A4902A- HP Rack System/E, 41U, 19" quartz
A4902D- HP Rack System/E, 41U, 19" graphite ■

Technical Data

Save valuable floor space with the vertically extendible HP Rack System/E

Designed and built to the highest HP quality standards, the Rack System/E delivers leading edge protection in the simplest form. Ease of use, integration and installation characterizes this 41U rack that is comprised of:

- 63% Perforated, locking rear door (ordered as A5213AZ/A5213DZ)
- Bolt-on front/back anti-tip feet
- Numbered columns
- Fully perforated top cap
- 3-inch urethane casters
- Leveling feet
- Side panels

Multiple racks may be tied together to create continuous data center rack space. Individual racks may be expanded an additional 8Us of vertical space.

Standards

Conforms to the Electronic Industries Association (EIA) standard 310-D. It is a Type A cabinet with 41U of vertical mounting space. One 'U' is equal to 44.45 mm (1.75 in).

Customer must order rear door, A5213AZ(quartz)

A5213DZ (graphite)

Features

- Ability to move and ship fully integrated racks
- Optimized ventilation with fully perforated top, and rear door
- Extendibility can add 8Us of vertical mounting space
- Easy, bolt-on (front and back) anti-tip feet
- Numbered 12-gauge steel columns for easy installation and secure racking of up to 907 kg (2000 lbs) of equipment
- Columns include threaded inserts (AVKs) at strategic locations for quick installation of common accessories such as the tie kit, front door and PDUs

Shipping/Setup

- Can fit through most doorways around the world
- Packaging designed for integrated rack shipment
- Self-tuning pallet adjusts for variable integrated rack weights
- Shipping pallet includes ramp for easy set-up

Product Number
A4902D

Tools required for setup:

- Torx T25 screwdriver
- Phillips #2 screwdriver
- 13mm Socket wrench

Warranty

One- year replacement

Specifications

Color (A4902A- quartz)
Columns and base: Slate gray
Top: Quartz gray
Side panels: Quartz gray
Rear door: Quartz gray

Color (A4902D- graphite)
Columns and base: Graphite metallic
Top: Graphite metallic
Side panels: Graphite
Rear door: Graphite metallic

Material
Columns: 12-gauge, cold-rolled steel
Base: 10-gauge, cold-rolled steel
Top cap: 18-gauge, cold-rolled steel

Weight
Rack (empty): 100.45 kg (221 lbs)
Rack (empty) on shipping pallet: 169.3 kg (372.5 lbs)
Rear door (unpacked): 10.68 kg (23.5 lbs)
Anti-tip foot: 16.14 kg (35.5 lbs)

Supported weight
Load capacity:
On shipping pallet: 816 kg (1800 lbs);
Off shipping pallet: 907 kg (2000 lbs)
Casters rating: 453.6 kg (1000 lbs) per caster

* Dimensions are for reference only

Related Products

Other sizes available are:

- **A4901A (quartz)**
- **A4901D (graphite)**
  - 33U of vertical mounting space, includes side panels, bolt-on (front and back) anti-tip feet
- **A4900A (quartz)**
  - 25U of vertical mounting space,includes side

Profundidade - 742 mm

Optional Accessories

J1506A/ J1506D	Side Panel Kit (1 kit per rack) included in standard rack
J1509A/ J1509D	Front Door: Perforated, lockable
J1512A/ J1512D	Tie Kit
J1514A/ J4387A	Filler Panels (set of 6)
J1518A/ J1518D	Keyboard Kit, retractable
J1519A/ J1519D	Monitor Kit
J1520A/ J1520D	Plain Shelf, static
J1521A	Lift Hooks (set of 4)
J1522A	Mounting Hardware

hp-ux 11i
oes

hp-ux 11i operating environments
enterprise release

hp-ux 11i
oes

hp-ux 11i operating environments benefits

greatly simplified software deployment

- Only one reboot needed to install the Operating Environment (OE) of your choice
- No codewords are necessary to access any of the functionality/application products resident on the OE media
- Comprehensive offering of Network, Mass Storage, and I/O Drivers available during install process
- Online Diagnostics loaded during cold install

simple to purchase license

- Each OE license product contains licensing for the base HP-UX O/S and all of the included HP applications

attractive pricing

- Pricing of the OE licenses reflects a built-in advantage over purchasing individual OE components separately

published testing results

- Testing results of application products in the OEs will be published on docs.hp.com for worldwide access both inside and outside HP

simple to purchase software support

- Simplification in Software Support ordering and contract administration has been achieved in parallel with the introduction of HP-UX 11i Operating Environments
- For more information, please visit: http://nternet.fc.hp.com/catscore/communic.htm

hp-ux 11i

Functionality in Base HP-UX (version B.11.11)

hp-ux 11i
oes

getting to know hp-ux operating environments

- HP-UX version B.11.11 is at the heart of each HP-UX 11i Operating Environment and provides the sound foundation onto which each OE Solution is built
- Two global base HP-UX bundles are delivered at B.11.11 and are differentiated by bitness: HPUXBase64 for 64-bit capable hardware, and HPUXBase32 for 32-bit capable hardware

HP-UX 11i Core Functionality
HPUXBase64 (64-bit)
HPUXBase32 (32-bit)

5808

11i (B.11.11) operating system features

major new features of hp-ux 11i (version B.11.11 and future)

- Built-in Unlimited Simultaneous User Level License for HP-UX
- Includes Linux APIs
- Introduces online replacement and addition of I/O cards for N-Class and L-Class servers
- Fully supports the low-end A500 and A400 servers, designed for ISP operation, where performance per rack and serviceability are keys
- Supports L2000 and L1000, an economical N-Class server with an upgrade path to IA-64
- Supports the V2500/V2600 platform
- Offers VERITAS (JFS 3.3) file system support
- Has improved and expanded file system support from CacheFS
- Supports NFS over TCP/IP
- Adds systems management improvements (PRM enhancements)
- Offers secure defaults and intrusion detection
- Has extensive performance tuning for one-way to 32-way configurations

HP Smart Array 641 Controller
HP Smart Array 642 Controller
HP 64MB BBWC Enabler

Standard Features

The Smart Array Advantage

HP's innovative design and integration work of the Smart Array family of products creates customer value that is unmatched in the industry. Use of Smart Array products across multiple applications results in a much lower Total Cost of Ownership (TCO) than any other server storage RAID products. The HP Smart Array family brings an unparalleled return on investment through:

Data Compatibility	Data Compatibility among all models of Smart Array controllers allows simple and easy upgrades any time needs for higher performance, capacity, and availability increase. Even successive generations of Smart Array controllers understand the data format of other Smart Array Controllers.
Consistent Configuration and Management Tools	All Smart Array products utilize a standard set of management and utility software. These tools minimize Total Cost of Ownership (TCO) by reducing training requirements and technical expertise necessary to install and maintain the HP server storage.
Universal Hard Drive	Form factor is for use across multiple HP ProLiant servers, disk enclosures and storage systems. With compatibility across many enterprise platforms, you are free to deploy and re-deploy these drives to quickly deliver increased storage capacity, migrate data between systems, and easily manage spare drives.
Pre-Failure Warranty	Pre-Failure Warranty means Insight Manager not only reports when a drive is going to fail but allows replacement of failing drives prior to actual failure. For complete details, consult the HP Support Center or refer to your HP Server documentation.

Key Features for both Smart Array 641 and Smart Array 642 Controllers

- Compatibility with all Ultra 320, Ultra3 and Ultra2 LVD family products. In addition, a seamless upgrade to next generation HP high performance and high capacity mainstream Ultra320 Smart Array controllers.
- Recovery ROM protects against a ROM corruption.
- Ultra320 SCSI technology delivers high performance and data bandwidth up to 320-MB/s bandwidth per channel.
- Modular, easy-to-upgrade design lets you optimize performance as needed with the 64MB BBWC Enabler, from 64-MB of memory for RAID and read cache to 128-MB of memory for RAID, read cache, and BBWC.
- Mix-and-match LVD SCSI compatibility protects your investments and lets you deploy drives as needed.
- Software consistency among all Smart Array family products: Array Configuration Utility XE (ACU-XE), Array Configuration Utility (ACU), Insight Manager (CIM), Array Diagnostic Utility (ADU) and SmartStart.
- 64-bit, 133-MHz PCI-X interface boosts bandwidth above 1B/s burst transfer rate over PCI-X bus.
- 64-bit memory addressing supports servers with greater than 4 GB of memory.
- 64-MB memory optimizes performance and data throughput.

NOTE: 64 MB of DDR memory used for RAID and read cache.

Online Management Features	Online Capacity Expansion, Online RAID Level Migration, Online Stripe Size Migration, Online Spares (Global), User Selectable Expand and Rebuild Priority
Channels	▪ **SA 641 : Single Channel** provide the ability to support up to 6 drives or 880.8GB ▪ **SA 642 : Dual Channels** provide the ability to support up to 20 (6 internal, 14 external) drives or 2.9TB

Key Features for 64MB BBWC Enabler

- Battery-backed Cache protects cached data in the event of a power outage, server failure or controller failure.
- 72 hours of battery charge protects the data for an entire weekend.
- 3 years of battery life.
- Modular, easy-to-upgrade design lets you optimize performance as needed with the 64MB BBWC Enabler, from 64-MB of memory for RAID and read cache to 128-MB of memory for RAID, read cache, and BBWC.

Data Compatibility

Data compatibility among all models of Smart Array Controllers means customers can instantly upgrade their Smart Array products to get to higher performance, capacity and availability. Unlike competitive products, successive generations of Smart Array products understand the data format of other Smart Array controllers, providing investment protection for your HP storage solution.

QuickSpecs

S806

HP Smart Array 641 Controller
HP Smart Array 642 Controller
HP 64MB BBWC Enabler

Overview

Smart Array 641 Controller

The new Smart Array 641 Controller (SA-641) is a 64-bit, 133-MHz PCI -X dual SCSI channel PCI array controller for entry level hardware-based fault tolerance. Utilizing a SCSI channel (1 internal) of the SA-641 allows you to configure up to 6 internal hard drives to store up to 880.8 GB of storage. The SA-641 provides high reliability and increased performance over the LC2 controller, thus providing excellent value and lowering the total server ownership cost. In addition, the SA-641 is data compatible with all Ultra 320, Wide Ultra3 and Wide Ultra2 drives, offering an unparalleled degree of investment protection. Designed and integrated with HP entry-level and workgroup ProLiant servers, this product provides worry-free data protection.

Smart Array 642 Controller

The new Smart Array 642 Controller (SA-642) is a 64-bit, 133 MHz PCI-X dual SCSI channel PCI array controller for entry level hardware-based fault tolerance. Utilizing both SCSI channels (1 internal and 1 external) of the SA-642 allows you to configure up to 20 hard drives (6 internal, 14 external) to store up to 2.9TB of storage per PCI slot. The SA-642 provides high reliability and increased performance over the Smart Array 532, thus providing excellent value and lowering the total server ownership cost. In addition, the SA-642 is data compatible with all Ultra 320, Wide Ultra3 and Wide Ultra2 drives, offering an unparalleled degree of investment protection. Designed and integrated with HP entry-level and workgroup ProLiant servers, this product provides worry-free data protection.

The Smart Array 641/642 Controller provides ProLiant DL and ML servers with an entry-level hardware RAID protection for OS and log files, where hardware RAID is needed at an entry-level price point.

64-MB BBWC (Battery-Backed Write Cache) **Enabler**

The new 64MB BBWC Enabler is a transportable 64MB battery module increasing the total memory of the controller to 128MB for RAID, read cache, and BBWC. The transportability of the battery memory module protects the write cache data from unexpected power loss, system board failure, or controller board failure. Data retained in the write cache will be protected for up to 72 hours, allowing time to restore power, or transport the module to a functioning system board or array controller. The modular design of the battery memory module is transportable between the Smart Array 641 and Smart Array 642 controllers.

64MB BBWC (Battery Backed Write Cache) Enabler allows the 641/642 controllers an option to add transportable BBWC for improved controller performance and increases the total controller memory to 128MB.

invent

Standard Features

Ease of Use

Consistency and Upgradeability make the Smart Array family unique in the industry:

- GUI based configuration, management and diagnostic software tools
- Common data formatting between generations of products
- Data migration between servers and external storage enclosures

Compatibility

Servers

For up to date compatibility, please see the following URL for complete Smart Array 641 and Smart Array 642 compatibility and support information. http://h18006.www1.hp.com/products/servers/proliantstorage/arraycontrollers/index.html

Operating Systems

5803

Microsoft® Windows® 2000 (Server/Adv Server)
Microsoft Windows 2003 (when available)
Microsoft Windows NT® 4.0
NetWare 6
NetWare 5.x
Linux Red Hat 2.1 Advanced Server
Linux Red Hat 7.3
Linux Red Hat 8.0
SuSE SLES 7
IBM OS/2 Warp Server for ebusiness
SCO Open Server 5.05, 5.0.7 (to be released 1Q, 03)
SCO UnixWare 7.1.1
SCO Open UNIX® 8
SCO UnixWare 7.1.3 (to be released 4Q, 02)

Software Suite

All Smart Array products share a common set of configuration, management and diagnostic tools, including Array Configuration Utility XE (ACU-XE), Array Configuration Utility (ACU), Array Diagnostic Utility (ADU), and Insight Manager. This software consistency of tools reduces the cost of training for each successive generation of product and takes much of the guesswork out of troubleshooting field problems. These tools lower the total cost of ownership by reducing training and technical expertise necessary to install and maintain the HP server storage.

Insight Manager

- Powerful server and server options/storage manager tool
- Monitors over 1200 server parameters
- Configuration/Diagnostic Utilities
- HP Array Configuration Utility (ACU)
  - Powerful Web based configuration utility for all Smart Array controllers
  - Provides a graphical view of HP drive array configurations
  - Allows for management of multiple arrays over a secure internet connection from anywhere in the world
  - Easy to use Wizards for configuration
  - Runs online on Windows NT v4.0, Windows 2000 and NetWare
- HP Options ROM Configuration for Arrays (ORCA)
  - Rapid configuration during initial install of the OS
- HP Array Diagnostic Utility (ADU)
  - Powerful diagnostic utility for all Smart Array controllers

S804

Standard Features

Performance

HP's High Performance Architecture sets new boundaries of industry performance expectations!

- Wide Ultra320 SCSI (320 MB/s bandwidth) per channel
- High-performance 64-bit architecture
- 64-bit, 133-MHz PCI-X bus (1033 MB/s bandwidth)

Capacity

Smart Array 641	Given the internal server storage need for rapid capacity expansion, the SA-641 offers: • Single SCSI channel support up to 6 internal disk drives • Up to 880.8GB of storage per PCI slot
Smart Array 642	Given the internal server storage need for rapid capacity expansion, the SA-642 offers: • Dual SCSI channels support up to 20 (6 internal, 14 external) disk drives • Up to 2.9 TB of storage per PCI slot

Availability

Provides increased server uptime by providing advanced storage functionality:

- Online RAID Level Migration (between any RAID level)
- Online Capacity Expansion
- Logical Drive Capacity Extension
- Global Online Spare
- Pre-Failure Warranty

Fault Prevention

The following features offer detection of possible failures before they occur, allowing preventive action to be taken:

- S.M.A.R.T.: Self Monitoring Analysis and Reporting Technology first developed at HP detects possible hard disk failure before it occurs, allowing replacement of the component before failure occurs.
- Drive Parameter Tracking monitors drive operational parameters, predicting failure and notifying the administrator.
- Dynamic Sector Repairing continually performs background surface scans on the hard disk drives during inactive periods and automatically remaps bad sectors, ensuring data integrity.
- Smart Array Cache Tracking monitors integrity of controller cache, allowing pre-failure preventative maintenance.
- Environment Tracking for External Storage System: Monitors fan speed and cabinet temperature of ProLiant Storage System and newer HP storage enclosures.

Fault Tolerance

Keeps data available and server running while a failed drive is being replaced; several fault tolerance configurations are supported including:

Distributed Data Guarding (RAID 5)	This allocates parity data across multiple drives and allows simultaneous write operations. It is recommended for up to 14 hard drives.
Drive Mirroring (RAID 1, 1+0)	This allocates half of the drive array to data and the other half to mirrored data, providing two copies of every file. It is a high-performance RAID.

Fault Recovery

Minimizes downtime, reconstructs data, and facilitates a quick recovery from drive failure.

Recovery ROM	Recovery ROM provides a unique redundancy feature that protects from a ROM image corruption. A new version of firmware can be flashed to the ROM while the controller maintains the last known working version of firmware. If the firmware becomes corrupt, the controller will revert back to the previous version of firmware and continue operating. This reduces the risk of flashing firmware to the controller.
On-Line Spares	Up to two spare drives can be installed prior to drive failure. If a failure occurs, recovery begins with an On-Line Spare and data is reconstructed automatically.

NOTE: On-Line Spares can only be used with RAID level 1, 1+0, and 5.

Service & Support, CarePaq and Warranty Information

Software Product Services

- Standalone telephone support
- Rights to new license version
- Media and documentation updates

580

Hardware Product Services

- Installation services
- On-site maintenance (includes warranty support)
- Response time upgrades during the warranty period
- Post-warranty coverage
- RAID setup and performance consulting via statement of work

For additional hardware installation and maintenance information, please refer to the URLs listed below:
http://www.compaq.com/services/carepaq/us/install/
http://www.compaq.com/services/carepaq/us/hardware/

Warranty Upgrade Options

- Response - Upgrade on-site response from next business day to same day 4 hours
- Coverage - Extend hours of coverage from 9 hours x 5 days to 24 hours x 7 days
- Duration - Select duration of coverage for a period of 1, 3, or 5 years

CarePaq Information

Sample part numbers:

3 years, uplift to 5 x 9, Next Day Response	FM-**XHW-36
3 years, uplift to 5 x 9, 4-hour Response	FM-**4HR-36
3 years, uplift to 7 x 24, 4-hour Response	FM-**724-36

NOTE: ** represents a two digit product specific code.

- CarePaq is defined as an upgrade to the product warranty attribute, available for a specific duration and hours of coverage.
- CarePaq is not available for less than the product's warranty duration.
- CarePaq is available for sale anytime during the warranty period for most products, but the commencement date will be the same as the Warranty Start Date (delivery date to end user customer). Proof of purchase may be required.
- CarePaq services are prepaid.

For additional CarePaq (hardware & software) information, as well as orderable part numbers, please refer to the URL listed below:
http://www.compaq.com/services/carepaq/index.html

AIT 35 GB, LVD Hot Plug (Carbon)	216886-B21
20/40-GB, DAT Hot Plug (Carbon)	215488-B21

Technical Specifications

Smart Array 642

Protocol	Ultra320 SCSI
SCSI Electrical Interface	Low Voltage Differential (LVD)
Drives Supported	Up to 20 (6 internal and 14 external) Ultra 320, Ultra3 and Ultra2 SCSI hard drives
SCSI Port Connectors SA-642	One external and one internal SCSI port
Data Transfer Method	64-Bit PCI bus-master
PCI Bus Speed	64-bit, 133-MHz PCI-X (1 GB/s maximum bandwidth)
PCI	3.3 volt CPI slot compatibility only
Simultaneous Drive Transfer Channels	Two
Channel Transfer Rate	640-MB/s total; 320-MB/s per channel
Software upgradeable Firmware	Yes
Cache Memory	64 MB of DDR memory used for RAID and read cache
Logical Drives Supported	32
Maximum Capacity	2.9 TB (20 X 146.8-GB)
Memory Addressing	64-bit, supporting servers memory greater than 4-GB
RAID Support	RAID 5 (Distributed Data Guarding)
	RAID 1+0 (Striping & Mirroring)
	RAID 1 (Mirroring)
	RAID 0 (Striping)
Upgradeable Firmware	2-MB Flashable ROM
Disk Drive and Enclosure Protocol Support	Ultra 320, Ultra2 and Ultra3
Dimensions (HxWxD)	12.3 X 4.2 X 0.6 in/31.24 x 10.7 x 1.5 cm
Warranty	*Maximum:* The remaining warranty of the HP server product in which it is installed (to a maximum three-year limited warranty)
	Minimum: One-year, on-site limited warranty
	Pre-Failure Warranty: Drives attached to the Smart Array Controller and monitored under Insight Manager are supported by a Pre-Failure (replacement) Warranty. For complete details, consult the HP Support Center or refer to your HP Server Documentation.

98

SMART ARRAY 641

Protocol	Ultra320 SCSI
SCSI Electrical Interface	Low Voltage Differential (LVD)
Drives Supported	Up to 6 Ultra 320, Ultra3 and Ultra2 SCSI hard drives
SCSI Port Connectors SA-641	one internal SCSI port
Data Transfer Method	64-Bit PCI bus-master
PCI Bus Speed	64-bit, 133-MHz PCI-X (1 GB/s maximum bandwidth)
PCI	3.3 volt CPI slot compatibility only
Simultaneous Drive Transfer Channels	Two
Channel Transfer Rate	320-MB/s total; 320-MB/s per channel
Software upgradeable Firmware	Yes
Cache Memory	64 MB of DDR memory used for RAID and read cache
Logical Drives Supported	32
Maximum Capacity	880.8 GB (6 X 146.8 GB)
Memory Addressing	64-bit, supporting servers memory greater than 4 GB
RAID Support	RAID 5 (Distributed Data Guarding)
	RAID 1+0 (Striping & Mirroring)
	RAID 1 (Mirroring)
	RAID 0 (Striping)
Upgradeable Firmware	2-MB Flashable ROM
Disk Drive and Enclosure Protocol Support	Ultra 320, Ultra2 and Ultra3
Dimensions (HxWxD)	12.3 X 4.2 X 0.6 in/31.24 x 10.7 x 1.5 cm
Warranty	*Maximum:* The remaining warranty of the HP server product in which it is installed (to a maximum three-year limited warranty)
	Minimum: One-year, on-site limited warranty
	Pre-Failure Warranty: Drives attached to the Smart Array Controller and monitored under Insight Manager are supported by a Pre-Failure (replacement) Warranty. For complete details, consult the HP Support Center or refer to your HP Server Documentation.

5796

Technical Specifications

64-MB BBWC ENABLER

Cache Memory	64 MB of DDR memory for RAID, read cache, and BBWC: ECC protection, battery-backed, and removable
Cache Batteries	Up to 3 days of battery life, removable for easy replacement
Dimensions (HxWxD)	3.5 X 1.8 X .54 in/8.89 x 4.6 x 1.37 cm

HP-UX Virtual Partitions (vPars) enables you to run multiple instances (versions) of the HP-UX 11i Operating Environment (OE) simultaneously on one server with each OE instance hosting its own set of applications in a fully isolated environment. Created through software, virtual partitions provide application and operating systems isolation that run on single server nodes or within single-system hard partitions. Each virtual partition runs its own image of the operating system and can fully host its own applications—offering complete software isolation. The capability of CPU migration allows users to add and delete dynamically (without reboot) CPUs from one virtual partition to another. This enables applications to coexist in the same server while assuring complete privacy. In addition, functionality is provided to dynamically create, modify or even delete the isolated operating environments on a running server without interrupting non-related partitions.

In comparison to nPartitions, vPars provide greater flexibility and granularity while nPartitions provide greater fault isolation. Greater flexibility in vPars is achieved with the ability—using simple software commands—to add and delete dynamically (without reboot) CPUs from one virtual partition to another. In addition, multiple vPars can function within an nPartition providing greater granularity (1 CPU).

HP-UX Virtual Partitions (vPars) is available on the following HP servers running HP-UX Superdome, rp8400, rp7410, rp7405, rp7400, rp5470, rp5405.

benefits

vPars provides the following benefits:

- **Increased system** utilization by partitioning previously unused portions of the ser Typically, a server is only using 50% of its capacity.
- **Greater flexibility** of resources through: 1) multiple but independent operating environments per server (with as low as 1 CPU granularity per partition) and 2) th movement of CPU power between vPars depending on workload requirements.
- **Increased isolation** of applications, their operating systems, and assigned resou memory, and I/O), with individual reconfiguration and rebooting of the individual p without affecting other partitions and their applications.
- **Server consolidation** by running multiple workloads with their unique Operating configuration needs on the same server at the same time. They are excellent for c creating test platforms without investing in more hardware.

[1]At this time, vPars is available only on HP-UX 11i on certain PA-RISC servers.

5791

Preface

The *HP System Partitions Guide* describes nPartition system administration procedures, concepts, and principles for HP rp7405/rp7410 servers, HP rp8400 servers, and HP Superdome servers running the HP-UX 11i operating system.

This preface has the following sections:

- *About This Book: Overview of Chapters* on page 4
- *How to Buy This Book* on page 6
- *Related Information* on page 7
- *Publication History* on page 10
- *Notational Conventions* on page 11

Reader Comments and Feedback

Hewlett-Packard welcomes your feedback on this publication. Please address your comments to `edit@presskit.rsn.hp.com` and note that you will not receive an immediate reply. All comments are appreciated.

5x90

About This Book: Overview of Chapters

1. *nPartition System Overviews* on page 31

   This chapter introduces Hewlett-Packard's nPartition system features, server models, nPartition concepts, administration tools, and HP-UX 11i support for nPartitions.

2. *Planning nPartition Configurations* on page 109

   This chapter describes how you can plan nPartition configurations for HP rp7405/rp7410, rp8400, and Superdome servers. Details include the configuration requirements for nPartitions and HP recommendations.

3. *Using Console and Service Processor Interfaces* on page 125

   This chapter covers the service processors and nPartition console interfaces available for HP's nPartition servers.

4. *An Overview of nPartition Boot and Reset* on page 161

   This chapter presents an overview of booting and reset concepts and issues for HP nPartition servers.

5. *Booting and Resetting nPartitions* on page 197

   This chapter presents procedures for booting and resetting nPartitions and procedures for configuring an nPartition's boot-related options.

6. *Managing nPartitions* on page 243

   This chapter presents the procedures for creating, configuring, and managing nPartitions on HP servers that support them.

7. *Listing and Managing Server Hardware* on page 305

   This chapter covers the tools and methods for listing details about the hardware assigned to nPartitions. This chapter also covers getting information about server hardware, and managing the hardware resources in nPartitions and their server complexes.

8. *Online Add and Replacement (OLAR) of PCI Cards* on page 365

   This chapter presents background information and procedures for performing PCI I/O card *online addition and replacement* (OLAR) on HP's nPartition servers.

5789

9. *Processor Instant Capacity on Demand (iCOD)* on page 397

   This chapter covers using Hewlett-Packard's processor iCOD (Instant Capacity on Demand) product on nPartitions.

   iCOD is an *optional* software product that enables you to instantly increase or adjust processing power within nPartitions. As you need more or fewer processors, you use iCOD tools to adjust the number of activated processors in the nPartition.

10. *Processor Sets (Psets) on nPartitions* on page 419

    This chapter describes how to use and manage processor sets (Psets) on nPartition systems.

    Using Psets, you can create multiple independent processor groups in an nPartition. Each Pset has its own processors, schedules, and attributes. Because Psets are dynamic, you can create, modify, and destroy Psets instantly as your system needs demand.

11. *Virtual Partitions (vPars) Management on nPartitions* on page 441

    This chapter describes how to create, configure, and manage HP's virtual partitions within an HP Superdome nPartition (hard partition) system environment. Each virtual partition can boot a single instance of the HP-UX B.11.11 operating system.

    The HP virtual partitions (vPars) software is an *optional* feature that you can use to further subdivide a server's resources into multiple, smaller virtual machines through software partitioning.

    By configuring multiple virtual partitions within an nPartition, you can boot multiple instances of HP-UX B.11.11 in a single nPartition.

How to Buy This Book

You can purchase a printed copy of the *HP System Partitions Guide* from Hewlett-Packard's `http://software.hp.com` Web site. When at this Web site, click the **Documentation** link for a list of current publications.

The `http://www.software.hp.com/BOOKS_products_list.html` Web site lists technical books currently available for sale, including this book.

You also can find this book by searching for "Partitions Guide" using the HP software depot search facility.

5287

Related Information

For the most current HP-UX 11i nPartition administration details refer to this publication, the *HP System Partitions Guide*.

You also can find other information on general HP-UX 11i administration, HP nPartition server hardware management, and diagnostic support tools in the following publications.

Web Site for HP Technical Documentation: http://docs.hp.com

The main Web site for Hewlett-Packard technical documentation is the `http://docs.hp.com` site, which has complete information available for free.

HP-UX 11i Information

The following Web site and publications are available for info about the HP-UX 11i operating system.

- `http://docs.hp.com/hpux/os/11i/` — This is the portion of the docs.hp.com Web site that has complete HP-UX 11i information.

Books about HP-UX Published by Prentice Hall

The `http://www.hp.com/hpbooks/` Web site lists the HP books that Prentice Hall currently publishes, such as HP-UX books including:

- *HP-UX 11i System Administration Handbook*
  `http://www.hp.com/hpbooks/prentice/ptr_0130600814.html`
- *HP-UX Virtual Partitions*
  `http://www.hp.com/hpbooks/prentice/ptr_0130352128.html`

HP Books are available worldwide through bookstores, online booksellers, and office and computer stores.

Publication History

The publication history for the *HP System Partitions Guide* includes the following editions.

Sixth Edition — April 2003, 5187-3603. CD-ROM, Web (`http://docs.hp.com/`), and print delivery.

You can order this book in print from the `http://software.hp.com` Web site.

Updates include HP rp7405 server details, vPars A.02.02 information, and other changes throughout.

Fifth Edition — August 2002, B2355-90762. CD-ROM, EPSS, Web (`http://docs.hp.com/`), and print delivery.

Fourth Edition — June 2002, B2355-90752. CD-ROM, EPSS, and Web (`http://docs.hp.com/`) delivery.

Third Edition — March 2002, B2355-90746. CD-ROM, EPSS, and Web (`http://docs.hp.com/`) delivery.

Second Edition — December 2001, B2355-90744. CD-ROM, EPSS, and Web (`http://docs.hp.com/`) delivery.

First Edition — September 2001, B2355-90736. CD-ROM, EPSS, and Web (`http://docs.hp.com/`) delivery.

5783

Notational Conventions

The following notational conventions are used in this publication.

WARNING

A warning lists requirements that you must meet to avoid personal injury.

CAUTION

A caution provides information required to avoid losing data or avoid losing system functionality.

NOTE

A note highlights useful information such as restrictions, recommendations, or important details about HP product features.

- `Commands and options` are represented using `this font`.
- **`Text that you type exactly as shown`** is represented using **`this font`**.
- *`Text to be replaced with text that you supply`* is represented using *`this font`*.

  Example:
  "Enter the `ls -l` *`filename`* command" means you must replace *`filename`* with your own text.
- **Keyboard keys and graphical interface items (such as buttons, tabs, and menu items)** are represented using **this font**.

  Examples:
  The **Control** key, the **OK** button, the **General** tab, the **Options** menu.
- **Menu —> Submenu** represents a menu selection you can perform.

  Example:
  "Select the **Partition —> Create Partition** action" means you must select the **Create Partition** menu item from the **Partition** menu.
- `Example screen output` is represented using `this font`.

1 nPartition System Overviews

This chapter introduces Hewlett-Packard's nPartition system features, server models, nPartition concepts, administration tools, and HP-UX 11i support for nPartitions.

- The first sections of this chapter introduce the nPartition system environment and the HP servers that support nPartitions.
- Details about nPartition concepts are given starting with the section *Overview of nPartitions* on page 60.
- Descriptions of tools and HP-UX features for using nPartitions are given starting with the section *Tools for Managing nPartitions* on page 70.

For nPartition configuration requirements and related HP recommendations, refer to the chapter *Planning nPartition Configurations* on page 109.

For procedures to manage nPartitions, refer to the chapter *Managing nPartitions* on page 243.

Introduction

Hewlett-Packard's nPartition system capabilities enable you to configure a single server complex as one large system or as multiple smaller systems.

Each nPartition definition establishes a subset of the server hardware resources that are used as an independent system environment. An nPartition includes: one or more *cells* (containing processors and memory) that are assigned to the nPartition as well as all *I/O chassis* connected to those cells.

All processors, memory, and I/O in an nPartition are used exclusively by software running in the nPartition. Thus, each nPartition runs its own instance of the Boot Console Handler (BCH) interface and independently boots and reboots instances of HP-UX 11i.

By defining multiple nPartitions within an nPartition server, you establish hardware partitioning that enables a single server complex to run multiple instances of the HP-UX 11i operating system.

You also can establish *virtual partitions* within an nPartition on HP Superdome servers. The HP virtual partitions software enables you to further subdivide an nPartition's active hardware resources by using software partitioning to create one or more virtual partitions (vPars). Each virtual partition can load/boot HP-UX B.11.11 independently. Refer to the chapter *Virtual Partitions (vPars) Management on nPartitions* on page 441 for details.

The HP-UX 11i June 2003 release supports nPartitions on the following servers:

- HP rp7405/rp7410 server (`model` string: 9000/800/rp7410)
- HP rp8400 server (`model` string: 9000/800/S16K-A)
- HP Superdome 16-way (`model` string: 9000/800/SD16000)
- HP Superdome 32-way (`model` string: 9000/800/SD32000)
- HP Superdome 64-way (`model` string: 9000/800/SD64000)

For server hardware details see *Supported HP Server Models* on page 34.

S764

You can reconfigure a server's nPartition definitions without physically modifying the server's hardware configuration by using HP's software-based nPartition management tools.

You can reconfigure any nPartition to include more, fewer, and/or different hardware resources. Doing this requires shutting down the operating system running in the nPartition and resetting the nPartition to reconfigure it; this *reboot for reconfig* operation is performed using the `shutdown -R` HP-UX command (using the `-R` option, not `-r`).

With HP's nPartition servers, you can start with a system that meets your needs now and add more components (cells and I/O) as your needs increase.

For example, with a Superdome server you can add cells, I/O chassis, and/or upgrade to larger-capacity systems as needed. A Superdome 16-way server can be upgraded to a Superdome 32-way server, and likewise the Superdome 32-way server can be upgraded to Superdome 64-way server. You also can add I/O expansion cabinets to a Superdome server at any time.

Administration Tools for nPartitions

You can use several administration tools to manage nPartitions in a server complex, including the service processor, consoles, Boot Console Handler (BCH) interfaces, HP-UX commands, and Partition Manager.

- Server complex's **service processor (GSP or MP)**, which includes the Command menu, partition consoles, partition Virtual Front Panels, partition Console Logs, and the Chassis Log viewer.
- **nPartition console and BCH interface**, which provides console access (through the service processor) as well as interactive control before HP-UX has booted on an nPartition.
- **HP-UX nPartition commands** (including `parstatus`, `parcreate`, `parmodify`, and others) enable you to list, monitor, configure, and manage nPartitions from HP-UX.
- The **Partition Manager** utility (`/opt/parmgr/bin/parmgr`) provides a graphical interface for listing and managing nPartitions.

See *Tools for Managing nPartitions* on page 70 for more details.

5763

Supported HP Server Models

The HP servers that support nPartitions include the following models:

- HP rp7405/rp7410 server—See *rp7405 / rp7410 Server Model* on page 36.
- HP rp8400 server—See *rp8400 Server Model* on page 38.
- Three models of HP Superdome servers—See *Superdome Server Models* on page 40.

These nPartition servers have different hardware configurations and limits, as described in the following sections, and all include support for nPartitions.

Within each HP nPartition **server cabinet** are multiple **cells**, each of which contains processors and memory. The nPartition cabinets are shown in Figure 1-1 on page 35; cells are discussed in *Cells* on page 47.

Each nPartition server cabinet also may have multiple **I/O chassis** that provide PCI slots for I/O cards. Each I/O chassis connects to one of the cells in the server. See *nPartition I / O Chassis and PCI Card Slots* on page 48.

HP Superdome servers also support optional **I/O expansion cabinets** to provide additional I/O chassis. See *I / O Chassis in HP Superdome IOX Cabinets* on page 51.

All hardware within a server—including all cells, I/O chassis, cables, cabinet hardware, and power and utilities components—is considered to be a **server complex**.

An HP Superdome complex can consist of one cabinet or two server cabinets, and can also include one or two I/O expansion cabinets (to provide additional I/O chassis).

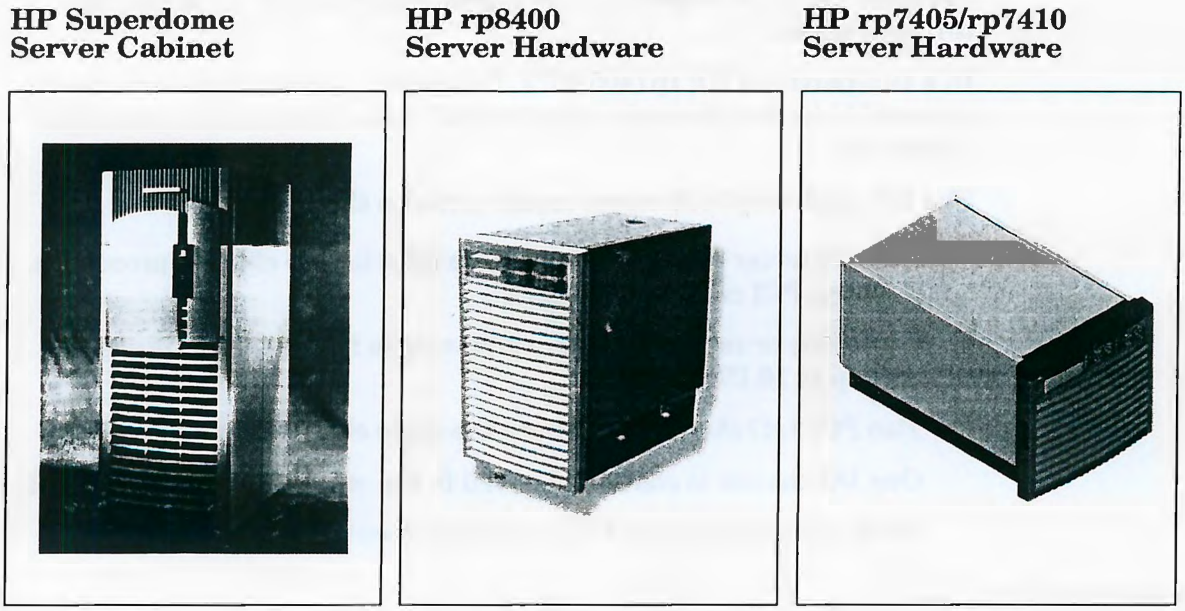
Each HP rp7405/rp7410 or HP rp8400 server complex consists of a single server cabinet only.

