated in the paper.

The paper presents the results of the compilation of the Supplementary Table for Finland. This output, calculated with the University of Freiburg methodology, is compared with the results of the national model estimated by the Finnish Centre for Pensions. The total amount of pension entitlements computed by this institution (268 per cent of GDP in 2007) is higher than the amount computed in the Supplementary Table via the accumulated benefit obligations (ABO) approach (235 per cent) but lower as compared with the projected benefit obligations (PBO) approach (295 per cent). The analysis of these differences should be investigated. Attention should be given to the possible factors behind the different results: different databases, different assumptions?

In the Supplementary Table, the method for computing the item "Household social contribution supplements" should be explained. In principle, according to the methodology defined by the CMFB task force on the Statistical Measurement of the Assets and Liabilities of Pension Schemes in General Government, it should be equal to the start of year pension entitlements times the discount rate. In this case, a discount rate of 5 per cent was apparently used, which is different from the hypothesis of 3 per cent discount rate of the Freiburg model.

Some doubts were raised about the significance of the item "Other (actuarial) increase of pension entitlements". In our view, this item can be seen in two different (non- mutually exclusive) ways:

(i) This amount could mean that the social insurance scheme is under or over financed if the values are positive or negative, respectively. This conclusion may have important economic policy implications.

(ii) The existence of important amounts in this item of the Supplementary Table may indicate there are shortfalls in the model due to, e.g., wrong estimation procedures and or assumptions.

In the paper, a doubt is also raised in relation to the inclusion of "Employer imputed social contributions" in the core and non-core accounts. In this respect,

5 Paula Koistinen-Jokiniemi.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

our interpretation is that this item should be included both in the core and non-core accounts but with different values:

(i) "In cases where pension entitlements of schemes for government employees are not recorded in the core accounts, by convention the employers' imputed contributions are calculated as equal to the difference between current benefits payable and actual contributions payable (by both employees and government as employer)." (ESA Rev § 4.10).

(ii) In the Supplementary Table, "Employer imputed social contributions" is a balancing item to match the differences between the change in entitlements and the transactions (equivalent to item 3. for Social security).

3.4 CANADA

The paper *"The pension satellite account in Canada"* presented by Statistics Canada[6] is a good example of estimating pension entitlements in national accounts through a satellite account. The provision of a long time series allows for a deeper analysis of results and for a better interpretation of the data, which is useful for analytical purposes.

One of the most striking features of the information presented for the Canadian pension system is the level and stability of the unfunded pension plans liabilities as compared with the average European reality. In Canada this amounts to 15 per cent of GDP while in Europe it ranges between 200 and 300 per cent of GDP.

Some issues can be raised by the analysis of the data shown in the presentation. The most relevant are the fact that changes in the Social Security strategy resulted in the accumulation of assets after 2000 and the upward trend in "Other individual registered saving plans" after 2002. Both issues could be further discussed.

Additionally, some details on the methodology and sources used for the compilation of data (e.g. transactions and other flows) could be given. In particular, the main assumptions used in the estimates of the pension satellite account (discount rate, wage increases (ABO/PBO), GDP growth) could be explained.

Finally, valuation issues and data gaps for individual registered savings plans are mentioned. A description of these issues and of the solutions found would be of great interest.

4 CONCLUSIONS

The subject of estimating pension entitlements is still in an initial phase, thus still being subject to future discussion and, therefore, many issues are somewhat grey areas. We suggest then several issues to further reflect on.

6 Joe Wilkinson.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

The quantitative work of the models, even though concerning ex-post observations ("accrued-to-date liabilities") relies on future assumptions of variables such as the discount rate, demographic projections, etc. To which extent these assumptions used within the national accounts framework are coordinated with the bodies responsible for the sustainability analysis, such as the Working Group on Ageing?

These assumptions, which are used to estimate pension entitlements across countries, like GDP growth and discount rates, are sometimes harmonized between countries. Is this a reasonable hypothesis? Does "one fit all"? Could these estimations be improved in order to take into account specific national differences, incorporating country-specific assumptions?

Since there may exist practical difficulties to separating concepts other than pensions (e.g. health related), shouldn't these future benefits be also recorded as General government liabilities? So far, they are potential, but they are as well clearly a responsibility of governments towards their citizens.

Most European countries face challenges due to the migration phenomenon. The existence of strong migration flows to Europe changes the demography of these countries. Migration means a younger population and, therefore, an increase of Social Security sustainability. Should the assumptions used to estimate pension entitlements (e.g., demographic assumptions) be modified? Do these assumptions take into account migration trends?

The publication of consistent and comparable data for pension entitlements will clearly show differences across countries. These differences are already evident in the results obtained through the University of Freiburg methodology. What could be the reaction of financial markets to these results? What could be the reaction of policy makers under these results?

Several organizational issues must still be debated, e.g., the responsibility for the compilation of these aggregates, the publication policy, etc.

The process of revising ESA is still ongoing. In particular, the new ESA will include a specific chapter on pensions. The current version of this chapter proposes that all government sponsored unfunded employer defined benefit schemes are recorded only on the noncore accounts. This leads us to the following practical suggestions:

(i) An operational definition of "unfunded" should be given, especially when schemes have reserves with large assets (introduction of a threshold?)

(ii) How to define a government sponsored scheme? A clear definition of sponsor should be provided.

SESSION V

COUNTRY EXPERIENCES IN COMPILING PENSION ENTITLEMENTS PART II

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

INTRODUCTION

In Session V, Marshall Reinsdorf considers actuarial measures of defined benefit (DB) pension plan wealth and income of US Households. The author describes in detail the organisation of the US pension system. The National Income and Product Accounts (NIPAs) provide a full picture of the operations of defined contribution (DC) pension plans, in which the level of benefits depends on the balance in the DC plan account. However, in DB pension plans, the level of benefits is determined by a formula that typically takes into account the length of service and some measure of final or average pay, so that the appropriate wealth concept is be the expected net present value of the benefit entitlements. The author discusses two alternative calculations: the "cash accounting approach", which records household income as being equal to the contributions from the employer to the DB pension plan plus the returns on plan assets, and the "accrual approach", which records household income when rights to DB pension benefits are accrued. The advantage of the latter is the reduction in volatility of the measure of household income. The estimates are presented using ABO for the private plans and the PBO approach for the government plans in relation to the benefit formula.

Janusz Jablonowski (Narodowy Bank Polski) considers pension entitlements under social insurance schemes in Poland. The author starts with a detailed definition of the structure and main features of the pension system in Poland, composed of the Social Insurance Fund (FUS), which was reformed in 1999, the Pension and Disability Fund for farmers (FER), the State budget pensions and the private pension schemes. The second part of the papers focuses on modelling issues. The Central Bank of Poland has used the PROST model and the Freiburg model. Thus, the author compares the results of the Freiburg model with the models from the Ageing Working Group. The differences are mainly explained by differences in the type of system covered (closed system versus open system), the outcomes of projections (accrued-to-date liabilities versus revenues) and the values for wage growth (fixed at 1.5% versus varying across the Member States).

Albert Braakmann and Jens Grütz (Destatis) present their results on the pension entitlements of civil servants in Germany, which amounted to 44% of GDP if compiled on an actuarial basis. Regarding the idea of higher frequency data, the authors say that the calculation of labour costs of civil servants on an actuarial basis is not feasible with quarterly data. The calculations are strongly dependent on the assumptions made. The authors stress that the supplementary table provides a rather complete picture of pension insurance by showing the effect on the entitlements of changes in the actuarial assumptions or pension reforms. The assumptions regarding the discount rate and the wage growth rate should be harmonised, according to the authors. A detailed documentation of the procedures and parameters used in the compilation of the supplementary table is also recommended. Nevertheless, the supplementary table does not substitute for the comprehensive analysis of old-age insurance systems like the open system liabilities.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

The three papers of Session V are discussed by *Dominique Durant* (Banque de France). In relation to the first paper, the discussant makes a very didactic and useful simulation by summarising the information on US household wealth and income from the BD plans in a partial supplementary table. With regard to the Polish experience, the discussant makes an attempt to use the aggregated Freiburg model with the AWG assumption in order to estimate pension entitlements in line with the sustainability work of the European Commission while avoiding the building of a costly model for social security. Finally, in connection with the German experience, the discussant attempts to build up a semi-aggregated (by group) model for the civil servant scheme, which is part of social security.

ACTUARIAL MEASURES OF DEFINED BENEFIT PENSION PLAN

WEALTH AND INCOME OF US HOUSEHOLDS[1]

BY MARSHALL REINSDORF[2]

In the US National Income and Product Accounts (NIPAs) pension plan assets are classified as belonging to persons. This makes employers' contributions to pension plans and the interest and dividends earned on the plans' assets part of personal income. Benefit payments to retirees and contributions made by employees to pension funds have no effect on the NIPA measures of personal income and saving because they are regarded as financial transactions, i.e. a change the form in which households hold their wealth. For this reason, benefits and employee contributions are reported in addendum section rather than the main section of the NIPA table that provides details on pension plan operations, table 6.11.

The current NIPA treatment provides a full picture of the operations of the pension plans that are structured as defined contribution (DC) plans. These plans can be regarded as analogous to bank accounts owned by the plan participants, as the level of benefits in retirement depends on the balance in the DC plan account. In contrast, in a defined benefit (DB) pension plan, the level of benefits is determined by a formula that typically considers length of service and some measure of final or average pay. If the assets of the plan are insufficient to pay the promised benefits, the employer who sponsors the plan must cover the shortfall by making additional contributions. This obligation of the employer represents an additional source of pension wealth for the participants in an underfunded plan besides the assets of the plan. Thus, for DB plans, the wealth concept that is appropriate for many important questions is the expected present value of the benefits to which the plan participants are entitled. The measure of investment income must then be the theoretical amount of interest accruing on this actuarial wealth, and the measure of pension-related compensation must be the expected present value of the benefits that the plan participants earn through service to the employer over the year, less any contributions that employees themselves make to fund those benefits.

Recording as income of households the amounts that a DB pension plan receives from employer contributions and returns on assets may be termed the "cash accounting approach" (though it is not cash accounting in a literal sense, as contributions that are declared but not yet disbursed are still counted). The alternative "accrual approach" records household income when entitlements to

1 Marshall Reinsdorf, US Bureau of Economic Analysis, 1441 L St., NW, Mail stop BE-40, Washington, DC 20230, Marshall.Reinsdorf@BEA.gov.

2 The estimates in this draft paper are preliminary estimates for research purposes and are subject to revision. I am grateful to David Lenze for assistance with this project.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

pension benefits are accrued. One of the important advantages of the accrual approach is a reduction in volatility of the measure of household income. Employers sometimes make no contribution or a reduced contribution for a period of several years, but then make a large "catch up" contribution to bring the gap between the plan's assets and its accrued benefit liability back into the acceptable range. Such lumpy behavior of employer contributions can cause sharp swings in the cash accounting measure of households' income from DB plans, particularly if the analysis is done at the state level rather than at the national level.

I POSSIBLE APPROACHES TO MEASURING BENEFIT ACCRUALS

Though the accrual approach avoids the timing distortions in the recording of pension income that arise under the cash accounting approach when employers skip contributions and then catch up later, the accrual approach has its own disadvantage. We do not need to make assumptions to measure transactions that have actually occurred. In contrast, the accrual approach is sensitive to assumptions about interest rates, mortality rates, separation rates and retirement ages used to calculate the expected present value of benefits and decisions about how to account for effects of future pay increases and future years of service.

Dependence on assumptions creates an inherent source of imprecision that is not present in cash accounting estimates. Furthermore, actuarial estimates made by different plans are likely to use different assumptions, so if we add them up to get a national total in the same way that we add up employer's actual contributions to pension plans, we will be combining estimates based on inconsistent assumptions. Indeed, the totals in this paper of households' accrued pension income or pension wealth generally do not incorporate adjustments for differences in assumptions across plans or over time, except for an adjustment of reported actuarial values for differences in the assumed rate of interest.

If the assumptions used in the actuarial calculations are exactly realized and if plan features and other key variables never change, annual contributions that are equal to the actuarial measure of participants' income will make the assets held by the plan match the actuarial value of the participants' wealth and exactly fund the benefits due. Yet despite the theoretical correspondence between cash and accrual accounting measures of pension wealth and income under ideal circumstances, they are unlikely to coincide in practice.

Actuarial estimates for employees who are not going to retire in the current year also depend on the decision about how to treat future pay increases. The "accrued benefit obligation" (ABO) approach considers only the present value of the benefits earned to date, meaning the benefits that would be due if the employee were to separate from the employer or otherwise lose the opportunity to accrue benefits under the plan. For a typical DB plan with a benefits formula based on years of service multiplied by a measure of average or final pay, the ABO measure of benefits earned during the plan year includes both

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

the effects of an extra year of service and the effects of the salary increase received during the plan year.[3]

An advantage of the ABO approach is that the benefits to which the employee has legally become entitled is a concept that fits the usual definition of a liability well. Yet a scenario in which the employee ceases to accrue benefits under the plan seems to be of questionable relevance if the probability of such an event occurring is remote. If there is little chance that the plan will be subject to a termination or freeze or that the employee will separate from the employer in mid-career, an approach that spreads the build-up of pension wealth over the career more smoothly may correspond better to the incentives that are perceived by plan sponsors and participants than benefits accrued-to-date, whose growth typically accelerates rapidly near the end of the career. To do this, the estimates must reflect the pension benefits that the employee would receive at the projected retirement date taking into account projected future pay increases.