5762
21

Hardware Models: Superdome, rp8400, and rp7405/rp7410 nPartition Servers

HP Superdome, HP rp8400, and HP rp7405/rp7410 server cabinets are shown in Figure 1-1.

Figure 1-1 **HP nPartition Server Hardware**



HP Superdome Server Cabinet

HP rp8400 Server Hardware

HP rp7405/rp7410 Server Hardware

rp7405/rp7410 Server Model

HP rp7405/rp7410 servers scale from one to two cells and include complete support for hard partitions (nPartitions).

Figure 1-2 on page 37 shows an overview of the HP rp7405/rp7410 server hardware architecture.

You can configure a single nPartition using one or both cells, or can configure up to two separate nPartitions within an HP rp7405/rp7410 server complex.

In a two-partition HP rp7405/rp7410 complex, you would use cell 0 and its core I/O in one nPartition, and use cell 1 and its core I/O in the other nPartition.

The HP rp7405/rp7410 server model includes these features:

- *A single server cabinet* that includes all cells, I/O chassis, processors, memory, PCI cards, and core I/O.
- *Either one or two cells.* Each cell has up to four PA-RISC processors and up to 16 DIMMs.
- *Two PCI I/O chassis* that share the same chassis hardware.

  One I/O chassis is connected to cell 0, the other is connected to cell 1.

  Each I/O chassis has 8 PCI card slots, numbered from 1 to 8.

NOTE On HP rp7405/rp7410 servers, two PCI slots by convention are dedicated for use by a combination LAN/SCSI card: PCI domain 0 slot 1 (the first slot on the left) and PCI domain 1 slot 8 (the last slot on the right).

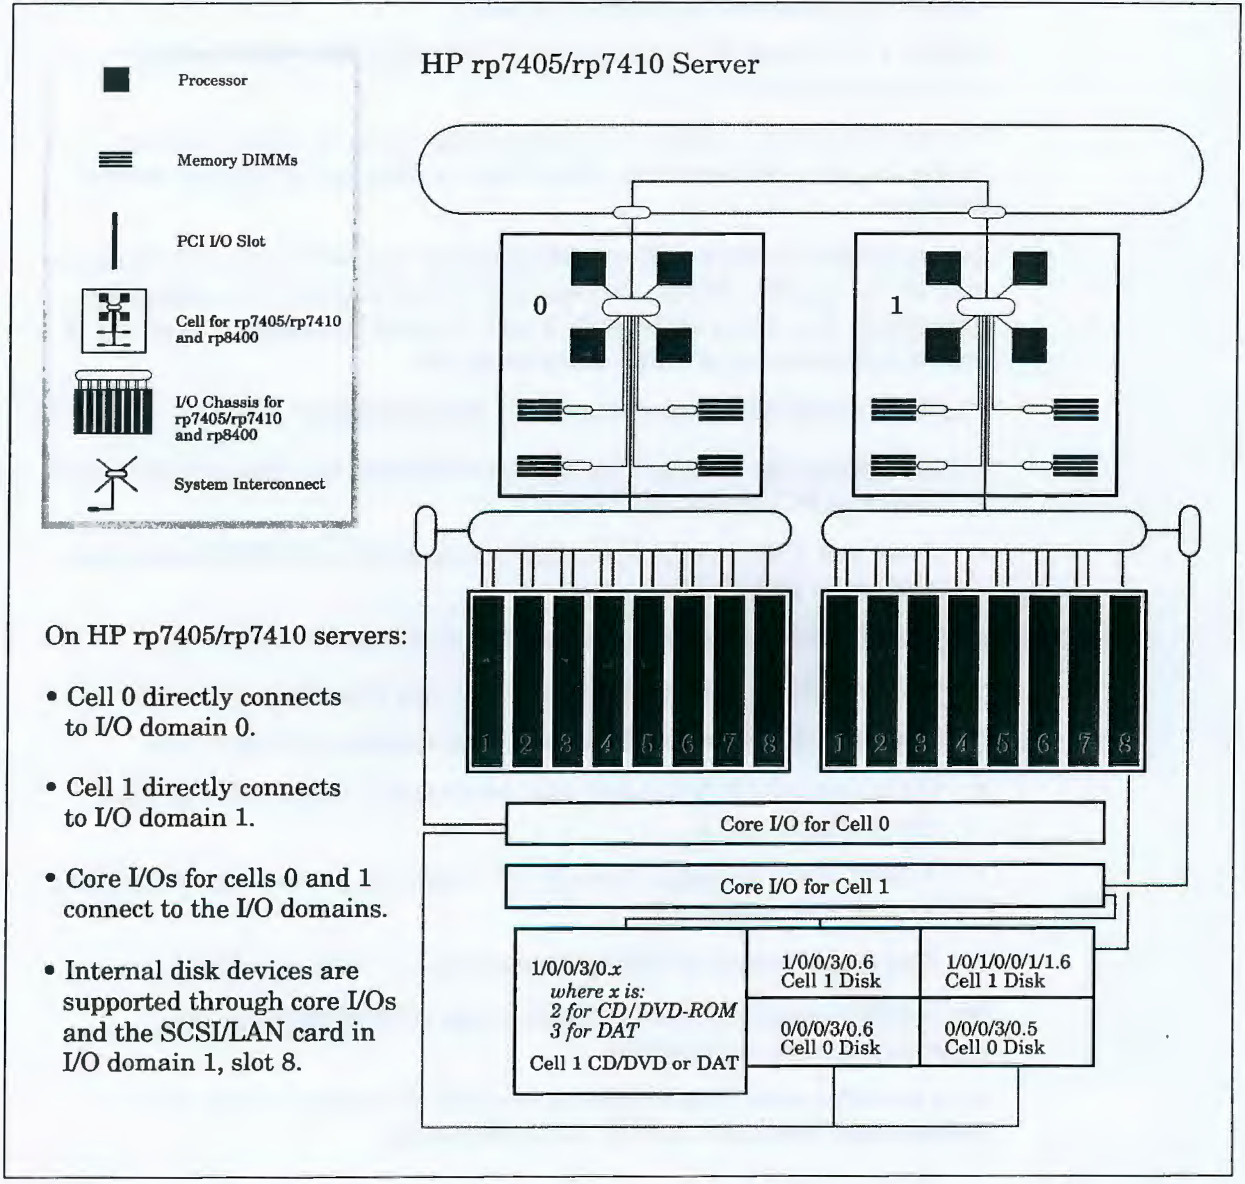
- *Up to two core I/O devices*, one connected to cell 0, and the other connected to cell 1.
- *A total server complex capacity of*: 2 cells, 8 processors, 32 DIMMs, and 16 PCI card slots.
- The model string for HP rp7405/rp7410 servers is `9000/800/rp7410`.

HP rp7405/rp7410 servers currently include a single server cabinet that is rack-mounted only. In the future HP also will support a stand-alone HP rp7405/rp7410 server configuration.

S760
2D

Also see *nPartition System Hardware Details* on page 47 for more information about HP rp7405/rp7410 server features.

Figure 1-2 **HP rp7405/rp7410 Server Architecture Overview**



On HP rp7405/rp7410 servers:

- Cell 0 directly connects to I/O domain 0.
- Cell 1 directly connects to I/O domain 1.
- Core I/Os for cells 0 and 1 connect to the I/O domains.
- Internal disk devices are supported through core I/Os and the SCSI/LAN card in I/O domain 1, slot 8.

5759

rp8400 Server Model

HP rp8400 servers scale from one to four cells and include complete support for hard partitions (nPartitions).

Figure 1-3 on page 39 shows an overview of the HP rp8400 server hardware architecture.

You can configure a single nPartition using some or all cells, or can configure up to two separate nPartitions within an HP rp8400 server complex.

In a multiple-partition HP rp8400 complex, you would use cell 0 and its core I/O in one nPartition, and use cell 1 and its core I/O in the other nPartition. Any other cells (cells 2 and 3) could be assigned to either of the two nPartitions, or could be unassigned.

The HP rp8400 server model includes these features:

- *A single server cabinet* that includes all cells, I/O chassis, processors, memory, PCI cards, and core I/O.
- *From one to four cells*. Each cell has up to four PA-RISC processors and up to 16 DIMMs.
- *Two PCI I/O chassis* that share the same chassis hardware.

  One I/O chassis is connected to cell 0, the other is connected to cell 1.

  Each I/O chassis has 8 PCI card slots, numbered from 1 to 8.
- *Up to two core I/O devices*, one connected to cell 0, and the other connected to cell 1.
- *A total server complex capacity of*: 4 cells, 16 processors, 64 DIMMs, and 16 PCI card slots.
- The model string for HP rp8400 servers is `9000/800/S16K-A`.

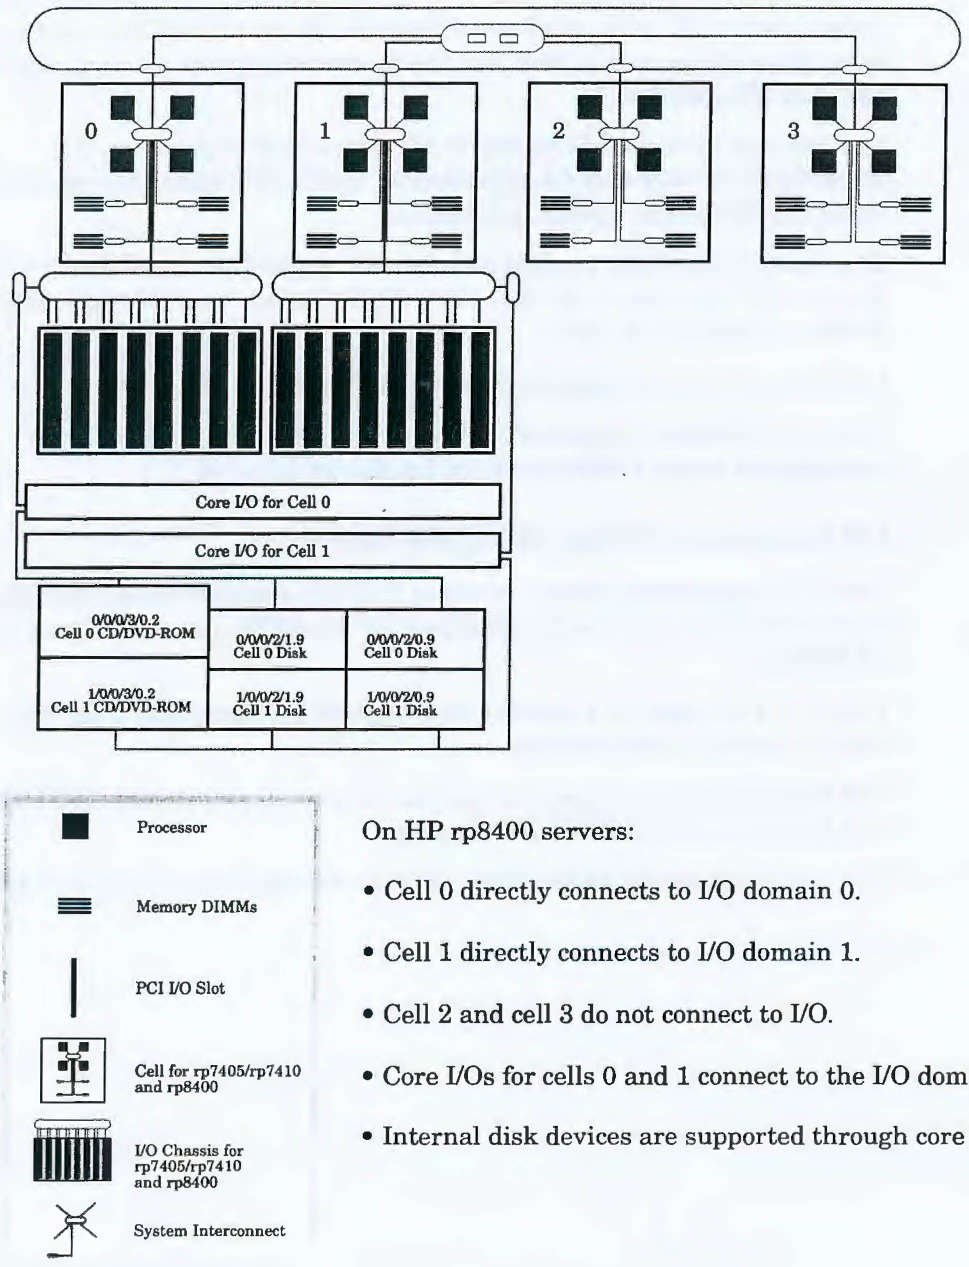
HP rp8400 servers include a single server cabinet that can be rack-mounted or stand-alone.

Also see *nPartition System Hardware Details* on page 47 for more information about HP rp8400 server features.

5758

Figure 1-3 HP rp8400 Server Architecture Overview

HP rp8400 Server



On HP rp8400 servers:

- Cell 0 directly connects to I/O domain 0.
- Cell 1 directly connects to I/O domain 1.
- Cell 2 and cell 3 do not connect to I/O.
- Core I/Os for cells 0 and 1 connect to the I/O domains.
- Internal disk devices are supported through core I/Os.

5757

Superdome Server Models

HP Superdome servers scale up to 16 cells and include complete support for hard partitions (nPartitions). You can configure a single nPartition using some or all cells, or can configure multiple nPartitions within the same Superdome server complex (up to one nPartition for each cell that has core I/O attached).

You can add up to two Superdome I/O expansion cabinets to the Superdome 32-way and 64-way models. Each I/O expansion cabinet has up to six additional 12-slot I/O chassis.

The three Superdome models include: *HP Superdome 16-Way (SD16000) Server*, *HP Superdome 32-Way (SD32000) Server*, and *HP Superdome 64-Way (SD64000) Server*.

Details on these models are given in the following sections.

Also see *nPartition System Hardware Details* on page 47 for more information about HP Superdome hardware features.

HP Superdome 16-Way (SD16000) Server

The HP Superdome 16-way server is a single-cabinet server that has from two to four cells, each with four HP PA-RISC processors and up to 32 DIMMs.

Figure 1-4 on page 41 shows an overview of the Superdome 16-way server hardware architecture.

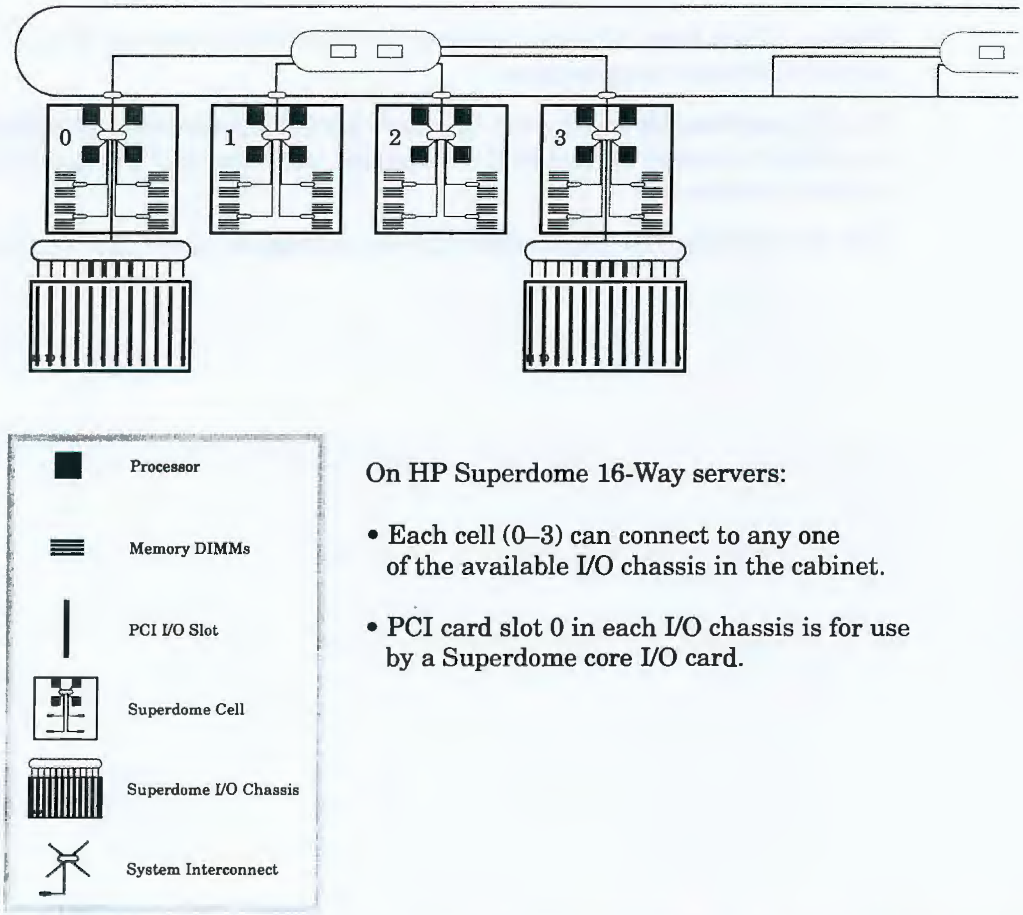
The Superdome 16-way server can have up to 16 processors, 128 DIMMs, and up to four 12-slot PCI I/O chassis.

The model string for Superdome 16-way servers is `9000/800/SD16000`.

5756

Figure 1-4 HP Superdome 16-Way Architecture Overview

HP Superdome 16-Way Server (SD16000)



On HP Superdome 16-Way servers:

- Each cell (0–3) can connect to any one of the available I/O chassis in the cabinet.
- PCI card slot 0 in each I/O chassis is for use by a Superdome core I/O card.

5755

HP Superdome 32-Way (SD32000) Server

The Superdome 32-way server is a single-cabinet server that has from two to eight cells, each with four HP PA-RISC processors and up to 32 DIMMs.

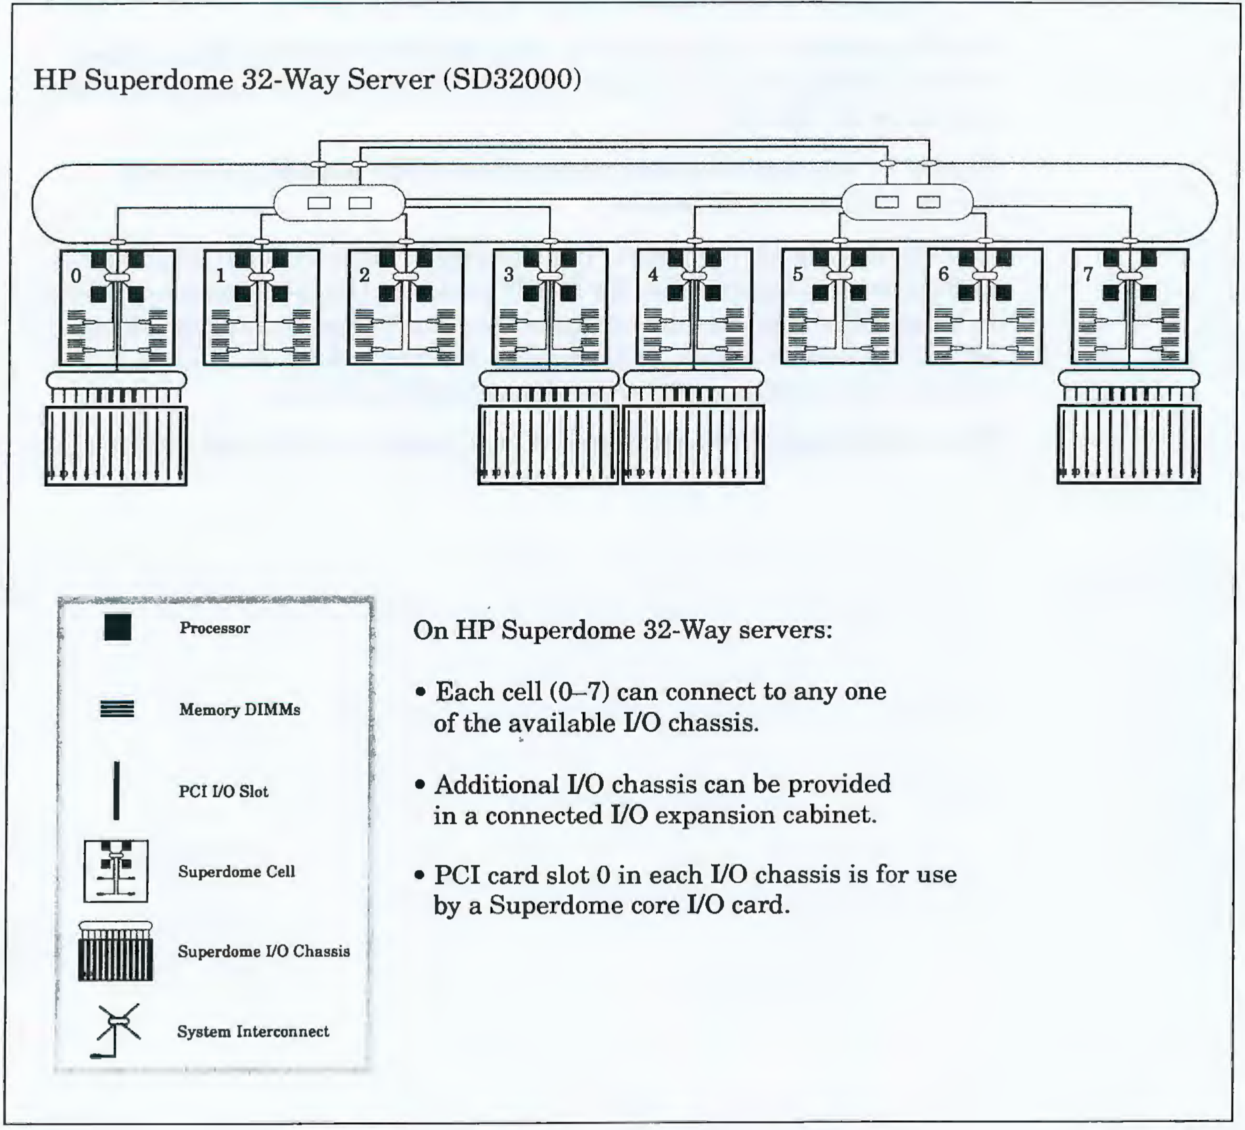
Figure 1-5 on page 43 shows an overview of the Superdome 32-way server hardware architecture.

The Superdome 32-way server can have up to 32 processors, 256 DIMMs, up to four internal 12-slot PCI I/O chassis, plus optional I/O expansion cabinet hardware.

The model string for Superdome 32-way servers is `9000/800/SD32000`.

57 54
21

Figure 1-5 **HP Superdome 32-Way Architecture Overview**



On HP Superdome 32-Way servers:

- Each cell (0–7) can connect to any one of the available I/O chassis.
- Additional I/O chassis can be provided in a connected I/O expansion cabinet.
- PCI card slot 0 in each I/O chassis is for use by a Superdome core I/O card.

HP Superdome 64-Way (SD64000) Server

The Superdome 64-way server is a tightly interconnected dual-cabinet server that has from 4 to 16 cells, each with four HP PA-RISC processors and up to 32 DIMMs.

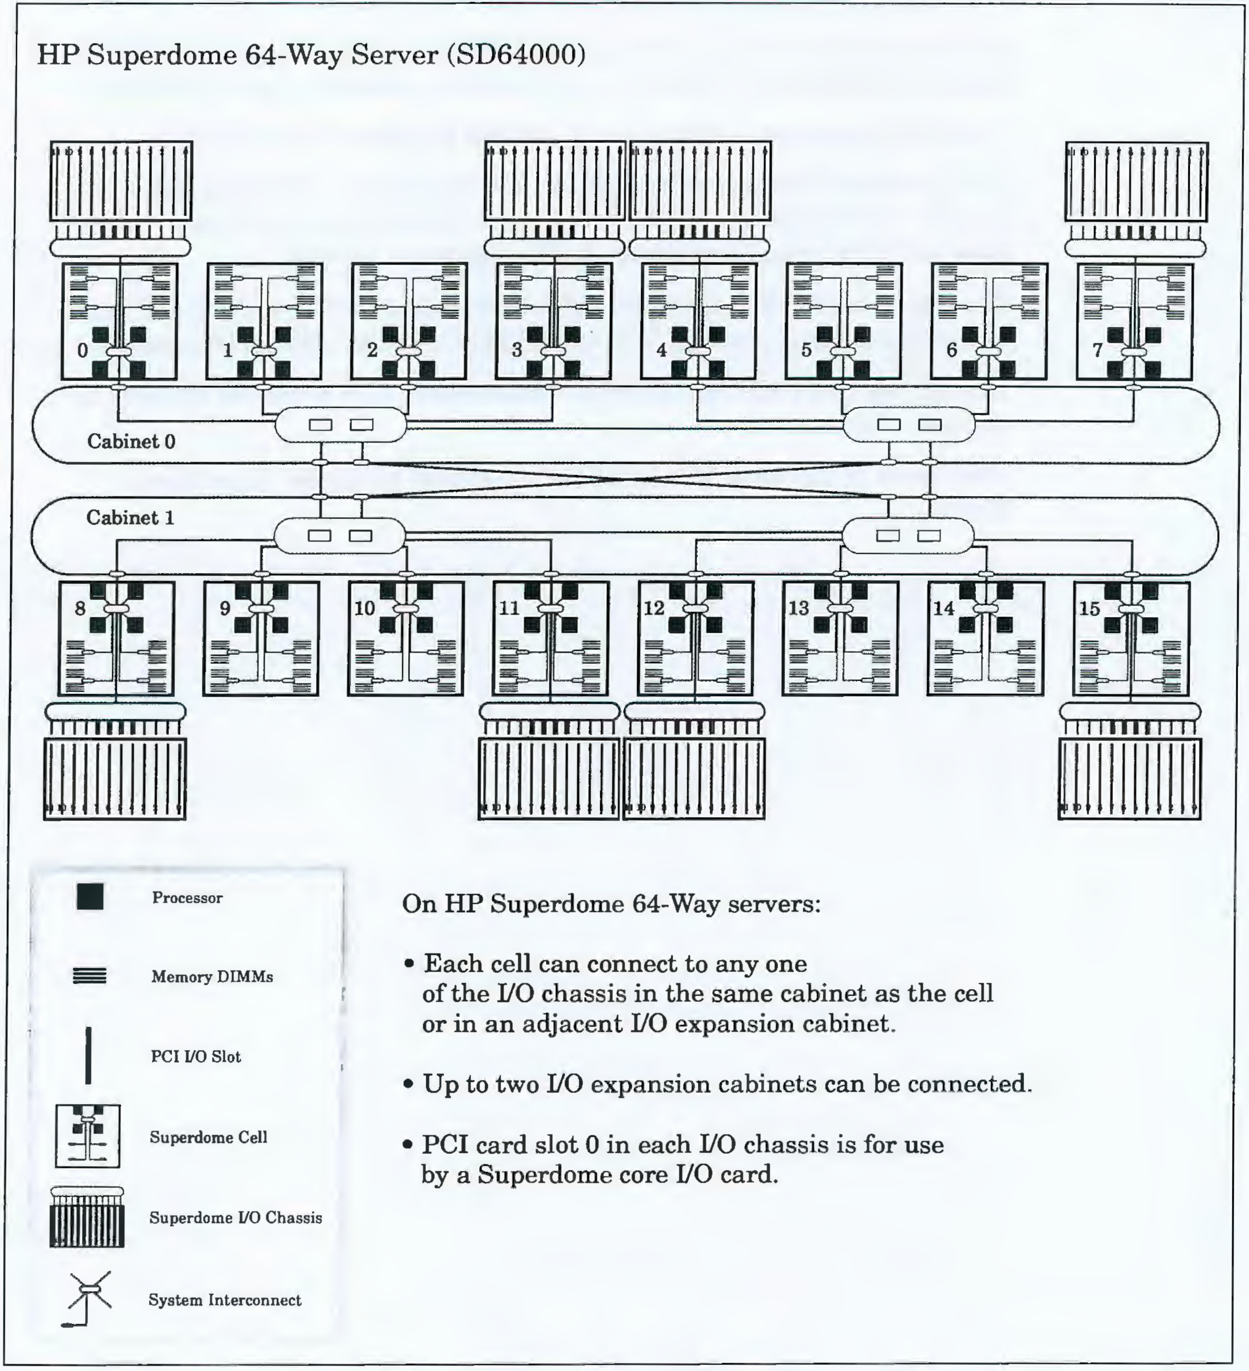
Figure 1-6 on page 45 shows an overview of the Superdome 64-way server hardware architecture.

The Superdome 64-way server can have up to 64 processors, 512 DIMMs, and up to eight internal 12-slot PCI I/O chassis. (Each of the two cabinets in a Superdome 64-way server provides up to 32 processors, 256 DIMMs, and up to four 12-slot PCI I/O chassis.) HP Superdome 64-way servers also can have optional I/O expansion cabinet hardware.

The model string for Superdome 64-way servers is `9000/800/SD64000`.

5x52

Figure 1-6 **HP Superdome 64-Way Architecture Overview**



On HP Superdome 64-Way servers:

- Each cell can connect to any one of the I/O chassis in the same cabinet as the cell or in an adjacent I/O expansion cabinet.
- Up to two I/O expansion cabinets can be connected.
- PCI card slot 0 in each I/O chassis is for use by a Superdome core I/O card.

5751

HP Superdome I/O Expansion Cabinet

HP Superdome 32-way and Superdome 64-way servers can include I/O expansion cabinets in addition to the server cabinet(s) in the complex.

Each I/O expansion cabinet has a cabinet number of either 8 or 9.

A Superdome I/O expansion cabinet includes up to 3 I/O bays, with two 12-slot I/O chassis in each bay. This provides for up to 6 chassis with a total of 72 PCI card slots in each I/O expansion cabinet.

The Superdome I/O expansion cabinet is a standard-size cabinet that, space permitting, you can mount peripherals in as well as I/O chassis.

See the section *I/O Chassis in HP Superdome IOX Cabinets* on page 51 for more details.

Also refer to the book *I/O Expansion Cabinet Guide for Superdome Servers*.

nPartition System Hardware Details

This section gives physical details about the Hewlett-Packard servers that support nPartitions, including HP Superdome, rp8400, and rp7405/rp7410 servers.

The following nPartition server hardware topics are covered here:

- *Cells* on page 47
- *Processors: HP PA-RISC CPUs* on page 48
- *nPartition I/O Chassis and PCI Card Slots* on page 48
- *Internal Disk Devices for HP rp7405/rp7410 and rp8400 Servers* on page 55
- *nPartition Service Processor (GSP or MP) Hardware* on page 56

Also see *Supported HP Server Models* on page 34 for an introduction to the HP nPartition-capable server models, including architectural overviews.

Cells

This section briefly describes cell hardware details for HP's nPartition servers.

Each cell in an HP nPartition server contains HP PA-RISC processors, memory DIMMs, and provides the connection to any I/O chassis attached to the cell.

For details about cell ID formats, see *Specifying Cells and I/O Chassis to Commands* on page 87. For details about configurable cell attributes, see *Cell Properties* on page 61.

All cells assigned to an nPartition **must** have the same firmware revisions and the same type/speed of processors and **should** have identical memory configurations. On HP servers that have multiple nPartitions, each nPartition can have different types of cells.

All processors in a cell **must** be of the same type and speed. All memory DIMMs in a cell **should** be identical for best performance.

In *HP Superdome* servers, each cell can support up to 32 memory DIMMs and 1–4 processors.

5749

In *HP rp7405/rp7410 and rp8400* servers, each cell can support up to 16 memory DIMMs and 1–4 processors.

Each HP Superdome cell can be connected to an I/O chassis that resides either in the same cabinet as the cell or in an I/O expansion cabinet.

In HP rp7405/rp7410 and rp8400 servers, cell 0 connects to I/O chassis 0, and cell 1 connects to I/O chassis 1.

Processors: HP PA-RISC CPUs

This section describes the supported processor (CPU) types for HP nPartition servers.

Within each cell in an nPartition server, *all processors* must operate at the same speed. If multiple cells reside in a server, each cell can run a set of processor whose operating speed is different from the processors in the other cell(s) in the server.

In HP Superdome cells, the following processors types are supported: PA8600 (552 MHz) or PA8700 (650, 750, or 875 MHz).

In HP rp7405/rp7410 and rp8400 servers, the supported processor types are: PA8700 (650, 750, or 875 MHz).

To list the operating speed of processors in a cell, you can use the `parstatus` HP-UX command or the `PR` command from an nPartition's BCH Information menu.

For example, `parstatus -V -c 2` lists hardware details about cell 2, including the operating speed and processor type for the cell.

Refer to the chapter *Listing and Managing Server Hardware* on page 305 for details on listing cell processor info, including a reference chart of cell processor frequencies.

nPartition I/O Chassis and PCI Card Slots

This section has details about the I/O chassis and PCI card slot locations in various models of HP nPartition servers and I/O expansion cabinets, and details about slot frequencies and power capabilities.

The following I/O chassis and slots are discussed here:

- *I/O Chassis in HP Superdome Compute Cabinets* on page 49

5748

- *I/O Chassis in HP Superdome IOX Cabinets* on page 51
- *I/O Chassis for HP rp7405/rp7410 and rp8400 Servers* on page 54

I/O Chassis in HP Superdome Compute Cabinets

Each HP Superdome I/O chassis can connect to one cell in the same compute cabinet.

A Superdome I/O chassis has 12 slots, numbered from 11 to 0. The HP Superdome core I/O card *fits only in slot 0.*

Card slot details for Superdome I/O chassis are in Table 1-1.

Table 1-1 HP Superdome I/O Chassis: Card Slot Details

Slot Number	11	10	9	8	7	6	5	4	3	2	1	0
Signaling (Volts)	5.0 / 3.3				3.3				5.0 / 3.3			
Hardware Fabric	single rope				dual rope				single rope			
Cards Accepted	PCI cards keyed as 5-volt or universal.				PCI cards keyed as 3.3-volt or universal.				PCI cards keyed as 5-volt or universal.			

In HP Superdome I/O chassis, all slots can operate as 64-bit slots and can accept 66 MHz PCI cards.

HP Superdome I/O chassis slots 0–3 and 8–11 can accept cards that are physically keyed as 5-volt cards or are keyed as universal cards. These slots normally operate at 33 MHz with 5-volt signaling, but when a 66 MHz capable card is detected they are switched by software to operate at 66 MHz with 3.3-volt signaling.

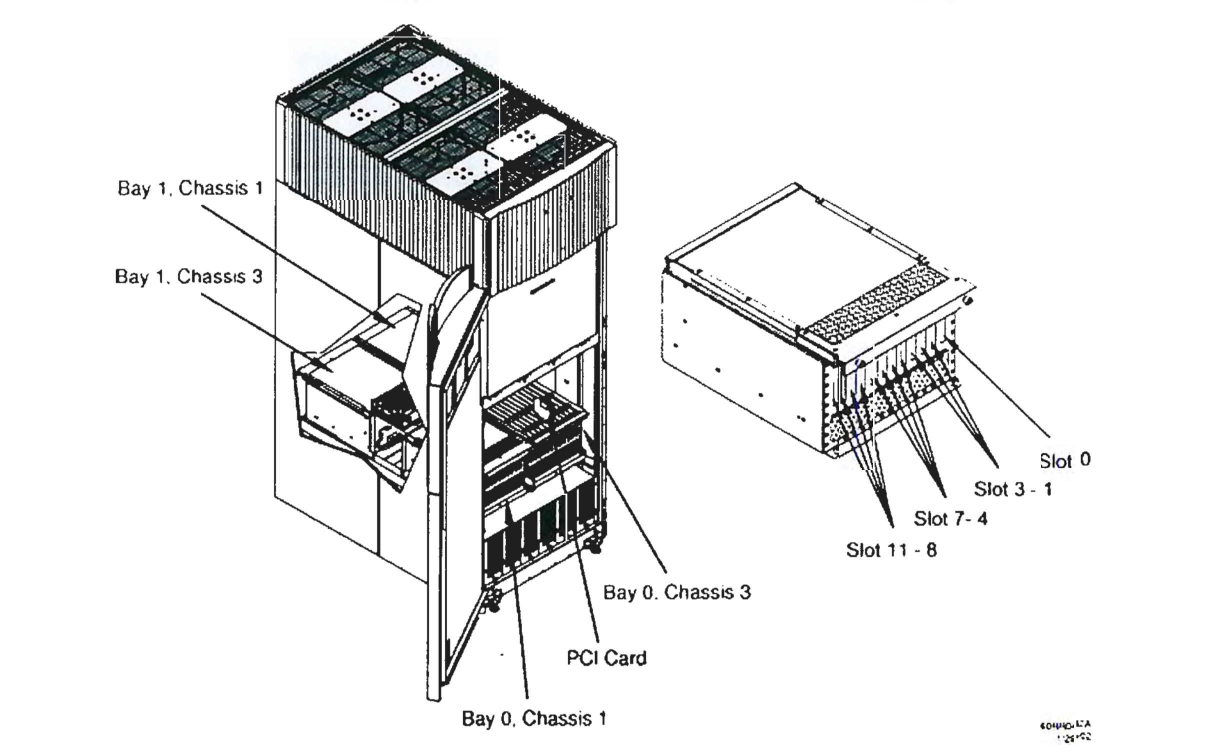
Slots 4–7 in a Superdome I/O chassis can accept cards that are physically keyed as 3.3-volt cards or are keyed as universal cards. These slots can operate at 66 MHz or 33 MHz with 3.3-volt signaling only.