Several methods exist for spreading the accretion of the pension wealth that is the employee is ultimately expected to enjoy, or "projected benefit obligation" (PBO), over the course of the career. In the financial statements of private business, the projected unit credit (PUC) method is generally used for the estimates of pension expenses that are labeled as "PBO". This method resembles the ABO approach except in the way that it adjusts for expected future pay increases. Assuming that the benefit formula is some percent of final pay for each year worked, the PUC valuation of the current service cost (i.e. benefits that employees have accrued in the current year) will be based not on the current pay level but on the projected level of pay in the final year of the career. In contrast, current service cost under the ABO approach will include the effect of any raise received during the current year on the value of benefits accrued in past years. (See the example in the appendix.)

A few state and local government pension plans also use the PUC method in their actuarial reports, but most of these plans instead use the level percent of pay version of the "entry age normal" method (Novy-Marx and Rauh, 2009). The entry age normal method attributes the value of the projected benefit obligation to service in any year in proportion to the fraction of the total projected earnings over the course of the career that come from that year. This yields estimates of the employer's "normal cost" for service in each year that are a constant percent of pay, as shown in the example in the appendix. Although to avoid confusion, the term "PBO" ought to be reserved for the project unit credit method, the entry age normal method also uses the projected benefits at the time of retirement as the basis for its estimates.

Assuming that pay rises over the course of the career, both the projected unit credit and the entry age normal method give higher estimates of pension plan income in the early and middle years of the career than does the ABO approach. Because they reflect anticipated future salary growth in their valuation of the

3 If the salary increase component were omitted, the cumulative total at the time of retirement of benefits earned and interest on the current liability would fall short of the current liability at the time of retirement.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

pension benefits earned in the current year, they tend to yield smoother, more uniform profiles of pension plan income over a typical career. Indeed, the objective of the entry age normal method is to maximize smoothness.

A rationale for smoothing comes from the option value model of pension earnings proposed by Lazear and Moore (1988) and used by Stock and Wise (1990) and Lumsdaine, Stock and Wise (1990.) In the option value model, an employee's pension wealth includes both the ABO entitlement and the value of the option to raise the present value of future benefits via future service. To induce an employee to retire early and accept pension benefits whose present value equals the ABO, an employer will generally have to offer a "buy-out" that compensates the employee first, for foregone future pay net of the opportunity cost of the employee's time and second, for the foregone opportunity to earn higher pension benefits. If the ABO valuation of the pension entitlement is too low because it ignores the option value to increase the pension by future employment, a reasonable alternative is simply to let the present value of the projected pension benefits build up in some smooth fashion over the course of the career.

To measure wealth and income from private sector pension plans, I use an ABO approach. For private sector plans, loss of the opportunity to earn further benefits due to a plan freeze or plan modification (such as a conversion to a cash balance plan) must be regarded as a realistic possibility. In 2006, about 900,000 employees were in private plans that had been frozen. Employees in the private sector can also lose the opportunity to earn additional benefits from a bankruptcy, or even an acquisition, of the plan sponsor.[4] Finally, changing jobs is likely to mean changing employers for employees of small or medium size businesses (though some private industries have multi-employer plans).

In contrast, changes to government pension plan provisions that affect current participants are unusual, and the risk of losing the opportunity to earn future benefits is generally small for most government employees. An approach that spreads the build-up of the projected pension wealth at retirement in over the career is therefore a reasonable alternative for government plans.

The use of different approaches for private sector and government sector plans is also convenient because, whereas ABO information is more available in a usable form for private plans, PBO information is more available for government plans. Most government plans make actuarial estimates of their benefit liability with a level percent of pay formula, where the percent is chosen so that contributions equal to the percent of pay over the course of the career will fully fund the liability for pension benefits at the time of retirement.

Nevertheless, reporting ABO approach estimates for government plans would also have some advantages. Obligations that are explicit and that cannot be escaped fit the usual definition of a liability more precisely than a concept that includes

4 As discussed below, in the event of bankruptcy of the plan sponsor, benefits worth approximately the ABO level of pension wealth are covered by insurance from the Pension Benefit Guarantee Corporation.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

obligations that are expected to arise from future events if pay raises continue their historical pattern and no changes are made to the plan's features. And even though state and local governments have rarely made changes that affect those already enrolled in a plan, proposals to do so have at least been considered by governments not in financial distress, and would likely be implemented by a government that was in financial distress.[5] Presenting ABO estimates for state and local DB plans would allow them to be compared with private DB plans on a uniform basis. Finally, a practical consequence of the use of a PBO is that more of employee's growth in pension wealth will be attributed to imputed interest income on their already-accrued pension wealth and less will be attributed to current service cost. In the 2008 SNA, the employer's imputed contributions include only the current service cost, so the use of the PBO approach is likely to result in comparatively low estimates of the compensation component of pension income. Imputed contributions may even tend to be negative under the PBO approach, and for mature plans the estimates from the ABO approach are likely to be, on average, nearer to actual contributions.

2 ORGANIZATION OF THE US PENSION SYSTEM

Both DB and DC pension plans play key roles in financing retirement for US households, but in the private sector, newly established plans are almost invariably DC plans. Even at older firms with DB plans, these plans may be closed to new hires. As a result, a significant fraction of private sector DB plans have matured, in the sense of having reached the point where contributions no longer exceed benefit payouts to retired participants. Nevertheless, the number of private sector DB plans in existence is declining very slowly and remains above 40,000.

The US also has over 2500 DB pension plans for employees of state and local governments. DB plans remain predominate in the state and local government sector, though some state and local government employees also have access to a supplementary DC plan or have just a DC plan. Finally, Federal government agencies and Federal government enterprises (such as the Post Office and the Tennessee Valley Authority) sponsor about 40 DB plans for their employees. The Federal government also makes DC plans available to its employees, and for civilian Federal employees hired after 1984, employer contributions to the DC plan help to compensate for a reduction in the generosity of the DB plan.

Besides DB and DC pension plans, many US households have self-funded retirement accounts (such as IRAs, or "individual retirement arrangements") and almost everyone is covered by social security. Social security is a government social insurance program rather than a pension plan because entitlements to benefits do not arise from an explicit or implicit contract with an employer. The classification of social security as a social insurance program in the NIPAs means

5 For example, although the government of Virginia is not in financial distress, a recent report to the Virginia House of Delegates included a proposal that state employees should start contributing 2 percent of their pay to their pension plan. At the other extreme, a bankruptcy judge has recently ruled that union contracts requiring the city of Vallejo in California to preserve its current pension plans are subject to modification by the bankruptcy court.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

that household income from social security is measured by benefit payments. Neither social security nor the self-funded retirement accounts will be discussed in this paper, but the presence of social security has influenced the design of the pension plans that are the focus of this paper.

3 ESTIMATES FOR PRIVATE DB PENSION PLANS

To estimate households' income and wealth from private DB plans, I obtained data sets from the Pension Benefit Guarantee Corporation (PBGC) of IRS Form 5500 tax returns for the years from 2000 to 2006. These tax returns report actuarial estimates of benefit expenses for DB plans, and they also report contributions, benefits and investment income. The PBGC constructs data sets covering virtually all of the information on the Form 5500 for DB plans. The Department of Labor also constructs data sets covering Form 5500, but those data sets omit the actuarial information. The PBGC classifies returns into years based on the starting date of the period that they cover, so that plans whose fiscal year starts before December 31, 2006 are included in the 2006 data set. In contrast, the Pension Bulletins published by the Labor Department classify returns into years based on ending dates. In this paper I use the PBGC's plan year definition, which causes my figures for employer contributions to differ significantly from the Labor Department figures in some years. The number of returns filed each year ranges from 43,000 to 46,000.

The Form 5500 data sets are supposed to contain a census of private DB plans, except for a small number of plans whose benefits are provided through group annuities purchased from life insurers. Nevertheless, estimating national totals is not simply a matter of adding up the relevant variables on pension plan assets, income, actuarial liability, and benefits accrued. Comparisons across years of ending and beginning assets, numbers of plan participants, and plan identification numbers imply that significant numbers of plans are missing from the data sets for 2000 to 2002. Using overlapping estimates of ending and beginning assets adjusted for revisions to previously reported values, I estimate that about 15 percent of plans are missing in 2000, falling to 8.7 in 2001 and 5.6 in 2002. Furthermore, screening for erroneous data entries by comparing variables that are supposed to agree (such as ending balances from one year and beginning balances from the following year) or at least be in the same range, reveals many data entry mistakes. Finally, values are often missing for key variables, particularly for smaller plans, which do not have to provide complete information. To fill in missing value and to replace erroneous values that I could not correct, I use predicted values from regression models. For example, the various measures of plans' actuarial liability reported on the actuarial information schedule of Form 5500 are generally highly correlated with each other, so if the current liability or the benefits accrued through service is missing, related actuarial variables can often be used to predict the missing value. Even if all of the actuarial variables are missing, reasonably good predictions can still be constructed using counts of active and retired participants and benefit levels.

A baseline for comparison with the actuarial measures of pensions is a cash accounting approach that uses private pension plan assets to measure pension

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

wealth of households. The income to households from employer contributions recorded under this approach is quite variable, rising from about $33 billion in 2000 to about $100 billion in 2002-3 (table 1.) Large holding gains during the bull market that lasted from 1995 to early 2000 left many plans overfunded, allowing their sponsors to take contribution holidays in 2000 and 2001. Holding losses followed in 2000-2002 with the bursting of the dot-com bubble, obliging employers to increase contributions to restore funding levels. Yet despite the increase in contributions, the holding losses left the plans with $400 billion less in assets at the end of 2002 than the $2 trillion they had at the beginning of 2000. These losses were then reversed by a four year string of holding gains, leaving the plans with $2.5 trillion in assets at the end of 2006.

Saving by the plans played almost no role in their growth of assets. Plan saving was close to zero from 2002 to 2006 because benefits net of employee contributions were high and rising, reaching $150 billion in 2006.[6] The high benefit payments and lack of saving reflect the maturing of these plans as their participants increasingly move into the retirement phase of the life cycle.

Actuarial measures of private DB pension plan income of households are more stable than the cash accounting measures. The actuarial value of benefits earned rises smoothly from around $67 billion in 2000 to about $79 billion in 2006 (table 2), with an average level over the seven years of $73.5 billion, close to the $79 .6 average of the employer contributions. On the other hand, the imputed interest cost of the actuarial current liability of the plans is, on average, almost twice as high as the actual investment income shown in table 1. The actuarial liability of the plans is lower than their assets in 2000 and 2001, and only 10 to 25 percent higher in later years, so the main reason why the imputed interest on this liability is higher than the actual investment income from the plan assets is that the assumed interest rate is higher than the realized rate of return on assets excluding holding gains. The low level of actual investment income reflects the reliance of the plans on holding gains as a source of funding for benefits, so by including the imputed interest in household income we are, in effect, including expecting holding gains in income. This makes the actuarial measures of household income and saving in table 2 higher than the cash accounting measures in table 1. Table 2 also shows that estimates of plan actuarial liabilities are sensitive to assumptions about interest rates and other factors.

4 FEDERAL GOVERNMENT PROGRAMS FOR PRIVATE SECTOR RETIREES

Although the US generally eschews a Bismarkian approach to pensions, the Federal government does have two programs that provide pension benefits to

6 The benefits in table 1 include lump sums paid at retirement to retirees in lieu of benefits during retirement or to life insurers for annuity contracts to provide benefits during retirement. Furthermore, investment income on life insurance reserves for group annuity contracts purchased by employers or DB plans are excluded from the investment income shown in table 1. The Labor Department's *Private Pension Plan Bulletin* for 2005 estimates the value of the group annuity contracts at 10 to 15 percent of the total for plan assets.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

private sector retirees. These programs are easily overlooked, as they are classified as social protection provided by government in the US national accounts and they are comparatively small. Nevertheless, they are important to include if one wishes to have a complete picture of DB pension benefits in the US.

A THE PBGC

Terminated plans that enter into trusteeship with the PBGC because they are unable to pay promised benefits cease to be included in the Form 5500 data sets, but the rights of their participants to benefits do not vanish. The PBGC insures the benefits that have been accrued in private DB plans up to a statutory maximum (currently $4500 per month for a 65 year old without survivor's benefits, or $4050 with a survivor annuity). The insurance coverage is financed with premiums paid by the plans. Besides the premium income, the assets of terminated plans are used by the PBGC to pay promised benefits. In 2008, for example, plans that were terminated had an average funding ratio of 59 percent (PBGC 2008 Annual Report, p. 13.) In 2007, the PBGC disbursed $4.3 billion in benefits and assistance to multiemployer plans, which are typically assisted rather than terminated (table 3.) Insurance bridges the gap between a terminated plan's assets and its accrued benefit obligation, so of this amount, only $2.6 billion is included in the government social benefits portion of personal income in the NIPAs.

Under a cash accounting approach to measuring pension plans, the households' pension wealth is lost when plan assets are appropriated by the PBGC. In contrast, under an accrual accounting approach, only a tiny change in pension wealth due to forfeited benefits over the maximum and revisions to certain assumptions should be recorded when a plan is terminated. (In a termination situation, appropriate assumptions about things like when participants will file for benefits are different from the appropriate assumptions for calculating the ABO of an ongoing plan.)

The PBGC's estimate of the present value future benefits from trusteed plans rises from under $10 billion in 2000 to $65.1 billion in 2007 (table 2, line 13, or table 3, line 5.) Yet this rapid rise is partly a reflection of a decline in the assumed interest rate from 7 percent to 5.3 percent. Measured at the 2008 interest rate assumption of 6.6 percent, the present value of future benefits fell to $56.6 billion. On the other hand, the PBGC's estimate of the interest cost of its benefit liability, which represents interest income to households under the accrual accounting approach, rose to $3.4 billion in 2008 from $3.3 billion in the previous year. To provide additional background on the operations of the PBGC, table 3 also shows its investment income. This investment income could be seen as income that would have been included in household income had the pension plan that owned the underlying assets not failed.

B THE RAILROAD RETIREMENT BOARD

The second Federal government program that provides pensions to private sector employees covers the railroad industry. The Railroad Retirement Board receives payroll taxes levied on wages and salaries in the railroad industry and

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

pays benefits to railroad retirees and their survivors. Railroad employees neither pay social security taxes nor receive social security benefits, but Tier I of the railroad retirement pension is integrated with social security and has equivalent taxes and benefits. Tier II of railroad retirement provides additional benefits similar to those of a DB pension plan. In the NIPAs, personal income from both Tier I and Tier II is recorded when benefits are disbursed, just as occurs with social security.[7]

In 2007, the benefits paid by the Tier II retirement account amounted to about $4 billion. The payroll tax receipts were $2.6 billion dollars, of which about $2 billion were paid by the employers, with the balance paid by employees. The payroll taxes are flat or falling over the years from 2000 because the combined employer and employee tax rate declined from 21 percent in 2000 to 16 percent in 2008. This rate is automatically adjusted to maintain a balance between plan assets and the current expenses for benefits and administration.

I do not yet have actuarial estimates for Tier II of railroad retirement (but in any event the amounts involved are relatively small.) A reasonable estimate of the plan sponsor's normal cost would be some fraction of the employer's payroll tax, and a reasonable estimate of present value of future benefits would be substantially larger than the plan assets. An actuarial valuation report from December 2004 estimates a liability for future benefits and administrative expenses under Tier II for current and former employees of $49 billion, approximately $47.5 billion of which appears to be for future benefits (US Railroad Retirement Board Twenty-Third Actuarial Valuation of the Assets and Liabilities under the Railroad Retirement Acts as of December 31, 2004.) Assets on hand were $27.3 billion, implying an unfunded accrued liability for benefits of about $20 billion. Nevertheless, projections of the required payroll tax rate in future years are relatively stable, suggesting that the payroll tax rate already is at least high enough to cover the interest on the unfunded accrued liability. (Railroad employment is falling, a trend that has continued since the late 1940s, so if the tax rate were only sufficient to cover current service costs, a substantial tax rate increase would eventually be needed as the unfunded benefit liability became large relative to the payroll base.) Indeed, the employer's Tier II payroll tax rate, which was 13.1 percent in 2004 and 12.1 percent in 2007, is substantially higher than the 2004 Report's estimate of employer's normal cost, which was 6 percent of payroll.

5 STATE AND LOCAL GOVERNMENT PLANS

DB pension plans are an important component of the compensation of the employees of most state and local governments and, unlike private DB plans, they are not in decline. Indeed, a DB pension is the only source of monthly retirement benefits that retirees from some of these governments receive, because some state and local governments have opted not to participate in social security.

7 The Flow of Funds Accounts of the Federal Reserve Board treat Tier II like other DB pension plans, however.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

For almost all private sector employees and for Federal government civilian employees hired after 1984 social security is a key source of financial resources during retirement, so much larger contributions to the pension plan are needed if the participants are not covered by social security. State and local government plans also tend to escalate their benefit payments based on a measure of inflation, which increases the amount of contributions that they need. On the other hand, to reduce the cost to the employer, many of these plans require the employees themselves to make a portion of these contributions.

State and local government plans remain less important than private plans in terms of total numbers of participants, with just over 14 million active participants in 2006, compared to around 20 million active participants in private DB plans (table 5.) They are also less important when measured by employer contributions, with $67.8 billion in 2006 compared with $87.9 billion for private plans. Nevertheless, the cash accounting measure of the income that they generate for households is about the same as for the private DB plans, rising from $141 to $161 billion in 2004-2006, compared to a rise from $149 to $155 billion for the private plans. One reason for this is the higher investment income of state and local plans.

State and local plans have higher investment income than private plans because they have more assets, $3.1 trillion at the end of 2006, for example, compared with $2.5 trillion for private plans. The assets of state and local government plans reflect the fact that their total contributions, including employee contributions, are generally higher than total contributions to private DB plans, and they had lower holding losses in the bear market of 2000-2002. Also, around 55 percent of their participants are still in their working years, compared to around 45 percent for the private plans. State and local government plans therefore have a higher average saving level (around $22 billion per year over 2000-2006, compared with a negative average for the private plans) and smaller net benefit disbursements (an average of $100.6 billion per year compared with $134.2 billion for private plans.)

Lenze (2009) uses a BEA data set covering 124 plans or plan families to make actuarial estimates of household income and wealth from state and local government pension plans. (Due to the high right skew of the plan size distribution, this data set captures most of national total for the measures of interest.) The Census Bureau collects cash accounting data on state and local government pension plans, but not actuarial data. BEA has therefore collected actuarial information directly from the financial reports of the larger state and local plans and from a sample of smaller plans.

Most state and local government plans calculate the actuarial value of benefits earned with a PBO approach using a level percent of pay formula. One of the key objectives that funding schemes for pension plans seek to achieve is avoidance of rapid increases in costs, such as those that occur under a pay-as-you-go scheme when the covered population ages. The level-percent-of-pay approach goes furthest in accomplishing the cost-smoothing objective, because over an employee's career the benefit cost grows at the rate of growth of the salary. In contrast, assuming a final pay benefit formula, the growth rate of ABO benefits accrued is usually greater than or equal to the sum of the salary growth rate,

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

the interest rate, and the average mortality rate of active participants, so sharp increases in costs as employees near the end of their career can cause overall pension costs for an aging workforce to rise quickly. In the early and middle years of the career, the PBO approach used by state and local government plans gives much higher cost estimates than the ABO approach, a relationship that is reversed in the final few years.

Despite the tendency of the PBO approach to frontload pension costs, the PBO measure of benefits earned net of employee contributions, labelled "employer's normal cost" in table 6, is lower than the employer contributions in 2003-2006. In 2006, for example, it is about $52 billion, compared to cash contributions of $68 billion. The plans' estimates of employer's normal costs are held down by the high rates of interest that they assume (which average about 8 percent) when discounting the future benefit payments. At these rates, the interest on the actuarial liability ($262 billion in 2006) is much greater than the actual investment income ($93 billion in 2006 according to table 5), and even after combining holding gains and investment income, the realized returns on average fall short of the actuarial interest cost. (Average realized gains are $180 billion over 2000-2006, while the average interest cost of the actuarial liability is $219 billion.) As a result of the accumulated interest costs at the assumed rates, the plans' PBO actuarial liability exceeds their assets by $179 billion in 2006.

Switching to an ABO approach and adjusting the interest rate assumptions to 6 percent raises the measure of benefits earned in 2006 from $52 billion to $71 billion (table 7).[8] Thus, the positive effect on the estimate of benefits earned of reducing the interest rate assumption dominates the negative effect of changing to the ABO approach. On the other hand, for total household income and for household wealth, the effect of changing to the ABO approach is greater than the effect of changing the interest rate assumption. Factoring in the reduced interest cost of the plans' accrued liability, overall household income in 2006 falls from $313.6 billion under the PBO approach with an average discount rate near 8 percent to $242.9 billion under the ABO approach with a 6 percent discount rate. On an ABO basis, the plans' funded ratio rises from 92 percent in 2002 to 102.6 percent in 2006, while on a PBO basis their funded ratio is just 84 in 2002, rising to around 95 percent in 2006.

Lenze (2009) also considers the effect of further reducing the interest rate assumption to the risk-free rate on a 20 year Treasury bond. In 2006, this rate is 4.9 percent, which raises the estimate of benefits earned to nearly $80 billion (table 8.) The plans' surplus of assets over the accrued liability of 12.6 percent of payroll in 2006 at the 6 percent rate used in table 7 becomes a deficit of 24.3 percent of payroll, about the same as the 28.7 percent of payroll seen in table 4 under the PBO approach.

8 To change the interest rate assumption, Lenze (2009) uses the formula that the PBGC uses to find the effects of changing the interest rate on plans' termination liability. The PBGC's termination liability formula multiplies the liability for retired participants, by exp(-0.0538(i*-i)), where i* is the desired rate and i is the rate used by the plan. For active and separated participants, the adjustment factor is exp(-0.1502(i*-i)).

6 FEDERAL GOVERNMENT PENSION PLANS

DB pension plans for Federal government employees have less than one-third the number of active participants as state and local government plans, and about a fifth as many as private DB plans. Nonetheless, these plans have much larger saving than the state and local government plans, and in 2006, they had almost the same employer contributions as the private plans, about $91 billion (table 9.) In other words, under the cash accounting approach, in 2006 DB plan-related compensation for a group of 4 million Federal employees is as large as it is for a group of 20 million private sector employees.

Why might this be? Plan freezes, and high income and holding gains from investments help to reduce required contribution levels in the private sector. Moreover, military plans have very early retirement dates and they, along with the pre-1983 Federal civilian plan, have relatively high benefits because their participants do not receive social security. Yet differences in investment returns and average benefit levels explain only a fraction of the gap in average contributions per active participant. (The Federal net benefits total about $100 billion in 2006, compared to about $150 billion for private benefits.) The other reason is that the Federal plans are deliberately building asset levels in order to make up for past underfunding via employer contributions that exceed the employer's normal cost. Around half of the Federal employer contributions are designated as "catch up" contributions. The Federal plans are therefore an example of the potential for distortions in the timing of measured pension-related compensation under the cash accounting approach.

Despite the rapid growth in Federal plans' assets since the catch up contributions began, in 2007 their assets remained under $1 trillion, far less than their benefit liability of $2.6 trillion (table 10.) Thus, whereas state and local government plans and private sector plans have funding ratios of over 90 percent, the assets of Federal plans amount to only about 40 percent of their actuarial liability. The Federal plans are disadvantaged in this comparison, however, by their assumptions of low rates of interest together with a PBO approach that includes projected inflation in pay and benefits.[9]

Even using their conservative approach to actuarial measurement, the normal cost for Federal plans is only about $40 billion in 2007, less than half the level of benefits accrued or normal cost for the private or the state and local government plans. Even after adding in the interest cost of the accrued benefit liability, the actuarial measure of the household income generated by Federal DB pension plans is much lower than for the private sector or for state and local governments. Thus the cash accounting and accrual accounting approaches give very different pictures of the relative amounts of pension-related compensation that Federal government employees receive.

9 The low rates of interest are a reflection of the fact that these plans invest almost entirely in Treasury securities, which yield low rates of interest. Thus, in a strict sense, the plans are almost entirely unfunded, as Treasury securities are a liability of the employer.

7 ESTIMATES OF TOTAL HOUSEHOLD INCOME AND WEALTH UNDER THE TWO APPROACHES

Combining the employer contributions and investment income of private, state and local government and Federal plans, the cash accounting measure of DB pension plan income received by US households ranges from 4.5 percent of disposable person income (DPI) in 2001 (a year when contributions had not yet responded to the holding losses of the dot-com stock market crash) to 4.9 percent in 2002-2003 (table 11).The accrual accounting measures of benefits earned and interest accruing on the benefit liability reported by the plans yield much higher estimates of household pension plan income, however. These estimates range from 7.3 percent of DPI in 2006 to 7.6 percent in 2001 and 2002. Adopting the actuarial approach to measure DB pension income would therefore add about 2 percentage points to the estimate of the personal saving rate.

The gap between the actuarial and cash accounting measures of pension-related income is entirely due to the excess of the theoretical interest on the actuarial liability over the investment income that is actually generated by the plan assets – indeed, the actuarial value of benefits earned is lower than the employer contributions. One reason for this is that the private and state and local pension plans rely on expected holding gains to help fund benefits. On the assumption that investment income plus expected holding gains produce a 7 percent return on assets, including expected holding gains on plan assets in the cash accounting measure of investment income would close about two-thirds of the gap between it and the interest on the actuarial liability. The shortfall in investment income also reflects the fact that the plans' assets are smaller than the plans' actuarial liability for benefits by amounts that range between 15 and 25 percent of DPI. Thus, US households appear wealthier and thriftier when their pension plan wealth and saving are measured on an accrual basis.