Slots 4–7 also are **dual-rope slots**, which have two connections between the slot's local bus adapter (LBA) and the I/O chassis system bus adapter (SBA). All other slots are **single-rope slots**, which have a single connection between the slot LBA and the I/O chassis SBA. The dual-rope slots can have greater sustained bandwidth than single-rope slots.

5747

The Superdome I/O chassis and slot locations are shown in Figure 1-7.

Figure 1-7 **HP Superdome I/O Chassis and PCI Card Slot Locations**



As Figure 1-7 shows, I/O chassis in HP Superdome compute cabinets reside both in the cabinet's front (I/O bay 0) and its rear (I/O bay 1). When you face each I/O bay, the left I/O chassis is chassis 1 and the right chassis is I/O chassis 3. In I/O chassis in a Superdome compute cabinet, PCI slot 11 is to the left and slot 0 is to the right.

In HP Superdome I/O expansion cabinets, the I/O chassis are identical but are positioned sideways, with either slot 0 or slot 11 at the bottom.

Accessing Superdome Compute Cabinet I/O Chassis and PCI Slots

Step 1. To access the I/O chassis in an HP Superdome compute cabinet, you must open either the cabinet's front door (to access I/O bay 0) or its rear door (to access I/O bay 1). In each I/O bay—when facing the bay—I/O chassis 1 is on the left and chassis 3 is on the right.

See Figure 1-7 on page 50 for details.

Step 2. To access the PCI card slots in an HP Superdome compute cabinet's I/O chassis, you must remove the cover from the top of the I/O chassis.

In each Superdome compute cabinet I/O chassis—when facing the chassis—PCI slot 0 is on the right and PCI slot 11 is on the left.

I/O Chassis in HP Superdome IOX Cabinets

Up to two I/O expansion (**IOX**) cabinets can reside in an HP Superdome complex.

I/O expansion cabinets are numbered cabinets 8 and 9.

The IOX cabinet uses the same I/O chassis as the Superdome compute cabinet. Each IOX I/O chassis has 12 slots, numbered from 11 to 0. See Table 1-1 on page 49 for details about the card slots.

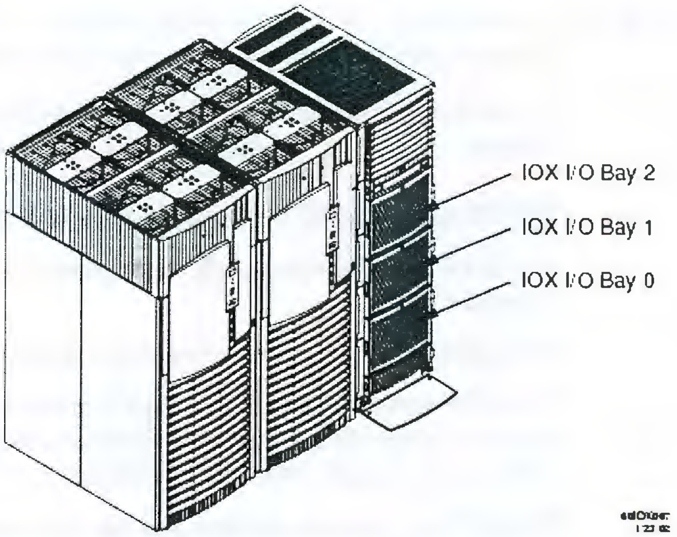
Each I/O expansion cabinet has its own power supplies, fans, and utilities (which are connected to the Superdome server's service processor bus).

The I/O chassis (and PCI card slots) within each I/O expansion cabinet are made available to nPartitions through direct I/O chassis-to-cell connections—exactly as internal Superdome server cabinet I/O chassis are connected to cells.

Three I/O bays can be housed in each IOX. These bays are numbered from bottom to top: I/O bay 0, bay 1, and bay 2, as shown in Figure 1-8.

Figure 1-8 **I/O Expansion Cabinet (IOX) for HP Superdome**

5745



Each I/O bay in an IOX houses two I/O chassis: the left chassis is I/O chassis 1, right is chassis 3. Thus, an IOX can have up to six I/O chassis that can connect to the cells in an attached Superdome compute cabinet.

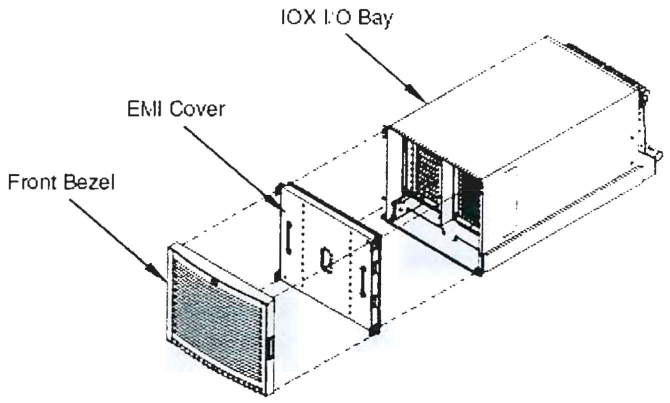
Accessing Superdome IOX I/O Chassis and PCI Card Slots

This procedure describes how to access the I/O chassis and PCI card slots in an HP Superdome I/O expansion cabinet (IOX).

Step 1. To access the I/O chassis in an IOX bay, you must remove the front bezel from the bay, and also remove the EMI cover, as shown in Figure 1-9.

The two I/O chassis in each IOX bay are accessible when the I/O bay slides out from the IOX cabinet.

Figure 1-9 IOX Bezel, Cover, and Bay



Step 2. To access the PCI card slots in an IOX I/O chassis, remove the I/O chassis cover.

To access slots in chassis 1 of the bay remove the cover from the *left* side of the I/O bay, or remove the cover from the *right* side of the bay to access I/O chassis 3's PCI card slots. See Figure 1-9 for details.

I/O Chassis for HP rp7405/rp7410 and rp8400 Servers

HP rp7405/rp7410 and rp8400 servers have two I/O chassis, each with 8 slots numbered left to right from 1 to 8.

Both HP rp7405/rp7410 and rp8400 server cabinets have a single I/O bay on the cabinet's rear that houses the two I/O chassis or "I/O domains". When you face the I/O bay, viewing the rear of the cabinet, the chassis on the left is I/O chassis 0, and right is I/O chassis 1.

Cell 0 connects to chassis 0 and cell 1 connects to chassis 1.

In HP rp7405/rp7410 servers, two PCI card slots *are reserved* for use by a SCSI/LAN card: chassis 0, slot 1 and chassis 1, slot 8. This is a 64-bit card that operates at 66 MHz and 3.3-volt signaling.

HP rp7405/rp7410 and rp8400 I/O chassis card slot details are listed in Table 1-2.

Table 1-2 **HP rp7405/rp7410 and rp8400 I/O Chassis: Card Slot Details**

Slot Number	1	2	3	4	5	6	7	8
Signaling (Volts)	3.3	3.3	3.3	3.3	3.3	3.3	5.0 / 3.3	5.0 / 3.3
Hardware Fabric	dual rope							single rope
Cards Accepted	PCI cards keyed as 3.3-volt or universal.						PCI cards keyed as 5-volt or universal.	

All slots in HP rp7405/rp7410 and rp8400 I/O chassis can operate as 64-bit slots and can accept 66 MHz PCI cards.

HP rp7405/rp7410 and rp8400 I/O chassis slots 1–6 accept cards physically keyed as 3.3-volt cards or keyed as universal cards. These slots can operate at 66 MHz or 33 MHz with 3.3-volt signaling only.

Slots 7 and 8 in rp7405/rp7410 and rp8400 I/O chassis accept cards keyed as 5-volt cards or keyed as universal cards. These slots normally operate at 33 MHz with 5-volt signaling, but when a 66 MHz capable card is detected they are switched by software to operate at 66 MHz with 3.3-volt signaling.

5742

On both HP rp7405/rp7410 and rp8400 servers, slots 1–7 are **dual-rope slots**, which have two connections between the slot's local bus adapter (LBA) and the I/O chassis system bus adapter (SBA). The core I/O connections (slot 0) and slot 8 are **single-rope slots**, which have a single connection between the slot LBA and the I/O chassis SBA. The dual-rope slots can have greater sustained bandwidth than single-rope slots.

Internal Disk Devices for HP rp7405/rp7410 and rp8400 Servers

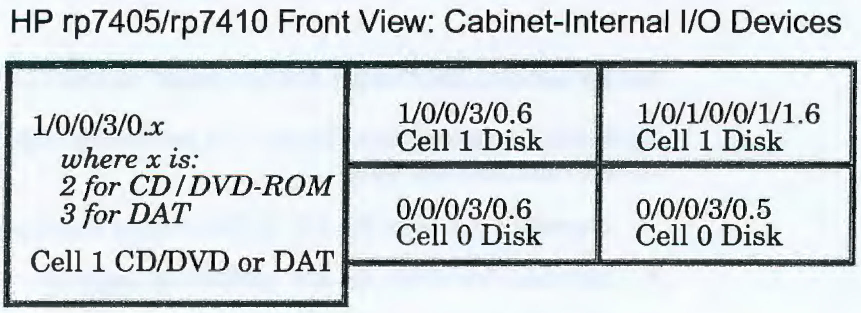
This section covers hardware paths and locations for the internal disk devices in rp7405/rp7410 and rp8400 servers:

- *Disk Devices in HP rp7405 / rp7410 Cabinets* on page 55
- *Disk Devices in HP rp8400 Cabinets* on page 56

Disk Devices in HP rp7405/rp7410 Cabinets

The hardware paths for internal drives in an HP rp7405/rp7410 cabinet are shown in Figure 1-10.

Figure 1-10 **HP rp7405/rp7410 Internal Storage Hardware Paths**



HP rp7405/rp7410 Front View: Cabinet-Internal I/O Devices

1/0/0/3/0.*x* *where x is:* *2 for CD / DVD-ROM* *3 for DAT* Cell 1 CD/DVD or DAT	1/0/0/3/0.6 Cell 1 Disk	1/0/1/0/0/1/1.6 Cell 1 Disk
	0/0/0/3/0.6 Cell 0 Disk	0/0/0/3/0.5 Cell 0 Disk

As Figure 1-10 shows, in an HP rp7405/rp7410 cabinet the top internal disk drives connect to cell 1 through the core I/O for cell 1 (for 1/0/0/3/0.6) and the LAN/SCSI card in slot 1_8 (I/O chassis 1 slot 8, for 1/0/1/0/0/1/1.6).

Both of the bottom disk drives (0/0/0/3/0.6 and 0/0/0/3/0.5) connect to cell 0 through the core I/O for cell 0.

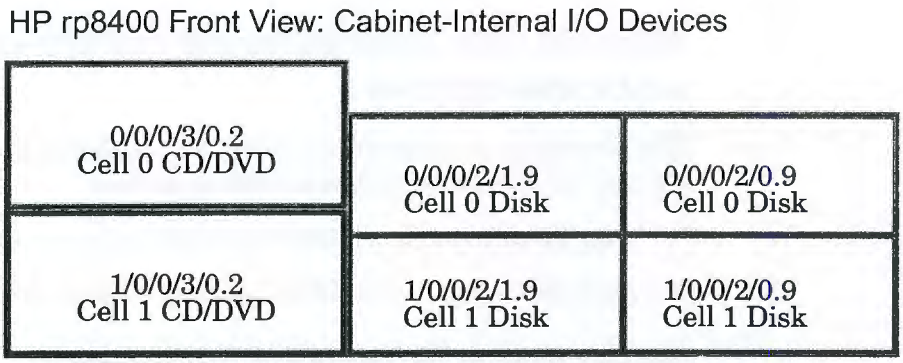
A CD/DVD-ROM drive or DAT drive connects to cell 1 through the core I/O card for cell 1, thus it can be accessed through cell 1's nPartition only.

5241

Disk Devices in HP rp8400 Cabinets

The hardware paths for internal drives in an HP rp8400 cabinet are shown in Figure 1-11.

Figure 1-11 **HP rp8400 Internal Storage Hardware Paths**



As Figure 1-11 shows, in an HP rp8400 cabinet the top internal drives connect to cell 0 through its core I/O card, and the bottom internal drives connect to cell 1 through the cell 1 core I/O card.

nPartition Service Processor (GSP or MP) Hardware

This section introduces the service processor (GSP or MP) hardware in HP's nPartition servers:

- *Service Processor for HP rp7405 / rp7410* on page 57
- *Service Processor for HP rp8400* on page 58
- *Service Processor for HP Superdome* on page 59

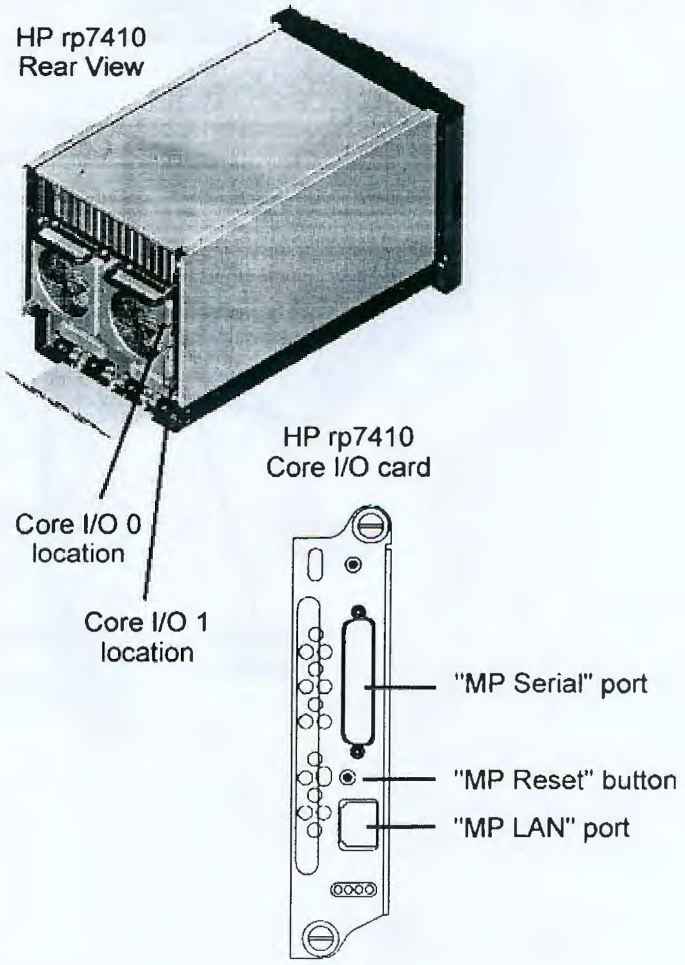
For further details on connecting to and using an nPartition server's service processor, refer to the chapter *Using Console and Service Processor Interfaces* on page 125.

S7410
21

Service Processor for HP rp7405/rp7410

On HP rp7405/rp7410 servers, service processor functionality is provided in the core I/O card, shown in Figure 1-12. The rp7405/rp7410 core I/O card's customer LAN port, which permits remote telnet access to the service processor, is labeled "MP LAN". The "MP Serial" port is single DB25 serial port from which three DB9 serial connectors are available (a DB25-to-3xDB9 dongle must be connected). A direct RS-232 serial connection to the service processor is available through the DB9 connector labeled "Console". Remote modem access to the service processor can be provided through the DB9 connector labeled "Remote".

Figure 1-12 **HP rp7405/rp7410 Service Processor LAN and Serial Ports**

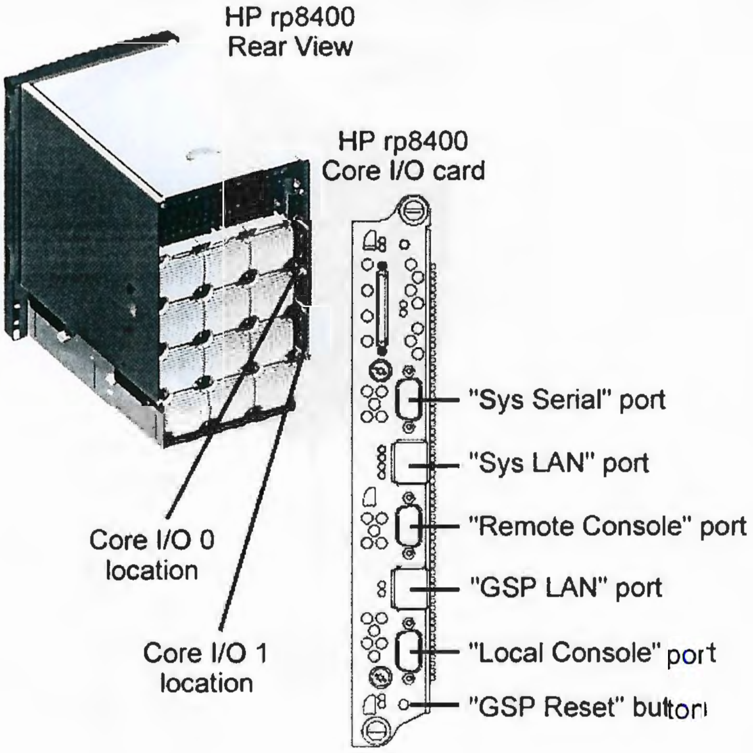


S739

Service Processor for HP rp8400

On HP rp8400 servers, service processor functionality is provided in the core I/O card, shown in Figure 1-13. The rp8400 core I/O card's customer LAN port, which permits remote telnet access to the service processor, is labeled "GSP LAN". A direct RS-232 serial connection to the service processor is available through the "Local Console" port. The "Remote Console" port is for external, remote modem access to the service processor.

Figure 1-13 **HP rp8400 Service Processor LAN and Serial Ports**

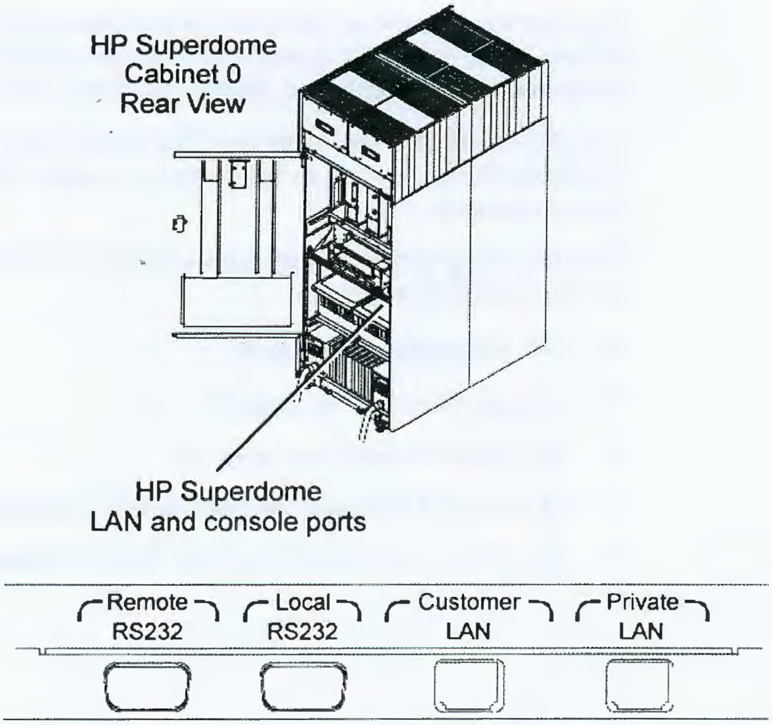


5738

Service Processor for HP Superdome

On HP Superdome servers, service processor functionality is provided by the “GSP UGUY and SUB” cabinet hardware, which can be seen in the rear of the cabinet above the LAN and console ports (see Figure 1-14). Use the *cabinet 0 (not cabinet 1) LAN and RS-232 connections* to access the service processor. The cabinet 0 “Customer LAN” port provides remote telnet access to the service processor. A direct RS-232 serial connection to the service processor is available through the “Local RS232” port. The “Remote RS232” port is for external, remote modem access to the service processor.

Figure 1-14 **HP Superdome Service Processor LAN and Serial Ports**



Overview of nPartitions

On HP's nPartition servers, each **nPartition** is a “logical system” that has its own dedicated portion of the server hardware that can run a single instance of the HP-UX 11i operating system. Each nPartition can boot, reboot, and operate independently of any other nPartitions and hardware within the same server complex.

Each nPartition has one or more **cells** (containing processors and memory) that are assigned to the nPartition for its exclusive use. Any **I/O chassis** that is attached to a cell belonging to an nPartition also is assigned to the nPartition. (Each chassis has PCI card slots plus any I/O cards and attached devices, and may also have **core I/O**.)

The **server complex** includes all hardware within an nPartition server: all cabinets, cells, I/O chassis, I/O devices and racks, management and interconnecting hardware, power supplies, and fans.

You can configure one or more nPartitions within a server complex, allowing the hardware to function as a single HP-UX 11i system or as many systems.

The following concepts and issues related to nPartitions are introduced in the rest of this section:

- *Cell Properties* on page 61
- *Genesis Partition* on page 63
- *Partition Numbers* on page 64
- *nPartition Local and Remote Access* on page 64
- *nPartition Active and Inactive States* on page 66

5736

Cell Properties

Cells in an HP nPartition server have various properties that determine how the cells can be used and managed.

The cell properties discussed here include: *Assigned and Unassigned Cells*, *Base Cells*, *Core Cells*, and *Active and Inactive Cells*.

To list details about all cells in a server complex, you can use the `parstatus -C` HP-UX command or Partition Manager.

The `parstatus -C` command output includes the current nPartition assignments, usage, and I/O details for the cells.

```
# parstatus -C
[Cell]
                        CPU     Memory                                 Use
                        OK/     (GB)                           Core    On

#
```

Assigned and Unassigned Cells

Each cell in an nPartition server complex either is *assigned* to one of the nPartitions in the complex, or it is *unassigned* and thus is not used by any of the nPartitions. If an I/O chassis is attached to an unassigned cell, then the chassis likewise is not assigned to an nPartition.

Cells that are unassigned are considered to be available resources; they are on the server complex's "free cell list" and are free to be assigned to any of the existing nPartitions, or can be used to create new nPartitions.

Base Cells

For the HP-UX 11i release, all cells within an Partition are **base cells.**

The HP-UX 11i utilities for managing nPartitions automatically set the cell type to base cell, if you do not specify the cell type.

Core Cells

One cell in each nPartition must serve as the **active core cell**. The core cell is a cell that is connected to an I/O chassis that has **core I/O**. The core cell controls the nPartition until HP-UX has booted, and it provides console access for the nPartition.

The core cell's core I/O provides console access for the nPartition through the service processor (GSP or MP).

The monarch processor on the core cell runs the Boot Console Handler (BCH) code while all other processors are idle until HP-UX is booted.

Although an nPartition can have multiple **core-capable cells** (any assigned cell that has an I/O chassis with core I/O), only one core I/O is actively used in an nPartition (the one belonging to the active core cell).

To be *eligible* as a core cell, a cell must be assigned to the nPartition, it must be active, and it must be attached to an I/O chassis containing functional core I/O.

The core cell is selected by system firmware in the early stages of the nPartition boot process.

By default—on HP Superdome and HP rp8400 servers—the lowest numbered eligible cell in an nPartition is selected as the core cell.

By default on HP rp7405/rp7410 servers only, cell 1 is selected as the core cell if it is eligible.

You can define up to four **core cell choices (or "alternates")** for an nPartition (two core-capable cells are currently supported on HP rp7405/rp7410 and HP rp8400 servers). The core cell choices are cells that you prefer to be selected as the nPartition's core cell. If your first core cell alternate cannot be used, then the second choice is checked; if the second choice fails, then any other choices are tried, in the order you specified.

When none of the core cell choices can serve as the active core cell, the nPartition then attempts to select an eligible cell using the default process.

Active and Inactive Cells

Cells that are assigned to an nPartition and have booted to form an nPartition are **active cells** whose resources (processors, memory, and any attached I/O) can be actively used by software running in the nPartition.

5734

Cells that are **inactive** either are not assigned to an nPartition, or they have not participated in *partition rendezvous* to form an nPartition with any other cells assigned to the nPartition. (Partition rendezvous is the point during the nPartition boot process when all available cells in an nPartition join together to establish which cells are active for the current boot of the nPartition.)

For example, a cell can be inactive when it is powered off, has booted with a "n" use-on-next-boot value, or is assigned to an nPartition that has been reset to the ready for reconfig state.

The resources belonging to inactive cells are not actively used by an nPartition. For a cell's resources to be actively used the cell must boot and participate in partition rendezvous.

Genesis Partition

The **Genesis partition** is the initial, one-cell nPartition created within a server complex. The Genesis partition is *just like any other nPartition* except in how it is created.

If your server complex has its nPartitions pre-configured by HP, you do not need to create a Genesis partition.

However, you always have the option of creating a Genesis partition by using the service processor (GSP or MP) Command menu's `CC` command, `G` option, to "wipe out" any existing nPartition definitions and start a new complex configuration that includes only the Genesis partition.

You can use HP-UX utilities running on the Genesis partition as the method for configuring all nPartitions in the complex. The Genesis partition always is partition number 0.

When it is first created, the Genesis partition consists of one cell that is connected to an I/O chassis that has core I/O installed. The Genesis partition also should have a bootable disk (or a disk onto which you can install HP-UX).

If HP-UX is not installed on the Genesis partition's disk(s), you can boot the Genesis partition to the Boot Console Handler (BCH) menu and from that point install HP-UX. This installation requires either having access to an HP-UX install server, or a CD-ROM drive (or DVD-ROM drive) connected to the cell's I/O chassis.

After you boot HP-UX on the Genesis partition, you can modify the nPartition to include additional cells. You also can create other, new nPartitions and can modify them from the Genesis partition or from any other nPartition running HP-UX.

Note that—once you create additional nPartitions—you do not necessarily have to use the Genesis partition to perform your nPartition management and configuration tasks.

Partition Numbers

Each nPartition has its own unique **partition number** that the nPartition commands and utilities use for identifying the nPartition.

When you create an nPartition, the utility you use assigns the nPartition the lowest available partition number. For example, the Genesis partition always is partition number 0 because it is the first and only nPartition in the server complex when it is created, and the second nPartition to be created is partition number 1.

After you remove an nPartition, no cells are assigned to the nPartition. As a result, the nPartition tools can assign cells to the partition number when creating a new nPartition.

For example, if you remove partition number 2, then the `parcreate` command or Partition Manager tool can assign cells to partition number 2 when creating a new nPartition, if all lower-numbered nPartitions (partition numbers 0 and 1) already are defined.

nPartition Local and Remote Access

Your access to an nPartition—whether local or remote—determines your ability to configure and manage the nPartition. Some capabilities require *local* partition access while other capabilities only require that you login to *any* of the nPartitions in the server complex, including remote partitions.

Local nPartition

When you login to HP-UX running on an nPartition, or when you access an nPartition's BCH interface or console, the nPartition you are accessing is considered to be the **local nPartition**.

5732

Remote nPartition

All nPartitions in the complex *other than the one you are accessing* are considered to be **remote nPartitions**.

You can use the `parstatus -w` command to list the partition number for the local nPartition.

```
# parstatus -w
The local partition number is 1.
# parstatus -P
[Partition]
Par                 # of  # of I/O
Num Status          Cells Chassis  Core cell  Partition Name (first 30 chars)
=== ============    ===== ======== ========== ===============================
 0  active            2       2    cab0,cell0 feshd2
 1  active            1       1    cab1,cell2 feshd5
#
```

Tools Requirements and Limits for Use in Local and Remote nPartitions

The following list describes many of the administration requirements for using HP-UX tools on a local or remote nPartition. For detailed procedures, refer to these chapters: *Booting and Resetting nPartitions* on page 197, *Managing nPartitions* on page 243, and *Listing and Managing Server Hardware* on page 305.

- **Listing Information**—You can use the `parstatus` command or the Partition Manager utility from *any* nPartition to list nPartition and complex information.
- **Adding (Assigning) a Cell** to an nPartition—You can use `parmodify` or Partition Manager from *any* nPartition to assign a cell to any nPartition in the server complex.
- **Removing (Unassigning) a Cell** from an nPartition—You can unassign an *inactive cell* from its nPartition by using `parmodify` or Partition Manager on any nPartition. However, to unassign an *active cell* you must use these tools from the *local* nPartition (the nPartition to which the cell is assigned).
- **Powering On or Off a Cell**—To power on or off a cell that is *unassigned*, you can use `frupower` or Partition Manager on any nPartition. To power on or off an *assigned cell*, the cell must be *inactive* and you must use `frupower` or Partition Manager from the *local* nPartition (the nPartition to which the cell is assigned).

- **Rebooting or Shutting Down HP-UX**—To reboot or shut down HP-UX you must issue the `/usr/sbin/shutdown` command and appropriate options (such as `-r`, `-R`, `-h`, `-R -H`, or others) from the *local* nPartition.
- **Turning Attention Indicators (LEDs) On or Off**—You can use the `fruled` command or Partition Manager to control the attention indicators for all hardware in the server complex from *any* nPartition.

nPartition Active and Inactive States

Each nPartition's boot state either is *active* or *inactive*.

Active nPartition

An nPartition that is **active** has at least one cell that is active (not in a boot-is-blocked state). When an nPartition is active, the nPartition's available cells complete partition rendezvous and then the Boot Console Handler (BCH) interface is loaded and is displayed on the nPartition's console. HP-UX is loaded and run from BCH on an active partition.

Inactive nPartition

An **inactive partition** is considered to be in the **ready for reconfig** state, because all cells assigned to the nPartition either remain at a boot-is-blocked state or are powered off.

Use the `parstatus -P` HP-UX command to list all nPartitions and their boot states (active or inactive).

```
# parstatus -P
[Partition]
Par                # of  # of I/O
Num Status         Cells Chassis  Core cell  Partition Name (first 30 chars)
=== ============ ===== ======== ========== ===============================
 0  inactive       2       1     ?          feshd5a
 1  active         2       1     cab1,cell2 feshd5b
#
```

To make an inactive partition *active*, use the service processor (GSP or MP) Command menu's `BO` command. The `BO` command clears the boot-is-blocked flag for all cells assigned to the nPartition, thus allowing the cells to rendezvous and enabling the nPartition to run the BCH interface. (If all of an nPartition's cells are powered off, you must power on its cells to enable the nPartition to become active.)

5730

To make a partition *inactive*, you can issue commands from HP-UX, the BCH interface, or the service processor (GSP or MP) Command menu.

- When HP-UX is running on an nPartition, you can make the nPartition inactive by issuing the `shutdown -R -H` command to shut down HP-UX, reboot all cells, and hold all cells at a boot-is-blocked state.
- When the BCH interface is available for an nPartition, you can make the nPartition inactive by issuing the BCH interface's `RECONFIGRESET` command. This reboots all cells assigned to the nPartition and holds all cells at a boot-is-blocked state.
- If an nPartition is active but is not responsive (that is, if you can neither login as root to issue the `shutdown -R -H` command nor access the nPartition's BCH interface from its console), then use the service processor Command menu's `RR` command to make the nPartition inactive. This reboots all cells assigned to the nPartition and holds all cells at a boot-is-blocked state.

CAUTION Issuing the service processor Command menu's `RR` command immediately halts all processing and I/O activity on the specified nPartition. Be certain to *correctly specify* which nPartition is to be reset to the ready for reconfig state.

All three methods above reboot an nPartition and hold all of its cells at boot-is-blocked; as a result the rebooted nPartition is placed in the ready for reconfig (inactive) state.

5729

Complex Profiles

Each HP nPartition server's **Complex Profile** includes the data that determine how the server's hardware is assigned to and used by nPartitions.

When you configure nPartitions and modify nPartition settings, the commands and utilities you use lock and unlock the server's Complex Profile when revising it.

The Complex Profile consists of two parts: *Stable Complex Configuration Data* (complex-wide settings) and *Partition Configuration Data* (individual nPartition settings).

You can modify nPartition configurations (and thus revise the Complex Profile) by using the server's service processor Command menu, nPartition Boot Console Handler (BCH) interfaces, or HP-UX nPartition commands and Partition Manager.

Each Complex Profile contains the following information for the server complex.

- **Stable Complex Configuration Data**

  This portion of the Complex Profile stores complex-wide information, including the following details:

  — The name of the complex

  — Which cells are assigned to which nPartitions, and which cells are unassigned (those on the free cell list, which are available to be assigned to any nPartition)

  — The model number, model string, product numbers, and the serial number for the complex

  The server complex's service processor stores the master copy of the Stable Complex Configuration Data. Each cell also stores a copy if this data.

- **Partition Configuration Data**

  This portion of the Complex Profile stores nPartition-specific information.

5728

The Partition Configuration Data includes the following details for each nPartition in the server complex:

- The nPartition's name, number, and IP address
- The PRI, HAA, and ALT boot paths and boot actions (path flags)
- The use-on-next-boot setting for each cell

  This determines whether the cell is allowed to become active and join (rendezvous) the rest of the cells in the nPartition.
- The core cell choices

  This is a list of any cells that are preferred to be selected as the nPartition's active core cell.

Each nPartition has its own Partition Configuration Data, a copy of which is stored on each cell in the nPartition. The server's service processor also stores copies of this data for all nPartitions.

The server's service processor manages all Complex Profile data and keeps all copies of the data coherent.

Complex Profile Locks

Locking and unlocking Complex Profiles is automatically managed by the commands and utilities that you use to configure and modify nPartitions. Portions of the Complex Profile data are updated when you modify nPartition configurations or server complex configurations. For more details on nPartition reconfiguration, including procedures for manually unlocking complex profiles, refer to the chapter *Managing nPartitions* on page 243.

5727
28

Tools for Managing nPartitions

You can use several different software tools to create, modify, and monitor a server's nPartitions and related server complex hardware.

These tools have capabilities that overlap in some cases, but each tool also has unique features and access requirements.

The tools for managing nPartitions are:

- Service Processor (GSP or MP) menus
- Virtual Front Panel (VFP) interfaces
- Boot Console Handler (BCH) interfaces
- HP-UX nPartition Configuration Commands
- Partition Manager (`/opt/parmgr/bin/parmgr`)
- System Administration Manager (SAM, `/usr/sbin/sam`)

NOTE

The service processor in HP servers is sometimes called the Management Processor (MP) and sometimes the Guardian Service Processor (GSP).

Regardless of the name, the service processor in these servers provides approximately the same features and performs essentially the same role.

Throughout this document, the term "service processor" refers to both the MP and GSP service processors.

Table 1-3 lists the nPartition management tools and describes each tool's features and capabilities.

Use Table 1-3 to select the most appropriate nPartition management tool based on the tasks you need to perform and the ways in which you can access the system.

Table 1-3 **Management Tools for nPartitions**

Partition Tool	Features and Restrictions
Service Processor (GSP or MP) menus	The service processor menus provide a complex-wide service interface that allows access to complex hardware and nPartitions defined within the complex. Also refer to the chapter *Using Console and Service Processor Interfaces* on page 125 for details. • Availability—Using service processor menus requires logging in to the service processor. Your service processor login account determines your level of access to the complex hardware and nPartitions. • Features—Service processor commands, access to nPartition consoles, Virtual Front Panels (VFPs) for live nPartition status details, ability to power cycle hardware, ability to reset and TOC nPartitions, ability to view live chassis codes, and access to console and chassis code log files. • Tasks Supported—Monitoring and listing status for all nPartitions and hardware within a server complex. Viewing chassis codes. nPartition console access. nPartition reset and complex hardware power control.
Virtual Front Panel (VFP) interfaces	The VFP interface provides a real-time display of nPartition and cell *boot states* and *activities*. Also refer to the chapter *Using Console and Service Processor Interfaces* on page 125 for details. • Availability—Viewing the VFP interface for an nPartition (or entire system) requires logging in to the service processor. Your service processor user account determines which nPartition VFPs you can access. • Features—Real-time text summaries of nPartition and cell boot states and activities. • Tasks Supported—Monitoring nPartition boot progress and associated cell status.

5725

Table 1-3 Management Tools for nPartitions (Continued)

Partition Tool	Features and Restrictions
Boot Console Handler (BCH) interface	The BCH interface is the method for interacting with an nPartition before it has booted HP-UX. Each nPartition's BCH interface provides menus for configuring nPartition settings and booting HP-UX. Also refer to the chapter *Using Console and Service Processor Interfaces* on page 125 for details. • Availability—Using an nPartition's BCH interface requires accessing the nPartition's console through the service processor Console menu. • Features—Allows you to select which device and which HP-UX kernel is booted, to configure the *boot actions* for devices, and to software-deallocate CPUs, memory, and cells. • Tasks Supported—Configuring and managing the HP-UX boot process, getting nPartition-specific information, resetting the local nPartition, configuring various nPartition settings.
HP-UX nPartition Configuration Commands	The HP-UX nPartition configuration commands allow you to configure, modify, and monitor nPartitions and hardware within a server complex. See the section *Using HP-UX nPartition Configuration Commands* on page 85 for details. The commands include `parcreate`, `parmodify`, `parstatus`, `parremove`, `parunlock`, `fruled`, and `frupower`. • Availability—Using the HP-UX nPartition configuration commands requires logging in to HP-UX running on an nPartition. All users can issue the `parstatus` and `fruled` commands, but all other commands require `root` user permissions. • Features—These commands allow you to manage nPartitions and hardware when HP-UX is in single– or multi-user mode and when you are logged in with text-only terminal access. • Tasks Supported—Configuring, modifying, and getting information about nPartitions and hardware within a server complex.

5924

21

Table 1-3 Management Tools for nPartitions (Continued)

Partition Tool	Features and Restrictions
Partition Manager (parmgr)	Partition Manager (/opt/parmgr/bin/parmgr) provides a graphical interface for configuring, modifying, and managing nPartitions and hardware within a server complex. See the section *Using the Partition Manager Utility* on page 106 for details. • Availability—You can use Partition Manager when HP-UX is running in multi-user mode on the nPartition. You can use Partition Manager as a stand-alone X window application (parmgr) and can launch it from SAM. Partition Manager also can be launched from a PC Web browser. • Features—Provides a graphical user interface and also supports Web console access. Performs additional error checking beyond what the HP-UX nPartition configuration commands support. Also supports I/O card online addition and replacement. • Tasks Supported—Configuring, modifying, and getting information about nPartitions and hardware within a hard-partitionable server complex. • Detailed Information—See the parmgr online help.
System Administration Manager (SAM)	When using SAM (/usr/sbin/sam) in graphical mode, you can launch Partition Manager from SAM. See Partition Manager, above, for details.