Table 1 Household wealth and income from private defined benefit plans: cash accounting approach (cont'd)

(billions of current year dollars)

Addendum				
13	Active participants (millions)	21.0	20.4 [4]	19.9 [5]
14	Total participants (millions)	42.7	42.5	42.2
15	Employer contributions, National Income and Product Accounts (Table 6.11d, 2008 revision)	92.8	89.7	93.3
16	Disposable personal income	8,680.9	9,062.0	9,640.7

1) Totals for 2000, 2001 and 2002 include imputations for missing observations. The reported totals have been adjusted up by 15.7 percent, 9.2 percent, and 5.3 percent in 2000, 2001 and 2002, respectively.
2) Consists of data discrepancies as measured by comparing opening and closing balance sheets reported by the plans to the income and holding gains reported by the plans.
3) Difference between reported assets at year end and the assets that the tax returns for the following year show as present at the beginning of that year, after adjustments for missing tax returns.
4) Includes 0.7 million participants in frozen plans. (Frozen plans cannot be identified before 2005).
5) Includes 0.9 million participants in frozen plans.

APPENDIX

An Illustration of the ABO Approach, the Projected Unit Credit Method and the Entry Age Normal Method

A simple hypothetical pension plan illustrates some of the differences between three possible ways of calculating pension benefit liabilities. These are the accrued benefit obligation (ABO) approach, and the projected unit credit (PUC) method, which is often labeled the projected benefit obligation (PBO) approach in corporate financial reports, and the constant percent of pay version of the entry age normal (EAN) method (which is also sometimes called a PBO approach).

Participants in the pension plan work for 3 years, retire in the 4th year, and die in the 5th year. Their salary grows 5 percent per period from a starting level of $25,000. Vesting is immediate, there are no breaks in service, and there is no early retirement. The accrued retirement benefit equals 10 percent of salary times the number of periods worked times final salary. The interest rate is 15 percent.

Table A follows a single participant through the career and retirement. It shows that the PUC and EAN measures of the future benefit liability are higher than the ABO liability except at retirement, when all measures are equal. The PUC and EAN service cost measures are higher than the ABO one at first, but are much lower in the last year of the career. As a result, based on averages over the entire career, the largest measure of service cost is the ABO one.

Table I Illustration of different approaches to measuring benefit liability and service cost for a single employee

	Assumptions			Liability for future benefits		
Age	Salary	Benefits paid	Accrued benefits	ABO	Projected unit credit	Entry age normal
1	25,000	0	0	0	0	…
2	26,250	0	2,500	1,890	2,084	2,276
3	27,563	0	5,250	4,565	4,793	5,008
4	0	8,269	8,269	8,269	8,269	8,269
5	0	0	0	0	0	0

Service cost			Service cost as a percentage of salary		
ABO	Projected unit credit	Entry age normal	ABO	Projected unit credit	Entry age normal
1,644	1,812	1,979	6.58	7.25	7.92
2,079	2,084	2,078	7.92	7.94	7.92
2,625	2,397	2,182	9.52	8.70	7.92
0	0	0	N.A.	N.A.	N.A.
N.A.	N.A.	N.A.	N.A.	N.A.	N.A.

Table B follows a plan that starts with 10 newly hired participants, and adds 10 new hires in each of the next two years. Hiring then ceases. As the workforce ages, the ABO measure of service cost rises faster than the PUC measure. The EAN measure using the level percent of pay version of the entry age normal method does not rise at all. If the distribution of ages in the workforce is uniform, the ABO measure of service cost is higher than the PUC and EAN ones, so on the whole the ABO approach tends to attribute the growth of pension wealth more to compensation in the form of imputed contributions (and the other methods tend to it attribute it more to property income in the form of imputed interest earned on the plan's benefit liability).

Table 2 Illustration of different approaches to measuring benefit liability and service cost for the plan from inception to termination

(dollar amounts in thousands)

	Assumptions			Future benefit liability		
Year	Payroll	Benefits paid	Accrued benefits	ABO	Projected unit credit	Entry age normal
1	250	0	0	0	0	…
2	513	0	25	18.9	20.8	22.8

GENERAL GOVERNMENT PENSION LIABILITIES IN POLAND

BY JANUSZ JABLONOWSKI [1]

I STRUCTURE AND MAIN FEATURES OF THE PENSION SYSTEM IN POLAND:

A SOCIAL INSURANCE FUND – FUS

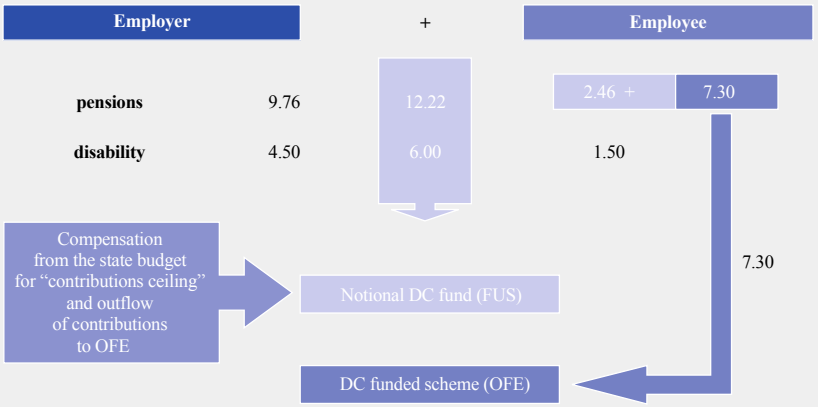
The standard retirement age for women is 60, and for men 65. There is a possibility to retire earlier, at age 55 and 60 respectively, when certain conditions are met.

During the pension reform from 1999, an individual notional account was created for each member born after 1969, and also for those members who have decided to enter to the new system, and were born between 1949 and 1969. For the latter group the virtual amount of contributions were assigned to the account to reflect the up-to-date amount of collected contributions. Persons born before 1949 stayed in the old PAYG system, where the pension depends on 10 years of all contributory periods chosen by the scheme member.

In the new system pension entitlement is based on total amount of indexed notional contributions collected on members' individual accounts. There is no minimum insurance period that is required to receive the old-age pension. **The amount of pension is calculated just before the retirement by dividing the total amount of indexed contributions, collected during contributory period on individual account, by life expectancy expressed in months, published by the National Statistical Institute.** In addition to this part paid from "new" FUS, the other one, coming from funded mandatory pension schemes (so called OFE) is added. The first, very few payments of the new pensions, consisting of both above mentioned parts starts in 2009.

Life expectancy tables are unified for both genders – so there are no separate life expectancy tables for women and men.

Pension entitlements are indexed on basis of CPI plus 20% of real increase in salaries on annual basis.



There is a ceiling for maximum amount of annual contributions – once the amount of gross income (which is the basis for calculation of the contributions) reaches the amount equal to 30 times average annual salary in the economy (or 250% of monthly average salary), the contributions are not collected until the end of the year. This "ceiling" mechanism was to promote other forms of private pension schemes.

Chart I Flows of pension and disability contributions in FUS

(percentages up to date for 2009)

Source:

The FUS is an unfunded system – there are almost no assets, but only small annual book reserves for uncollected amounts of contributions.

To prevent possible future liquidity constraints in FUS pension payments, resulting from unexpected losses, a buffer fund (Demographic Reserve Fund) was created. Up to now its assets are not very significant, since they amounted to PLN 3,5bln in 2007, which stands for less than 5% of the annual FUS pension expenditures.

In case of default of the FUS, the state budget guarantees the payment of social benefits.

Additionally, to cover the losses resulting from the outflow of part of contribution to the open pension funds the state budget supports FUS with significant transfers.

In Polish pension system there are no separate rules for civil servants.

B PENSION AND DISABILITY FUND – FER (FARMERS)

The standard retirement age is the same as in the FUS system: women retire at age of 60, men retire at age of 65, with possibility to retire earlier, at age of 55 and 60 respectively.

Pensions depend on the length of contributory period, independently from amounts of collected contributions.

Contributions are much lower than in the FUS system, and are paid quarterly, calculated as 30% of basic pension for farmers (equivalent of around 30€/q).

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

This is an unfunded defined benefit scheme, where the amount of pension depends on the sum of contributory and non-contributory periods.

Low amounts of contributions are sufficient to cover only 8% of FER pension and disability expenditures. The remaining 92% of expenditures are paid from state budget transfers.

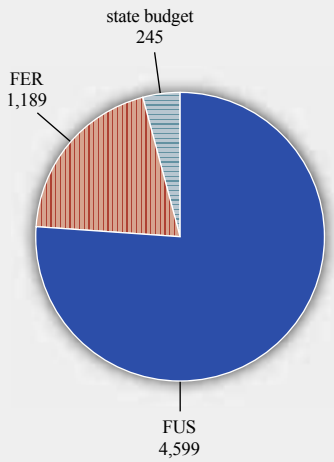
C STATE BUDGET PENSIONS

Benefits paid from the state budget.

Two groups of beneficiaries:
- Judges and prosecutors,
- Professional soldiers, police, officers of Government Protection Bureau, Internal Security Agency, Intelligence Agency, Central Anti-corruption Bureau, Polish Border Guard, custom duties services, prison services, firemen.

No pension & disability contributions.

Pension amount reflects the final salary (e.g. last 3 soldier's pays before the retirement) – usually they are higher than average pensions from the FUS.



Pension can not exceed 75% of the last salary.

Possible retirement with pension limited to 40% of the last salary, but already after 15 years of duty, regardless of age (e.g. possible 38 year old pensioners!).

Pension entitlements indexed on common basis of CPI plus 20% of real increase in salaries.

Chart 2 Average monthly number of pensioners in general government schemes

(2007; in thousands)

D PRIVATE PENSIONS SCHEMES

Mandatory funded pension schemes (OFE)

Employee pension programmes (PPE) created by individual employers:
- Employee pension fund,
- Agreement on contributing employee contributions to an investment fund by the employer,
- Group investment employee life insurance agreement conducted with an insurance company in the term of a group life insurance linked to capital investment funds.

Individual Pension Accounts (IKE) provided by banks, insurance companies, investment funds societies and brokerage businesses.

2 THE MODELING ISSUES

A UP-TO-DATE EXPERIENCES

PROST: the ECB offered the NBP a training course in 2007 on PROST, a model developed by the World Bank, which simulates the effect of the pension reform. Results obtained with use of that model were very difficult to interpret because after modeling of the reform from 1999 it was uneasy to adjust the model parameters in such a way, that the projected data suited the actual data between 1999 and 2007. Due to large number of errors in outcomes the model is not in use anymore.

Freiburg model: actually the only model which was capable to project more predictable levels of pension liabilities for Poland. The initial results obtained in 2007 were promising, though too volatile. Further fine-tuning of assumptions and additional data were required to achieve more stable outcomes.

B CURRENT DEVELOPMENTS

In the 2008 update of pension liabilities calculations only the Freiburg model was used for Poland. Because the simulations of very long term forecasts of pension liabilities, covering around 50 years in the future were prepared for the very first time for Poland in 2007, there was still high degree of uncertainty if currently available data and modeling solutions were matching all necessary components, which properly reflected the economic reality of the Polish pension system. The only reliable model, which could serve as a benchmark for the Freiburg model, the AWG model from ZUS,[2] could not be adjusted to project the methodologically similar outcomes. Therefore, after two years of efforts there were still unanswered questions: 1) whether the pension liabilities projected by the Freiburg model were reliable and, 2) whether to build own, country specific and expensive model to simulate the up-to-date liabilities of the pension system or rely on existing general model of Freiburg University? In 2009 the idea

2 Social Insurance Institution – a central government independent body that manages FUS, part of social security funds subsector in ESA95.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

arose to adjust the Freiburg model to adapt its output to pension expenditures prepared by the AWG in the 2009 Ageing Report.[3] The table below sums up the differences and similarities between two types of simulations:

Table I Comparison between AWG model and Freiburg model

	Freiburg	AWG
Type of the system covered	Closed (no entrance for new workers)	Open (entrance for new workers allowed)
Outcome	Accrued-to-date liabilities	Revenues and expenditures
Coverage of the systems	General government	General government
Coverage of types of benefits	Gross pension benefits, early retirement, disability, survivors	Gross pension benefits, early retirement, disability, survivors
Wage growth	Fixed (real) 1,5%	Varying (real)
Demographics	EUROPOP	EUROPOP
Time horizon	2007 – Infinity (?)	2007-2060
Currency	Euro/National	Euro

Source: European Commission for each MS.