523

HP-UX 11i Release Features

The *HP-UX 11i June 2003 Release Notes* lists the latest feature additions and changes to HP-UX operating system and the various “operating environment” bundles.

Each of the HP-UX operating environment bundles includes its own collection of applications. You can install any *one* of the operating environments at a time.

Use the **`swlist -l bundle`** command to list all installed software bundles, including operating environments.

The *Read Before Installing or Updating HP-UX 11i, June 2003* booklet, which is distributed with HP-UX media, also has current details on release and operating environment features.

The release notes and “Read Before” booklet also are available on the **`http://docs.hp.com/`** Web site.

The HP-UX 11i operating environments are described in the following list.

- HP-UX 11i Operating Environment

  This is an integrated and tested software solution for servers. It contains the base HP-UX 11i operating system and selected drivers and applications.

- HP-UX 11i Enterprise Operating Environment

  This is an operating environment marketed and supported only for commercial servers. It contains everything in the basic HP-UX 11i Operating Environment plus additional applications.

- HP-UX 11i Mission Critical Operating Environment

  This is an operating environment marketed and supported only for commercial servers. It contains everything in the HP-UX 11i Enterprise Operating Environment plus additional applications.

- HP-UX 11i Technical Computing Environment

  This is an operating environment marketed and supported for technical computing servers and workstations. It contains the base HP-UX 11i operating system and selected drivers and applications.

5322

- HP-UX 11i Minimal Technical Operating

  This is an operating environment defined for HP workstations. It contains all the base functionality. However, compared to the Technical Computing Operating Environment, the set of additional applications is greatly reduced.

HP-UX Hardware Paths for nPartitions

The HP-UX hardware path for nPartition systems is provided in the format described here.

The `/usr/sbin/ioscan` HP-UX command reports the hardware path for active components within the nPartition in which the command is issued.

You also can use the `/usr/bin/rad -q` command to list details about active I/O slots and cards in the local nPartition.

NOTE The `ioscan` and `rad` commands only report information about the *currently active* hardware components *in the local partition.*

These commands do not report details for hardware that is not assigned to the local nPartition or hardware that is inactive in the nPartition.

Hardware Paths in nPartitions

The components of nPartition hardware paths are:

`a/b/c/d/e.f.g`

where these components are as described in the following list.

- `a`

  Is the global cell number.

- `b`

  Is a processor (10–13), memory (5), or a system bus adapter (0). Each I/O chassis has a single system bus adapter.

- `c`

  Is a local bus adapter (the *LBA*, one for each PCI card slot in the chassis). The LBA connects its corresponding PCI card slot with the system bus adapter.

NOTE The LBA number *is not necessarily the same* as the PCI slot number.

S720

Use the rad -q command to list all active PCI slots in an nPartition along with their corresponding hardware paths. See *PCI Card Slot and Hardware Path Numbering* on page 79.

- d

  Is the card's address on the slot's PCI bus.

  Typically this is 0 (zero), although the core I/O card has multiple devices and addresses in a single card.

- e

  Is the function for the I/O card. Typically this is 0 (zero) for single-function cards.

- f

  Is the target of the I/O device, or SCSI ID.

- g

  Is a device-specific address such as a SCSI controller (initiator).

See the *ioscan* (1M) manpage for details on using ioscan to list hardware path information.

Example 1-1 **ioscan Output for a One-Cell HP Superdome nPartition**

The following example shows ioscan output for a one-cell nPartition.

In this example, the hardware path for the cell is 12, indicating that the cell is in slot 4 in cabinet 1. See *Specifying Cells and I/O Chassis to Commands* on page 87 for details about cell path formats.

```
# ioscan
H/W Path          Class                        Description
=======================================================
                  root
12                cell
12/0                  ioa                      System Bus Adapter (804)
12/0/0                   ba                    Local PCI Bus Adapter (782)
12/0/0/0/0                     tty             PCI Serial (103c1048)
12/0/0/1/0                     lan             HP PCI 10/100Base-TX Core
12/0/1                   ba                    Local PCI Bus Adapter (782)
12/0/2                   ba                    Local PCI Bus Adapter (782)
12/0/3                   ba                    Local PCI Bus Adapter (782)
12/0/4                   ba                    Local PCI Bus Adapter (782)
```

```
12/0/6                 ba                    Local PCI Bus Adapter (782)
12/0/6/0/0                   ext_bus         SCSI C87x Ultra Wide Differential
12/0/6/0/0.5                    target
12/0/6/0/0.5.0                     disk      SEAGATE ST39173WC
12/0/6/0/0.6                    target
12/0/6/0/0.6.0                     disk      SEAGATE ST39173WC
12/0/6/0/0.7                    target
12/0/6/0/0.7.0                     ctl       Initiator
12/0/8                 ba                    Local PCI Bus Adapter (782)
12/0/9                 ba                    Local PCI Bus Adapter (782)
12/0/10                ba                    Local PCI Bus Adapter (782)
12/0/11                ba                    Local PCI Bus Adapter (782)
12/0/12                ba                    Local PCI Bus Adapter (782)
12/0/14                ba                    Local PCI Bus Adapter (782)
12/5                memory                   Memory
12/10               processor                Processor
12/11               processor                Processor
12/12               processor                Processor
12/13               processor                Processor
#
```

PCI Card Slot and Hardware Path Numbering

On nPartition servers, the PCI card slot numbers (within an I/O chassis) are not necessarily the same as their *local bus adapter* (LBA) number, such as is reported by the `ioscan` or `rad` HP-UX commands.

Table 1-4 shows the correlations among PCI slots and their LBA numbers.

Table 1-4 I/O Numbering: PCI slots and Busses (LBAs)

PCI Card Slot	HP Superdome LBA Number	HP rp8400 and HP rp7405/rp7410 LBA Number
0	0	0
1	1	8
2	2	10
3	3	12
4	4	14
5	6	6
6	14	4
7	12	2
8	11	1
9	10	—
10	9	—
11	8	—

The **`rad -q`** command lists each active PCI slot, its associated HP-UX hardware path, and other slot details.

The **`ioscan -C ba`** command lists the active PCI slots ("Local PCI Bus Adapter") for your nPartition.

The order in which `ioscan` reports the PCI slots (in LBA number order) *does not* correspond to the order in which the slots physically are arranged (PCI card slot order, left-to-right or right-to-left).

5716
21

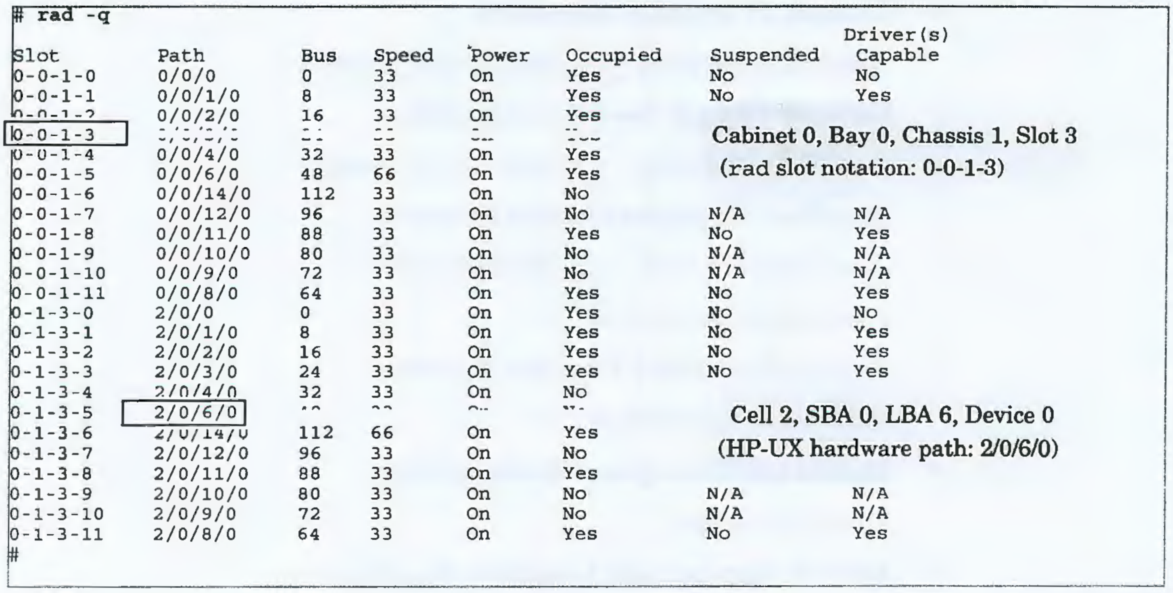
rad Command Output in nPartitions

This section covers the rad command's output on nPartitions. For complete details, see the *rad* (1M) manpage.

NOTE When adding or replacing I/O cards, use the SAM (/usr/sbin/sam) procedures when possible rather than equivalent rad command procedures.

See also the *sam* (1M) and *rad* (1M) manpages.

On HP nPartition servers, the rad command reports PCI card slot details as shown in the following example output. The rad command reports each available PCI slot (*cabinet-bay-chassis-slot*), its corresponding HP-UX hardware path (*cell/sba/lba/device*), and more details.



```
# rad -q
                                                                   Driver(s)
Slot        Path        Bus    Speed   Power   Occupied   Suspended   Capable
0-0-1-0     0/0/0       0      33      On      Yes        No          No
0-0-1-1     0/0/1/0     8      33      On      Yes        No          Yes
0-0-1-2     0/0/2/0     16     33      On      Yes
0-0-1-3     0/0/3/0     24     33      On      Yes
0-0-1-4     0/0/4/0     32     33      On      Yes
0-0-1-5     0/0/6/0     48     66      On      Yes
0-0-1-6     0/0/14/0    112    33      On      No
0-0-1-7     0/0/12/0    96     33      On      No         N/A         N/A
0-0-1-8     0/0/11/0    88     33      On      Yes        No          Yes
0-0-1-9     0/0/10/0    80     33      On      No         N/A         N/A
0-0-1-10    0/0/9/0     72     33      On      No         N/A         N/A
0-0-1-11    0/0/8/0     64     33      On      Yes        No          Yes
0-1-3-0     2/0/0       0      33      On      Yes        No          No
0-1-3-1     2/0/1/0     8      33      On      Yes        No          Yes
0-1-3-2     2/0/2/0     16     33      On      Yes        No          Yes
0-1-3-3     2/0/3/0     24     33      On      Yes        No          Yes
0-1-3-4     2/0/4/0     32     33      On      No
0-1-3-5     2/0/6/0     48     33      On      No
0-1-3-6     2/0/14/0    112    66      On      Yes
0-1-3-7     2/0/12/0    96     33      On      No
0-1-3-8     2/0/11/0    88     33      On      Yes
0-1-3-9     2/0/10/0    80     33      On      No         N/A         N/A
0-1-3-10    2/0/9/0     72     33      On      No         N/A         N/A
0-1-3-11    2/0/8/0     64     33      On      Yes        No          Yes
#
```

Cabinet 0, Bay 0, Chassis 1, Slot 3
(rad slot notation: 0-0-1-3)

Cell 2, SBA 0, LBA 6, Device 0
(HP-UX hardware path: 2/0/6/0)

The rad command only lists slots in PCI chassis that are assigned to the local nPartition and are active.

Licensing Information: Getting Product Details

When you license a software product to run on an HP system, you may need to provide machine or system details to the software vendor as part of the software registration process.

This section describes how to obtain information you may need when licensing non-HP software to run on an HP nPartition server.

For complete information about software product licensing, refer to the company that manufactures or sells the software you plan to use.

To license software for use on HP-UX running on an nPartition, you may need to provide the following details about the nPartition or its server complex:

- **Unique Machine (Complex) Identifier**

  `/usr/bin/getconf _CS_MACHINE_IDENT`

- **Unique nPartition Identifier**

  `/usr/bin/getconf _CS_PARTITION_IDENT`

- **Unique Virtual Partition Identifier**

  `/usr/bin/getconf _CS_PARTITION_IDENT`

- **Machine (Complex) Serial Number**

  `/usr/bin/getconf _CS_MACHINE_SERIAL`

  `/usr/sbin/parstatus -X`

- **Server (Complex) Product Number**

  `/usr/sbin/parstatus -X`

- **Hardware (Complex) Model String**

  `/usr/bin/model`

- **HP-UX Version and Installed Bundles**

  For the HP-UX version: `/usr/bin/uname -r`

  For all bundles installed: `/usr/sbin/swlist -l bundle`

5714

nPartition and Virtual Partition Unique Identifiers

NOTE Use the getconf command or the confstr() call to obtain unique identifiers. Do not use the uname -i command, which *does not report unique IDs* for nPartition systems.

In order to guarantee compatibility on current and future platforms, use the interfaces to *getconf* (1) and *confstr* (3C) to retrieve unique machine identifiers.

The interfaces include the _CS_PARTITION_IDENT and _CS_MACHINE_IDENT parameters:

- For a *nPartition-specific* or a *virtual partition-specific* unique ID use this command:

  /usr/bin/getconf _CS_PARTITION_IDENT

  The unique partition identifier value for a virtual partition environment has virtual partition-specific data added that does not appear for an equivalent non-vPars environment. See the examples that follow.

- For a *complex-specific* unique ID use this command:

  /usr/bin/getconf _CS_MACHINE_IDENT

On HP PA-RISC nPartition servers, the complex, nPartition, and virtual partition unique IDs are based in part on the machine serial number.

To retrieve the machine serial through these interfaces, specify the _CS_MACHINE_SERIAL parameter to them.

See the *confstr* (3C) manpage for details on these parameters and their use.

Example 1-2 **Unique IDs for an nPartition and Complex**

The following examples show nPartition-unique and complex-unique IDs returned by the getconf command, as well as the local nPartition number and machine serial number.

```
# parstatus -w
The local partition number is 1.
# /usr/bin/getconf _CS_PARTITION_IDENT
Z3e02955673f9f7c9_P1
```

```
# /usr/bin/getconf _CS_MACHINE_IDENT
Z3e02955673f9f7c9
# /usr/bin/getconf _CS_MACHINE_SERIAL
USR2024FP1
#
```

Example 1-3 Unique IDs for Virtual Partitions (vPars)

The following example shows the virtual partition-unique ID returned by the getconf command, as well as the local nPartition number and the current virtual partition's name.

```
# parstatus -w
The local partition number is 0.
# vparstatus -w
The current virtual partition is Shad.
# getconf _CS_PARTITION_IDENT
Z3e0ec8e078cd3c7b_P0_V00
#
```

For details on virtual partitions, refer to the chapter *Virtual Partitions (vPars) Management on nPartitions* on page 441.

5312

Using HP-UX nPartition Configuration Commands

HP-UX 11i provides you with several HP-UX commands for configuring and managing nPartitions and related server hardware.

The nPartition commands include: `parcreate`, `parmodify`, `parremove`, `parstatus`, `parunlock`, `fruled`, and `frupower`. Table 1-5 on page 86 describes each of these commands.

Using these commands you can create, modify, monitor, and remove nPartitions; get detailed server hardware information; and manipulate attention indicators (LEDs) and power.

When using these commands, you can specify cells and I/O chassis with the notations shown in *Specifying Cells and I/O Chassis to Commands* on page 87.

NOTE

The HP-UX nPartition configuration commands are supported only on HP servers that support nPartitions.

These commands are supported by HP-UX kernels built with nPartition support enabled (the `hd_fabric` driver), and they use the libfab.1 library.

Table 1-5 describes the nPartition configuration commands and lists sections where you can find each command's syntax and details.

Table 1-5 HP-UX nPartition Configuration Commands

Command	Description
`parcreate`	Create a new nPartition; `root` permission is required. See *parcreate Command* on page 93.
`parmodify`	Modify an existing nPartition; `root` permission is required. See *parmodify Command* on page 95.
`parremove`	Remove an existing nPartition; `root` permission is required. See *parremove Command* on page 98.
`parstatus`	Display nPartition information and hardware details for a server complex. See *parstatus Command* on page 99.
`parunlock`	Unlock Complex Profile data (use this command with caution); `root` permission is required. See *parunlock Command* on page 101.
`fruled`	Blink the attention indicators (LEDs) or turn them off. This command can control these indicators for cells, I/O chassis, and cabinet numbers. See *fruled Command* on page 102.
`frupower`	Display status or turn power on or off for cells and I/O chassis; `root` permission is required. See *frupower Command* on page 104.

5710

Specifying Cells and I/O Chassis to Commands

Use the cell and I/O chassis notation described in this section when you manage, configure, and inquire about cells and I/O chassis using the HP-UX nPartition configuration commands.

Details are in the *Cell Specification Formats* and *I/O Specification Format* sections that follow.

Cell Specification Formats

Use either of the following two formats to specify cells when using the HP-UX nPartition configuration commands: *Global Cell Number Format* or *Cell Hardware Location Format*.

- **Global Cell Number Format**

  The global cell number format is identical to the cells' HP-UX hardware path, as reported by `ioscan`. In global format, each cell is given a single unique number that indicates the cell's relative location in the entire server complex.

Table 1-6 Cell IDs in Global Cell Number Format

Cell Slot	0	1	2	3	4	5	6	7
rp7405/rp7410 Global Format	0	1	—	—	—	—	—	—
rp8400 Global Format	0	1	2	3	—	—	—	—
Superdome Cabinet 0 Global Format	0	1	2	3	4	5	6	7
Superdome Cabinet 1 Global Format	8	9	10	11	12	13	14	15

- **Cell Hardware Location Format**

  In cell hardware location format, each cell is identified using two numbers that specify the *cabinet* and the *cell slot with the cabinet* where the cell resides: *cabinet/slot*.

Table 1-7 Cell IDs in Hardware Location Format

Cell Slot	0	1	2	3	4	5	6	7
rp7405/rp7410 HW Loc Format	0/0	0/1	—	—	—	—	—	—
rp8400 HW Loc Format	0/0	0/1	0/2	0/3	—	—	—	—
Superdome Cabinet 0 HW Loc Format	0/0	0/1	0/2	0/3	0/4	0/5	0/6	0/7
Superdome Cabinet 1 HW Loc Format	1/0	1/1	1/2	1/3	1/4	1/5	1/6	1/7

Both of these cell ID formats specify each cell's precise physical location in a server complex. For example, `parstatus -c9` and `parstatus -c1/1` specify the same cell.

```
# parstatus -c9
[Cell]
                        CPU     Memory                                Use
                        OK/     (GB)                          Core    On
Hardware   Actual       Deconf/ OK/                           Cell    Next Par
Location   Usage        Max     Deconf    Connected To        Capable Boot Num
========== ============ ======= ========= =================== ======= ==== ===
cab1,cell1 active base  4/0/4    8.2/ 0.0 -                   no      yes  1

# parstatus -c1/1
[Cell]
                        CPU     Memory                                Use
                        OK/     (GB)                          Core    On
Hardware   Actual       Deconf/ OK/                           Cell    Next Par
Location   Usage        Max     Deconf    Connected To        Capable Boot Num
========== ============ ======= ========= =================== ======= ==== ===
cab1,cell1 active base  4/0/4    8.2/ 0.0 -                   no      yes  1

#
```

I/O Specification Format

Use the following I/O hardware location format when specifying an I/O chassis to the HP-UX nPartition configuration commands:

cabinet/*bay*/*chassis*

The *cabinet*, *bay*, and *chassis* fields specify the physical location of the I/O chassis. The values of these fields are as follows.

- *cabinet*

  specifies the cabinet number where the I/O chassis resides.

  On HP rp7405/rp7410 and rp8400 servers, the cabinet number always is `0`.

  On HP Superdome servers, the cabinet number can be:

  — `0` — the left Compute cabinet.

  — `1` — the right Compute cabinet, if present.

  — `8` — an I/O Expansion cabinet, if present.

  — `9` — an I/O Expansion cabinet, if present.

- *bay*

  specifies the I/O bay (within a cabinet) where the I/O chassis resides.

  On HP rp8400 and HP rp7405/rp7410 servers, the bay number always is `0`.

  On HP Superdome servers, the bay number can be:

  — `0` — the *front* bay of a Compute cabinet, or the *bottom* bay of an I/O Expansion cabinet.

  — `1` — the *rear* bay of a Compute cabinet, or the *middle* bay of an I/O Expansion cabinet.

  — `2` — the *top* bay in an I/O Expansion cabinet.

- *chassis*

  specifies the I/O chassis (within a bay).

  On HP rp8400 and HP rp7405/rp7410 servers, the chassis number is:

  — `0` — Chassis 0, which connects to cell 0 and is the left chassis as *viewed from the cabinet rear*: the left eight PCI card slots.

- 1 — Chassis 1, which connects to cell 1 and is the right chassis as *viewed from the cabinet rear*: the right eight PCI card slots.

On HP Superdome servers, the chassis number is:

- 1 — Chassis 1, the left chassis in the bay, as viewed when facing the bay/chassis.
- 3 — Chassis 3, the right chassis in the bay, as viewed when facing the bay/chassis.

In HP Superdome servers all chassis are 12-slot I/O chassis, both in Compute cabinets and in I/O Expansion cabinets.

The example below shows the `parstatus` command listing details about two different I/O chassis (cabinet 0/bay 0/chassis 1, and cabinet 0/bay 1/chassis 3).

```
# parstatus -i0/0/1
[Chassis]
                                        Core Connected  Par
Hardware Location   Usage               IO   To         Num
=================== ============ ==== ========== ===
cab0,bay0,chassis1  absent              -    -          -

# parstatus -i0/1/3
[Chassis]
                                        Core Connected  Par
Hardware Location   Usage               IO   To         Num
=================== ============ ==== ========== ===
cab0,bay1,chassis3  active              yes  cab0,cell0 0

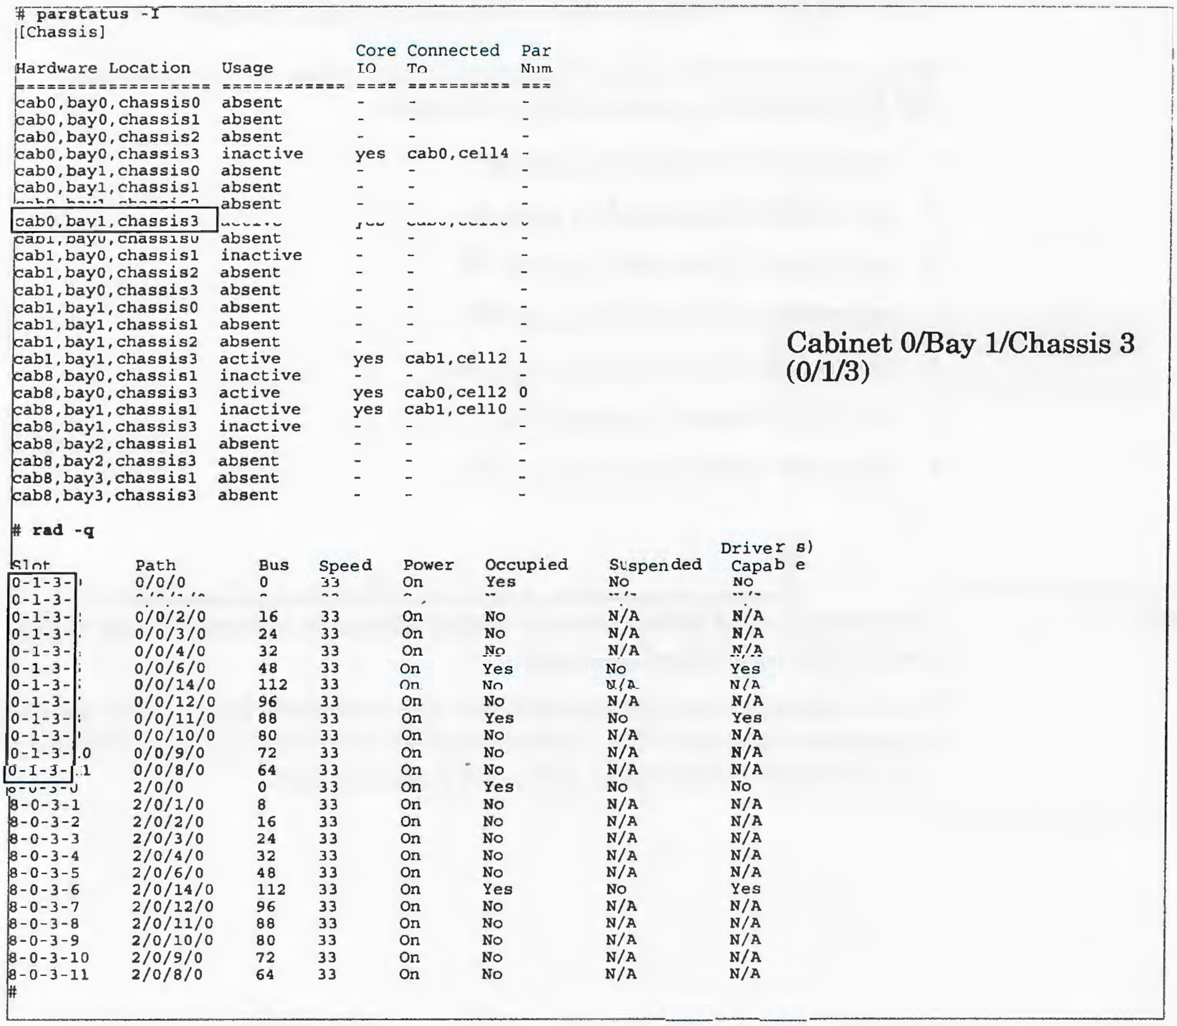
#
```

Use the `parstatus -I` command to list all I/O chassis within a server complex, regardless of the chassis cell connections and nPartition assignments.

Use the `rad -q` command to list the *currently available* PCI I/O slots in the local nPartition and their status.

In the following example, both the `parstatus` and `rad` commands show details for various chassis and slots, including chassis 0/1/3.

S706
21



```
# parstatus -I
[Chassis]
                                   Core Connected  Par

nPartition Commands—Details and Syntax

This section has details and command-line syntax for the following HP-UX nPartition configuration commands:

- *parcreate Command* on page 93
- *parmodify Command* on page 95
- *parremove Command* on page 98
- *parstatus Command* on page 99
- *parunlock Command* on page 101
- *fruled Command* on page 102
- *frupower Command* on page 104

NOTE

The sections that follow provide useful reference information for using the HP-UX nPartition commands.

For the most current information for these commands, see their online manpages: *parcreate* (1M), *parmodify* (1M), *parremove* (1M), *parstatus* (1), *parunlock* (1M), *fruled* (1M), and *frupower* (1M).

S7004

parcreate Command

The /usr/sbin/parcreate command creates a new nPartition.

This command assigns the specified cells (and any attached I/O chassis) to an nPartition after removing the cells from the free cell list. This command assigns a number to the new nPartition and returns the partition number of the newly created nPartition.

Root permission is required to use parcreate.

See the *parcreate* (1M) manpage for complete details. Also refer to the section *Creating a New nPartition* on page 260 for procedures and examples.

Synopsis

```
parcreate [-P PartitionName] [-I IPaddress]
-c cell:[cell_type]:[use_on_next_boot]:[failure_usage]
[-c...]
[-b path] [-t path] [-s path] [-r cell] [-r...] [-B] [-k
s_lock]
```

Options

-P *PartitionName*

Specifies the name of the new nPartition.

-I *IPaddress*

Specifies the IP address that should be used by management tools (like SAM) to address this nPartition.

-c *cell*:[*cell_type*]:[*use_on_next_boot*]:[*failure_usage*]

Specifies the cell(s) to be assigned to the nPartition.

- The only valid *cell_type* value is:

base	Base cell (the default).

- The valid *use_on_next_boot* values for cells are:

y	Participate in reboot. (The default.)
n	Do not participate in reboot.

- The only valid *failure_usage* value is:

ri	Reactivate with interleave (the default).

5703

`-b` *path* Specifies the primary (PRI) boot path.

`-t` *path* Specifies the alternate (ALT) boot path.

`-s` *path* Specifies the secondary (HAA) boot path.

`-r` *cell* Specifies the core cell choices. One to four cells can be specified.

`-B` Specifies to boot the nPartition. The default is not to boot the nPartition and leave it in the ready for reconfig state.

S702

parmodify Command

You can use the /usr/sbin/parmodify command to modify the following attributes of an existing nPartition:

Partition name
Cell assignments (add cells or remove cells)
Attributes of existing cells (such as the use-on-next-boot value)
Core cell and core alternate cells
Boot paths (the primary, alternate, and HA alternate paths)

Root permission is required to use this command.

See the *parmodify* (1M) manpage for complete details. Also refer to the chapter *Managing nPartitions* on page 243 for procedures and examples.

Synopsis

```
parmodify -p PartitionNumber
-a cell:[cell_type]:[use_on_next_boot]:[failure_usage]
[-a...] |
-m cell:[cell_type]:[use_on_next_boot]:[failure_usage]
[-m...] | -I IPaddress | -r cell [-r...] | -d cell [-d...] |
-b path | -t path | -s path | -P PartitionName | -B | -k
s_lock:p_lock
```

The -p option is required.

Options

The parmodify command supports the following command-line options.

-p *PartitionNumber*

Specifies the nPartition to be modified. *PartitionNumber* specifies the unique number (integer) assigned to the nPartition. The -p option is required.

Note that you must also to specify any one or more of the following options.

-a *cell*:[*cell_type*]:[*use_on_next_boot*]:[*failure_usage*]

Specifies the cell(s) to be added to the nPartition.

- The valid *cell_type* value is:

base	Base cell. (The default.)

- The valid *use_on_next_boot* values for cells are:

y	Participate in reboot. (The default.)

`n` Do not participate in reboot.

- The only valid *`failure_usage`* value is:

  `ri` Reactivate with interleave (the default).

`-m` *`cell`*`:[`*`cell_type`*`]:[`*`use_on_next_boot`*`]:[`*`failure_usage`*`]`

Modify attributes of a cell already assigned the nPartition.

For details on *`cell_type`*, *`use_on_next_boot`*, and *`failure_usage`* see the `-a` option's descriptions (above).

`-I` *`IPaddress`*

Specifies the IP address that should be used by management tools (like SAM) to address this nPartition.

`-r` *`cell`*

Specifies the core cell and core alternate cells. One to four core cell choices can be specified.

`-d` *`cell`*

Remove the specified cell from the nPartition.

`-b` *`path`*

Specifies the primary (PRI) boot path.

`-t` *`path`*

Specifies the alternate (ALT) boot path.

`-s` *`path`*

Specifies the secondary (HAA) boot path.

`-P` *`PartitionName`*

Specifies the name of the nPartition.

`-B` Specifies whether to boot the nPartition. The default is not to boot.

When you modify an *inactive* nPartition and specify the `-B` option, the nPartition is booted (and becomes active) immediately after it is modified.

S700
20

When you modifying an *active* nPartition and specify the -B option, you must perform a reboot for reconfig of the modified nPartition. You must perform this reboot for reconfig before any other cell assignments can take place in the server complex.

3699

parremove Command

The /usr/sbin/parremove command removes an existing nPartition. This removes all cells from the nPartition and destroys the nPartition definition.

To remove the *local* nPartition (the nPartition from which you issue this command), you must specify the -F option.

To remove a *remote* nPartition, the remote nPartition must be inactive: it must be shut down to the ready for reconfig state or the parremove command will not be able to remove the nPartition.

Root permission is required to run this command.

See the *parremove* (1M) manpage for complete details. Also refer to the section *Removing (Deleting) an nPartition* on page 278 for procedures and examples.

Synopsis

```
parremove -p PartitionNumber [-F]
```

Options

-p *PartitionNumber*

Specifies the nPartition number to be removed.

-F

Forcibly remove the nPartition. If the nPartition is inactive, the nPartition is removed. If the nPartition is active and if it is the local nPartition, the nPartition is removed.

If the nPartition is active but is not the local nPartition, then the nPartition *will not* be removed.

5698

parstatus Command

The /usr/sbin/parstatus command displays information about the nPartitions or hardware within a server complex. If you specify no arguments, parstatus lists information about several of the major components of the server complex.

You can specify an individual entity (cell, I/O chassis, cabinet, or nPartition) to restrict the output to information about that component.

All users can issue this command.

See the *parstatus* (1) manpage for complete details. Also refer to the chapters *Managing nPartitions* on page 243 and *Listing and Managing Server Hardware* on page 305 for procedures and examples.

Synopsis

```
parstatus -s
parstatus -w
parstatus [-X]
parstatus [-A] [-M] -C|-I
parstatus [-M] -B|-P
parstatus [-M] -i IOchassis [-i...]
parstatus [-V|-M] -c cell [-c...]
parstatus [-V|-M] -b cabinet [-b...]
parstatus [-V|-M] -p PartitionNumber [-p...]
```

Options

`-s` Indicate (through parstatus exit status) whether the system is an HP server that supports nPartitions.

`-w` Display the nPartition number for the local nPartition.

`-X` Display the server complex's attributes.

`-A` Only display the available resources in the complex.

`-V` Increase the amount of information displayed.

`-M` Produce output suitable for machine parsing.

`-C` Show information for all the cells in the complex.

`-I` Show information for all I/O chassis in the complex.

`-B` Show information for all cabinets in the complex.

`-P` Show information for all nPartitions in the complex.

`-c` *`cell`*

Show information about the specified cell.

`-i` *`IOchassis`*

Show information about the specified I/O chassis.

`-b` *`cabinet`*

Show information about the specified cabinet.

`-p` *`partition`*

Show information about the specified nPartition.

5696
21

parunlock Command

The /usr/sbin/parunlock command unlocks the Stable Complex Configuration Data or Partition Configuration Data.

Use this command with caution.

Root permission is required to run this command.

See the *parunlock* (1M) manpage for details. Also refer to the section *Unlocking Complex Profiles* on page 303.

Synopsis

```
parunlock [-p PartitionNumber] [-s]

parunlock -A
```

Options

-p *PartitionNumber*

Unlock the Partition Configuration Data of the specified nPartition.

-s — Unlock the Stable Complex Configuration Data.

-A — Unlock the Stable Complex Configuration Data and the Partition Configuration Data of all the nPartitions in the complex.

5695

fruled Command

The /usr/sbin/fruled command *blinks* hardware attention indicators (LEDs) or *turns them off*.

This command can control the cell attention LEDs in all HP nPartition servers, as well as the I/O chassis LEDs on Superdome servers. The fruled command also can *start and stop blinking* the cabinet number LCDs on HP Superdome compute cabinets and I/O expansion cabinets.

See the *fruled* (1) manpage for details. Also refer to the section *Turning Attention Indicators (LEDs) On and Off* on page 323 for procedures and examples.

Synopsis

```
fruled [-f|-o] [-B] -c cell [-c...]
fruled [-f|-o] [-B] -i IOchassis [-i...]
fruled [-f|-o] -b cabinet [-b...]
fruled [-f] -C [-l cabinet] [-l...]
fruled [-f] -I [-l cabinet] [-l...]
```

Options

-f
: Turn off specified attention LED(s). This is the default.

The -f and -o options are mutually exclusive.

-o
: Start blinking the specified attention LED(s). The -o option is unavailable with -C or -I.

-B
: Start or stop blinking the cabinet number LCD of the cabinet that contains the cell or I/O chassis.

The -B option is only available with -c and -i.

-c *cell*

Blink or turn off the specified *cell* attention LED.

cell can be specified either in the local (*cabinet/slot*) or global (*cell_ID*) format.

-i *IOchassis*

Blink or turn off the specified *IOchassis* attention LED.

-b *cabinet*

5694

Start or stop blinking the cabinet number LCD of the specified *cabinet*.

`-C` Turn off all cell attention LEDs.

`-l` *cabinet*

Limit the scope of the `-C` or `-I` option to a given *cabinet*.

5693
28

frupower Command

The /usr/sbin/frupower command turns on, turns off, or displays the current status of power for cells and I/O chassis in nPartition servers.

NOTE

The frupower command (and Partition Manager) permits you to power on or off *inactive* cells and I/O chassis that are assigned to the current nPartition or are not assigned to any nPartition.

See the *frupower* (1M) manpage for details. Also refer to the section *Powering Cells and I/O Chassis On and Off* on page 312 for procedures and examples.

Syntax

```
frupower [ -d | -o | -f ] -c cell [-c...]

frupower [ -d | -o | -f ] -i IOchassis [-i...]

frupower [-d] -C [-l cabinet] [-l...]