As it can be seen in the table above, there are few, but important, differences between these two types of simulations:

1. Type of the system covered:
   – AWG: for each next year of the forecast (t+1, t+2, … , t+n) allows the entrance of new workers, who are for the first time starting their carriers, to increase the total number of employees in the model, which can be called "open" system.
   – Freiburg model: as in other similar types of calculations of the up-to-date liabilities, the number of employees/contributors is fixed and the system is "closed" for the entrance of the new ones.

2. The outcomes of projections:
   – AWG: pension systems expenditures, prepared with use of many country specific models, individually by each MS.
   – Freiburg model: accrued-to-date liabilities, either ABO or PBO[4], one model with country specific adjustments.

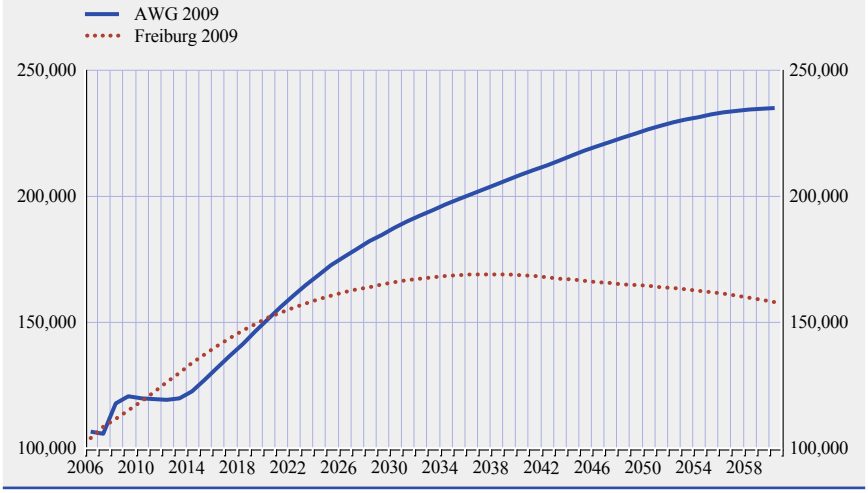
3. Wage growth:
   – AWG: different, individual rates for each MS. For EU27 the growth for whole period of the projection was stable and close to 1.7% in real terms.

3 http://ec.europa.eu/economy_finance/publications/publication14992_en.pdf
4 ABO = Accrued Benefit Obligation; PBO = Projected Benefit Obligation or Projected Unit Credit Method

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

The growth rate for Poland was much higher especially until 2030, which can be followed on Chart 4.

– Freiburg model: for all countries participating in the "benchmark" exercise supervised by the ECB/Eurostat, the flat 1.5% growth rate in real terms was used for better comparability between countries.



For Poland the pension expenditure projections for FUS presented in 2009 Ageing Report, were prepared with use of the country specific model developed in the Social Insurance Office (ZUS). For the practical reasons, and during current stage of analyses, it was possible only to adjust the outcome of the Freiburg model to AWG–related model, in practice to obtain open system expenditures with use of the Freiburg model, rather than accrued-to-date liabilities with use of ZUS model, which would probably require very deep and time-consuming reconstruction of the ZUS model.

C OUTCOMES OF THE EXERCISE

On the Chart 3 there are two curves presenting diverging open system expenditures of FUS in the time horizon until 2060.

When analyzing the 3 major differences between two models listed above, one can easily spot that two first have been made consistent, but there's a remaining difference in terms of wage growth assumptions. The chart below presents difference between Freiburg model flat 1,5% real growth rate and varying across AWG projection real wage growth rate for Poland.

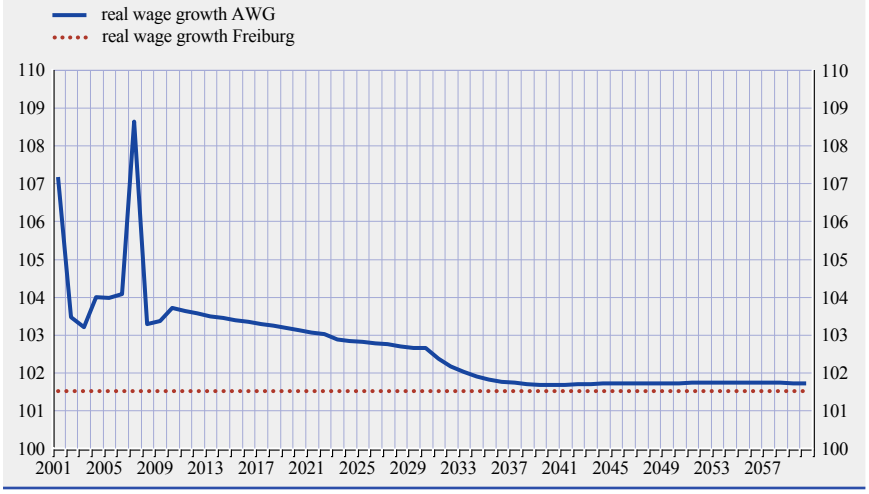


Chart 3 Open system expenditures with different wage growth rate assumptions, PLN mln

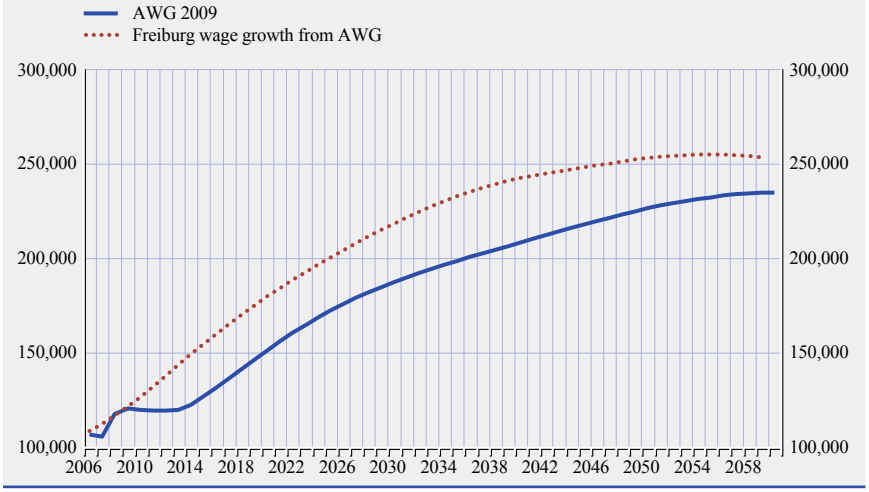
Source:

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Chart 4 Comparison between Freiburg model and AWG wage growth assumptions for Poland



Source:

After replacing the flat 1,5% rate model used in the Freiburg model with the one used in the AWG projections (Chart 4), the convergence between open system expenditures projected by two models became more apparent, as it can be seen on the Chart 5:

Chart 5 Open system expenditures with the unified wage growth rate assumptions

(PLN million)

3 CONCLUSIONS

The sharp rise in open system expenditures observed between Chart 3 and 5, resulting in significant increase in pension entitlements, was the effect of simple replacement of the wage growth rates. When comparing wage growth rate curves from Chart 4 a following conclusion can be suggested: significant and quick accumulation of pension contributions in the first 2 decades of the projection, coming from fast growing wages (despite contributions' ceiling), caused significant increase in pension entitlements starting from 2nd decade until the end of projection. That might mean the significant sensitivity of the pension entitlements forecasts on wage growth progress in countries, which experience fast economic development, and are converging slowly towards EU27 average 1,7% wage growth rate assumed in 2009 Ageing Report.

After obtaining more consistent paths of open system expenditures, the checking of levels of pension liabilities of the closed system with new, higher wage growth assumptions followed. With 1,5% real wage growth the level of pension liabilities measured with a PBO method and 3,0% real discount rate amounted to 330% of GDP in 2007. After switching to varying wage growth used in AWG projections the level of pension liabilities in 2007 increased to 382% of GDP.

To check the plausibility of the projection the additional switch was proposed: having open pension system expenditures from AWG, it is possible, though not maybe in all cases, to close the system for entrance of newcomers and let survive the existing cohorts, then calculate the annual stocks on the basis of projected flows (i.e. closed system expenditures), and then discount the stocks with the given discount rate to obtain present value of expected payments. So far, the project has not started yet.

PENSION ENTITLEMENTS OF CIVIL SERVANTS IN GERMANY – LEVEL AND THEIR CHANGE OVER TIME

BY ALBERT BRAAKMANN, JENS GRÜTZ AND THORSTEN HAUG,[1]

1 INTRODUCTION

Foreseeable demographic changes in the future put the issue of old-age insurance in the spotlight of public interest. At the European level as well, sustainability is an important matter. Particularly since the Stability and Growth Pact came into effect, the development of the deficit and debt of general government are attentively observed. In response to the growing information requirements, concepts for a new, comparable and more comprehensive presentation of old-age insurance in National Accounts are being developed. This paper presents first results for the pension entitlements of Federal civil servants in Germany.

2 PENSION ENTITLEMENTS AND THEIR INFLUENCE ON LABOUR COSTS

To allow for international comparisons, the amount of pension entitlements is often put into relation to the gross domestic product (GDP). The question if a single value, like pension entitlements as share of GDP, can be interpreted as an indicator for a sustainable development is not paramount here. This article rather focuses on the development of labour costs and how the level of labour costs is influenced through the method of calculation of the pension entitlements and its underlying parameters. The calculation method will only be described as extensive as necessary for the understanding. A detailed description of the methods can be found in our publications on the pension entitlements of the statutory pension insurance[2] and on those of the civil servants.[3] The calculation of pension entitlements is a new field of activity for national accountants in Germany. All results are preliminary and are based on the 2005 pension report of the Federal Government.[4] The data basis used for the report (and

our calculations) is the statistics of active civil servants and pensioners for 2003. Mortality rates are derived from the pension report. All calculations have been carried out using the Projected Benefit Obligation (PBO) Method. Future (universal) pay rises and expected promotions are incorporated into the calculations under this method. Promotions are simulated based on current data. The level of pay rises is consistent with the assumptions of the Federal Government in the reports of the statutory pension insurance[5] of the respective years. The discount rate of the base calculations equals the return of Federal bonds with a duration of 15 years.

3 RECORDING OF PENSION ENTITLEMENTS IN THE REVISED SNA

The newly introduced supplementary table on pension schemes in the SNA 2008 addresses an important purpose. It provides comparable information on pension entitlements for all systems of old-age insurance in a comprehensible form. Problems like the transfer of pension entitlements from systems booked within the core system to systems outside of the core systems do not occur. Furthermore the structure of the supplementary table presents the transition from the opening balance to the closing balance through inclusion of social contributions, social benefits, revaluations and other changes in volume.

The entitlements of the civil servants (including soldiers) in Germany amount to 950.63 billions EUR[6] at the end of 2003, equal to 44 per cent of GDP. The following simulations are restricted to include Federal civil servants for ease of calculation. The pension entitlements of this group of civil servants totals to 57.62 billions € at the 1st of January 2003. With the acquisition of entitlements through another year of service and capital income (household social contribution supplements) the pension entitlements grew, whereas pension benefits paid and revaluations reduced the pension entitlements (revaluations were negative due to a slight increase in the discount rate, and decrease in wage expectations). At the end of 2003 the pension entitlements reached a level of 58.90 billions €, which is a net increase of 1.28 billions €, or 2.2%.

The change in pension entitlements[7] corresponds to the development of labour costs and therefore equals employer social contributions.[8] If this figure is set in relation to the salaries and wages paid, an implicit contribution rate can be calculated for the civil servants pension scheme. Table 1 shows an increase in pension entitlements

5 [Rentenversicherungsbericht 2003]: „Bericht der Bundesregierung über die gesetzliche Rentenversicherung, insbesondere über die Entwicklung der Einnahmen und Ausgaben, der Schwankungsreserve sowie des jeweils erforderlichen Beitragssatzes in den künftigen 15 Kalenderjahren gemäß §154 SGB VI (Rentenversicherungs-bericht 2003)“, Bundestagsdrucksache 15/2144, 04.12.2003.

6 Not including the entitlements of the few civil servants in the so called indirect government service (mainly social insurance carriers).

7 In the context of occupational pension schemes the term used is ‘current service cost’. This economically significant factor, that represents the increase in claims for another year of service, is determined as a residual in our calculations.

8 If the employees provide own contributions, those have to be deducted from employers social contributions.

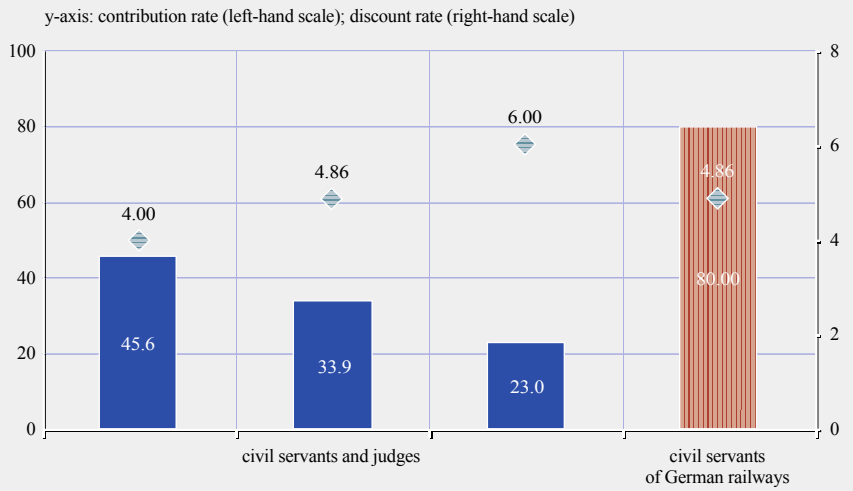
2.1-2.3	+ Increase in pension entitlements due to social contributions	1,345
2.4	+ Household social contributions supplements	2,881
4	- Reduction in pension entitlements due to payment of pensions	-2,025
7-9	+/- Revaluations	-926
10	Pension entitlements 31/12/2003	58,896

for civil servants of 1.35 bn in 2003. If related to paid remuneration, the implicit contribution rate can be determined to be at a level of 33.9%.