frupower [-d] -I [-l cabinet] [-l...]
```

Options

`-d` Display power status of the specified cells or I/O chassis. This is the default.

`-o` Power on the specified cells or I/O chassis.

The -o and -f options are mutually exclusive. The -o and -f options are unavailable with -C and -I.

`-f` Power off the specified cells or I/O chassis.

`-c cell`

The specified *cell* is powered on/off or the power status is displayed.

A *cell* can be specified either in the local (*cabinet/slot*) or global (*cell_ID*) format.

`-i IOchassis`

The specified *IOchassis* is powered on/off or the power status is displayed.

`-C` Display power status of all cells. By default the scope is the entire complex if the -l option is not specified.

5692

-I — Display power status of all I/O chassis. The scope is the entire complex if the -l option is not specified.

-l *cabinet* — Limit the scope of the -C or -I option to the specified *cabinet*.

S691

Using the Partition Manager Utility

The Partition Manager utility (/opt/parmgr/bin/parmgr) provides a graphical user interface for configuring nPartitions and managing resources within a server complex.

This section introduces these topics about Partition Manager: *Partition Manager Primary Window*, *Running Partition Manager*, *Requirements and Limits*, and *Partition Manager Online Help*.

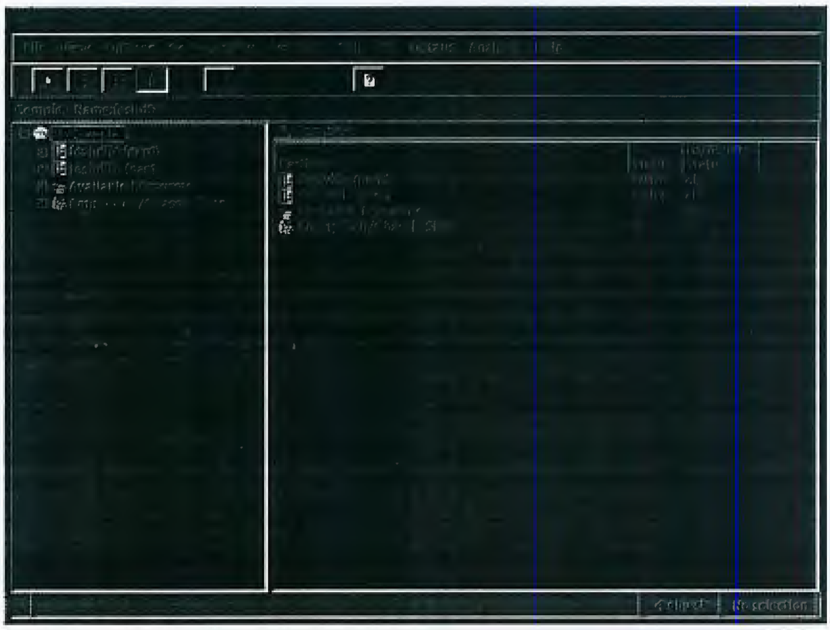
Complete information is in the online help.

Partition Manager Primary Window

The Partition Manager primary window (shown below in Figure 1-15) is the utility's main window for selecting cells, nPartitions, and tasks (menu items).

When you run Partition Manager, by default the program performs an Analyze Complex Health task. If any problems are found, a window reporting those problems is displayed. The primary window is the first window displayed after any complex health analysis results.

Figure 1-15 **Partition Manager Primary Window**



S690
21

The left side of the primary window lists all nPartitions, available resources (installed hardware that is not assigned to an nPartition), and empty cell and I/O chassis slots. Selecting an item on the left side of the primary window displays its details on the primary window's right side.

Running Partition Manager

You can access Partition Manager using any one of the following methods.

- Run Partition Manager directly from the HP-UX command line by issuing this command: `/opt/parmgr/bin/parmgr`

  Command-line options are listed in the *parmgr* (1M) manpage.

- Run SAM (`/usr/sbin/sam`) in graphical mode and select **Partition Manager** to launch Partition Manager.

- Access Partition Manager through a PC Web browser.

  Web access requires that an Apache Web server be installed, configured, and activated on the nPartition where you will run Partition Manager. See the online help's **Starting and Exiting** section for Web configuration details.

When running Partition Manager directly or when launching it from SAM, you must set and export the nPartition system's DISPLAY environment variable. The DISPLAY variable specifies where (which X server) the system displays X windows. You also must use the `xhost` command on the X server to grant access for the nPartition system to display windows on the X server.

See the example below and the *X* (1) and *xhost* (1) manpages for details.

nPartition System

```
# hostname
feshd5a
# export DISPLAY=razmataz:0
# printenv DISPLAY
razmataz:0
#
```

X Server

```
$ hostname
razmataz
$ xhost + feshd5a
feshd5a being added to access control list
$
```

S689

Requirements and Limits

The following are requirements and limits of Partition Manager.

See the *parmgr* (1M) manpage for other requirements.

- Partition Manager provides graphical interfaces only, and does not provide a terminal (text mode) interface.
- Using Partition Manager requires `root` permission.
- HP-UX must be running in multi-user mode to support Partition Manager.
- You can run only one instance of Partition Manager or SAM (`/usr/sbin/sam`) per user login session. To run multiple instances of Partition Manger, you must login separately to launch each.

  Both Partition Manager and SAM use the same lock file (/var/sam/lock/lock_console) to ensure that no more than one instance of either application runs at a time per user login session.
- Partition Manager uses the same driver and library as the HP-UX nPartition commands (the hd_fabric driver and libfab.1 library).
- Partition Manager also provides PCI online card add and replace functionality similar to SAM's, and uses the libolrad.1 library for this functionality.

Partition Manager Online Help

The Partition Manager online help gives complete details on using the Partition Manager utility.

Select the **Help —> Overview** menu item for an online overview.

You also can view Partition Manager help from a Web browser by issuing the following command:

```
/opt/netscape/netscape file:/opt/webadmin/parmgr/help/C/assistance.html
```

Web Site for Partition Manager Information: http://www.software.hp.com/products/PARMGR/info.html

You can find online information about Partition Manager, including manpages, help files, and an interactive demonstration version of Partition Manager, at the `http://www.software.hp.com/products/PARMGR/info.html` Web site.

2 Planning nPartition Configurations

This chapter describes how you can plan nPartition configurations for HP rp7405/rp7410, rp8400, and Superdome servers. Details include the configuration requirements for nPartitions and HP recommendations.

For related procedures to manage nPartitions, refer to the chapter *Managing nPartitions* on page 243.

Also, for an introduction to nPartition features, refer to the chapter *nPartition System Overviews* on page 31.

S687

nPartition Requirements and Recommendations

The hardware *requirements* shown below determine which cells are eligible to be assigned to an nPartition.

Also consider the nPartition *recommendations*, which can improve an nPartition's performance and availability.

Configuration Requirements for nPartitions

Every nPartition you configure must meet the following hardware requirements.

- ☐ All cells in an nPartition **must** have the same *processor revision level and clock speed*. That is, the IODC_HVERSION must be identical for all processors.
- ☐ The same firmware revision **must** be present on all cells within an nPartition.
- ☐ At least one cell in every nPartition **must** be connected to an I/O chassis that has core I/O.

  Only one core I/O is active per nPartition. If an nPartition has multiple cells that are connected to I/O chassis with core I/O, only the core I/O connected to the *active core cell* is active.

Configuration Recommendations for nPartitions

You also should, as possible, configure nPartitions to meet the following configurations for better performance and availability.

- ☐ Each nPartition's size **should** be a power of two: 1, 2, 4, 8, or 16 cells.

  This provides the best memory interleaving and performance characteristics.

  You can configure nPartitions of any size, but those whose size is a power of two have best memory performance.
- ☐ The I/O chassis containing the active core I/O also **should** have an HP-UX boot disk and method of installing or recovering HP-UX (such as a CD-ROM/DVD-ROM drive, network connection to an install server, or tape drive).

5686
21

This allows the nPartition to boot or recover HP-UX, even if only the nPartition's core cell is functioning.

❑ You **should** assign multiple core-capable cells to each nPartition.

This allows the nPartition to boot at least to the BCH interface if a core cell fails to boot.

(Disregard this recommendation if you are configuring multiple nPartitions in an HP rp8400 server or HP rp7405/rp7410 server, each of which has a maximum of two core cells.)

❑ The memory configuration of all cells in an nPartition **should** be identical to achieve best performance.

Each of an nPartition's cells should have:

— the same *number of DIMMs*

— the same *capacity (size)* and the same *locations (population)* of DIMMs

This avoids cell interconnect (crossbar) "hot spots" by distributing memory evenly across all of the nPartition's cells.

❑ The memory configuration of each cell **should** include a multiple of two memory ranks per cell.

Each memory rank is 4 DIMMs. If possible, install memory in sets of 8 DIMMs: 8 DIMMs or 16 DIMMs on HP rp7405/rp7410, HP rp8400, and HP Superdome cells. On HP Superdome cells, you also can install 24 DIMMs or 32 DIMMs per cell.

This provides a performance improvement by doubling the cell's memory bandwidth, as compared to having one memory rank installed.

This also can provide an availability improvement, in that if one memory rank fails the cell still has at least one functional rank of memory.

(At this time memory rank 0 must be functional for a cell to boot.)

❑ Each nPartition **should** have PRI (primary), HAA (high-availability alternate), and ALT (alternate) boot paths defined and configured, and their path flags appropriately configured for your purposes.

5685

The PRI and HAA paths should be configured to reference disks that are connected to different cells, if possible, with HAA being a mirror of the root volume and PRI being the root volume. ALT should be the path of a recovery or install device.

Under this configuration, if the cell to which the PRI disk is connected fails or is otherwise inactive and the HAA disk's cell is available, the nPartition still can boot HP-UX.

Even if the PRI and HAA devices connect to the same cell (such as on a multiple-partition HP rp8400 server), the HAA device can be used to boot the nPartition to HP-UX should the PRI device fail.

5684
21

Configuration Process: Selecting Cells for an nPartition

The following steps provide a basic procedure for selecting which cells to assign to the nPartitions you will create in an HP server.

Selecting Cells for an nPartition

Step 1. Determine the sizes of all nPartitions you will create in the server complex.

Before creating any nPartitions, determine how many nPartitions you plan to configure and establish each nPartition's size (the number of cells).

Step 2. Select the largest undefined nPartition.

If you will configure multiple nPartitions in the complex, assign cells to the largest nPartition first and then configure next largest, and so on, and configure the smallest nPartition last.

Step 3. Choose which cells you will assign to the nPartition by using the nPartition configuration chart for the server model on which you are configuring the nPartitions.

These charts list which cell slots HP supports for assigning to nPartitions, based on the nPartition size and server model.

For nPartition sizes for which HP recommends multiple configurations, select the first available set of cells. For example, for a two-cell nPartition select configuration 2A, if possible, before selecting 2B or 2C.

Step 4. Confirm that the cells you have selected are eligible to be assigned to the nPartition.

For the cells to be eligible, they must meet these requirements:

- The cells **must** not be assigned to another nPartition.
- The cells **must** meet the nPartition hardware requirements (the required processor, firmware, and memory configurations).

S683
21

- The cells **should** be present (installed) in the server and powered on. You can assign cells that are not present or on when using `parcreate` or `parmodify`. However, you should install and power on cells *before* assigning them to nPartitions in order to allow commands to automatically check the cells' compatibility with any other cells in the nPartition. Also note that assigning a cell that is not present or on will cause the nPartition to wait 10 minutes for the cell during the nPartition boot process, if the cell has a "y" use-on-next-boot setting.

If any of the cells does not adhere to these requirements, go back to *Step 3* and select a different set of cells for the nPartition.

Step 5. Assign the cells to the nPartition.

You can either create a new nPartition that includes the selected cells, or you can modify an existing nPartition so that it conforms to the nPartition configuration recommended by the configuration chart.

For specific procedures for assigning cells, refer to the chapter *Managing nPartitions* on page 243.

Step 6. If you still have additional nPartitions for which to select and assign cells, continue with *Step 2*.

Select the largest remaining undefined nPartition, and go back to *Step 2* to choose and assign cells for it.

HP Superdome nPartition Configuration Guidelines

On HP Superdome servers, the locations of the cells you assign to each nPartition and the resulting loads on server interconnections can affect system performance within the server's nPartitions.

HP offers specific guidelines for configuring nPartitions on HP Superdome servers in order to ensure good system performance.

NOTE The guidelines in this section apply to HP Superdome servers only.

These guidelines follow two basic configuration principles:

1. Avoid sharing interconnecting hardware (crossbars and crossbar links) among multiple nPartitions.
2. *Minimize* the number of crossbar links used by each nPartition, *but do not overload* crossbar links by creating nPartitions that can generate more cell communications traffic across the links than the links can support. Overloading crossbar links degrades performance.

The above principles are incorporated into the guidelines below, and are accounted for in the charts of recommended HP Superdome nPartitions.

Also see *nPartition Requirements and Recommendations* on page 110 for other details.

Configuration Guidelines for HP Superdome nPartitions

Use these guidelines to help determine which cells to assign to the nPartitions you create on HP Superdome servers.

❑ **Define nPartitions in order of size.**

Assign cells to the nPartition that has the largest cell count first. Then select cells for the next largest nPartition, and so on, and finally choose cells for the nPartition with the fewest cells last.

5681

This provides more appropriate cell assignments for larger nPartitions (those with more cells). Any smaller nPartitions with fewer cells are more easily accommodated in the remaining, available cells.

❑ **Place each nPartition within an empty cabinet, if possible.**

This applies to nPartitions in HP Superdome 64-way servers only.

If possible, assign each nPartition cells from a cabinet whose cells have no nPartition assignments. Do this before assigning cells from a cabinet that already has cells assigned to an nPartition.

To select cells for nPartitions that are larger than six cells, on HP Superdome 64-way servers, refer *Superdome 64-way Supported nPartition Configurations* on page 121. For such larger nPartitions, assigning some cells from both cabinet 0 and cabinet 1 provides better performance by better distributing cell communications across crossbar links.

These guidelines can help minimize contentions for using the server's interconnecting hardware (crossbars and crossbar links).

❑ **Assign each nPartition cells from an unused "cell quad", if possible.**

Each "cell quad" is a set of four cells that share the same cabinet backplane connections (crossbar chips). Within each HP Superdome cabinet, cell slots 0–3 comprise one cell quad, and cell slots 4–7 comprise the second cell quad.

Because cells in a quad share the same crossbar chips, they have the best cross-cell memory performance.

Partitions with cells on different crossbar chips have higher memory latency (worse memory performance) than nPartitions whose cells all share the same crossbar chip.

5680

Chart of Supported HP rp7405/rp7410 nPartition Configurations

Figure 2-1 lists the nPartition configurations that HP supports for HP rp7405/rp7410 servers.

Figure 2-1 **HP rp7405/rp7410 Supported nPartition Configurations**

	HP rp7405 HP rp7410	
Cell Slots	0	1
One-Cell Partitions	1B	1A
Two-Cell Partition	2A	2A

8679

Chart of Supported HP rp8400 nPartition Configurations

Figure 2-2 lists the nPartition configurations that HP supports for HP rp8400 servers.

Figure 2-2 **HP rp8400 Supported nPartition Configurations**

	HP rp8400			
Cell Slots	0	1	2	3
One-Cell Partitions	1A	1B		
Two-Cell Partitions	2A		2A	
	2B			2B
	[illegible]	[illegible]		
		2D	2D	
		2E		2E
Three-Cell Partitions	3A	3A	3A	
	3B		3B	3B
		[illegible]	[illegible]	[illegible]
Four-Cell Partition	4A	4A	4A	4A

On HP rp8400 servers, each nPartition must include either cell 0 or cell 1 because these two cells are the server's only core-capable cells.

Charts of Supported HP Superdome nPartition Configurations

Figure 2-3 lists the nPartition cell configurations that HP supports for Superdome 16-way and Superdome 32-way servers.

Figure 2-4 lists the nPartition cell configurations that HP supports for Superdome 64-way servers.

Example nPartition configurations that use these charts to determine which cells to assign to nPartitions appear in *nPartition Example Configurations for an HP Superdome Server Complex* on page 122.

5677

5675

nPartition Example Configurations for an HP Superdome Server Complex

This section shows example cell assignments to demonstrate the procedure for selecting cells for two sample server complex configurations.

For reference in the following examples, Figure 2-3 on page 120 and Figure 2-4 on page 121 list a unique number for each nPartition *configuration set*. (For example, config set 6 shows the four two-cell nPartition configurations that HP recommends for Superdome 32-way servers.)

The following two examples are given here:

- *Example nPartition Configuration for a Superdome 32-way Server* on page 123
- *Example nPartition Configuration for a Superdome 64-way Server* on page 124

S674
21

Example 2-1 Example nPartition Configuration for a Superdome 32-way Server

This example configures an HP Superdome 32-way server with one six-cell nPartition and one two-cell nPartition.

A Superdome 32-way server with a six-cell and two-cell nPartition would be configured with nPartitions 6A and 2B, as shown in Figure 2-3 on page 120.

In Figure 2-3, configuration sets 5–13 are eligible to be assigned on Superdome 32-way servers. The nPartition cell assignments are:

1. 6A (config set 11), the recommended six-cell nPartition.
2. 2B (config set 6), because cells 0 and 2 (2A) are assigned to 6A.
3. nPartitions 6A and 2B use all cells in the complex.

Example
Superdome 32-way complex nPartition configuration:
one six-cell nPartition and one two-cell nPartition.

1	6A	6A	6A	6A		6A		6A
					2B		2B	
2	6A	6A	6A	6A		6A		6A
3	6A	6A	6A	6A	2B	6A	2B	6A

S673
21

Example 2-2

Example nPartition Configuration for a Superdome 64-way Server

This example configures an HP Superdome 64-way server with one seven-cell nPartition and two four-cell nPartitions.

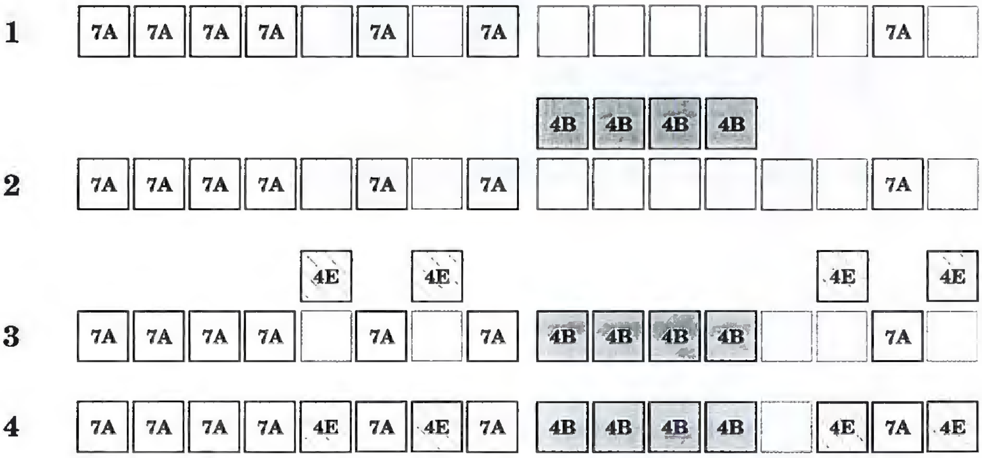
A Superdome 64-way server with a seven-cell nPartition and two four-cell nPartitions would be configured with nPartitions 7A, 4B, and 4E, as shown in Figure 2-4 on page 121.

In Figure 2-4, configuration sets 14–34 are eligible to be assigned on Superdome 64-way servers. The nPartition cell assignments are:

1. 7A (config set 25), the first recommended seven-cell nPartition.
2. 4B (config set 21), because cells in 4A are used by 7A.
3. 4E (config set 22), because some or all cells in 4A–D are assigned.
4. Partitions 7A, 4B, and 4E use all cells except one (cabinet 1, cell 4).

The following illustrations shows how the Superdome 64-way nPartition configurations would be selected, using Figure 2-4 to determine which recommended nPartitions to use.

Example
Superdome 64-way complex nPartition configuration:
one seven-cell nPartition and two four-cell nPartitions.



1	7A	7A	7A	7A		7A		7A							7A	
									4B	4B	4B	4B				
2	7A	7A	7A	7A		7A		7A							7A	
					4E		4E							4E		4E
3	7A	7A	7A	7A		7A		7A	4B	4B	4B	4B			7A	
4	7A	7A	7A	7A	4E	7A	4E	7A	4B	4B	4B	4B		4E	7A	4E

3 Using Console and Service Processor Interfaces

5672

This chapter covers the service processors and nPartition console interfaces available for HP's nPartition servers.

NOTE

The **service processor** in HP servers is sometimes called the Management Processor (MP) and sometimes the Guardian Service Processor (GSP).

Regardless of the name, the service processor in these servers provides approximately the same features and performs essentially the same role.

Throughout this document, the term "service processor" refers to both the MP and GSP service processors.

Service Processor (GSP or MP) Introduction

The **service processor** (GSP or MP) utility hardware is an independent support system for nPartition servers. It provides a way for you to connect to a server complex and perform administration or monitoring tasks for the server hardware and its nPartitions.

The main features of the service processor include the Command menu, nPartition consoles, console logs, chassis code viewers, and nPartition Virtual Front Panels (live displays of nPartition and cell states).

For details, see *Service Processor Features* on page 128.

The service processor is available when its cabinet has standby power, even if the main (48-volt) cabinet power switch is turned off.

Access to the service processor is restricted by user accounts. Each user account is password protected and provides a specific level of access to the server complex and service processor commands.

Multiple users can independently interact with the service processor because each service processor login session is private. However, some output is mirrored: the Command menu and each nPartition console permit one interactive user at a time and mirror output to all users accessing those features. Likewise, the service processor mirrors live chassis codes to all users accessing the Live Chassis Logs feature.

Up to 16 users can simultaneously login to the service processor through its network (customer LAN) interface and they can independently manage nPartitions or view the server complex hardware states.

Two additional service processor login sessions can be supported by the local and remote serial ports. These allow for serial port terminal access (through the local RS-232 port) and external modem access (through the remote RS-232 port).

In general, the service processor (GSP or MP) on nPartition servers is similar to the service processor on other HP servers, while providing enhanced features necessary for managing a multiple-nPartition server.

For example, the service processor manages the complex profile, which defines nPartition configurations as well as complex-wide settings for the server.

S670

The service processor also controls power, reset, and TOC capabilities, displays and records system events (chassis codes), and can display detailed information about the various internal subsystems.

5669
2l

Service Processor Features

The following list describes the primary features available through the service processor (GSP or MP) on HP rp7405/rp7410, HP rp8400, and HP Superdome servers.

- **Command Menu**

  The Command menu provides commands for system service, status, access configuration, and manufacturing tasks.

  To enter the Command menu, enter `CM` at the service processor Main menu. To exit the service processor Command menu, enter `MA` to return to the service processor Main menu.

  See *Using Service Processor Commands* on page 140 for details.

  Service processor commands are restricted based on the three levels of access: Administrator, Operator, and Single Partition User. See *Service Processor Accounts and Access Levels* on page 131 for details.

- **Consoles**

  Each nPartition in a server complex has its own console.

  Enter `CO` at the service processor Main menu to access the nPartition consoles. To exit the console, type **^b** (**Control-b**).

  See *Console Access to nPartitions* on page 150 for details.

  Each nPartition's console output is reflected to all users currently accessing the console.

  One console user can have interactive access to each nPartition's console, and all other users of the console have read-only access. To gain write access for a console, type **^e cf** (**Control-e c f**).

  Each nPartition's console provides access to:

  — Boot Console Handler (BCH) interface for the nPartition.

    The BCH interface is available if the nPartition has booted but has not yet loaded or booted the HP-UX operating system.

  — HP-UX console for the nPartition.

The nPartition console provides console login access to HP-UX and serves as /dev/console for the nPartition.

- **Console Logs**

  Enter **CL** from the service processor Main menu to access the console logs menu. To exit the console log, type ^b (**Control-b**).

  Each nPartition has its own console log, which has a history of the nPartition console's output, including boot output, BCH activity, and any HP-UX console login activity.

  See *Console Log Viewing* on page 155 for details.

  The console log provides a limited history; it is a circular log file that overwrites the oldest information with the most recent.

  All console activity is recorded in the console's log, regardless of whether any service processor users are connected to the console.

- **Error Logs, Activity Logs, and Live Chassis Codes**

  Enter **SL** to access the chassis log viewer. To exit the chassis viewer type ^b (**Control-b**).

  Three types of chassis code log views are available: activity logs, error logs, and live chassis code logs.

  See *Chassis Code Log Viewing* on page 156 for details.

  The activity log and error log provide views of past chassis codes.

  The *live chassis code* view provides:

  — Real-time view of chassis codes.

  — Options for filtering the live chassis code output to show only the chassis codes related to a specific cell (**C**), a specific nPartition (**P**), or alerts (**A**, for codes of alert level 3 and higher). Type **U** to view unfiltered codes (all chassis codes).

  All logs (activity, error, and live) can be displayed in different formats, including: keyword format, text format, hex (with keywords), and raw hex format.

  When viewing chassis logs, type **V** followed by a format selector to change the display format.

- **Virtual Front Panel (VFP) for an nPartition**

  Each nPartition's Virtual Front Panel (VFP) displays real-time status of the nPartition boot status and activity, and details about all cells assigned to the nPartition. The VFP display automatically updates as cell and nPartition status changes. A system-wide VFP also is provided.

  Enter `VFP` at the Main menu to access the View Front Panel menu. To exit a Virtual Front Panel, type `^b` (**Control-b**).

  See *Using Virtual Front Panels* on page 159 for details.

Service Processor Accounts and Access Levels

To access the service processor interface for a server complex, you must have a user account that enables you to login to the service processor.

Each server complex has its own set of service processor user accounts, which are defined for the server complex and may differ from accounts on other complexes.

Service processor user accounts have a specific login name, password, and access level.

The three user account access levels are:

- **Administrator Account**

  Provides access to all commands, and access to all nPartition consoles and Virtual Front Panels.

  Can manage user accounts (using the Command menu `SO` command) and can reconfigure various service processor settings.

- **Operator Account**

  Provides access to a subset of commands, and access to all nPartition consoles and Virtual Front Panels.

  Can reconfigure the service processor.

- **Single Partition User Account**

  Provides access to a restricted subset of commands, and access to a single nPartition's console and a single nPartition's Virtual Front Panel.

  Can only execute commands that affect the *assigned nPartition*.

  Cannot execute commands that could potentially affect multiple nPartitions or affect the service processor configuration.

Each user account can permit multiple concurrent login sessions (if it is a "multiple use" account), or restrict account access to a single login session (for "single use" accounts).

Accessing Service Processor Interfaces

This section describes how to login to the service processor (GSP or MP) for an nPartition server complex.

You can connect to a server complex's service processor using the following methods:

- Connecting through the **customer LAN port** by using `telnet`, if login access through the customer LAN is enabled for the service processor.

  On HP Superdome servers, the customer LAN hardware is labeled "Customer LAN". On HP rp8400 servers it is "GSP LAN". On HP rp7405/rp7410 servers it is the only LAN port on the core I/O.

  Use `telnet` to open a connection with the service processor, then login by entering the account name and corresponding password.

- Connecting through the **local RS-232 port** using a direct serial cable connection.

  On HP Superdome server hardware, the local RS-232 port is labeled "Local RS-232". On HP rp8400 servers it is the "Local Console" port. On HP rp7405/rp7410 servers it is the 9-pin D-shaped connector (DB9) labeled "Console".

- Connecting through the **remote RS-232 port** using external model (dial-up) access, if remote modem access is configured.

  On HP Superdome server hardware, the remote RS-232 port is labeled "Remote RS-232". On HP rp8400 servers it is the "Remote Console" port. On HP rp7405/rp7410 servers it is the DB9 connector labeled "Remote".

S664

Example 3-1 Service Processor Login Session

The following output shows a sample login session for a server whose service processor's hostname is "hpsys-s".

```
> telnet hpsys-s
Trying...
Connected to hpsys-s.rsn.hp.com.
Escape character is '^]'.
Local flow control off

MP login: Accountname
MP password:

                           Welcome to the

    MP MAIN MENU:

         CO: Consoles
        VFP: Virtual Front Panel
         CM: Command Menu
         CL: Console Logs
         SL: Show chassis Logs
         HE: Help
          X: Exit Connection

MP>
```

S663
2X

Logging in to a Service Processor

This procedure connects to and logs in to a server complex's service processor (GSP or MP) using `telnet` to access the customer LAN.

If connecting through the local or remote RS-232 port, skip *Step 1* (instead establish a direct-cable or dial-up connection) and begin with *Step 2*.

Step 1. Use the HP-UX `telnet` command on a remote system to connect to the service processor for the server complex.

You can connect directly from the command line, for example:

```
telnet sdome-g
```

or run `telnet` first, and then issue the `open` command (for example, `open sdome-g`) at the `telnet>` prompt.

All `telnet` commands and escape options are supported while you are connected to the service processor. See the *telnet*(1) manpage for details.

(On non-HP-UX platforms such as various PC environments you can instead use an alternate `telnet` program.)

Step 2. Login using your service processor user account name and password.

```
GSP login: Accountname
GSP password: Password
```

Step 3. Use the service processor menus and commands as needed and log out when done.

To log out, select the Exit Connection menu item from the Main menu (enter **X** at the `GSP>` prompt or `MP>` prompt).

You also can terminate a login session by issuing the `telnet` escape key sequence **^]** (type: **Control-right bracket**) and entering **`close`** at the `telnet>` prompt.

NOTE If possible, you should log out of any consoles and menus before terminating your telnet session.

5662

If accessing HP-UX on an nPartition, *log out of HP-UX* before exiting the console and service processor sessions. (Otherwise an open HP-UX login session will remain available to any other service processor users.)

S68
3

Using Service Processor Menus

The service processor (GSP or MP) has a set of menus that give you access to various commands, consoles, log files, and other features.

See *Navigating through Service Processor Menus* on page 138 for details on using these menus.

The following menus are available from the service processor Main menu (which is the menu you first access when logging in):

- **Console Menu**—Provides access to consoles for the server's nPartitions.
- **Virtual Front Panel Menu**—Provides a Virtual Front Panel for each nPartition (or for the entire server complex).
- **Command Menu**—Includes service, status, system access, and manufacturing commands.
- **Console Log Viewer Menu**—Allows access to the server's console logs.
- **Chassis Log Viewer Menu**—Allows access to the server's chassis code logs.
- **Help Menu**—Provides online help on a variety of service processor topics and on all service processor Command menu commands.

These menus provide a central point for managing an nPartition server complex outside of HP-UX.

The service processor menus provide many tools and details not available elsewhere. More administration features also are available from the nPartition BCH interfaces, or from HP-UX commands and utilities running on one of the server complex's nPartitions.

NOTE

Some specific service processor menu options and features differ slightly on different hardware platforms and firmware revisions. However, most features are identical and behave as described here.

Figure 3-1 Overview of Service Processor (GSP or MP) Menus

Navigating through Service Processor Menus

Figure 3-2 on page 139 shows the commands and options for returning to the service processor Main menu and for ending a service processor login session.

The following list also includes tips for navigating through service processor menus and using various menu features:

- `Control-b`

  Exit current console, console log, chassis log, or Virtual Front Panel.

  When accessing an nPartition's console, any log files, or any Virtual Front Panel (VFP), you can exit and return to the Main menu by typing `^b` (**Control-b**).

- `Q` (or lower-case `q`)

  Exit or cancel current menu prompt.

  Enter `Q` (or lower-case q) as response to any menu prompt to exit the prompt and return to the previous sub-menu.

  You can do this throughout the service processor menus, including the console menus, various command menu prompts, and the log and VFP menus.

  Note that, from the Command menu prompt (`GSP:CM>` or `MP:CM>`) you must enter **`MA`** (not Q) to return to the Main menu. However, you can enter `Q` or `q` to cancel any command.

- **Control-]**

  Escape the service processor connection and return to the telnet prompt.

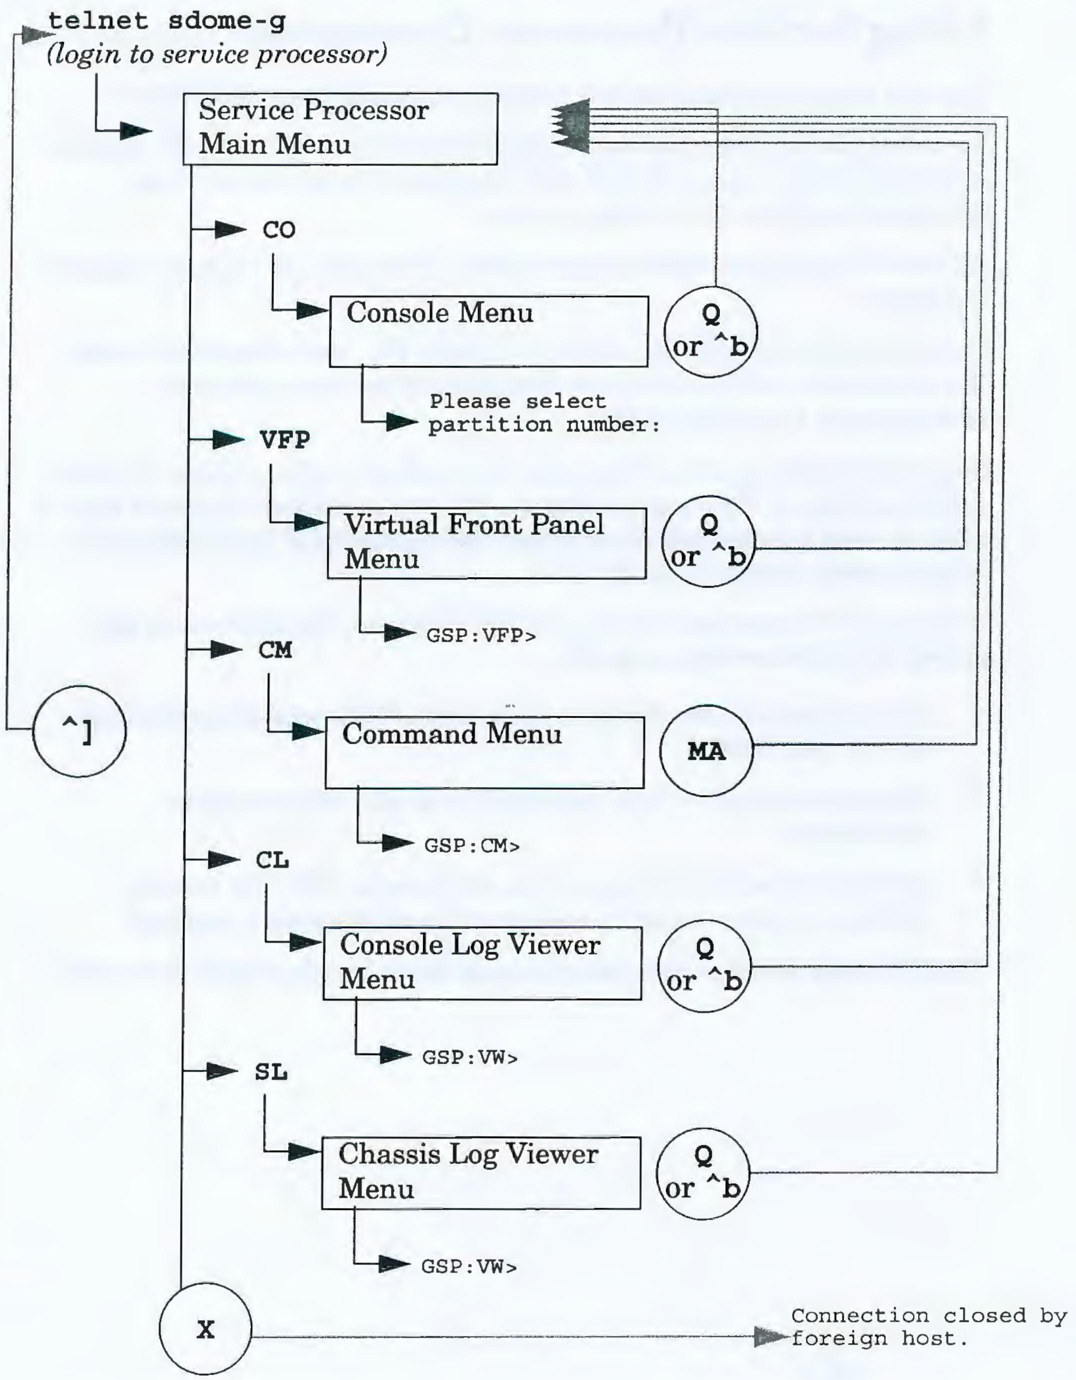
  At any time during your `telnet` connection to a service processor, you can type the `^]` (**Control-right bracket**) escape sequence.

  This key sequence escapes back to the `telnet` prompt. When at the `telnet>` prompt you can use the following commands, among others: **`?`** (print telnet command help information), **`close`** (close the current connection), and **`quit`** (exit telnet).

  To return to the service processor connection, type enter (or return) one or more times.

S658
21

Figure 3-2 Navigating through Service Processor (GSP or MP) Menus



S657

Using Service Processor Commands

You can issue commands at the service processor Command menu.

To access the service processor Command menu, enter **CM** at the service processor's Main menu. To exit the Command menu, enter the **MA** command to return to the Main menu.

All service processor users accessing the Command menu share access to the menu.

Only one command can be issued at a time. For each command issued, the command and its output are displayed to all users currently accessing the Command menu.

Some commands are restricted and are available only to users who have Administrator or Operator privileges. You can issue any command that is valid at your access level by entering the command at the Command menu prompt (`GSP:CM>` or `MP:CM>`).

When you list commands using the **HE** command, the commands are shown in the following categories:

- Service commands—Support boot, reset, TOC, and other common service activities.
- Status commands—Give command help and system status information.
- System and access configuration commands—Provide ways to configure system security and console and diagnostic settings.

The following sections give more details about the available commands.

5656

Commands Commonly Used at the Service Processor

Table 3-1 summarizes commands that are commonly used by system administrators. These commands are available to all service processor users.

Table 3-1 Service Processor: Commonly Used Commands

Command	Description
BO	Boot an nPartition past an inactive boot-is-blocked (BIB) state to make it active.
CP	Display nPartition cell assignments.
HE	Help: list the available commands.
LS	Display LAN connected console status.
MA	Return to the service processor Main menu.
PD	Set the default nPartition for the current session.
PS	Display detailed power and hardware configuration status.
RS	Reset an nPartition.
RR	Reset an nPartition to a *ready for reconfiguration* state, which makes the nPartition inactive.
SYSREV	Display all cabinet FPGA and firmware revisions. (HP rp8400 and HP rp7405/rp7410 only.)
TC	Send a TOC signal to an nPartition.
TE	Broadcast a message to all users of the Command menu.
WHO	List all users connected to the service processor.

The above commonly used commands appear in the service, status, and the system and access configuration categories.

For additional commands, by category, see the following sections.

Service Processor Commands: Quick Reference

The following tables list commands available from the service processor Command menu:

- *Service Commands* on page 142
- *Status Commands* on page 143
- *System and Access Configuration Commands* on page 144

NOTE For a complete and current list of all service processor commands, enter the **HE** command at the service processor Command menu.

Service Commands

The service commands available provide boot, reset, power, TOC, status, and other commands for common service activities.

Table 3-2 Service Processor: Service Commands

Command	Description
BO	Boot an nPartition past an inactive boot-is-blocked (BIB) state to make it active.
DF	Display FRU information of an entity.
MA	Return to the Main menu.
MFG	Enter the manufacturing mode. (Administrator only.)
MR	Modem reset.
PE	Power entities on or off. (Administrator and operator only.)
RE	Reset entity. (Administrator and operator only.)
RR	Reset an nPartition to a *ready for reconfiguration* state, which makes the nPartition inactive.

S6S4

Table 3-2 Service Processor: Service Commands

Command	Description
RS	Reset an nPartition.
SYSREV	Display all cabinet FPGA and firmware revisions. (HP rp8400 and HP rp7405/rp7410 servers only.)
TC	Send a TOC signal to an nPartition.
TE	Broadcast a message to all users of the Command menu.
VM	Margin the voltage in a cabinet. (HP Superdome servers only.)
WHO	Display a list of users connected to the service processor.

Status Commands

The status commands provide command help and system status information, such as hardware status and nPartition configurations.

Table 3-3 Service Processor: Status Commands

Command	Description
CP	Display nPartition cell assignments.
HE	Display the list of available commands.
IO	Display I/O chassis connections to cells. (HP Superdome servers only.)
LS	Display LAN connected console status.
MS	Display the status of the modem.
PS	Display detailed power and hardware configuration status.

S653

System and Access Configuration Commands

The system and access configuration commands provide ways to configure system security and console and diagnostic settings. These commands also enable you to modify some complex configuration settings. Some of these commands are restricted (users with an “Operator” or “Single Partition User” access level can issue a subset of these commands).

Table 3-4 **Service Processor: System and Access Configuration Commands**

Access Level(s)	Command	Description
Administrator	`AR`	Configure the automatic system restart for an nPartition.
Administrator, Operator	`CA`	Configure asynchronous and modem parameters.
Administrator, Operator	`CC`	Initiate a complex configuration.
Administrator	`DATE`	Set the time and date.
Administrator	`DC`	Reset parameters to default configuration.
Administrator, Operator	`DI`	Disconnect remote or LAN console.
Administrator	`DL`	Disable LAN console access.
Administrator	`EL`	Enable LAN console access.
Administrator, Operator, Single Partition User	`ER`	Configure remote/modem port access options.
Administrator, Operator	`FW`	Firmware update utility. (HP rp8400 and HP rp7405/rp7410 servers only.)
Administrator, Operator, Single Partition User	`ID`	Display and/or change certain Stable Complex Configuration Data fields, which describe the complex identity.
Administrator	`IF`	Display network interface information.

5657

Table 3-4 **Service Processor: System and Access Configuration Commands**

Access Level(s)	Command	Description
Administrator, Operator	`IT`	Modify command interface inactivity time-out.
Administrator	`LC`	Configure LAN connections.
Administrator, Operator, Single Partition User	`LS`	Display LAN connected console status.
Administrator	`ND`	Enable/disable network diagnostics.
Administrator, Operator	`PD`	Set the default nPartition for the current session.
Administrator, Operator	`PWRGRD`	Configure power grid settings. (HP rp8400 and HP rp7405/rp7410 servers only.)
Administrator, Operator	`RL`	Rekey complex profile lock.
Administrator	`SO`	Configure security options and access control.
Administrator, Operator	`XD`	Service processor diagnostics and reset options.

Network Configuration for a Service Processor

This section describes how to list and configure the network settings for service processor (GSP or MP) hardware. These settings are used for connections to the service processor and are not used for HP-UX networking.

Details on configuring service processor networking are given in the procedure *Configuring Service Processor Network Settings* on page 148.

The service processor utility hardware on HP Superdome servers has two network connections: the customer LAN and private LAN. The service processor on HP rp8400 and HP rp7405/rp7410 servers do not have a private LAN but have only customer LAN connections.

Features of service processor LANs are given in the following list.

- **Customer LAN for Service Processor**

  The **customer LAN** is the connection for login access to the service processor menus, consoles, commands, and other features.

  All HP nPartition servers have a customer LAN.

  On HP Superdome servers, the customer LAN port is labeled "Customer LAN". On HP rp8400 servers it is "GSP LAN". On HP rp7405/rp7410 servers it is the only LAN connection on each core I/O board.

- **Private LAN for Service Processor (Superdome Only)**

  The **private LAN** is the connection to the Superdome service support processor (SSP) workstation.

  Only Superdome servers have a private LAN.

To *configure* service processor network settings, you can use the the Command menu's LC command.

To *list* the current service processor network configuration use the LS command.

The following examples show service processor LAN status for various HP nPartition servers.

Default Service Processor Network Settings

Table 3-5 and Table 3-6 list the default customer LAN and private LAN network settings for nPartition servers. Only Superdome servers have a private LAN.

Table 3-5 Default Configuration for Service Processor Customer LAN (All nPartition Servers)

Customer LAN IP Address	192.168.1.1
Customer LAN Host Name	gsp0
Customer LAN Subnet Mask	255.255.255.0
Customer LAN Gateway	192.168.1.1

SD49

Table 3-6 Default Configuration for Service Processor Private LAN (HP Superdome Servers Only)

Private LAN IP Address	192.168.2.10
Private LAN Host Name	priv-00
Private LAN Subnet Mask	255.255.255.0
Private LAN Gateway	192.168.2.10

Configuring Service Processor Network Settings

This procedure (Command menu, **LC** command) configures the service processor's customer LAN and private LAN network settings from the service processor Command menu.

Step 1. Connect to the server complex's service processor, login as an administrator, and enter **CM** to access the Command menu.

Use `telnet` to connect to the service processor, if possible.

If a service processor is at its default configuration (including default network settings), you can connect to it using either of these methods:

- Establish a direct serial cable connection through the service processor's local RS-232 port, a 9-pin D-shaped connector (DB9).

  On HP Superdome servers this port is labeled "Local RS-232". On HP rp8400 servers it is the "Local Console" port. On HP rp7405/rp7410 servers use the DB9 connector that is labeled "Console".

- Access a PC or workstation on the same subnet as the service processor, modify its network routing tables to include the default customer LAN IP address, then `telnet` to the service processor. The procedure to modify networking and connect is:

  1. Access a PC or workstation on the service processor's subnet.
  2. Modify the network routing tables for the PC or workstation by using the **`route add 192.168.1.1`** ***`ClientName`*** command, where *`ClientName`* is the network name of the PC or workstation.

5648
71

From a PC command prompt: `route add 192.168.1.1 ClientName`
On an HP-UX workstation login as root and use this command:

```
/usr/sbin/route add 192.168.1.1 ClientName
```

After you reconfigure the service processor's networking, you can remove these network routing table changes with the `route delete...` command.

3. Enter this command to confirm the new network connection to the service processor: **`ping 198.168.1.1 -n 2`**

4. Use the **`telnet 192.168.1.1`** command from the PC or workstation to connect to the service processor.

Step 2. From the service processor Command menu, enter **`LS`** to *list* the current network settings, and if needed use the **`LC`** command to *reconfigure* the network settings for the service processor.

You must be logged in as an administrator to use the `LC` command.

The `LC` command enables you to modify the customer LAN and/or the private LAN configuration.

You can cancel all changes to the service processor LAN configuration at any time by replying **`Q`** to any of the `LC` command's prompts.

S647

Console Access to nPartitions

The service processor Console menu provides access to all nPartition consoles within the server complex.

Enter `CO` from the service processor Main menu to access an nPartition's console. To exit the nPartition console, type `^b` (**Control-b**) to return to the Main menu.

Each nPartition in a complex has a single console. However, multiple connections to the console are supported, allowing multiple users to simultaneously view the console output. Only one connection per console permits write-access.

To force (gain) console write access for an nPartition's console, type **`^ecf`** (**Control-e c f**).

Each nPartition console can display a variety of information about the nPartition, including:

- Partition startup, shutdown, and reset output.
- Boot Console Handler (BCH) menus, if the nPartition has not yet booted the HP-UX operating system and has completed Power-On Self Tests (POST).
- The HP-UX login prompt and "console shell access".

nPartition Console Access versus Direct HP-UX Login

You may need to consider the following factors when deciding whether to interact with an nPartition through the service processor console interface or a direct HP-UX login:

- Whether you want to log your activity to the nPartition's console log (all console activity is stored at least temporarily).
- Whether HP-UX is installed, booted, and properly configured on the nPartition.

  If HP-UX is not installed on an nPartition, you should access the nPartition's console (through the service processor) in order to install and configure HP-UX.

5646

You should login to HP-UX running on an nPartition when you do not need to use service processor features and do not want to record a log of your activity.

Before HP-UX has booted, the service processor nPartition consoles are the primary method of interacting with an nPartition.

After an nPartition has booted HP-UX, you should be able to connect to and login to the nPartition by using `telnet` or `rlogin` to remotely login.

If the HP-UX kernel booted on the nPartition does not have networking fully configured, you may need to login using a service processor nPartition console connection to set up the nPartition's networking configuration (using `/sbin/set_parms`).

To view the /dev/console messages for HP-UX running on an nPartition, you can access the nPartition's console, view its console log, or use the `xconsole` command or `xterm -C` command and option. See the *xconsole* (1) or *xterm* (1) manpages for details.

Boot Console Handler (BCH) Access

S645

Each nPartition in a server complex has its own Boot Console Handler (BCH) interface. When an nPartition is booted to BCH, its BCH interface is available through the nPartition's console.

The nPartition BCH interface enables you to manage and configure the HP-UX boot process for an nPartition. You also can configure some settings for the local nPartition, get some information about the nPartition and its server complex, and perform other tasks such as reboot.

Figure 3-3 shows details on accessing and using an nPartition's BCH interface, including the following points:

- To access an nPartition's console type `CO` from the service processor (GSP or MP) Main menu.
- To force console write access, type `^ecf` (**Control-e c f**).
- To exit the console, type `^b` (**Control-b**) to return to the Main menu.

The BCH interface is available after an nPartition's cells have been powered on; its hardware has completed all Power-On Self Tests (POST); and the cells have booted past boot-is-blocked, rendezvoused, and BCH has started executing. Refer to the chapter *An Overview of nPartition Boot and Reset* on page 161 for details.

Once you begin the HP-UX boot process and load ISL, the BCH interface is no longer available.

The BCH menus and commands for nPartitions differ slightly from the commands menus for BCH on other HP 9000 server systems.

To display the *current* BCH menu and commands, type `DI`.

The BCH interface's `HELP` command lists BCH command or menu details.

5642

Console Log Viewing

Each nPartition in a server complex has its own console log that stores a record of the nPartition's most recent console activity.

To access an nPartition's console log, enter `CL` from the service processor Main menu and select which nPartition's console log you want to view. To exit the console log viewer, type `^b` (**Control-b**) to return to the Main menu.

When viewing an nPartition's console log, type `P` to view the previous page of the console log, or type `N` (or **Enter**) to view the next page.

When you enter an nPartition's console log viewer it displays the oldest data in the log first and allows you to page through the log to view the more recently recorded activity.

Each nPartition's console log is a circular log file that records approximately 30 to 40 pages of data. All nPartition console activity is written to this log file, regardless of whether a user is connected to the nPartition console.

As an nPartition's console log is written the oldest data in the log is overwritten by current data, as needed, so that the last 30 to 40 pages of console output always is available from the console log viewer.

5641

Chassis Code Log Viewing

The service processor's **chassis log viewer** enables you to view chassis codes that are emitted throughout the entire server complex.

To enter the chassis log viewer enter `SL` at the service processor Main menu. To exit the viewer type `^b` (**Control-b**) to return to the Main menu.

Chassis codes are data that communicate information about system events from the source of the event to other parts of the server complex. Chassis code data indicates what event has occurred, when and where it happened, and its severity (the *alert level*).

All chassis codes pass from the event source through the service processor. The service processor takes any appropriate action and then reflects the chassis codes to all running nPartitions. If an nPartition is running event monitoring software, it may also take action based on the chassis codes (for example, sending notification e-mail).

System administrators, of course, may have interest in viewing various chassis codes—especially chassis codes that indicate failures or errors.

Hardware, software, and firmware events may emit chassis codes as a result of a failure or error, a major change in system state, or basic forward progress. For example: a fan failure, an HPMC, the start of a boot process, hardware power on or off, and test completion all result in chassis codes being emitted.

While HP-UX is running on an nPartition, it constantly emits a "heartbeat" chassis code (at alert level 0) to indicate that the operating system still is functioning and has not hung.

NOTE

Each nPartition server cabinet's **front panel attention LED** is automatically *turned on* when one or more chassis codes of *alert level 2* or higher have not yet been viewed by the administrator. When this attention LED is on, entering the chassis log viewer turns the LED off.

You can remotely check this attention LED's on/off status by using the service processor Command menu's `PS` command, `G` option.

S640

On nPartition servers, chassis codes are recorded in the server complex **activity log** (for events of alert level 0 or alert level 1) or the **error log** (for events alert level 2 or higher).

```
GSP> SL

Chassis Logs available:

    (A)ctivity Log
    (E)rror Log
    (L)ive Chassis Logs

    (C)lear All Chassis Logs
    (Q)uit

GSP:VW> L

        Entering Live Log display

        A)lert filter
        C)ell filter
        P)artition filter
        U)nfiltered
        V)iew format selection
        ^B to Quit

Current filter: ALERTS only
```

Log Viewing Options: Activity, Error, and Live Chassis Logs

When you enter the chassis log viewer by entering `SL` at the service processor (GSP or MP) Main menu, you can select from these viewers:

- **Activity Log Viewer**

  Allows you to browse recorded chassis codes of alert level 0 or 1.

- **Error Log Viewer**

  Allows you to browse recorded chassis codes of alert level 2 or higher.

- **Live Chassis Logs Viewer**

  Displays chassis codes in real time as they are emitted.

  By default, the live chassis code viewer has the *Alert filter* enabled, which causes it to display only the events of alert level 3 or higher.

  To view all chassis codes in real-time, type `U` for the *Unfiltered* option.

You also can filter the live codes by cell (`C`) or nPartition (`P`). *Cell filter*: only display chassis codes emitted by a specific cell in the server complex. *Partition filter*: only display chassis codes emitted by hardware assigned to a specific nPartition.

When viewing chassis code logs, type `V` to change the display format. The viewers can show chassis codes in text format (`T`), keyword format (`K`), or raw hex format (`R`).

Using Virtual Front Panels

The Virtual Front Panel (VFP) provides ways to monitor the chassis codes for a particular nPartition or the entire server complex (all nPartitions).

The VFP presents a real-time display of activity on the selected nPartition(s) and it automatically updates when cell and nPartition status change.

To access the VFP feature, enter **VFP** from the service processor Main menu. To exit the VFP, type **^b** (**Control-b**) to return to the Main menu.

When you access a Virtual Front Panel, you can either select the nPartition whose VFP you want to view or select the system VFP to view summary information for all nPartitions in the server complex.

```
E indicates error since last boot
     Partition 0  state            Activity
     ------------------            --------
     Cell(s) Booting:    710 Logs

  #  Cell state                    Activity
  -  ----------                    --------
  0  Early CPU selftest            Cell firmware test                   232  Logs
  1  Early CPU selftest            Processor test                       230  Logs
  2  Memory discovery              Physical memory test                 242  Logs

GSP:VFP (^B to Quit) >
```

When you access a service processor using a single-partition user account, using the VFP feature enables you to view only the VFP for the nPartition to which you have access.

S636

4 An Overview of nPartition Boot and Reset

5635

This chapter presents an overview of booting and reset concepts and issues for HP nPartition servers.

For procedures to boot, reboot, and configure boot options, refer to the chapter *Booting and Resetting nPartitions* on page 197.

NOTE For details on booting and rebooting virtual partitions within an nPartition, refer to the chapter *Virtual Partitions (vPars) Management on nPartitions* on page 441.

Types of Booting and Resetting for nPartitions

All standard boot and reboot methods are supported for HP nPartition servers, though some boot and reset procedures differ slightly or use different tools than on other HP servers.

HP's nPartition servers also provide two special types of reboot and reset for managing nPartitions: performing a **reboot for reconfig**, and resetting an nPartition to the **ready for reconfig** state.

The following list summarizes all types of booting, rebooting, and resetting that are supported for HP nPartition systems. See the *Reboot for Reconfig* and *Ready for Reconfig State* items for a discussion of these nPartition-specific boot processes.

NOTE When rebooting HP-UX on an nPartition under normal circumstances—such as when *not* reconfiguring or halting it—use the `shutdown -r` command.

- **Reboot**

  A **reboot** shuts down HP-UX and reboots the nPartition.

  Only the nPartition's *active* cells are rebooted.

  To perform a standard reboot of an nPartition use the `shutdown -r` command.

- **Halt**

  A **halt** shuts down HP-UX, halts all processing on the nPartition, and does not reboot.

  To perform this task use the `shutdown -h` command.

  To reboot a halted nPartition use the service processor Command menu's `RS` command.

- **Reset**

  A **reset** resets the nPartition immediately. Only the nPartition's *active* cells are reset.

  You can reset an nPartition using the BCH interface's `REBOOT` command or the service processor Command menu's `RS` command.

  The `RS` command *does not check* whether the specified nPartition is in use or running HP-UX—be certain to correctly specify the nPartition.

- **Boot an nPartition from the Service Processor (GSP or MP)**

  A **boot** initiated from the service processor boots an inactive nPartition past the *ready for reconfig* state.

  The nPartition's cells proceed past boot-is-blocked (BIB), rendezvous, and the nPartition boots to the BCH interface.

  To boot an inactive nPartition, use the service processor Command menu's `BO` command.

- **Boot HP-UX from the BCH Interface**

  To **boot** HP-UX on an nPartition, use the BCH interface's `BOOT` command and specify the device path from which the program loaders and HP-UX kernel .

  The BCH interface's `BOOT` command loads and boots HP-UX on an nPartition. This command also can be used to load and interact with the Initial System Loader (ISL) interface. Likewise on Superdome servers the virtual partitions monitor (`MON>` prompt) is loaded following the `BOOT` command.

- **Reboot for Reconfig**

  A **reboot for reconfig** shuts down HP-UX, resets all cells assigned to the nPartition, performs any nPartition reconfigurations, and boots the nPartition back to the BCH interface.

  To perform a reboot for reconfig of the local nPartition, use the `shutdown -R` command.

  All cells—including any inactive cells and all newly added or deleted cells—reboot and are reconfigured. All cells with a "y" *use-on-next-boot* setting participate in partition rendezvous and synchronize to boot as a single nPartition.

S637

After you assign a cell to an nPartition, or remove an active cell from an nPartition, you can perform a reboot for reconfig of the nPartition to complete the cell addition or removal.

If an nPartition is configured to boot HP-UX automatically, it can do so immediately following a reboot for reconfig.

- **Ready for Reconfig State**

  A reboot to the **ready for reconfig** state shuts down HP-UX, resets all cells assigned to the nPartition, performs any nPartition reconfigurations, and keeps all cells at a boot-is-blocked (BIB) state, thus making the nPartition and all of its cells inactive.

  When an nPartition is at the ready for reconfig state you can add or remove cells from the nPartition from a remote nPartition within the server complex.

  To put an nPartition into the ready for reconfig state use the `shutdown -R -H` command, the BCH interface's `RECONFIGRESET` command, or the service processor Command menu's `RR` command.

  To make an nPartition boot past ready for reconfig, use the service processor Command menu's `BO` command. The `BO` command makes the nPartition active by allowing its cells to boot past BIB, rendezvous, and boot to the BCH interface (and, if configured, automatically boot HP-UX).

- **TOC: Transfer-of-Control Reset**

  When you initiate a **transfer-of-control reset**, the service processor immediately performs a TOC reset of the specified nPartition, which resets the nPartition and allows a crash dump to be saved.

  If crash dump is configured for HP-UX on an nPartition, then when you TOC the nPartition while it is running HP-UX, the nPartition performs a crash dump and lets you select the type of dump.

  To perform a TOC reset, use the service processor Command menu's `TC` command.

  HP nPartition systems do not have TOC buttons on the server cabinet hardware.

S631
21

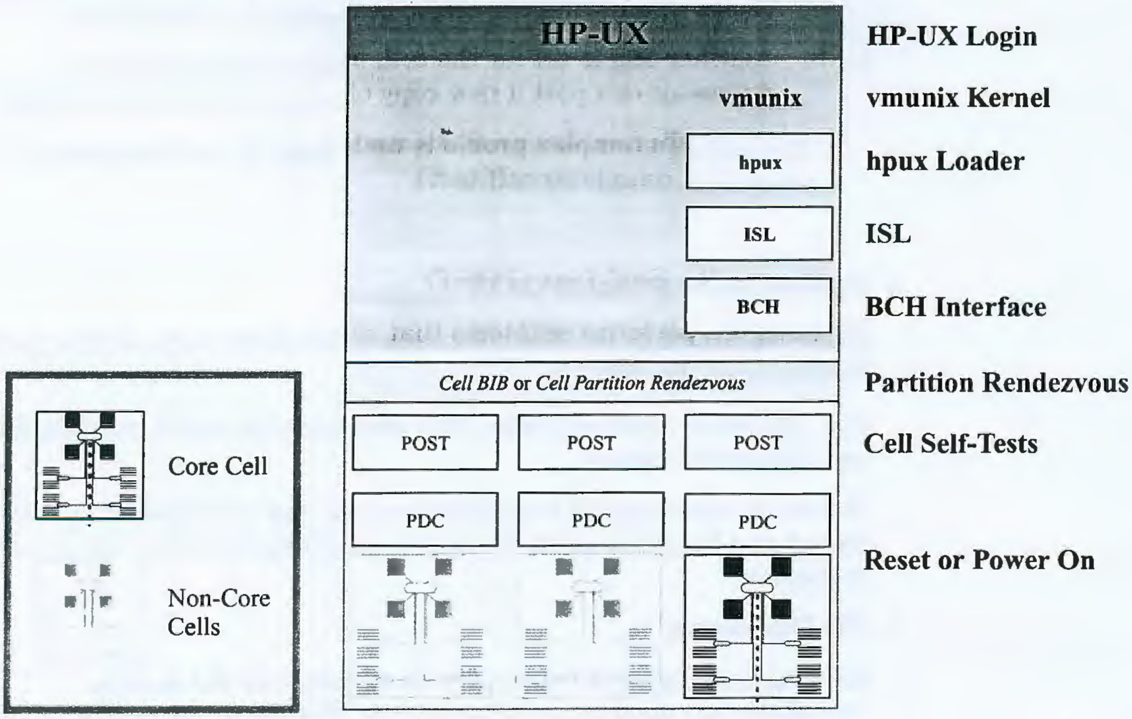
Boot Process for nPartitions, Cells, and HP-UX

The boot process for nPartitions is similar to the process on other HP servers. However, on HP nPartition servers, each cell boots and performs self tests (POST) separately, and one or more cells rendezvous to form an nPartition before providing a BCH interface for the nPartition.

NOTE This section covers nPartitions booting HP-UX in *non-vPars mode*.

For details on virtual partitions (vPars), refer to the chapter *Virtual Partitions (vPars) Management on nPartitions* on page 441.

Figure 4-1 **nPartition HP-UX Boot Process (non-vPars Mode)**



S630

Each nPartition goes through the boot process shown in Figure 4-1, from power on to booting HP-UX:

1. **Power On or Reset**

   The boot process starts when any of the following events occurs:

   - An nPartition is reset or rebooted.
   - The entire server complex is powered on.
   - Power is turned on for components in the nPartition (such as cells).

2. **Processor Dependent Code (PDC)**

   The monarch processor on each cell runs its own copy of the PDC firmware.

   a. The boot-is-blocked (BIB) flag is set for the cell.

      The BIB flag remains set until the service processor (GSP or MP) clears it, allowing the cell to boot as part of an nPartition.

   b. Another flag is set for the cell, indicating that the service processor can post a new copy of the complex profile to the cell.

      The cell's complex profile is updated later in the boot process, after it completes self-tests.

3. **Power-On Self-Test (POST)**

   Each cell performs self-tests that check the processors, memory, and firmware on the cell.

   If a component fails self-tests, it is deconfigured and if possible the cell continues booting.

   Following this step, all components in the cell are known and are tested and the cell reports its hardware configuration to the service processor.

4. **I/O Discovery**

   Each cell performs I/O discovery and configures I/O busses, including: any system bus adapter (the SBA for an I/O card cage) and its local bus adapters (LBAs, one per PCI card slot in the card cage).

5029

Following this, any I/O busses connected to the cell are known and configured by the cell.

5. **Boot-Is-Blocked (BIB) or Partition Rendezvous**

   Each cell either will remain at a boot-is-blocked state (spins at BIB) or will rendezvous with any other available cells in the nPartition.

   Cells that remain at BIB are *inactive*, and cells that rendezvous into the nPartition are *active*.

   - **Boot-Is-Blocked (BIB)**

     A cell remains at boot-is-blocked (and thus is *inactive*) in any of the following cases:

     — The cell has a "n" use-on-next-boot setting.

     — The cell boots too late to participate in nPartition rendezvous.

     — The cell's nPartition has been reset to the ready for reconfig state.

     In this case, all of the nPartition's cells remain at boot-is-blocked.

     — The cell fails self-tests that cause the cell to not be usable in the nPartition.

   - **Partition Rendezvous**

     Partition rendezvous of all cells occurs in the following manner:

     — Partition rendezvous begins when the first of the nPartition's cells has completed self-tests and I/O discovery.

     — The nPartition is allowed up to ten minutes for all cells with a "y" use-on-next-boot setting to participate in partition rendezvous.

       — Once all assigned cells with a "y" use-on-next-boot setting have entered the rendezvous stage, partition rendezvous can complete.

       All cells participating in rendezvous are active cells whose resources (processors, memory, I/O) are used by the nPartition.

5628

- If any cells with a "y" use-on-next-boot setting *do not* report to rendezvous, then ten minutes after rendezvous began the cells that have not reported become inactive cells, and all other reporting cells complete rendezvous and are active.

  The inactive cells' resources are not available to be used by the nPartition, although the cells still are assigned to the nPartition.

6. **Boot Console Handler (BCH)**

   The BCH interface provides the main method for interacting with an nPartition during its boot process.

   BCH runs on top of PDC, and it provides menus for getting nPartition status, for configuring nPartition boot settings, and for booting HP-UX and rebooting the nPartition.

   One processor on the nPartition's core cell runs BCH and all other processors in the nPartition are idle while the BCH interface is available.

   An nPartition can immediately proceed past BCH to boot HP-UX when the nPartition's boot paths are set and boot actions for the paths are configured to automatically boot.

7. **Initial System Loader (ISL) and Secondary System Loader (hpux)**

   In most situations you do not need to use the ISL and hpux interfaces.

   However, when using the BCH interface's BOOT command you can select to stop at the ISL prompt to perform more detailed booting tasks.

   For example, you can use the ISL interface to boot HP-UX in single-user or LVM-maintenance mode, or to boot an HP-UX kernel other than /stand/vmunix.

8. **HP-UX Operating System**

   The HP-UX operating system boots on an nPartition after ISL and the Secondary System Loader (hpux) specify which kernel is to be booted.

   By default, on HP-UX boot disks, the AUTO file specifies that the /stand/vmunix kernel is booted.

5627

For example, when you configure boot paths and boot actions to automatically boot HP-UX, the ISL and hpux loaders specify that the /stand/vmunix kernel is booted.

Overview of nPartition Boot Features

S026

This section lists several boot issues particular to HP nPartition servers.

Each nPartition is booted, rebooted, shut down, and reset individually. In many situations you can boot and reboot nPartitions using the same basic procedures that are used on other HP servers.

The following list describes notable features related to booting, rebooting, and power cycling nPartitions:

- Each nPartition can boot and reboot independently of other nPartitions. Resetting one nPartition has no effect on the others.
- You can perform many reset and power cycling tasks remotely.

  You can reset and control power from an nPartition server's service processor Command menu, from the BCH interface for an nPartition, or from HP-UX running on an nPartition.
- In order to contribute resources to an nPartition, the cells (and I/O chassis) assigned to the nPartition must be powered on and booted in time to participate in partition rendezvous.

  Otherwise, the cells will remain inactive (though still assigned to the nPartition) and their processors, memory, and any I/O will not available for use.
- Three boot path variables—PRI, HAA, and ALT—are supported for each nPartition.

  PRI typically is the primary HP-UX boot device, HAA typically is a mirror of the root volume, and ALT is for install or recovery media such as tape or DVD-ROM devices.
- You can specify a *boot action* for each boot path variable. The boot action determines what action (for example: boot HP-UX) is taken when the nPartition boots and reaches the BCH interface.

  To set boot actions, use the BCH Configuration menu's PathFlags (`PF`) command. The `setboot` command can configure the PRI actions only.

  When an nPartition boots to BCH, it attempts to perform the PRI path's boot action. The HAA path and ALT path boot actions also can be attempted, in that order, depending on the PRI settings.

5625

- *Before powering off* a cell, the cell should be inactive; unassigned; or assigned to an nPartition that either has been shut down and halted or has been reset to the ready for reconfig state.

  Powering on or powering off an I/O chassis *resets the cell* to which it is connected (if any). Follow the same guidelines for power cycling I/O chassis that you follow for power cycling cells.

S620

Tools for Managing nPartition Booting

HP nPartition servers support the following software tools for booting and resetting nPartitions and for configuring and managing nPartition boot settings.

These tools overlap in some of the functionality they provide, but each has unique capabilities.

The primary tools for managing nPartition booting are shown below.

- **Service Processor (GSP or MP)**—Using a server complex's service processor menus, you can reset partitions, put partitions into the ready for reconfig state, and TOC the partitions in the complex.

  The service processor also provides power on and power off commands for power cycling server hardware components.

- **Virtual Front Panel (VFP)**—Each nPartition has its own VFP that displays current cell and partition boot states and activities.

  For each server complex you also can access a system VFP that gives a live partition boot state and activity status for all nPartitions in the complex.

- **Boot Console Handler (BCH)**—Each partition's BCH interface provides commands for booting HP-UX, rebooting the partition, and putting the partition into the ready for reconfig state.

  You also can configure boot-related settings and check the partition's hardware and boot-setting configurations using BCH menus.

- **HP-UX System Loaders (ISL and hpux)**—You can use system loaders to list files that reside on a boot device, such as kernel files in /stand, and can specify boot arguments to the hpux loader.

  You can access the ISL and hpux loaders after issuing the BCH interface's BOOT command, when BCH gives you the following option:

  ```
  Do you wish to stop at the ISL prompt prior to booting?
  (y/n)
  ```

  Replying "n" (no, do not stop at ISL) skips the ISL prompt and proceeds to execute the AUTO file, which by default will boot HP-UX (/stand/vmunix) on the nPartition.

ISL: Initial System Loader

Replying "y" (yes, do stop at ISL) allows you to interact directly with a boot device's Initial System Loader (ISL) and the Secondary System Loader (hpux). Enter all ISL commands from the `ISL>` prompt.

hpux: Secondary System Loader

From the ISL prompt you also can enter commands that are executed by the Secondary System Loader (hpux). Preface your Secondary System Loader command with **hpux**. For example: `hpux ls /stand` to list the contents of the /stand directory on the booted device.

See the *isl* (1M) and *hpux* (1M) manpages for details.

- **HP-UX utilities**—Several HP-UX utilities allow you to check and set a partition's HP-UX boot options; check the boot settings of other partitions in the server complex; and perform reboot, shutdown, and reboot for reconfig tasks.

  The `reboot`, `shutdown`, `parmodify`, `parstatus`, and `setboot` commands provide these features. For details see the command manpages.

  The Partition Manager utility (`/opt/parmgr/bin/parmgr`) also provides some boot configuration capabilities; details are available in its online help.

S622

Configurable Boot Settings

Each nPartition has its own collection of boot-related settings that specify which hardware manages the boot process (the core cell), how the boot process proceeds (automatically boot HP-UX, or wait for BCH commands), and whether cells are configured as active cells when the nPartition boots.

nPartition boot settings are stored as part of the server Complex Profile data.

You can configure each nPartition's boot settings by using the nPartition's BCH interface or by running HP-UX utilities on the nPartition.

By using the `parmodify` HP-UX command or Partition Manager, you also can configure some boot settings for remote (non-local) nPartitions in the same server complex.

You can reconfigure boot settings at any time to change the nPartition's boot behavior, specify different boot devices, or adjust settings based on nPartition configuration changes. Some boot setting changes require rebooting to take effect.

Also see *Checklist and Guidelines for Booting nPartitions* on page 184 for details on ensuring a bootable nPartition configuration.

You can configure the following boot settings for each nPartition: boot device paths, boot actions, core cell choices, cell use-on-next-boot value.

- **Boot Device Paths**

  You can set boot device paths to reference the hardware paths where bootable devices reside within the local nPartition.

  The boot device paths include the primary boot device (PRI boot path), the high-availability alternate device (HAA boot path, such as a mirror of the root volume), and the alternate device (ALT boot path, such as an install or recovery device).

  The PRI path is the default device booted by the BCH interface's `BOOT` command.

  You can set boot paths using the BCH interface, the `parmodify` command, and Partition Manager. The `setboot` command can set the PRI and ALT paths only.

5621

- **Boot Actions**

  Each boot device path has an associated boot action, which is established by the path's "path flag" setting. The boot actions (path flag settings) are referenced automatically when an nPartition initially boots to the BCH interface.

  Boot actions have no effect on boot behavior when you manually boot HP-UX using the BCH interface's BOOT command.

  The boot action for the PRI boot path establishes what the nPartition does when it boots and first reaches the BCH interface: boot the PRI device, go to the BCH Main menu, or skip the PRI path and attempt to perform the HAA path's boot action. You also can specify what action to take if an attempt to boot a device fails (either go to BCH, or try the next path).

  Depending on the PRI path flag setting, the HAA boot action may be referenced. Likewise, the HAA setting determines whether the ALT boot actions may be referenced.

  You can set boot actions using the BCH Configuration menu's PathFlags (PF) command. The setboot command can configure only the PRI actions from HP-UX.

  For details use the BCH Command menu's HELP PF command.

  You can stop an nPartition from automatically booting, and instead access the nPartition's BCH interface, by typing a key within ten seconds of the nPartition booting to BCH.

```
Primary Boot Path:  0/0/1/0/0.8
     Boot Actions:  Boot from this path.
                    If unsuccessful, go to BCH.

...

Attempting to boot using the primary path.
-------------------------------------------------------------

 To discontinue, press any key within 10 seconds.
```

- **Core Cell Choices**

  The core cell is the cell that "runs" the nPartition before it boots HP-UX. A processor on the core cell serves as the monarch processor that runs Boot Console Handler (BCH). The core cell is the one whose core I/O is active for the nPartition.

5620

One cell is selected as the **active core cell** for the nPartition when the nPartition boots. By default, the lowest numbered eligible cell in the nPartition is chosen. To be eligible the cell must: be active, have a connection to functioning core I/O, and be assigned to the nPartition.

You can designate up to four **core cell choices**, which are considered in the order you specify as candidates to be selected as the active core cell for the nPartition.

If none of the core cell choices is eligible to serve as the core cell, then the nPartition attempts to select a core cell using the default algorithm (lowest numbered eligible cell).

When no active cell in an nPartition can be selected, the nPartition will remain at the ready for reconfig state and cannot boot to BCH.

- **Use-on-Next-Boot Value for a Cell**

  Each cell in an nPartition has an associated *use-on-next-boot* value that determines whether the cell's resources are used by the nPartition.

  This setting does not affect the cell's nPartition assignment. The use-on-next-boot value only determines whether the cell is an *active* or *inactive* member of the nPartition when the nPartition boots.

  When a cell's use-on-next-boot value is "y" (use the cell), the cell can participate in nPartition rendezvous and become an *active* member of the nPartition, which enables its processors, memory, and any connected I/O to be made available for use by the nPartition.

  When a cell has a use-on-next-boot value of "n" (do not use the cell), the cell cannot participate in partition rendezvous so it will be an *inactive* member of the nPartition when the nPartition boots: all processors, memory, and I/O will not be made available.

  After changing a cell's use-on-next-boot value you might need to reset the nPartition so that all cells have a chance to either participate in partition rendezvous or remain inactive at BIB. (For example, if the nPartition is in the ready for reconfig state, just boot it using the service processor Command menu's `BO` command; but if the nPartition is active and has booted HP-UX then perform a reboot for reconfig using the `shutdown -R` command.)

  The use-on-next-boot setting does not directly affect the nPartition's boot behavior, but it will cause I/O connected to a cell to be unavailable when the cell boots with a "n" use-on-next-boot value.

5619

For details on configure these boot-related settings for an nPartition refer to the chapter *Booting and Resetting nPartitions* on page 197.

S618

Listing nPartition Boot Settings

You can list an nPartition's boot-related settings by using the nPartition's BCH interface or by using HP-UX commands.

To *list boot settings* for nPartitions, use the following procedures:

- *Listing nPartition Boot Settings [BCH]* on page 178
- *Listing nPartition Boot Settings [HP-UX]* on page 181
- *Listing nPartition Boot Settings [Partition Manager]* on page 183

Also see the following sections for details on *configuring boot settings* for nPartitions.

- *Configuring Boot Paths and Boot Actions* on page 227
- *Configuring Autoboot and Autostart* on page 233
- *Configuring Automatic System Restart for an nPartition* on page 235
- *Configuring Fast Boot Settings (Self Tests) for an nPartition* on page 238
- *Boot Timer Configuration for an nPartition* on page 242

Listing nPartition Boot Settings [BCH]

Use BCH commands from the **Main menu, Information menu**, and **Configuration menu** to list an nPartition's boot settings.

Step 1. Login to the server complex's service processor (GSP or MP), access the nPartition's console, and access the BCH Main menu.

From the nPartition console you access the nPartition's BCH interface. If the nPartition is not at the BCH interface, you must either boot the nPartition or shut down HP-UX to return to the BCH interface.

Step 2. Access the BCH menu that provides the information you want to list.

The BCH interface's **Main menu, Information menu**, and **Configuration menu** provide commands for listing (and setting) boot options for the nPartition.

5617

- **BCH Main menu**

  If you are at one of the other BCH menus, enter **MA** to return to the BCH interface's Main menu.

Table 4-1 **BCH Main Menu Boot Settings**

PATH	Displays or sets the boot paths: primary (PRI), high-availability (HAA), and alternate (ALT).

- **BCH Configuration menu**

  From the BCH main menu, enter **CO** to access the Configuration menu.

Table 4-2 **BCH Configuration Menu Boot Settings**

AU	*Supported on HP Superdome servers only.* Displays or sets the auto-start flag, which determines whether the boot process proceeds following a self-test failure.
BOOTTIMER	Displays or sets the time allowed for booting.
CELLCONFIG	Displays or sets the (de)configuration of cells.
CORECELL	Displays or sets the core cell choices.
FASTBOOT	Displays or specifies whether certain self-tests are run during the boot process.
PATHFLAGS	Displays or sets the boot action for each boot path.

- **BCH Information menu**

  From the BCH Main menu, enter **IN** to access the Information menu.

Table 4-3 **BCH Information Menu Boot Settings**

BOOTINFO	Displays boot configuration information.

Step 3. At the appropriate BCH menu, issue the command to display the boot information of interest to you.

See the list in the previous step for commands and menus. Enter the command *with no arguments* to display (but not change) the boot setting.

S616

The following example shows using the PATH command to list the nPartition's boot paths, then accessing the BCH Configuration menu and issuing the PATHFLAGS command to list the nPartition's boot action settings for the PRI, HAA, and ALT boot paths.