For comparison: for public service employees, who are no civil servants, old-age insurance contributions of 19.5% for the statutory pension insurance and 8.45% for the supplementary old-age insurance for government employees have been set aside. In total, contribution payments amount to just fewer than 28%, up to the assessment ceiling. Under the conditions of the model framework, expenditures for public service employees are somewhat lower than those for civil servants.[9]

4 THE INFLUENCE OF MODEL ASSUMPTIONS ON THE LEVEL OF PENSION ENTITLEMENTS



The level of pension entitlements and the level of the implicit contribution rate are determined to a large extent by the parameters of the calculation. The most important factor is the discount rate. Chart 1 displays the interrelation of discount rate and contribution rate. It clearly illustrates that the shift of the discount rate from 4% to 6% reduces the contribution rate almost by half. At a discount rate of 4.86% (interest rate of 2003 for Federal government bonds with a duration of 15 years) one obtains the aforementioned contribution rate of 33.9%. A completely different situation is represented by the contribution rate calculated at the same discount rate for civil servants of German Railways, which reaches a level of 80%. This shows that additional factors may have a significant impact on the results. In this case the age structure of the civil servants differs significantly. Whereas the civil servants and judges are on average 42 years old, the civil servants of German railways show a mean age of 47 years. This substantial difference is due to the privatization in 1994, which ceased the recruitment of new civil servants in the railway sector, resulting in a steady increase of the average age of the remaining active civil servants. Since older civil servants redeem their entitlements earlier than young ones, the present value of their entitlements is larger, resulting in a comparatively high contribution rate of 80%.

9 A complete comparison of the labour costs of civil servants and workers is not feasible in the framework of this article. For this purpose, further factors, such as the lower gross wages of civil servants or the more extensive financial support in case of illness would have to be considered.

The considerable variation in results shows that the assumptions of the actuarial calculations have to be carefully determined and documented. Within the Eurostat/ECB Task Force on the statistical measurement of the assets and liabilities of pension schemes in general government (Task Force), a framework for the most important parameters has been agreed upon.[10] The Task Force proposal, and the implementation of the parameters in Germany are shown in Table 2.

A fundamental decision is made with choosing the PBO-method. It requires far-reaching assumptions about future economic growth, yet provides information which fulfils best the requirements set by national accounting. Whereas for

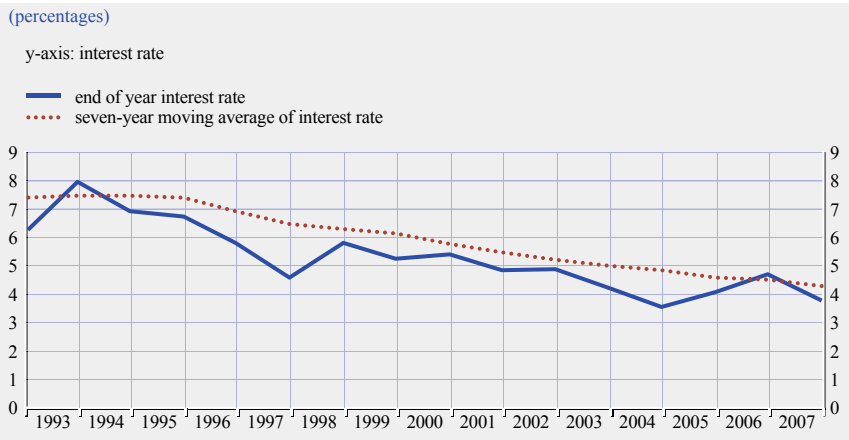
instance under the ABO-method (accumulated benefit obligation) a pension reform that changes indexation rules from wage indexation to price indexation does not change pension entitlements, a valuation using PBO results in lower pension entitlements facing the same reform. The higher informational value of PBO results improves international comparability of the calculations, though at the cost of requiring more assumptions. This fair-value accounting is consistent with the International Accounting Standards (IAS) and the accounting law reform in Germany. In income tax law however, Germany continues to use ABO-valuation, possibly for fiscal reasons. Thus, pay raises can only be considered while determining fiscally relevant pension entitlements if they are unquestionable. Even pay raises that are highly likely but not finalized cannot be considered here. In the framework of the supplementary table, Germany calculates pension entitlements according to the fair value principle (PBO). These are not comparable with the figure currently published in the core accounts under D.8, the change in occupational pension entitlements, which is determined according to the ABO-method.



In the Task Force it was discussed to use exclusively the economic assumptions of the European Commissions Report on Ageing[11] for most of the model parameters described above. For several reasons, however, one should deviate from this proposal. The EC Report on Ageing is only updated in multiannual periods. In Germany however, annually updated projections of the Federal Government are available which are used of the report on the statutory pension insurance. In using these assumptions, consistency can be guaranteed between the national report on the statutory pension insurance and the international supplementary table. Similar reasoning applies to the assumptions on mortality. The Europop mortality tables provides a sound data basis, the use of national figures however assures coherence in the framework of various national model calculations. This is especially important, if, in the course of the model calculations, repercussions of population- or labour market developments have to be considered.

With the Accounting Law Modernisation Act (BilMoG) the assessment of pension entitlements in Germany was simplified to some extent. According to IAS (and BilMoG) a discount rate has to be used with a duration matching the duration of each pension entitlement. BilMoG though allows as well the use of a discount rate based on a 15-year duration. This period of time reflects the long-term nature of pension liabilities, offers a comprehensible basis for the calculation of pension entitlements and was therefore implemented into our model. The second simplification based on BilMoG regulation included in our model refers to the way the discount rate is derived from the return of the underlying asset. As agreed upon in the Task Force, the return of Federal bonds is used. According to IAS, the cut-off date value at the end of the year is to be used. In German national accounts, however, BilMoG prescribes the use of the moving average of the last seven years. Hence, a wild fluctuation in results, as can be seen in Chart 2, is avoided.

11 The impact of ageing on public expenditure: projections for the EU25 Member States on pensions, health care, long-term care, education and unemployment transfers (2004-2050), Economic Policy Committee and the European Commission (DG ECFIN), http://europa.eu.int/comm/economy_finance/epc/epc_publications_en.htm

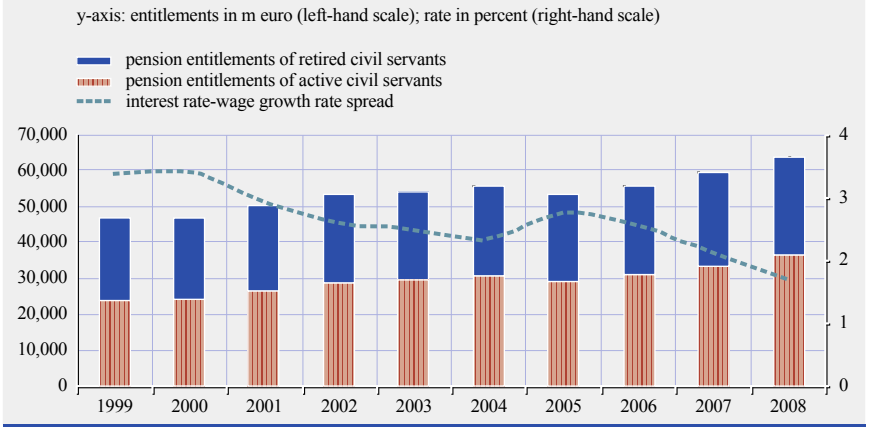

Chart 2 Development of interest rates in Germany

Source:

A persistent change in inflation expectations will realize in the model only with a certain delay, on the other hand one can assume that the counterpart to the discount rate, the assumptions on expected wage increases will be adjusted with a time lag as well. Since the level of pension entitlements is determined by the interest rate-wage growth rate spread, a smoothed average wage makes a good benchmark for the calculation of pension entitlements in practice. The unsmoothed interest rate-wage growth rate spread is problematic from a statistical view. A frequent use of the end of period interest rate will lead to significant fluctuations in the interest rate-wage growth rate spread, since this differential comprises one variable volatile for the short term – the market interest rate, and one variable that is stable in the long term – the productivity growth and accordingly the expected wage increases. The significance of the interest rate-wage growth rate spread for the calculation of pension entitlements is shown in Chart 3.

Chart 3 Development of pension entitlements – base 2003 due to changes in the interest rate–wage growth rate spread

The graph depicts a synthetic time series of pension entitlements from 1999 to 2008. The calculations are based on the same base data for the civil servants and their entitlements from the year 2003, while the parameters interest rate and wage growth vary. Wage growth rates are taken from the Federal government's report on the statutory pension insurance of the respective year, while the interest rate are determined as the seven-year moving average of Federal bonds with a duration of 15 years. The difference in level of pension entitlements therefore is solely caused by the variation of the assumptions. An actual increase or decrease of entitlements does not happen in this model calculation.

The interest rate–wage growth rate spread started at a level of around 3 percentage points at the beginning of the decade and decreased to around 2 percentage points at present. As expected, the decreased interest rate–wage growth rate spread results in higher pension entitlements. Chart 4 displays the connectivity of the interest rate- wage growth rate spread with the implicit contribution rate. Corresponding to the decreasing interest rate–wage growth rate spread, the implicit contribution rate (and with it labour costs) increases. It starts at a moderate level of 25% in 1999 and reaches 45% in 2008. What's more, the elasticity of pension entitlements varies with the level of the interest rate–wage growth rate spread. The lower the interest rate–wage growth rate spread, the lower is the relative change in pension entitlements for a given change in the spread.

Our analysis of the time series of pension entitlement and labour costs was based on a steady number of civil servants. The strong increase in pension entitlements and of the implicit contribution rate show that they cannot be easily interpreted

Chart 4 Development of the implicit contribution rate

as sustainability indicators. The supplementary table as a whole provides an important source of information. With its help, it can be observed how changes on actuarial assumptions, pension reforms or changes in the personnel structure affect the level of pension entitlements. The supplementary table has to be complemented by a compulsory appendix, as usual for annual reports. It should contain all necessary actuarial information, to guarantee the comparability of the different calculations.

5 EFFECTS ON GDP

ESA 1995 prescribes to determine imputed social contributions for civil servants pensions on the basis of actuarial calculations. In case these are to complex or time-consuming, or lack necessary data to be derived, ESA 1995 suggests to use pensions paid as a proxy. This fallback procedure is only considered to be applicable as long as the ratio of active civil servants to pensioners remains stable. Otherwise labour costs would be clearly underestimated if more civil servants would be hired than leaving, or significantly overestimated if many civil servants retire in a short period of time. ESA 1995 proposes the wage share method under such circumstances that is a ratio of implicit social contributions is applied to the current sum of wages paid. With this method, not only labour costs are determined, the absolute level of the GDP is affected as well, as far as the added value of the public sector is calculated using the input method.

Table 3 shows how current calculations using the wage share method as well as actuarial calculations would influence the level of GDP. In our current calculation of labour costs and value added in non-market shares of the public sector, a surcharge rate of 26.9% is used. This surcharge rate only varies if the contribution rate for the statutory pension insurance is changed. GDP amounts to € 2,492 billions at the current rate. If the implicit contribution rate for the year 2003 (37.9%[12]) is used instead of that, then GDP increases by 0.2 percent to € 2,496 billions. If the much lower interest rate- wage growth rate spread of the year 2008, with a corresponding

12 This figure includes pensioners' healthcare allowance; the contribution rate of the original calculation (33.9%) only includes direct pension payments.

Table 3 Methodical changes – Effects on GDP

Calculation of the compensation of employees using…	…the current method	…an implicit contribution rate	
		2003	2008
Surcharge/contribution rate (including pensioners healthcare allowance)	26.9	37.9	50.0
Share of compensation of employees of GDP in percent	3.85	4.01	4.35
Gross domestic product (in € billions)	2,492	2,496	2,504
Relative change in GDP	-	+0.2	+0.5

contribution rate of 50% is used, GDP would rise by 0.5 percent and reach a level of € 2,504 billions. These results show that the move to actuarially calculated contribution rates affects the level of nominal GDP and its rate of change. This effect however is rather limited to nominal GDP. If price-adjusted GDP is used, the change in labour costs will normally not affect the level and growth rate of the GDP, since the change in labour costs is a price effect. Therefore, business cycle analyses are not affected. If however nominal gross national income is employed, such as in the core of the gross national income own resources to finance the EU-budget, the effect can be quite significant.