```
Main Menu: Enter command or menu > PATH

     Primary Boot Path:  4/0/2/0/0.10
                         4/0/2/0/0.a     (hex)

HA Alternate Boot Path:  4/0/1/0/0.6
                         4/0/1/0/0.6     (hex)

   Alternate Boot Path:  4/0/1/0/0.5
                         4/0/1/0/0.5     (hex)

Main Menu: Enter command or menu > CO

---- Configuration Menu ------------------------------------

....

Configuration Menu: Enter command > PATHFLAGS

     Primary Boot Path Action
          Boot Actions:  Boot from this path.
                         If unsuccessful, go to next path.

HA Alternate Boot Path Action
          Boot Actions:  Boot from this path.
                         If unsuccessful, go to BCH.

   Alternate Boot Path Action
          Boot Actions:  Skip this path.
                         Go to BCH.

Configuration Menu: Enter command >
```

5615
21

Listing nPartition Boot Settings [HP-UX]

Use the **parstatus -V -p#** and **setboot** commands to list an nPartition's boot settings from HP-UX 11i.

NOTE Use the parstatus command to list various nPartition boot settings for *any* nPartition in a server complex.

The setboot command only provides information about the *local nPartition's* PRI and ALT boot paths and PRI boot actions.

Step 1. Login to HP-UX running on an nPartition.

If you want to list autoboot settings for an nPartition, you must login to the nPartition. To list other details, such as boot paths and core cell settings, you can login to any nPartition.

Step 2. Issue the **parstatus -V -p#** command to list detailed information about the specified nPartition (-p#), including boot-related details.

The boot setting information that parstatus -V -p# reports is equivalent to the following BCH commands: PATH, CELLCONFIG, and CORECELL.

The following example lists detailed information for nPartition number 0, including the nPartition's boot path settings, its core cell information, and each cell's use-on-next-boot settings.

```
# parstatus -V -p0
[Partition]
Partition Number         : 0
Partition Name           : jules00
Status                   : active
IP address               : 0.0.0.0
Primary Boot Path        : 0/0/2/0/0.13.0
Alternate Boot Path      : 0/0/2/0/0.0.0
HA Alternate Boot Path   : 0/0/2/0/0.14.0
PDC Revision             : 6.0
IODCH Version            : 23664
CPU Speed                : 552 MHz
Core Cell                : cab0,cell0
Core Cell Alternate [1]: cab0,cell0
Core Cell Alternate [2]: cab0,cell2
```

S614

```
[Cell]
                        CPU     Memory                                Use
                        OK/     (GB)                          Core    On
Hardware   Actual       Deconf/ OK/                           Cell    Next Par
Location   Usage        Max     Deconf    Connected To        Capable Boot Num
========== ============ ======= ========= =================== ======= ==== ===
cab0,cell0 active core  4/0/4    2.0/ 0.0 cab0,bay0,chassis1  yes     yes  0
cab0,cell2 active base  4/0/4    2.0/ 0.0 cab0,bay1,chassis3  yes     yes  0

[Chassis]
                                        Core Connected  Par
Hardware Location   Usage               IO   To         Num
=================== ============ ==== ========== ===
cab0,bay0,chassis1  active       yes  cab0,cell0 0
cab0,bay1,chassis3  active       yes  cab0,cell2 0

#
```

As the above example shows, the primary (PRI) boot path is 0/0/2/0/0.13.0, the active core cell is cell 0, and the core cell choices are cell 0 (first preference) and cell 2 (second preference). Both of the nPartition's cells are set to be used ("yes") the next time the nPartition boots. Both cells are actively used ("active core" and "active base").

Step 3. Issue the **setboot** command to list the *local nPartition's* PRI and ALT (but not HAA) boot paths, and to list the boot actions for the PRI boot path.

```
# setboot
Primary bootpath : 0/0/2/0/0.13.0
Alternate bootpath : 0/0/2/0/0.0.0

Autoboot is ON (enabled)
Autosearch is OFF (disabled)

Note: The interpretation of Autoboot and Autosearch has changed
for
systems that support hardware partitions. Please refer to the
manpage.
#
```

The setboot command reports the local nPartition's PRI and ALT boot path values, but does not list the HAA boot path.

The setboot command also reports the "autoboot" and "autosearch" settings for the PRI boot path. Combined, these two settings are equivalent to the PRI path's boot actions (its "path flags" setting).

S613
21

When autoboot is set to ON, the nPartition attempts to automatically boot from the PRI boot path when it first boots to BCH. Otherwise, when autoboot is OFF, the nPartition remains at the BCH interface on startup.

When autosearch is set to ON, the nPartition will attempt to perform the boot action for the HAA boot path if the PRI boot action is automatically attempted and fails to boot (when autoboot is ON). When autosearch is set to OFF, the nPartition remains at BCH if the PRI path is not automatically booted on startup.

Refer to the section *Configuring Autoboot and Autostart* on page 233 for other details and procedures.

Listing nPartition Boot Settings [Partition Manager]

This procedure (**Partition —> Show Partition Details** action, **General** tab) lists an nPartition's boot paths from Partition Manager.

Step 1. Run Partition Manager (`/opt/parmgr/bin/parmgr`) or access it from SAM or a Web browser.

Step 2. Select the nPartition whose boot path settings you want to view.

Partitions are listed on the left side of the Partition Manager primary window.

Step 3. Select the **Partition —> Show Partition Details** action and view the boot path settings in the **General** tab.

This displays the PRI, HAA, and ALT boot path values for the selected nPartition.

Checklist and Guidelines for Booting nPartitions

This section provides both a checklist to use when booting an nPartition, and a set of guidelines to consider when configuring nPartition boot settings.

Boot Checklist for nPartitions

Before you boot an nPartition, check the items listed here.

- ❑ All cells in the nPartition that have a "y" use-on-next-boot value should be powered on.

  If any cells that are set to be used are powered off, the nPartition will take longer to boot.

  During partition rendezvous, the nPartition will wait up to *10 minutes* for all cells that are designated to be used. Any cells not powered on will not be active or available in the nPartition.

- ❑ All I/O chassis and devices for the nPartition's active cells should be powered on.

- ❑ If any cells that have a "y" use-on-next-boot value are inactive, perform a reboot for reconfig of the nPartition (`shutdown -R`) to allow them to reset and become active during partition rendezvous.

- ❑ All complex profile information for the nPartition must be coherent.

  This means all cells assigned to the nPartition must have identical complex profile information (Partition Configuration Data).

  After you add a cell or remove and active cell from an nPartition, you must perform a reboot for reconfig of the nPartition (`shutdown -R`) to synchronize the complex profile data throughout the nPartition. The reboot for reconfig also causes all the nPartition's cells to reboot and allows cells to go through the partition rendezvous procedure.

Boot Configuration Guidelines for nPartitions

The following guidelines are points to consider when configuring boot settings for the nPartitions in your server complex.

- ❑ Configure HAA and ALT boot devices in addition to the PRI device.

By configuring HAA and ALT boot device paths, you establish additional bootable devices that provide redundancy in case the PRI device fails.

Also configure the path flags for the boot paths, to allow the HAA device to boot automatically if the device at the PRI path cannot boot.

- ❑ Ensure that the core I/O, PRI boot device, and network card(s) all are connected to same cell (the core cell).

  This configuration ensures that the core cell is directly connected to the I/O required for booting the nPartition and providing network connections. Having such a configuration eliminates the requirement for multiple cells to be functional to provide basic nPartition services.

- ❑ Have multiple core cells available within each nPartition, if possible.

  In order to have multiple core cell choices, the nPartition must have at least two cells, each connected to an I/O chassis and core I/O.

  Having such a configuration provides redundancy and potentially improved system availability. If one core cell has a failure or otherwise cannot serve as the active core cell, the second core-capable cell can serve as the active core cell.

  Disregard this guideline if configuring multiple nPartitions in an HP rp7405 / rp7410 or HP rp8400 server complex. HP rp7405/rp7410 servers and HP rp8400 servers have up to two core-capable cells only, so following this guideline would require having only one nPartition in the server complex.

S610

nPartition Boot Activity Monitoring

On HP nPartition servers you can monitor the nPartition boot process—from power-on or reset to HP-UX start-up—using the Virtual Front Panel (VFP) view of the nPartition.

Each nPartition has its own VFP that displays details about the nPartition's cells and the nPartition's boot state and activity.

NOTE After you add or remove cells from the nPartition, you must exit and re-enter the nPartition's VFP to update the list of cells the VFP displays.

Monitoring nPartition Boot Activity [Service Processor]

Use the following procedure (service processor Main menu, **VFP** option) to access an nPartition Virtual Front Panel for monitoring the nPartition's boot status.

Step 1. From the Main menu, enter **VFP** to select the Virtual Front Panel option.

```
 GSP MAIN MENU:

Utility Subsystem FW Revision Level: SR_XXXX_D

          CO: Consoles
         VFP: Virtual Front Panel
          CM: Command Menu
          CL: Console Logs
          SL: Show chassis Logs
          HE: Help
           X: Exit Connection

GSP> VFP
```

If you are accessing the service processor using a single-partition-user account, selecting the VFP option takes you directly to the nPartition's Virtual Front Panel.

If accessing the GSP using an operator or administrator account, you can select the VFP for any single nPartition, or can select a *system VFP* that displays the nPartition state and activity for all nPartitions within the server complex.

Step 2. Select the nPartition you wish to monitor.

Skip this step if you are accessing the service processor using a single-partition-user account.

```
 Partition VFP's available:

        #    Name
       ---   ----
        0)   jules00
        1)   jules01
        S)   System (all chassis codes)
        Q)   Quit

GSP:VFP> 1
```

Step 3. View the VFP details for information about the nPartition and its current boot state.

To exit the VFP and return to the service processor main menu, type **^b** (**Control-b**).

The VFP provides information about the nPartition state, nPartition activity, each cell's state, and each cell's activity. The VFP display updates as the cell or nPartition state and activities change.

```
E indicates error since last boot
     Partition 1  state                Activity
     ------------------                --------
     Cell(s) Booting:     57 Logs

  #  Cell state                        Activity
  -  ----------                        --------
  4  Booting                           Cell firmware test                   28  Logs
  6  Booting                           Cell firmware test                   28  Logs

GSP:VFP (^B to Quit) >
```

5608

Hanged HP-UX and Running HP-UX Detection

This section describes how you can determine whether HP-UX still is running on an nPartition even when you are unable to login or access the nPartition console.

You also may wish to reference the information in the procedure *Configuring Automatic System Restart for an nPartition* on page 235 for details on configuring an nPartition to reboot when HP-UX has hanged on it for over three minutes.

Detecting if HP-UX is Running or Hanged on an nPartition

To determine whether HP-UX is running or has hanged on an nPartition use this procedure (first check the Virtual Front Panel, then check the Chassis Logs menu's **Live Logs** display, then the nPartition's Console).

Refer to the chapter *Using Console and Service Processor Interfaces* on page 125 for details on service processor login accounts and features.

Step 1. Access and view the nPartition's Virtual Front Panel (VFP).

Login to the service processor (GSP or MP) for the server where the nPartition resides, enter `VFP` to access the VFP menu, and select the nPartition whose boot state you want to check.

- To exit an nPartition's VFP, type **^b** (**Control-b**).
- When HP-UX has booted on the nPartition, `HPUX heartbeat` is displayed as the partition state when you view the nPartition VFP.
- If HP-UX is alive, an asterisk (`*`) blinks on and off in the partition state area of the nPartition VFP.

Also see *Boot States and Activities for nPartitions and Cells* on page 194 for details interpreting the VFP status.

Step 2. If the nPartition VFP indicates that HP-UX has booted but is not alive, exit the VFP and view the live chassis logs for the nPartition.

At the GSP main menu, enter `SL` to enter the **Show chassis Logs** menu, and enter `L` to select the **Live Chassis Logs** display from the **Chassis Logs** menu.

S607

```
GSP> SL

Chassis Logs available:

     (A)ctivity Log
     (E)rror Log
     (L)ive Chassis Logs

     (C)lear All Chassis Logs
     (Q)uit

GSP:VW> L

         Entering Live Log display
```

Step 3. From the Live Log display, type **P** and select the nPartition whose chassis codes you want to view by typing the partition number.

By default the live chassis log viewer only displays alert codes.

When you select the partition filter, the live log's view changes to show all codes for the selected nPartition.

```
         Entering Live Log display

         A)lert filter
         C)ell filter
         P)artition filter
         U)nfiltered
         V)iew format selection
         ^B to Quit

Current filter: ALERTS only

P
Enter partition number to display

    Partitions available:
     #   Name
    ---  ----
     0)  feshd4a
     2)  feshd4b
     Q)  Quit
    Please select partition number: 0

Filtering partition 0
```

Step 4. When viewing the selected nPartition's live log display, determine whether HP-UX is emitting HEARTBEAT chassis codes.

To exit the live log display, type **^b** (**Control-b**)

Heartbeat for HP-UX

When HP-UX is running on the nPartition, the live log partition filter shows the nPartition's HP-UX HEARTBEAT chassis codes and corresponding ACTIVITY_LEVEL_TIMEOUT counter updates.

```
Filtering partition 0
Alert Level 0: No failure; Keyword: HEARTBEAT
Processor 0 ; Status: 15
Logged by HP-UX 26 during display_activity update subActivity 10
Legacy PA HEX chassis-code: f10f
0xf8e1a8001100f10f 0x000000000000f10f

HPUX 0,0,0   0  ACTIVITY_LEVEL_TIMEOUT
Alert Level 0: No failure; Keyword: ACTIVITY_LEVEL_TIMEOUT
Processor 0 timeout; Status:  0
Logged by HP-UX 0 during display_activity update subActivity 0
Activity Level/Timeout: 0% / 3 minutes
0x78e008041100f000 0x0000000200000000

HPUX 0,6,2   0  HEARTBEAT
Alert Level 0: No failure; Keyword: HEARTBEAT
Processor 0 ; Status: 15
Logged by HP-UX 26 during display_activity update subActivity 10
Legacy PA HEX chassis-code: f10f
0xf8e1a8001100f10f 0x000000000000f10f
```

Activity Timeout Counter

The nPartition activity timeout counter is reset every time HP-UX on the nPartition emits a HEARTBEAT chassis code. The timeout counter expires when no HEARTBEAT code has been emitted for three minutes in the nPartition.

See *Configuring Automatic System Restart for an nPartition* on page 235 for more details about the activity timeout counter.

Step 5. If the nPartition is not emitting HEARTBEAT chassis codes, then access the nPartition's console by entering **CO** from the service processor main menu and selecting the partition number for the nPartition.

Accessing the nPartition's console may help determine whether an HP-UX crash dump is occurring or any console or error messages were given.

5605

Step 6. Determine whether the nPartition needs to be reset in order to restore HP-UX to a running state.

Review the findings from the previous steps in this procedure.

HP-UX on the nPartition may be considered “hanged” if you observed all of the following VFP, live log, and console behaviors:

- The VFP indicates `HPUX heartbeat` in the partition state with no asterisk (`*`) blinking to indicate activity.
- The nPartition’s live log displays no `HEARTBEAT` chassis codes.
- The nPartition console is inactive with no indication of a crash dump or other error, and no console login or interactivity is possible.

If all of the above attempts to find signs of HP-UX activity on the nPartition fail, then you may need to reset the nPartition before HP-UX can be restored to a running state.

For details see the procedure *Rebooting or Resetting an nPartition* on page 214 or the procedure *Performing a Transfer-of-Control (TOC) Reset of an nPartition* on page 223.

5604

Troubleshooting Boot Issues

On HP nPartition servers, you might encounter different boot issues than on other HP servers.

The following boot issues are possible on nPartition servers.

- **Problem:** Not all cells boot to join (rendezvous) an nPartition.

  Causes: Some cells may have their use-on-next-boot value set to "n" (do not use), or the cells may have been powered off, or the cells may have booted too late to participate in partition rendezvous, or the cells have failed self-tests and cannot be used.

  Actions: Check the cell use-on-next-boot values and change them to "y" as needed then reboot for reconfig (`shutdown -R`). Check cell power (`frupower -d -C`) and power on any cells as needed, then reboot for reconfig.

  As the nPartition's cells reboot, observe the boot progress from the nPartition's VFP and note any problems the cells have proceeding from one boot state to the next; as needed review chassis logs and error logs using the service processor Show Chassis Logs (`SL`) menu.

- **Problem:** An nPartition takes a long time to boot (over ten minutes).

  Causes: One or more cells assigned to the nPartition that have a "y" use-on-next-boot value has not booted to participate in partition rendezvous, thus causing the rest of the nPartition's cells to wait for ten minutes for the cell to report.

  For example, the cell might not be installed, might be powered off, or might have been powered on or reset too late to rendezvous with the other cells.

  Actions: You can avoid the delay by performing any of the following actions, as needed. Perform a reboot for reconfig following any changes you make.

  — Set the cell's use-on-next-boot value to "n" (do not use).

  — Power on the cell.

  — Unassign (remove) the cell from the nPartition.

5603

- **Problem:** An nPartition does not boot to BCH and instead all cells remain at a boot-is-blocked (BIB) state.

  Causes: The nPartition has been reset to the ready for reconfig state, or no valid core cell is available to the nPartition.

  Actions: If the nPartition was reset to the ready for reconfig state, use the service processor Command menu's BO command to boot the nPartition base boot-is-blocked (to allow it to boot to its BCH interface).

  If no valid core cell was available to the nPartition when it booted, check the power for all core cell choices (a cell might be powered off) and power it on if needed.

  Also review the chassis logs for the nPartition to search for any core cell problems and failures.

5602

Boot States and Activities for nPartitions and Cells

On HP nPartition servers, the cell and nPartition boot process proceeds from one boot state to the next; cells and nPartitions complete various boot activities within each boot state before proceeding to the next boot state.

You can view current details about nPartition and cells boot states and activities by viewing the nPartition's Virtual Front Panel. From the service processor (GSP or MP) Main menu enter **VFP** to access the VFPs that are available for the server complex.

Table 4-4 on page 195 presents the nPartition and cell states and activities that you can observe from an nPartition's Virtual Front Panel.

You can view a Virtual Front Panel for a specific nPartition that includes details for all cells in the nPartition, as shown below.

```
E indicates error since last boot
     Partition 0  state              Activity
     ------------------              --------
     Cell(s) Booting:    904 Logs

  #  Cell state                      Activity
  -  ----------                      --------
  0  Late CPU selftest               Processor test                       299   Logs
  2  Late CPU selftest               Processor test                       299   Logs
  4  Memory discovery                Physical memory test                 304   Logs

GSP:VFP (^B to Quit) >
```

You also can view a system-wide VFP, which shows a summary of each nPartition's current state and its activity.

569

Inactive cells remain at a “Boot Is Blocked (BIB)” state following I/O discovery and do not participate in partition rendezvous.

Table 4-4 **HP nPartition and Cell Boot States and Activities**

Partition State	Partition Activity	Cell States	Cell Activities
Cell(s) Booting		Booting	Cell firmware configuration, Cell firmware test, Cell PDH controller configuration
Cell(s) Booting		Early CPU self-test	Processor test, Cell firmware test, Processor firmware slave rendezvous
Cell(s) Booting		Memory discovery	Physical memory test
Cell(s) Booting		Late CPU self-test	Processor test, Cell firmware test, Processor firmware slave rendezvous
Cell(s) Booting		I/O discovery	I/O system bus adapter configuration, I/O local bus adapter configuration
Cell(s) Booting		Remote fabric initialization	Partition rendezvous slave rendezvous
Memory Interleave	Memory controller configuration	Cell has joined partition	
At Boot Console Handler (BCH)	Partition firmware	Cell has joined partition	
ISL Menu		Cell has joined partition	
HPUX Loader Init		Cell has joined partition	

Table 4-4 HP nPartition and Cell Boot States and Activities (Continued)

Partition State	Partition Activity	Cell States	Cell Activities
HPUX Launch	Processor system initialization	Cell has joined partition	
HPUX Launch	Partition IPL launch configuration	Cell has joined partition	
HPUX Launch	Processor display_activity update	Cell has joined partition	
HPUX init process start		Cell has joined partition	
HPUX heartbeat		Cell has joined partition	

559a

5 Booting and Resetting nPartitions

This chapter presents procedures for booting and resetting nPartitions and procedures for configuring an nPartition's boot-related options.

For an introduction to nPartition boot issues, refer to the chapter *An Overview of nPartition Boot and Reset* on page 161.

NOTE For details on booting and rebooting virtual partitions within an nPartition, refer to the chapter *Virtual Partitions (vPars) Management on nPartitions* on page 441.

Accessing an nPartition Console and BCH Interface

Each nPartition has its own Boot Console Handler (BCH) interface that provides you a method for interacting with the nPartition before HP-UX has booted on it.

You must access an nPartition's console and BCH interfaces through the server complex's service processor (GSP or MP). See *Accessing nPartition Console and BCH Interfaces [Service Processor]* below for a detailed procedure.

On nPartition servers, each nPartition's BCH interface is available through the nPartition's console before HP-UX has booted. The BCH interface enables you to manage the nPartition's HP-UX boot process and to configure various boot-related settings.

NOTE

Always login to a server complex's service processor from a tty (not console) login session. You can check your current login terminal using the **`who -m`** command.

Do not login to a service processor from an nPartition console connection. Any use of the **^b** (**Control-b**) console exit sequence would exit the original console login—not the subsequent console-based login to the service processor—thus potentially stranding the console-based login (for example, if it too were accessing a console).

Accessing nPartition Console and BCH Interfaces [Service Processor]

The following procedure (login to service processor, select Console menu, select an nPartition) accesses an nPartition's console and BCH interface using the server complex's service processor.

Step 1. Login to the service processor (the GSP or MP) for the nPartition's server complex.

You can connect to the service processor using a direct physical connection, or using `telnet` for a remote connection.

ss97

In most situations, you can `telnet` to the service processor.

```
# telnet sdome-s
Trying...
Connected to sdome-s.rsn.hp.com.
Escape character is '^]'.
Local flow control off

GSP login: Accountname
GSP password:

                              Welcome to
               Superdome's Guardian Service Processor
```

Step 2. Select the Console menu (`CO`) from the service processor's Main menu.

The Console menu is the method for accessing nPartition consoles.

```
 GSP MAIN MENU:

Utility Subsystem FW Revision Level: SR_XXXX_D

            CO: Consoles
           VFP: Virtual Front Panel
            CM: Command Menu
            CL: Console Logs
            SL: Show chassis Logs
            HE: Help
             X: Exit Connection

GSP> CO
```

If you are accessing the service processor using a single-partition-user account, selecting the `CO` (console) option takes you directly to the nPartition's console.

If using an operator or administrator account, you can access the console for any of the nPartitions within the server complex.

Step 3. At the Console menu, enter the partition number for the nPartition whose console (and BCH interface) you wish to access.

Skip this step if you are accessing the service processor using a single-partition-user account.

If using an operator or administrator account, select the nPartition whose console you wish to access.

```
GSP> CO

    Partitions available:

     #    Name
    ---   ----
     0)   jules00
     1)   jules01
     Q)   Quit

    Please select partition number: 1

        Connecting to Console: jules01

        (Use ^B to return to main menu.)

        [A few lines of context from the console log:]

- - - - - - - - - - - - - - - - - - - - - - - - - - - - - - -

     SERvice menu                      Displays service commands

     DIsplay                           Redisplay the current menu
     HElp [<menu>|<command>]           Display help for menu or command
     REBOOT                            Restart Partition
     RECONFIGRESET                     Reset to allow Reconfig Complex Profile
----
Main Menu: Enter command or menu >

- - - - - - - - - - - - - - - - - - - - - - - - - - - - - - -
```

The console displays the last 10 lines of console output when you connect to it. This provides you a view of the most recent console activity.

Step 4. Gain interactive access to the nPartition console.

Press **Enter** to access the nPartition console's currently available prompt, if any. You will have either interactive or non-interactive access, as described in the sections *Interactive Console Access* and *Non-Interactive Console Access* in this step.

To exit the nPartition console and return to the service processor Main menu, type **^b** (**Control-b**) at any time.

Interactive Console Access

Typically the BCH interface, ISL interface, or the HP-UX login or command prompt is available from the nPartition console.

- **When an nPartition is at the BCH interface** you can access BCH commands from the nPartition's console and can reboot BCH if needed.
- **When an nPartition has booted to ISL** you can use the `EXIT` command to exit ISL and return to the nPartition's BCH interface.
- **When an nPartition has booted HP-UX**, in order to access the BCH interface you must reboot HP-UX and if necessary interrupt the automatic boot process. (To reboot the nPartition, use the `shutdown -r` command, or use `shutdown -R` if you also are changing the nPartition's cell configuration.)

Non-Interactive Console Access

In the following situations, you cannot interact with the nPartition's console. In these cases you can wait until the console is interactive or can force interactive access.

- **When the nPartition is resetting or is booting HP-UX** you cannot interact with software running on the nPartition.

  Once the nPartition has completed resetting, or has completed booting HP-UX, you can interact with the nPartition's BCH or HP-UX prompts.

  To determine an nPartition's boot state, use the nPartition's Virtual Front Panel (the VFP menu, available from the service processor Main menu).

- **When another user already is attached to the console** you can access the nPartition's console in spy (read-only) mode or can force write access by typing `^ecf` (**Control-e c f**).

  Spy mode allows you to view console information but does not enable you to enter commands. If you type when accessing an nPartition console in spy mode, the console prints the following message.

  ```
  [Read-only - use ^Ecf to attach to console.]
  ```

  When in spy mode, you can force access to the nPartition's console by typing `^ecf` (**Control-e c f**). Doing this provides you interactive console access and forces ("bumps") the user who was using the console into spy mode.

  ```
  [Bumped user - Admin.]
  ```

Boot Device Searching and Finding

You can search for and find bootable devices for an nPartition by using the BCH interface's SEARCH command. This command searches for and reports all bootable devices connected to any of the nPartition's currently active cells.

NOTE

You cannot access any I/O connected to an nPartition's *inactive* cells (cells not being used for the current nPartition boot) or cells *not assigned* to the local nPartition.

As a consequence, the BCH SEARCH command does not report any devices connected to cells that are not currently assigned and active in the local nPartition.

Finding Bootable Devices [BCH]

This procedure (BCH Main menu, SEARCH command) finds and lists the bootable devices that are available to an nPartition.

Step 1. Login to the server complex's service processor (GSP or MP) and access the nPartition's console.

From the nPartition console you access the nPartition's BCH interface to search for bootable devices.

If the nPartition is not at the BCH interface you must either boot the nPartition or shut down HP-UX to return to the BCH interface.

Step 2. From the BCH interface's Main menu, issue the SEARCH command to find and list bootable devices in the nPartition.

When accessing the nPartition's BCH interface, if you are not at the BCH Main menu then enter MA to return to the Main menu.

The SEARCH command reports all potential boot devices it locates.

```
---- Main Menu ---------------------------------------------------------------

     Command                             Description
     -------                             -----------
     BOot [PRI|HAA|ALT|<path>]           Boot from specified path
```

```
        PAth [PRI|HAA|ALT] [<path>]       Display or modify a path
        SEArch [ALL|<path>]               Search for boot devices
        ScRoll [ON|OFF]                   Display or change scrolling capability

        COnfiguration menu                Displays or sets boot values
        INformation menu                  Displays hardware information
        SERvice menu                      Displays service commands

        DIsplay                           Redisplay the current menu
        HElp [<menu>|<command>]           Display help for menu or command
        REBOOT                            Restart Partition
        RECONFIGRESET                     Reset to allow Reconfig Complex Profile
----
Main Menu: Enter command or menu > SEARCH

Searching for potential boot device(s)
This may take several minutes.

To discontinue search, press any key (termination may not be immediate).

   Path#  Device Path (dec)                       Device Type
   -----  -----------------                       -----------
   P0     0/0/1/0/0.15                            Random access media
   P1     0/0/1/0/0.12                            Random access media
   P2     0/0/1/0/0.11                            Random access media
   P3     0/0/1/0/0.9                             Random access media
   P4     0/0/1/0/0.8                             Random access media
   P5     0/0/1/0/0.6                             Random access media

Main Menu: Enter command or menu >
```

The SEARCH command lists up to the first 20 potential boot devices that it locates, and lists each with a path number (P0 through P19).

To boot a device that was reported by the SEARCH command, specify the path number or the full device path. For example, BOOT P0 would boot the path listed as path number P0.

HP-UX Booting on an nPartition

nPartitions boot and reboot HP-UX independently from each other. This section describes how to boot a single instance of HP-UX on an nPartition.

NOTE For details on booting HP-UX in virtual partitions (vPars), refer to the section *Booting HP-UX on Virtual Partitions* on page 487.

You can boot HP-UX on an nPartition using the BCH interface's BOOT command.

Each nPartition's BCH interface is available through its console. All nPartition consoles are available from the complex's service processor (GSP or MP) Console menu.

An nPartition will *automatically boot HP-UX* when its boot paths (PRI, HAA, ALT) and corresponding boot actions are appropriately set. For details see *Configuring Boot Paths and Boot Actions* on page 227.

On HP Superdome servers only, if one of the nPartition's components fails self-test and AUTOSTART is OFF then the nPartition stops booting at the BCH interface.

Booting HP-UX on an nPartition [BCH]

The following procedure (BCH interface **BOOT** command) boots HP-UX on an nPartition using the nPartition's BCH interface.

Step 1. Login to the server complex's service processor (GSP or MP), access the nPartition's console, and access the BCH Main menu.

From the nPartition console, you access the nPartition's BCH interface.

If the nPartition is not at the BCH interface, you must either boot the nPartition or shut down HP-UX to return to the BCH interface.

When accessing the nPartition's BCH interface, if you are not at the BCH Main menu then enter MA to return to the Main menu.

Step 2. Choose which device you wish to boot.

From the BCH Main menu, use the PATH command to list any boot path variable settings. The primary (PRI) boot path normally is set to the main boot device for the nPartition. You also can use the SEARCH command to find and list potentially bootable devices for the nPartition.

```
Main Menu: Enter command or menu > PATH

     Primary Boot Path:  0/0/2/0/0.13
                         0/0/2/0/0.d     (hex)

HA Alternate Boot Path:  0/0/2/0/0.14
                         0/0/2/0/0.e     (hex)

   Alternate Boot Path:  0/0/2/0/0.0
                         0/0/2/0/0.0     (hex)

Main Menu: Enter command or menu >
```

Step 3. Boot the device using the BCH interface's **BOOT** command.

You can issue the BOOT command in any of the following ways:

- **BOOT**

  Issuing the BOOT command with no arguments boots the device at the primary (PRI) boot path.

BOOT *bootvariable*

  This command boots the device indicated by the specified boot path, where *bootvariable* is the PRI, HAA, or ALT boot path.

  For example, BOOT PRI boots the primary boot path.

- **BOOT LAN INSTALL** or **BOOT LAN.*ip-address* INSTALL**

  The BOOT... INSTALL commands boot HP-UX from the default HP-UX install server or from the server specified by *ip-address*.

BOOT *path*

  This command boots the device at the specified *path*. You can specify the *path* in HP-UX hardware path notation (for example, 0/0/2/0/0.13) or in "path label" format (for example, P0 or P1) .

  If you specify the *path* in "path label" format then *path* refers to a device path reported by the last SEARCH command.

After you issue the BOOT command, the BCH interface prompts you to specify whether you want to stop at the ISL prompt.

To boot the /stand/vmunix HP-UX kernel from the device *without stopping at the ISL prompt*, enter **n** to automatically proceed past ISL and execute the contents of the AUTO file on the selected device. (By default the AUTO file is configured to load /stand/vmunix.)

```
Main Menu: Enter command or menu > BOOT PRI

     Primary Boot Path:  0/0/1/0/0.15

 Do you wish to stop at the ISL prompt prior to booting? (y/n)
 >> n

ISL booting  hpux

Boot
: disk(0/0/1/0/0.15.0.0.0.0.0;0)/stand/vmunix
```

To boot an HP-UX kernel other than /stand/vmunix, or to boot HP-UX in single-user or LVM-maintenance mode, stop at the ISL prompt and specify the appropriate arguments to the hpux loader.

558
2X

Booting an nPartition to the ISL Prompt

When you issue the BCH interface's BOOT command, you can stop an nPartition's booting at the Initial System Loader (ISL) interface in order to interact with the ISL prompt.

To exit ISL and return to the BCH interface, enter the EXIT command at the ISL prompt. For help enter HELP at the ISL prompt.

Normally you will not need to access ISL unless you need to use the Secondary System Loader (hpux).

For details about ISL, see the *isl* (1M) manpage. Details on the Secondary System Loader (hpux) are in the *hpux* (1M) manpage.

NOTE On HP nPartition servers many of the ISL commands *are not supported*. For example, AUTOBOOT, AUTOSEARCH, and PRIMPATH are not supported at ISL.

These and other features are instead supported on HP nPartition servers by each nPartition's BCH interface.

Booting an nPartition to ISL [BCH]

This procedure (BCH BOOT command, and reply **y** to "stop at the ISL prompt") boots an nPartition to the ISL prompt.

Step 1. Login to the server complex's service processor (GSP or MP), access the nPartition's console, and access the BCH interface.

From the nPartition console, you access the nPartition's BCH interface. If the nPartition is not at the BCH interface you must either boot the nPartition or shut down HP-UX to return to the BCH interface.

If an nPartition is configured to automatically boot HP-UX, you must interrupt the boot process before HP-UX boots, then manually boot HP-UX using the BOOT command (in the next step) to access the ISL interface on the nPartition.

Step 2. Boot the desired device using the BCH interface's **BOOT** command, and specify that the nPartition stop at the ISL prompt prior to booting (reply **y** to the "stop at the ISL prompt" question).

The EXIT command exits ISL and returns to the nPartition BCH interface, and the HELP command lists all available ISL interface commands.

```
Main Menu: Enter command or menu > BOOT 0/0/2/0/0.13

 BCH Directed Boot Path: 0/0/2/0/0.13

 Do you wish to stop at the ISL prompt prior to booting? (y/n)
>> Y

Initializing boot Device.

ISL Revision A.00.42  JUN 19, 1999

ISL>
```

Single-User or LVM-Maintenance Mode HP-UX Booting

On an nPartition you can boot HP-UX in single-user mode or LVM-maintenance mode by specifying options to the Secondary System Loader (hpux).

From the nPartition's console, use the BCH interface to boot the desired device and stop at the Initial System Loader (ISL) interface, then use the Secondary System Loader (hpux) to specify the options for booting HP-UX in the desired mode.

See the *hpux* (1M) manpage for details on using the Secondary System Loader (hpux).

Booting HP-UX in Single-User or LVM-Maintenance Mode [BCH, ISL, and hpux]

This procedure (BCH **BOOT** command, stop at ISL interface, use hpux loader with options) boots HP-UX in single-user mode or LVM-maintenance mode on an nPartition.

Step 1. Login to the server complex's service processor (GSP or MP), access the nPartition's console, and access the BCH interface.

From the nPartition console you access the nPartition's BCH interface. If the nPartition is not at the BCH interface you must either boot the nPartition or shut down HP-UX to return to the BCH interface.

Step 2. Boot the desired device using the BCH interface's **BOOT** command, and specify that the nPartition stop at the ISL prompt prior to booting (reply **y** to the "stop at the ISL prompt" question).

```
Main Menu: Enter command or menu > BOOT 0/0/2/0/0.13

 BCH Directed Boot Path: 0/0/2/0/0.13

 Do you wish to stop at the ISL prompt prior to booting? (y/n)
>> y

Initializing boot Device.

....
```

586

```
ISL Revision A.00.42  JUN 19, 1999

ISL>
```

Step 3. From the ISL prompt, issue the appropriate Secondary System Loader (hpux) command to boot the HP-UX kernel in the desired mode.

Use the hpux loader to specify the boot mode options and to specify which kernel (such as: /stand/vmunix) to boot on the nPartition.

- To boot HP-UX in single-user mode:

  ```
  ISL> hpux -is boot /stand/vmunix
  ```

- To boot HP-UX in LVM-maintenance mode:

  ```
  ISL> hpux -lm boot /stand/vmunix
  ```

- To boot HP-UX at the default run level:

  ```
  ISL> hpux boot /stand/vmunix
  ```

To exit the ISL prompt and return to the BCH interface, issue the `EXIT` command instead of specifying one of the above hpux loader commands.

See the *hpux* (1M) manpage for a detailed list of hpux loader options.

Example 5-1 **Example Single-User HP-UX Boot**

```
ISL Revision A.00.42  JUN 19, 1999

ISL> hpux -is /stand/vmunix

Boot
: disk(0/0/2/0/0.13.0.0.0.0.0;0)/stand/vmunix
8241152 + 1736704 + 1402336 start 0x21a0e8

....