6 CONCLUSIONS

If compiled on an actuarial basis, the pension entitlements of civil servants in Germany in 2003 amounted to a level of 44 percent of GDP. The level of pension entitlements and labour costs is strongly influenced by the assumptions made. A more complete picture of the systems of old-age insurance is provided by the supplementary table, which shows the effect of changes in the actuarial assumptions or of pension reforms on the level of entitlements. The supplementary table however does not replace a comprehensive analysis of systems of old-age insurance, e.g. based on open system liabilities.

The assumptions of the different member-states have to reflect the specific national circumstances yet accommodate the usual international accounting standards. Uniform assumptions for all EU or EMU member states do not guarantee comparable results, since they may not apply for some member states. Comparability can be better achieved if data from national data bases can be included as well. Model parameters with a very big influence, e.g. the discount rate, could however follow a coordinated approach. A detailed documentation of the procedures and parameters used, shown in the appendix to the supplementary table, could possibly be an alternative to uniform assumptions to improve transparency and traceability.

Calculation of labour costs of civil servants and other public service employees on an actuarial basis is not feasible for quarterly data. As a comparable method, the wage share method is considered as appropriate. The level of the surcharge rate can be determined using actuarial calculations from the supplementary table. It is questionable however, if the calculation of the imputed social contributions could be conducted on the base of pensions paid, since the development of pension payments can differ from the development of the remuneration of active civil servants for several reasons. One should also consider if the labour costs of civil servants could be determined with a comparable method, both in the core system and the supplementary table.

Separate calculations for comparatively small groups of civil servants, like the civil servants of German railways, are not considered meaningful. In national accounts, only one contribution rate should be calculated for a scheme. The entitlements of civil servants of different levels of the public sector should be calculated using uniform methods and assumptions.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

The actuarial calculation of pension entitlements affects nominal GDP by changing imputed social contributions, even at steady numbers of employees. Therefore, the crucial assumptions discount rate and wage growth rate should be harmonized. The assumptions on the wage growth rate are determined for a long-term horizon. Hence, the discount rate should be transformed to reflect long-term expectations as well. For this, the smoothened seven-year average is considered appropriate.

2.1 DISCOUNT RATE AND/OR WAGE GROWTH RATES ARE KEY PARAMETERS IN THE LEVEL OF PENSION LIABILITIES AND EXPENDITURES:

- *Accordingly, in American employer schemes, a higher discount rate increases the imputed property income and reduces the employer's contribution (employer normal cost). Does such a high discount rate (8% in US local Gvt plan) include a risk premium -if not holding gains- in the contribution supplement?*

"Despite the tendency of the PBO approach to frontload pension costs, the PBO measure of benefits earned net of employee contributions, labelled "employer's normal cost" in table 6, is lower than the employer contributions in 2003-2006. In 2006, for example, it is about $52 billion, compared to cash contributions of $68 billion. The plans' estimates of employer's normal cost are held down by the high rates of interest that they assume (which average about 8 percent) when discounting the future benefit payments. At these rates, the interest on the actuarial liability ($262 billion in 2006) is much greater than the actual investment income ($93 billion in 2006 according to table 5), and even after combining holding gains and investment income, the realized returns on average fall short of the actuarial interest cost."

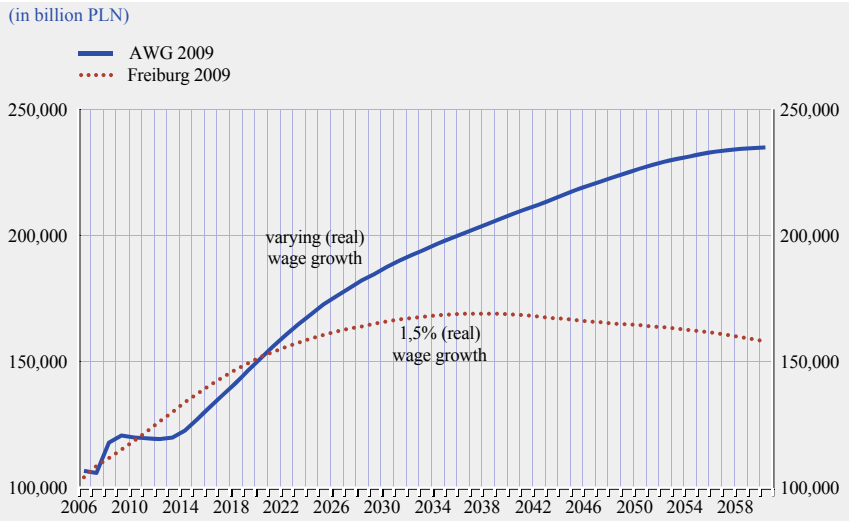

Table 10 Household Wealth and Income from State and Local Government DB Plans (US)

	Cash accounting	2000	2001	2002	2003	2004	2005	2006
1	**Household Income**	122.6	109.5	110.6	128.6	141.0	147.8	161.2

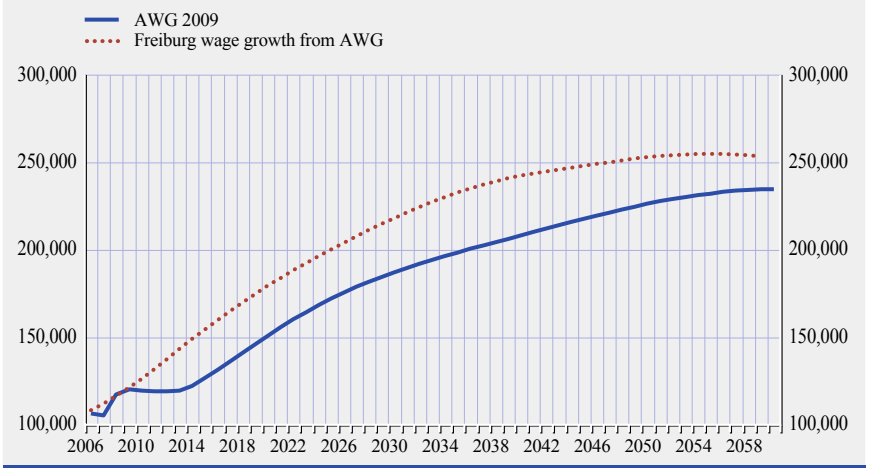
Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.



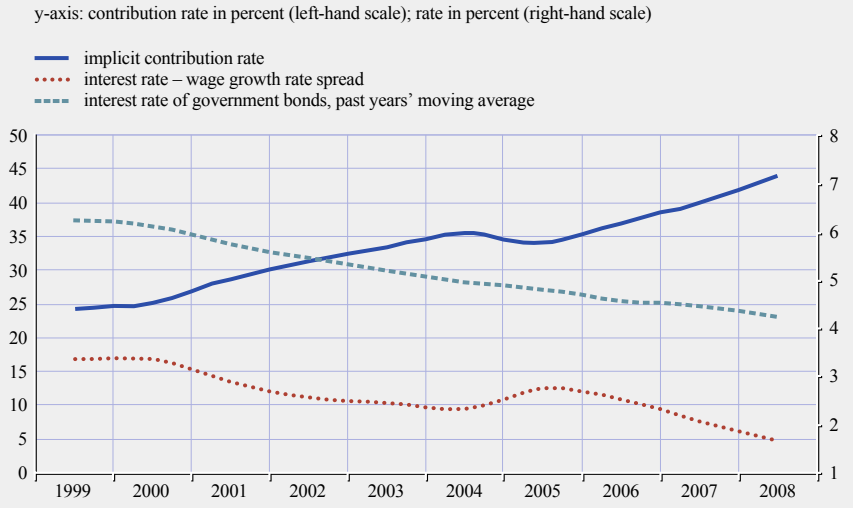
In the Polish benchmarking of Freiburg estimates on AWG estimates, the wage growth rate is the key parameter in the variation of future expenditures: the open system expenditure grow at the same pace when wage growth rates are the same... and same expenditures should lead to same pension entitlements.

Chart 1 Open system expenditure with own real wage growth rate

Source:

Chart 2 Open system expenditure with common real wage growth rate

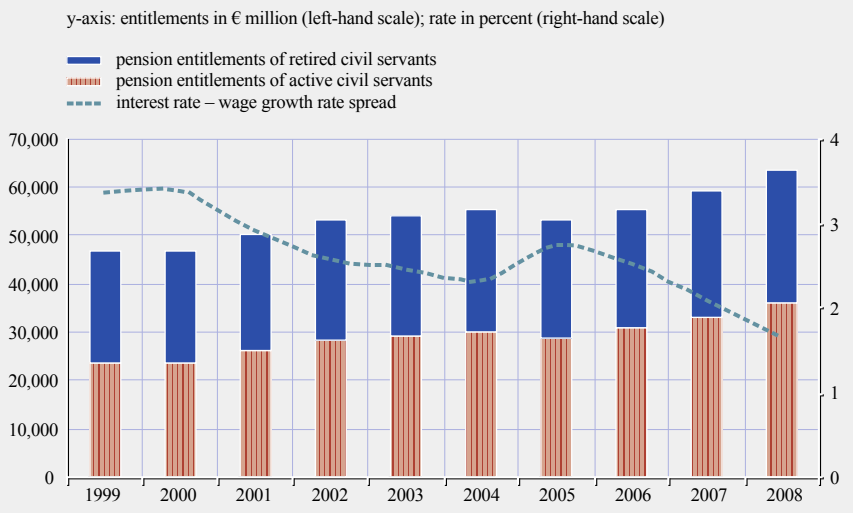
Source:



"Using a 3% discount rate and the Freiburg model, pension liabilities for 2007 amount to 330% of GDP if estimated with a 1.5% real wage growth rate and 382% of GDP if estimated with the AWG varying wage growth rate."

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

"Possible calculation of the liabilities using discounted stocks of the AWG expenditures, if the system can be closed" in other words, is it possible to use AWG assumption for the indexation of already accrued entitlements and to exclude entitlements to new comers?



In the **German model for civil servant**, a lower discount rate-wage growth rate spread increases strongly the pension entitlements and the implicit contribution rate.

Chart 3 Development of the implicit contribution rate

Source:

Chart 4 Development of pension entitlements – Base 2003 due to changes in interest rate – wage growth rate spread

- *In the three cases, an attempt for a minimum stability and homogeneity through schemes in the choice of the discount rate.*
- *Changing to a unique 6% for US estimates.*
- *7 years moving average 15 years Govt bond rate in Germany.*
- *3% real discount rate in Poland.*
- *Do high discount rates used by reporting agents (such as 8% in US local Gvt plan) and as a consequence by statisticians include a risk premium -if not holding gains- in the contribution supplement?*

2.2 ABO/PBO

- *In social security schemes, pensions are frequently indexed fully or partially on wage growth (Poland: 20% of real wage growth, Germany. PBO is recommended in new ESA when the benefit formula includes a factor for real wage increase before and after retirement.*
- *But, the choice between ABO and PBO may also depend on the probability to terminate the plan before the end of career:*

"For private sector plans, loss of the opportunity to earn further benefits due to a plan freeze or modification (such as a conversion to a cash balance plan) must be regarded as a realistic possibility. (In 2006, about 900,000 employees were in private plans that had been frozen.) Employees in the private sector can also lose the opportunity to earn additional benefits from a bankruptcy, or even an acquisition, of the plan sponsor.[2] Finally, changing jobs is likely to mean changing employers for employees of small or medium size businesses (though some private industries have multi-employer plans).

In contrast, changes to government pension plan provisions that affect current participants remain unusual, and the risk of losing the opportunity to earn future benefits is generally small for most government employees. A PBO approach, which spreads the build-up of the projected pension wealth at retirement in over the career, is therefore a reasonable alternative for government plans".

Nonetheless, international accounting standards for private companies recommend PBO accounting.

- *In the US, PBO is preferred by public schemes for its smoothing effect on employer's contributions.*

"Most state and local government plans calculate the actuarial value of benefits earned with a PBO approach using a level percent of pay formula. One of the key objectives that funding schemes for pension plans seek to achieve is avoidance of rapid increases in costs, such as those that occur under a pay-as-you-go scheme

2 As discussed below, in the event of bankruptcy of the plan sponsor, benefits worth approximately the ABO level of pension wealth are covered by insurance from the Pension Benefit Guarantee Corporation.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

when the covered population ages. The level-percent-of-pay approach goes furthest in accomplishing the cost-smoothing objective, because over an employee's career the benefit cost grows at the rate of growth of the salary. In contrast, assuming a final pay benefit formula, the growth rate of ABO benefits accrued is usually greater than or equal to the sum of the salary growth rate, the interest rate, and the average mortality rate of active participants, so sharp increases in costs as employees near the end of their career can cause overall pension costs for an aging workforce to rise quickly. In the early and middle years of the career, the PBO approach used by state and local government plans gives much higher cost estimates than the ABO approach, a relationship that is reversed in the final few years."

- *The ABO/PBO definition has to be clarified further:*
  - *In Germany, use of PBO changes the present value of future pensions owed to present retirees because the future pension depend on wage growth.*
  - *In US employer schemes, changes in ABO depend not only on wage growth but also on mortality rate and interest rate.*

2.3 FROM CASH ACCOUNTING TO ACTUARIAL ACCOUNTING

- Cash employer contributions are much more variable than actuarial employer contributions because they compensate for holding gains or losses on assets.

Table 11 Household Wealth and Income from Private Defined Benefit Plans (US)

	Cash accounting	2000	2001	2002	2003	2004	2005	2006

- Only the amount of pension paid is the same in both cases:
  - It is the only observed data, others being subject to actuarial estimates.
  - It may be used as a benchmark to estimate pension entitlements: the Polish paper aims at using the planed expenditures of social security by AWG in order to estimate the present value of pension entitlement (but open group expenditures are higher than close group expenditures).

Thank you to the authors, which papers were so interesting to read and comment!

CONCLUSIONS

The concluding remarks and the follow-up of the Workshop were made by Werner Bier (ECB), Eduardo Barredo (Eurostat) and Reimund Mink. The main concluding remarks of the meeting were presented as two headings: messages of a technical nature and those with a policy dimension.

A) TECHNICAL CONCLUSIONS

1. Accrued-to-date data on pension entitlements are part of the national accounts balance sheets.

2. Actuarial estimations to be made transparent.

3. Sensitivity analyses may be presented on an expert level.

4. Ensuring consistency of inputs for projections of pension modellers.

5. Accrued-to-date entitlements are not sustainability indicators.

From the presentations and discussions it was clear that accrued-to-date data on pension entitlements are part of the national accounts balance sheets. This is a statistical concept which is useful for analysis (all pension schemes are included, so providing a comprehensive picture).

Turning to implementation needs, these actuarial estimations are to be made transparent. In this vein, the supplementary table (2008 SNA and revised ESA 95) will foster the transparency required for this purpose. It was made clear that these additional data have no impact on EDP debt.

Another point addressed was to increase the transparency of the model assumptions and of the sensitivity analyses, which may be presented on an expert level. The scope of the work is limited to pensions – no other types of ageing expenditure are under consideration.

A further finding to arise from the discussion is the need to ensure consistency of the input used for the projections of pension modellers. The harmonisation of national models would be desirable, given the different nature of the models in Europe.

Finally, it was made clear that the accrued-to-date entitlements are not sustainability indicators. However, estimates on accrued-to-date entitlements can be used as an input for sustainability indicators (expansion to open systems and generational accounting).

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

B) POLICY CONCLUSIONS

1. The future development of pension entitlements is politically a very sensitive subject.

2. A proper communication strategy is of the essence.

3. The supplementary table as part of the new ESA transmission programme:
   - Estimation of data on pension entitlements; and
   - Increase in data coverage (of countries, types of flow, types of pension scheme).

4. Joint Eurostat/ECB Contact Group on Pensions will continue to work (all EU countries are represented, together with Switzerland and Norway), and in close cooperation with the Ageing Working Group (AWG).

The first remark with policy implications is that the future developments in the estimation of pension entitlements are politically a very sensitive subject.

Another aspect emphasised in the concluding remarks is that a proper communication strategy is of the essence.

The third comment is reiteration of the fact that a supplementary table, as part of the new ESA transmission programme, will be of utmost importance in order to estimate data on pension entitlements on a systematic basis. The expected increase in data coverage (of countries, types of flow and types of pension scheme) will contribute to the quality of these estimates.

Finally, the joint Eurostat/ECB Contact Group on Pensions will continue to work on the development of the quantitative analysis to prepare the grounds for the revised ESA transmission programme (expected for 2014). The Contact Group is composed of all EU countries, together with Switzerland and Norway. Ideally, this work should be undertaken in close cooperation with the sustainability work undertaken by the AWG.

CHAIRPERSONS, PRESENTERS, PANELISTS, DISCUSSANTS AND ORGANISERS OF THE WORKSHOP

Ana Almeida has been appointed to Deputy Head of the Statistics Department of the *Banco de Portugal*. Previously she was the Head of the National Financial Accounts and Securities Statistics Division of the Statistics Department and also the representative of the *Banco de Portugal* in the Euro Area Accounts Working Group of the ECB and in the Financial Accounts Working Group of Eurostat. Formerly, she was the Head of the Risk Control Unit of the Pension Fund of the *Banco de Portugal*. More recently, she has also been the representative of the *Banco de Portugal* in the Eurostat/ECB Contact Group on Pensions, contributing actively to the provision of Portuguese data to the objective of compiling statistics on pensions at the European level according to the new ESA.

Eduardo Barredo is Head of Unit G1 (Business Statistics: coordination and registers) in Directorate G (Business statistics). Until recently he was the Head of Unit C5 in Directorate C (National Accounts) and Co-chair of the Eurostat/ECB Contact Group and Task Force on Pensions.

Werner Bier is Deputy Director General Statistics of the European Central Bank.

Albert Braakmann is head of division in the national accounts department of the German Federal Statistical Office. He is responsible for national income, general government data, external economic transactions but also in charge of the German contributions to the revision of the SNA-93 and the ESA-95. Previously he worked a couple of years in the national accounts directorate of Eurostat.

Robert Dippelsman has been appointed to Deputy Division Chief of the Government Finance Statistics Division of the IMF's Statistics Department. Previously he was involved in the review of the 1993 SNA and of the Balance of Payments Manual.

Thomas Dominique works at the Ministry of Social affairs / General inspectorate of social security (IGSS) – Division of statistics, actuarial studies and social programming, vice-head of division. In charge of the social programming on improving the efficiency of the legislation in the area of people affected by incapacity for work. Responsible for the socio-economic projections in the context of the financial sustainability of the pension system. Member of the Ageing working group of the Economic Policy Committee of the European Commission. Member of the Indicator sub-group of the Social Protection Committee of the European Commission.

Dominique Durant is currently head of the statistics on non-banking financial institutions division in the Banque de France. Dominique Durant was head of

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

the financial account division between 2005 and 2008. She joined the Banque de France in 1991 and operated in banking supervision (1994-1998) and in monetary and financial statistics (1998-2005). In her different managing positions in statistics, she regularly leaded or published several analysis based on national accounts and financial statistics, regarding especially households' investments and savings, households pensions' entitlements, indebtedness and profitability of non financial corporations, investments and financial situation of insurance corporations and investment funds. Her background is public administration and economics (Science Po Paris post-graduate diploma in 1989) as well as financial economics (Paris I-Sorbonne University Money Banking Finance Master in 1993). She also holds a Master in Linguistics (1985). Since 2002, she teaches the basics of monetary and financial economics in the public French School for statistics and economic management (ENSAE), that provides initial training to the future managers of the national statistics institute.

Michel Englert works as Senior Economist in the Federal Planning Bureau in Belgium (FPB); he is since 1995 head of the General Directorate of the FPB. He is head of the delegations of Belgium to the Working Group on Ageing of the Economic Policy Committee of the ECOFIN Council and to the Working Group on macroeconomic and structural policies of the OECD. He is invited professor in macroeconomics at the "Facultés Universitaires Catholiques de Mons", Belgium. He is specialized in macroeconomic forecasting and scenario analysis, fiscal policy and in building socio-demographic models for assessing the long-term financial prospects for the Social Security.

Jens Grütz works in the Department of National Accounts at the Federal Statistical Office of Germany. He was a member of the Eurostat/ECB Taskforce on Pensions and member of the "Group of estimators" of the German statutory pension insurance.

Thorsten Haug is a research assistant in the department of National Accounts at the Federal Statistical Office of Germany since 2006. He works mainly on the calculation of pension entitlements in the context of the current SNA revision.

Matthias Heidler worked as a research assistant at the Research Center for Generational Contracts (RCG) in Freiburg, Germany. His research interests include the field of pension policy and pension modeling. He was involved in the benchmark calculations of public pension entitlements for 19 EU member states carried out by the RCG.

Janusz Jabłonowski works as Chief Specialist in the Department of Statistics of the National Bank of Poland. He has coordinated the work over the preparation of the Supplementary Table in Poland for the Task Force on Pensions. He is also a country representative in the Working Group for Government Finance Statistics.

Para verificar as assinaturas, acesse www.tcu.gov.br/autenticidade, informando o código 57399319.

Steven Keuning is Director General Statistics of the European Central Bank.

Paula Koistinen-Jokiniemi works as Head of Financial Statistics Unit in the Statistics Finland.

Reimund Mink works as a Senior Adviser in the Directorate General Statistics of the European Central Bank. He was Co-chair of the Eurostat/ECB Task Force on Pension and is now Co-chair of the Contact Group on the same subject. He also contributed to the drafting of the new SNA chapter 17 on pensions, co-drafted the new ESA chapter 17 on pensions and drafted several ESA chapters on units and on financial sectors, financial transactions, flows and balance sheets.

Christoph Müller works as a research assistant at the Research Center for Generational Contracts (RCG) in Freiburg, Germany. His research interests include the field of pension policy and pension modeling. He was involved in the benchmark calculations of public pension entitlements for 19 EU member states carried out by the RCG.

Heikki Oksanen works as an Adviser in the Research Directorate of the Directorate-General for Economic and Financial Affairs of the European Commission since 1998. He has published several articles on population ageing, pension reforms and sustainability of public finances with special reference to intergenerational equity.

Lourdes Prado works as Technical Advisor in the Directorate of Economic Accounts and Employment at the Instituto Nacional de Estadística (Spain). She has coordinated the working group set up in Spain for the estimation of pension entitlements and the supplementary table on pension schemes. She has represented the INE in the Task Force on Pension.

Bernd Raffelhüschen is professor for economics at the University of Freiburg, Germany and at the University of Bergen, Norway. Furthermore, he is the director of the Research Center for Generational Contracts (RCG) in Freiburg which carried out the benchmark calculations of public pension entitlements for 19 EU member states on behalf of the ECB. His current research interests include social policy and the field of fiscal sustainability analysis. Beside his contribution to international research projects – e.g. on behalf of the European commission as well as various EU countries – he is working – e.g. as a member of the so called "Rürup Kommission" (a governmental advisory commission) – on questions of applied social policy.

Marshall Reinsdorf is chief of the national economic accounts analysis and research group at the US Bureau of Economic Analysis. Before joining BEA, he researched bank failures at the Federal Deposit Insurance Corporation and price measurement US Bureau of Labor Statistics. The author of numerous published papers on economic measurement topics, he has a Ph.D. in economics from the University of Maryland.

Ad van Riet is Head of Fiscal Policies Division in the Directorate General Economics of the European Central Bank.

Marta Rodríguez works as Senior Economist-Statistician in the Directorate General Statistics of the European Central Bank. She has coordinated the work of the Contact Group and the Task Force on Pensions, together with Eurostat, since 2006. She has been the Secretary of the ESCB Working Group on Government Finance Statistics since 2003.

Gabriele Semeraro works in the Department for Economic and Financial Statistics at the Banca d'Italia, as head of the Financial Accounts unit. He was member of several task forces studying problems of statistical recording related to pension entitlements and transfers. As a member of the Eurostat/ECB Task Force he was involved in preparing the corresponding drafts for the 2008 SNA and the new ESA chapter on pensions.

John Verrinder works with Eurostat. Recently he has been appointed to Head of Unit C5 in Directorate C (National and European Accounts). He was Secretary of the Eurostat/ECB Task Force on Pensions and is now Co-chair of the Eurostat/ ECB Contact Group on the same subject. In these functions he contributed to the drafting of the new SNA chapter 17 dealing also with pensions and also co-drafted-the new ESA chapter 17 on pensions.

Gabe de Vries has worked with Statistics Netherlands and the Dutch association of Insurers on statistics on insurance and pensions. He now works as a consultant on projects concerning pensions, insurance and government with Eurostat, OECD, IMF and World Bank. He drafted the new ESA-chapter 16 on Insurance and contributed to the drafting of several ESA-chapters on financial transactions, distributive transactions and balance sheets. He is a member of the board of a company pension fund.

Olaf Weddige works as a research assistant at the Research Center for Generational Contracts (RCG) in Freiburg, Germany. His research interests include the field of pension policy and pension modeling. He was involved in the benchmark calculations of public pension entitlements for 19 EU member states carried out by the RCG.

John Walton has worked as a consultant of the Office for National Statistics as the UK Statistics Authority and of Eurostat on business statistics for insurance and pensions. He was a member of the OECD Task Forces on the treatment of non-life insurance and of FISIM in the national accounts. For nearly twenty years, John was a Trustee of a UK Defined Benefit employer pension fund and a member of the management board of this fund. As adviser to ONS, he was a member of the Eurostat/ECB Task Force on Pensions, giving advice as an outstanding expert on pensions. In this function and also before the creation of the Task Force, John contributed already to the discussion on how to improve the recording of pension schemes in the new statistical standards, including contributions to the discussions of the IMF EDG on pensions.