INIT: Overriding default level with level 's'

INIT: SINGLE USER MODE

INIT: Running /sbin/sh
#
```

HP-UX Install Source Booting

You can boot an nPartition from an HP-UX installation source—such as an install CD or an Ignite server—by specifying the install source using the BCH interface's BOOT command.

This allows you to install HP-UX on any of the nPartition's eligible devices.

NOTE For instructions on installing HP-UX, refer to the book *HP-UX 11i Installation and Update Guide*, which is supplied with the HP-UX operating environment media.

Booting from an HP-UX Install Source [BCH]

This procedure boots an HP-UX install source on an nPartition using the nPartition's BCH interface.

Step 1. Login to the server complex's service processor (GSP or MP), access the nPartition's console, and access the BCH interface.

From the nPartition console, you access the nPartition's BCH interface. If the nPartition is not at the BCH interface you must either boot the nPartition or shut down HP-UX to return to the BCH interface.

Step 2. Select the HP-UX install source that you wish to boot.

From the BCH main menu, you can boot from an Ignite server or install CD-ROM in order to install HP-UX.

You can use the SEARCH command to find and list potentially bootable devices for the nPartition, including any DVD-ROM devices that may have CD-ROM install media. The ALT boot path also might be set to the DVD-ROM device's path.

Step 3. Boot the install source using the BCH interface's **BOOT** command.

Specify the device path where the install media resides or specify the install server.

For details on booting, see *HP-UX Booting on an nPartition* on page 204.

Shutting Down HP-UX on an nPartition

When HP-UX is running on an nPartition, you can shut down HP-UX using either the `shutdown` command or the `reset` command.

NOTE The `reboot` command does not invoke the shutdown scripts associated with subsystems. The `shutdown` command invokes the scripts and terminates all running processes in an orderly and cautious manner.

On nPartitions you have the following options when shutting down HP-UX:

- To shut down HP-UX and **reboot** an nPartition: **`shutdown -r`**
- To shut down HP-UX and **halt** an nPartition: **`shutdown -h`**
- To perform a **reboot for reconfig** of an nPartition: **`shutdown -R`**
- To hold an nPartition at a **ready for reconfig** state: **`shutdown -R -H`**

For details see the *shutdown* (1M) manpage.

Shutting Down HP-UX on an nPartition [HP-UX]

This procedure shuts down HP-UX on an nPartition.

Step 1. Login to HP-UX running on the nPartition.

You can login to HP-UX on the nPartition either by directly connecting (with the `telnet` or `rlogin` commands) or by logging in to its complex's service processor (GSP or MP) and using the Console menu to access the nPartition's console.

Accessing the console through the service processor allows you to maintain console access to the nPartition after HP-UX has shut down.

Step 2. Issue the **`shutdown`** command with the appropriate command-line options.

The command-line options you specify dictate the way in which HP-UX is shut down, whether the nPartition is rebooted, and whether any nPartition configuration changes (adding or removing cells) take place.

Use the following list to choose an HP-UX shut down option for your nPartition.

- Shut down HP-UX and halt the nPartition.

  Issue the `shutdown -h` command to shut down and halt the nPartition.

  This leaves the nPartition and all its cells in an *active* state (the nPartition cannot be reconfigured) after HP-UX shuts down and halts.

  To reboot the nPartition you must reset the nPartition using the GSP command menu's `RS` command.

- Shut down HP-UX and reboot the nPartition.

  Issue the `shutdown -r` command to shut down and reboot the nPartition.

- Perform a *reboot for reconfig* of the nPartition.

  Issue the `shutdown -R` command to perform a reboot for reconfig.

  This shuts down HP-UX, reconfigures the nPartition if needed, and reboots the nPartition.

- Reboot the nPartition and put it in to the *ready for reconfig* state.

  Use the `shutdown -R -H` command to hold the nPartition in the ready for reconfig state.

  This leaves the nPartition and all its cells in an *inactive* state (the nPartition can be reconfigured remotely).

  To reboot the nPartition you must do so manually by using the service processor Command menu's `BO` command.

If HP-UX is halted on the nPartition, thus not allowing you to use the `shutdown` command, you can reboot or reset the nPartition by issuing commands from the service processor Command menu.

See *Rebooting or Resetting an nPartition* on page 214.

5587

Rebooting or Resetting an nPartition

When you perform a reboot or reset of an nPartition, all *active cells* in the nPartition reboot and return to BCH or HP-UX. Any *inactive* cells in the nPartition are not rebooted in this procedure.

You can reset and reboot an nPartition by using these procedures:

- *Rebooting or Resetting an nPartition [Service Processor]* on page 215
- *Rebooting or Resetting an nPartition [BCH]* on page 216
- *Rebooting or Resetting an nPartition [HP-UX]* on page 216

NOTE If possible you should down HP-UX before resetting an nPartition.

HP's nPartition servers also support other types of nPartition resetting.

See the following sections for details on these other nPartition reset methods:

- *Shutting Down HP-UX on an nPartition* on page 212
- *Performing a Reboot for Reconfig for an nPartition* on page 218
- *Holding an nPartition at the Ready for Reconfig State* on page 219
- *Performing a Transfer-of-Control (TOC) Reset of an nPartition* on page 223

Rebooting or Resetting an nPartition [Service Processor]

Use the service processor Command menu **RS** command to reset an nPartition from the service processor (GSP or MP).

Step 1. Login to the server complex's service processor (GSP or MP) and access the Command menu.

After logging in to the service processor, enter **CM** to select the Command menu.

```
GSP login: Accountname
GSP password: Password

....

GSP> CM

                     Enter HE to get a list of available commands

GSP:CM>
```

Step 2. At the Command menu, enter the **RS** command, specify which nPartition is to be reset, and confirm whether to reset it.

The Command menu's RS command resets all *active cells* in the nPartition and reboots them past partition rendezvous to BCH or HP-UX.

Be certain to correctly select which nPartition to be reset.

```
GSP:CM> RS

This command resets the selected partition.

WARNING: Execution of this command irrecoverably halts all
system
         processing and I/O activity and restarts the selected
         partition.

    #    Name
   ---   ----
    0)   jules00
    1)   jules01

   Select a partition number: 1

   Do you want to reset partition number 1? (Y/[N]) y
```

5580

```
    -> The selected partition will be reset.
GSP:CM>
```

If you are accessing the service processor using a single-partition-user account, the RS command selects which nPartition is to be reset: the nPartition that your account allows you to access.

If using an operator or administrator service processor account, you can select which of the server complex's nPartitions you want to reset.

Rebooting or Resetting an nPartition [BCH]

Use the **REBOOT** command to reset an nPartition from the BCH interface.

Step 1. Login to the server complex's service processor, access the nPartition's console, and access the BCH Main menu.

From the nPartition console you access the nPartition's BCH interface. If the nPartition is not at the BCH interface you must either boot the nPartition or shut down HP-UX to return to the BCH interface.

Step 2. From the nPartition's BCH main menu, enter the **REBOOT** command to reboot the nPartition.

The BCH interface's REBOOT command resets all *active cells* in the nPartition and reboots them past partition rendezvous to BCH or HP-UX.

```
Main Menu: Enter command or menu > REBOOT
Rebooting the partition ...
```

Rebooting or Resetting an nPartition [HP-UX]

Use the **shutdown -r** command to reset an nPartition from HP-UX running on the nPartition.

Step 1. Login to HP-UX running on the nPartition you want to reset.

You can login to HP-UX on the nPartition either by directly connecting (with the telnet or rlogin commands) or by logging in to its complex's service processor (GSP or MP) and using the Console menu to access the nPartition's console.

Step 2. Issue the **shutdown -r** command to reset the nPartition.

The `shutdown -r` command shuts down HP-UX and reboots the nPartition. All *active cells* in the nPartition are reset.

Performing a Reboot for Reconfig for an nPartition

During a **reboot for reconfig** of an nPartition, the HP-UX command that you issue (`shutdown -R`) performs the following tasks:

1. Shuts down HP-UX and resets all cells that are assigned to the nPartition, including any inactive cells.
2. Reconfigures the nPartition if necessary (adds or removes cells).
3. Boots all cells in the nPartition. Any cells with a “n” use-on-next-boot value remain inactive at BIB, and all other cells can rendezvous to form the nPartition.

You should perform a reboot for reconfig of an nPartition whenever you add or remove cells from the nPartition, and whenever you need to allow an inactive cell to join the nPartition (such as after changing a cell’s use-on-next-boot value from “n” to “y”).

Performing a Reboot for Reconfig [HP-UX]

Use the **`shutdown -R`** command to perform a reboot for reconfig for an nPartition.

Step 1. Login to HP-UX running on the nPartition.

You can login to HP-UX on the nPartition either by directly connecting (with the `telnet` or `rlogin` commands) or by logging in to its complex’s service processor (GSP or MP) and using the Console menu to access the nPartition’s console.

Step 2. Issue the **`shutdown -R`** command to perform a reboot for reconfig of the nPartition.

The `shutdown -R` command shuts down HP-UX, reboot all cells assigned to the nPartition, performs any nPartition reconfigurations, and boot all cells that have “y” use-on-next-boot values.

5577

Holding an nPartition at the Ready for Reconfig State

Resetting an nPartition to the **ready for reconfig** state performs any changes to the nPartition's configuration and holds the nPartition and all its cells in a boot-is-blocked (*inactive*) state.

To boot an nPartition after you have reset it to the ready for reconfig state, you must use the service processor (GSP or MP) Command menu's `BO` command.

You can hold an nPartition at the ready for reconfig state by using the following procedures:

- *Holding an nPartition at the Ready for Reconfig State [Service Processor]* on page 220
- *Holding an nPartition at the Ready for Reconfig State [BCH]* on page 221
- *Holding an nPartition at the Ready for Reconfig State [HP-UX]* on page 221

When you use the above methods to hold an nPartition at the ready for reconfig state, the commands perform the following tasks:

1. Shut down HP-UX (if using the `shutdown -R -H` command) and reset all cells that are assigned to the nPartition, including any inactive cells.
2. Reconfigures the nPartition if necessary (adds or removes cells).
3. Keeps all cells at a boot-is-blocked state; the nPartition and all cells assigned to it are inactive.

You should reset an nPartition to ready for reconfig whenever you need for the nPartition and its cells to be inactive. This enables you to modify the nPartition's configuration from the GSP or from HP-UX running on a remote nPartition in the same system complex.

Holding an nPartition at the Ready for Reconfig State [Service Processor]

Use the Command menu **RR** command to reset an nPartition to the ready for reconfig state from the service processor (GSP or MP).

Step 1. Login to the server complex's service processor and enter **CM** to access the Command menu.

```
GSP> CM

                                Enter HE to get a list of available commands

GSP:CM>
```

Step 2. At the service processor Command menu, enter the **RR** command, specify which nPartition is to be reset, and confirm whether to reset it to the ready for reconfig state.

The service processor's RR command resets all cells in the nPartition, performs any nPartition reconfigurations, and halts all cells at a boot-is-blocked state, thus making the nPartition and all its cells inactive.

Be certain to select the correct nPartition to be reset.

```
GSP:CM> RR

This command resets for reconfiguration the selected partition.

WARNING: Execution of this command irrecoverably halts all system
         processing and I/O activity and restarts the selected
         partition in a way that it can be reconfigured.

        #    Name
       ---   ----
        0)   jules00
        1)   jules01

    Select a partition number: 1

    Do you want to reset for reconfiguration partition number 1? (Y/[N]) y

    -> The selected partition will be reset for reconfiguration.
GSP:CM>
```

If you are accessing the service processor using a single-partition-user account, the RR command selects which nPartition is to be reset: the nPartition that your account allows you to access.

If using an operator or administrator GSP account, you can select which of the server complex's nPartitions you want to reset.

Holding an nPartition at the Ready for Reconfig State [BCH]

Use the **RECONFIGRESET** command to reset an nPartition to the ready for reconfig state from the nPartition's BCH interface.

Step 1. Login to the server complex's service processor, access the nPartition's console, and access the BCH interface.

From the nPartition console you access the nPartition's BCH interface. If the nPartition is not at the BCH interface you must either boot the nPartition or shut down HP-UX to return to the BCH interface.

Step 2. From the nPartition's BCH interface, enter the **RECONFIGRESET** command to reset the nPartition to the ready for reconfig state.

The RECONFIGRESET command resets all cells in the nPartition, performs any nPartition reconfigurations, and halts all cells at a boot-is-blocked state, thus making the nPartition and all its cells inactive.

```
Main Menu: Enter command or menu > RECONFIGRESET
Reset the partition for reconfiguration of Complex Profile ...
```

Holding an nPartition at the Ready for Reconfig State [HP-UX]

Use the **shutdown -R -H** command to reset an nPartition to the ready for reconfig state from HP-UX running on the nPartition.

Step 1. Login to HP-UX running on the nPartition.

You can login to HP-UX on the nPartition either by directly connecting (with the `telnet` or `rlogin` commands) or by logging in to its complex's service processor (GSP or MP) and using the Console menu to access the nPartition's console.

Step 2. Issue the **shutdown -R -H** command to reset the nPartition to the ready for reconfig state.

The `shutdown -R -H` command shuts down HP-UX, reset all cells in the nPartition, perform any nPartition reconfigurations, and halt all cells at a boot-is-blocked state, thus making the nPartition and all its cells inactive.

Performing a Transfer-of-Control (TOC) Reset of an nPartition

You can use the service processor Command menu's `TC` command to perform a transfer-of-control (TOC) reset of an nPartition.

If crash dump is configured for HP-UX on the nPartition, when you TOC the nPartition while it is running HP-UX the nPartition performs a crash dump and gives you an opportunity select the type of dump.

Performing a TOC Reset of an nPartition [Service Processor]

Use the Command menu **`TC`** command to perform a transfer-of-control (TOC) reset of an nPartition.

Step 1. Login to the server complex's service processor and enter **`CM`** to access the Command menu.

```
GSP> CM

                    Enter HE to get a list of available commands

GSP:CM>
```

Step 2. At the Command menu, enter the **`TC`** command, specify which nPartition is to be reset, and confirm whether to TOC the nPartition.

The `TC` command performs a transfer-of-control reset on the specified nPartition.

If you are accessing the service processor using a single-partition-user account, the `TC` command selects which nPartition is to be reset: the nPartition that your account allows you to access.

If using an operator or administrator account, you can select which of the server complex's nPartitions you want to TOC.

Be certain to select the correct nPartition to be reset.

```
GSP:CM> TC

This command TOCs the selected partition.
```

```
WARNING: Execution of this command irrecoverably halts all system
         processing and I/O activity and restarts the selected
         partition.

     #   Name
    ---  ----
     0)  jules00
     1)  jules01

Select a partition number: 0

    Do you want to TOC partition number 0? (Y/[N]) y

    -> The selected partition will be TOCed.
GSP:CM>
```

Step 3. After you initiate the TOC, you can observe its progress and select the type of crash dump through the nPartition's console.

Once the nPartition completes the dump, or once you cancel it, the nPartition reboots.

```
       ******* Unexpected TOC. Processor HPA FFFFFFFF'FC07C000 *******
                              GENERAL REGISTERS:

*** Dumping:   7% complete (32 of 457 MB) (device 64:0x2)
```

Booting an Inactive nPartition past Boot-Is-Blocked (BIB)

When all cells in an nPartition are at boot-is-blocked, the nPartition is *inactive*. This is the case, for example, when an nPartition is held at the ready for reconfig state.

You can boot an nPartition past the ready for reconfig state to make it active by using the service processor Command menu's BO (boot) command.

To determine whether an nPartition is in a boot-is-blocked (ready for reconfig) state, use the nPartition's Virtual Front Panel to monitor the nPartition's boot activity. If all of the nPartition's cells are at boot-is-blocked, the nPartition is halted at the ready for reconfig state.

Booting an Inactive nPartition past BIB [Service Processor]

Use the service processor Command menu **BO** command to boot an nPartition past the ready for reconfig state to make the nPartition active.

If you use the Command menu's BO command to attempt to boot an nPartition that already is active, the command has no effect.

Step 1. Login to the server complex's service processor and enter **CM** to select the Command menu.

```
# telnet sdome-s
Trying...
Connected to sdome-s.rsn.hp.com.
Escape character is '^]'.
Local flow control off

GSP login: Accountname
GSP password: Password

....

GSP> CM

                    Enter HE to get a list of available commands

GSP:CM>
```

Step 2. From the Command menu, enter the BO command and specify which nPartition is to be booted (released from boot-is-blocked).

As a result of the BO command, the complex's service processor releases the selected nPartition's cells from boot-is-blocked: the cells proceed to rendezvous to form an active nPartition, which no longer is in the ready for reconfig state.

```
GSP:CM> BO

This command boots the selected partition.

     #    Name
    ---   ----
     0)   jules00
     1)   jules01

    Select a partition number: 0

    Do you want to boot partition number 0? (Y/[N]) y

    -> The selected partition will be booted.
GSP:CM>
```

Any of the nPartition's cells that are not configured (those with a "n" use-on-next-boot value) remain inactive at boot-is-blocked.

When the nPartition becomes active it proceeds through the normal boot process and performs, as necessary, the boot action set for each of the boot paths (PRI, HAA, ALT).

SS69

Configuring Boot Paths and Boot Actions

You can configure each nPartition's boot *paths* (device paths for booting HP-UX) and boot *actions* (preferred automatic boot behavior) by using the following procedures:

- *Configuring Boot Paths and Actions [BCH]* on page 229
- *Configuring Boot Paths and Actions [HP-UX]* on page 230

By configuring boot paths and boot actions for an nPartition, you can set the nPartition to automatically boot from a primary source or, if the primary source fails, from backup devices.

Each nPartition's **boot device paths** list the hardware paths of devices for booting HP-UX on the nPartition.

The boot paths are:

- PRI—Primary boot path.
- HAA—High-availability alternate boot path, typically a mirror of the primary root volume.
- ALT—Alternate boot path. Typically used for install or recovery media (such as DAT or CD-ROM drive).

Each nPartition also has a set of **boot actions (path flags)**, which specify the *default actions to be automatically performed* when the nPartition boots to the BCH interface. Each of the three boot paths (PRI, HAA, and ALT) has its own path flag setting that defines its boot action.

The order in which an nPartition's boot actions are attempted is: PRI boot action, then HAA boot action (if necessary), and finally ALT boot action (if necessary).

The boot actions (path flag settings) for each boot path are:

- 0—Go to BCH.
- 1—Boot this path, if fail go to BCH.
- 2—Boot this path, if fail attempt to perform the next path's boot action.
- 3—Skip this path, attempt to perform the next path's boot action.

By default, all path flags are set to 0 ("Go to BCH").

The boot actions are performed *automatically* by the BCH interface when an nPartition boots to BCH, as possible and necessary. However, boot action settings *do not* affect the behavior of the BCH BOOT command.

Setting Autoboot through Boot Paths and Boot Actions

Each nPartition's **Autoboot setting** is established by the boot action (path flag) settings for the nPartition's boot paths.

For an nPartition to *automatically boot HP-UX*, it must be configured in the following way:

- The nPartition must have at least one bootable HP-UX device that is pointed to by the PRI, HAA, or ALT boot path variable.
- The path flag (boot action) setting for a bootable device's path variable must be set to "boot this path" (1 or 2).
- When the nPartition boots it must proceed to execute a bootable device's boot action that specifies to "boot this path", and it must find the device.

For example, an nPartition could automatically boot HP-UX with the following configuration: both the PRI and HAA paths point to bootable devices, and the PRI action is 2 ("boot this path, if fail attempt to perform the next path's boot action") and the HAA action is 1 ("boot this path, if fail go to BCH").

In this example configuration, the nPartition could automatically boot HP-UX even if the PRI path were not available. When the nPartition boots to BCH it first attempts to boot the PRI device. If the PRI device cannot be booted, because the PRI path flag specifies to "if fail attempt to perform the next path's boot action", it then refers to the HAA path and action. Because in this example the HAA path points to a bootable device, and because the HAA path flag specifies to attempt to boot the HAA device, the nPartition can still automatically boot HP-UX (if the HAA device is available).

Configuring Boot Paths and Actions [BCH]

Use the BCH Main menu **PATH** command and Configuration menu **PATHFLAGS** command to configure an nPartition's boot paths and boot actions (path flags) through its BCH interface.

To list all boot path and action settings for an nPartition, you also can use the BCH Information menu's BOOTINFO command.

Step 1. Determine which devices will be used for booting HP-UX on the nPartition, and determine the boot behaviors you desire.

You need to determine the hardware paths of all potential boot devices that you will configure as the PRI, HAA, and ALT boot paths.

You also need to determine which device you want to boot by default (if any), and which (if any) device you want to boot if the default device fails to boot.

Typically, the PRI path is set to the default boot device and the HAA path is set to the device you want to boot if PRI fails to boot.

Step 2. Login to the service processor (GSP or MP), access the nPartition's console, and access the BCH Main menu.

From the nPartition console you access the nPartition's BCH interface. If the nPartition is not at the BCH interface you must either boot the nPartition or shut down HP-UX to return to the BCH interface.

Step 3. At the BCH Main menu, set the boot path values using the **PATH** command.

To list the current boot path settings, enter **PATH** with no arguments.

To set a boot path, enter **PATH** ***VAR hwpath***, where *VAR* is the boot path variable (PRI, HAA, or ALT) and *hwpath* is a boot device's hardware path.

For example, to set the PRI boot path to a new value (4/0/2/0/0.10, in this case) enter PATH PRI 4/0/2/0/0.10, as shown below.

```
Main Menu: Enter command or menu > PATH PRI 4/0/2/0/0.10.0

    Primary Boot Path:  4/0/2/0/0.10
                        4/0/2/0/0.a    (hex)

Main Menu: Enter command or menu >
```

SS66

Step 4. Access the BCH Configuration menu by entering **CO** at the Main menu, and set the boot action for each boot path, as desired, by using the **PATHFLAGS** command.

At the BCH Configuration menu, you can list the path flags (boot actions) for all boot path variables by entering **PATHFLAGS** with no arguments.

To set the boot action for each of the boot paths, enter **PATHFLAGS** ***VAR action***, where *VAR* is the boot path variable (PRI, HAA, or ALT) and *action* is the boot action (0 for "go to BCH", 1 for "boot, if fail go to BCH", 2 for "boot, if fail try next path", or 3 for "skip this path, try next path").

For example, to configure an nPartition to boot from the PRI device or (if PRI fails to boot) the HAA device, use the following two BCH Configuration commands: **PATHFLAGS PRI 2** and **PATHFLAGS HAA 1**, as shown below.

```
Configuration Menu: Enter command > PATHFLAGS PRI 2

     Primary Boot Path Action
          Boot Actions:  Boot from this path.
                         If unsuccessful, go to next path.

Configuration Menu: Enter command > PATHFLAGS HAA 1

HA Alternate Boot Path Action
          Boot Actions:  Boot from this path.
                         If unsuccessful, go to BCH.

Configuration Menu: Enter command >
```

For other help in setting path flags, enter HELP PATHFLAGS at the BCH Configuration menu prompt.

Configuring Boot Paths and Actions [HP-UX]

Use the **parmodify -p#...** and **setboot...** commands to set nPartition boot path variables from HP-UX and to check and set the local nPartition's PRI boot action (the PRI path flag).

Step 1. Determine which devices will be used for booting HP-UX on the nPartition, and determine the boot behaviors you desire for the PRI boot path.

5565

Step 2. Login to HP-UX running on an nPartition in the complex.

You can modify the boot paths for any nPartition from any other nPartition in the complex when using the `parmodify` command.

However, when using the `setboot` command to modify the PRI and ALT paths or the PRI boot action, you can modify only the *local* nPartition's settings.

Step 3. Configure boot path settings using the **`parmodify -p#...`** command.

Use the following commands to set the boot path variables for a specified partition number (`-p#`):

- PRI path— `parmodify -p# -b` *`PRI`* where *`PRI`* is the hardware path.
- HAA path—`parmodify -p# -s` *`HAA`* where *`HAA`* is the hardware path.
- ALT path—`parmodify -p# -t` *`ALT`* where *`ALT`* is the hardware path.

If using the `setboot` command to set boot paths for the *local nPartition*, you can specify `setboot -p` *`PRI`* or `setboot -a` *`ALT`* but cannot set the HAA path variable.

You can list an nPartition's current boot path settings by issuing the `parstatus -V -p# | grep Path` command and specifying the partition number (`-p#`). The `setboot` command with no arguments lists the PRI and ALT settings for the local nPartition as well as the local nPartition's PRI path flags (boot actions).

For example, to set the PRI boot path to 0/0/4/0/0.8.0 and the HAA boot path to 0/0/4/0/0.9.0 for partition number 0, issue the `parmodify -p0 -b 0/0/4/0/0.8.0 -s 0/0/4/0/0.9.0` command, as shown below.

```
# parmodify -p0 -b 0/0/4/0/0.8.0 -s 0/0/4/0/0.9.0
Command succeeded.
#
```

Step 4. As needed, configure the PRI boot action for the *local nPartition* by using the **`setboot -b`** ***`Autoboot`*** **`-s`** ***`Autosearch`*** command.

The `setboot` command supports the following options for setting local nPartition boot actions:

`-b` **Autoboot setting** for the local nPartition:

`-b on` to automatically boot the PRI path.

`-b off` to not boot PRI.

`-s` **Autosearch setting** for the local nPartition:

`-s on` to attempt to perform the HAA path's boot action when PRI is not booted (either when `-b` is `off`, or when PRI fails to boot when `-b` is on).

`-s off` to never attempt to perform the HAA action.

For example, to always stop the local nPartition at BCH when booting, issue the `setboot -b off -s off` command.

See *Setting Autoboot through Boot Paths and Boot Actions* on page 228 or the *setboot* (1M) manpage for details.

Configuring Autoboot and Autostart

The **Autoboot setting** specifies whether an nPartition automatically boots HP-UX. You can configure each nPartition's Autoboot setting by modifying the nPartition's boot actions for its boot paths. See the *Autoboot Configuration* section.

On HP Superdome servers only, you can configure an **Autostart setting** for each nPartition to specify the nPartition's boot behavior when one or more self tests fails. See the *Autostart Configuration* section that follows.

Autoboot Configuration

Each nPartition's Autoboot setting is established by a combination of its boot path variable settings and the settings for each path's boot actions (determined by its path flags).

You can use the BCH Main menu's PATH command and the BCH Configuration menu's PATHFLAGS command to set boot paths and boot actions for an nPartition. You also can use the `parmodify` and `setboot` HP-UX commands to configure some of the boot path and action settings.

See *Configuring Boot Paths and Boot Actions* on page 227 for details on configuring these settings to enable Autoboot.

Autostart Configuration

On HP Superdome servers only, the BCH interface's Autostart setting for each nPartition determines the boot behavior when one of the nPartition's components (processors or memory) fails self test.

By default Autostart is set to OFF, and the nPartition stops at the BCH interface when a processor or DIMM fails self-test.

When Autostart is ON, the nPartition proceeds with the normal boot process and performs the boot actions for its boot paths as necessary.

CSG2

Configuring Superdome nPartition Autostart [BCH]

Use the BCH Configuration menu's **AU** command to configure Autostart for an nPartition on an HP Superdome server.

NOTE This procedure applies to nPartitions on HP Superdome servers only.

Step 1. Login to the Superdome complex's service processor (GSP), access the nPartition's console, and access the BCH Configuration menu.

From the nPartition console, you can access the nPartition's BCH interface. If the nPartition is not at the BCH interface you must either boot the nPartition or shut down HP-UX to return to the BCH interface.

From the BCH Main menu, enter **CO** to access the Configuration menu.

Step 2. From the BCH Configuration menu, use the **AU** command to list or set Autostart for the nPartition.

Enter **AU** with no arguments to list the Autostart setting.

Enter **AU ON** to set Autostart to ON, or **AU OFF** to set it to OFF.

5561

Configuring Automatic System Restart for an nPartition

The **automatic system restart** feature on nPartition servers enables you to configure an nPartition to be automatically rebooted when HP-UX hangs on the nPartition.

By default, automatic system restart *is disabled* for nPartitions.

To enable or disable automatic system restart, use the service processor Command menu's AR command, as described in *Configuring nPartition Automatic System Restart [Service Processor]* on page 236.

To use the AR command, you must login to the server complex's service processor using an account that has administrator authority.

CAUTION When automatic system restart is enabled for an nPartition, all cells in the nPartition automatically will be reset—and the nPartition will reboot—if HP-UX running on the nPartition is hung for three (3) minutes.

When HP-UX is booted on an nPartition, it indicates that it is "alive" by emitting a HEARTBEAT chassis code and an ACTIVITY_LEVEL_TIMEOUT chassis code approximately every four seconds.

The service processor manages automatic system restart for each nPartition through a timer that tracks the time since the nPartition was active. This timer is reset every time an ACTIVITY_LEVEL_TIMEOUT chassis code is emitted by HP-UX on the nPartition. If HP-UX does not emit this chassis code for three minutes then it emits an "Alert Level 13: System hang detected" chassis code. If the nPartition has automatic system restart enabled then the service processor issues a PARTITION_TIMEOUT_RESET chassis code, resets all cells assigned to the nPartition, and the nPartition reboots.

The following output shows the chassis codes (with keywords) for an HP-UX timeout and automatic reset.

SS60

```
129  GSP  0     *13 0x591008d1a000205f 0x000065060c0f1611 PARTITION_TIMEOUT_RESET
128  HPUX 0,0,0 *13 0x78e004d41100f000 0x0000000300000009
128  HPUX 0,0,0 *13 0x58e00c000000f000 0x000065060c0f1610 07/12/2001 15:22:16
```

Monitoring HP-UX Activity and Chassis Logs

You can monitor whether HP-UX is active on an nPartition through the nPartition's Virtual Front Panel and through the Chassis Logs viewer.

- You can track an nPartition's HP-UX activity through its Virtual Front Panel (VFP) display, which is available through the service processor. When HP-UX has booted on an nPartition, the nPartition's VFP blinks an HP-UX heartbeat indicator based on the HEARTBEAT chassis code.
- You also can track HP-UX activity though the service processor's Chassis Logs viewer, which enables you to view live (real-time) chassis codes as well as previously recorded error and activity chassis codes.

  For example, to monitor an nPartition's chassis codes in real time: from the service processor Main menu select `SL` for the Chassis Logs viewer, select the live chassis logs option, then type `P` and select which nPartition's chassis codes you want to monitor (to exit to the Main menu type **^b**).

Configuring nPartition Automatic System Restart [Service Processor]

Use the service processor Command menu's **AR** command to enable or disable automatic system restart for an nPartition.

Step 1. Login to the server complex's service processor (GSP or MP) and enter **CM** to access the Command menu.

Step 2. Issue the service processor Command menu's **AR** command to enable or disable automatic system restart for an nPartition.

To use the `AR` command, you must be logged in using an account that has administrator authority.

```
GSP:CM> AR

This command modifies the automatic system restart configuration of
the selected partition.
```

5559

```
         #   Name
        ---  ----
         0)  feshd5a
         1)  feshd5b

        Select a partition number: 0

        Automatic system restart for partition 0 is currently enabled.
        Do you want to disable automatic system restart? (Y/[N]) y

        -> Automatic system restart is disabled.
GSP:CM>
```

558

Configuring Fast Boot Settings (Self Tests) for an nPartition

The **fast boot settings** for an nPartition determine which self tests the nPartition performs during the power on or nPartition boot process.

You can configure nPartition fast boot settings by enabling and disabling various self tests using these procedures:

- *Configuring Fast Boot for an nPartition [BCH]* on page 239
- *Configuring Fast Boot for an nPartition [HP-UX]* on page 239

NOTE HP recommends that all self tests be performed for nPartitions.

When an nPartition reboots due to a system panic, HPMC, or TOC, all self tests are performed when the nPartition reboots.

On HP nPartition servers you can configure the following self tests:

- **PDH tests**—Processor-dependent hardware tests that test a checksum of read-only memory.

  Can be configured from BCH and HP-UX `setboot` as “PDH”.
- **Early CPU tests**—Firmware, cache, and CPU-specific tests that are performed out of firmware.

  Can be configured from BCH (as “EARLY”) and HP-UX `setboot` (as “early_cpu”).
- **Late CPU tests**—Firmware, cache, and CPU-specific tests that are performed out of memory and thus are faster than early CPU tests.

  Can be configured from BCH (as “LATE”) and HP-UX `setboot` (as “late_cpu”).

5557

Configuring Fast Boot for an nPartition [BCH]

Use the Configuration menu's FASTBOOT command to configure an nPartition's fast boot settings using its BCH interface.

Step 1. Login to the server complex's service processor (GSP or MP), access the nPartition's console, and access the BCH Configuration menu.

From the nPartition console you access the nPartition's BCH interface. If the nPartition is not at the BCH interface you must either boot the nPartition or shut down HP-UX to return to the BCH interface.

From the BCH Main menu, enter `CO` to access the Configuration menu.

Step 2. At the BCH Configuration menu use the **`FASTBOOT`** command to list or set the nPartition's fast boot settings.

Enter `FASTBOOT` with no arguments to display the current fast boot settings. This lists which self tests are set to be performed or skipped.

NOTE HP recommends that *all self tests* be performed for all nPartitions.

To *enable all tests* for an nPartition, use the **`FASTBOOT RUN`** command at the nPartition's BCH Configuration menu.

To *disable* an individual test, enter `FASTBOOT` *`test`* `SKIP`, where *`test`* is the name of the self test ("PDH", "EARLY", or "LATE").

To *enable* an individual test, enter `FASTBOOT` *`test`* `RUN`.

For details on setting self tests, enter `HELP FASTBOOT` at the Configuration menu.

Configuring Fast Boot for an nPartition [HP-UX]

Use the **`setboot`** command to configure an nPartition's self test configuration from HP-UX running on the nPartition.

Step 1. Login to HP-UX running on the nPartition whose self test configuration you want to change.

From HP-UX you can configure self tests for the *local* nPartition only.

556

Step 2. Enter the **`setboot -v`** command to list the current self test configuration for the local nPartition.

The self test details listed by `setboot -v` include:

> TEST—The keyword names of self tests that you can enable or disable.
> CURRENT—The nPartition's setting for the test in stable storage: on means the test is normally executed on each boot, `off` means the test is normally omitted on each boot, `partial` means some subtests normally are executed on each boot. This may differ from the NEXT BOOT settings.
> SUPPORTED—Whether the server supports the test completely (yes), partially (`partial`), or not at all (no).
> DEFAULT—The default setting for the test, either on, `off`, or `partial`.
> NEXT BOOT—The nPartition's self test behavior for the *next boot only*. If these settings differ from CURRENT, then the CURRENT settings are reestablished after the next boot.

The following example shows `setboot -v` output for an nPartition.

```
# setboot -v
Primary bootpath : 0/0/6/0/0.6.0
Alternate bootpath : 0/0/1/0/0.8.0

Autoboot is OFF (disabled)
Autosearch is OFF (disabled)

Note: The interpretation of Autoboot and Autosearch has changed for
systems that support hardware partitions. Please refer to the manpage.
TEST            CURRENT        SUPPORTED      DEFAULT        NEXT BOOT
----            -------        ---------      -------        ---------
all             partial        partial        partial        partial
  SELFTESTS     on             yes            on             on
    early_cpu   on             yes            on             on
    late_cpu    on             yes            on             on
  FASTBOOT      partial        partial        partial        partial
    full_memory off            no             off            off
    PDH         on             yes            on             on
  CEC           off            no             off            off
#
```

Step 3. Use the **`setboot...`** command to enable or disable boot-time self tests for the local nPartition.

You can use the following commands to configure tests:

`setboot -t` *`test_name`*`=[on|off|default]`

`setboot -T` *`test_name`*`=[on|off|default]`

5585

`test_name` is the name of the self test (“PDH”, “early_cpu”, “late_cpu”) or is “all” (for all tests).

The `setboot` command’s `-t` option changes the test setting in stable storage and affects all following boots. The `-T` option changes the test setting for the next boot only.

NOTE HP recommends that *all self tests* be performed for all nPartitions.

To *enable all tests* for an nPartition, use the following command:
`setboot -t all=on`

For example, to enable the early CPU tests and PDH tests but disable the late CPU tests issue the following command:

```
setboot -t early_cpu=on -t PDH=on -t late_cpu=off
```

This changes the local nPartition’s settings for these tests in its stable storage and uses these test configurations for all following boots.

After modifying an nPartition’s self test configuration, you can list the new settings with the `setboot -v` command.

For more details see the *setboot* (1M) manpage.

5554

Boot Timer Configuration for an nPartition

The boot timer setting establishes the number of seconds an nPartition will wait for a boot device before timing out.

When a boot device does not respond to a boot request within the number of seconds defined by the boot timer setting, the boot is considered unsuccessful.

Configuring an nPartition Boot Timer [BCH]

Use the Configuration menu's **BOOTTIMER** command to configure an nPartition's boot timer setting from its BCH interface.

Step 1. Login to the server complex's service processor (GSP or MP), access the nPartition's console, and access the BCH Configuration menu.

From the nPartition console, you access the nPartition's BCH interface. If the nPartition is not at the BCH interface, you must either boot the nPartition or shut down HP-UX to return to the BCH interface.

From the BCH Main menu, enter `CO` to access the Configuration menu.

Step 2. From the BCH Configuration menu, use the **BOOTTIMER** command to list or set the boot timer setting.

Enter `BOOTTIMER` with no arguments to list the current setting.

Enter `BOOTTIMER` *seconds* to set the boot timer setting to the specified (*seconds*) number of seconds.

SS53

21

6 Managing nPartitions

This chapter presents the procedures for creating, configuring, and managing nPartitions on HP servers that support them.

For an introduction to nPartition features, refer to the chapter *nPartition System Overviews* on page 31.

For nPartition configuration requirements and related HP recommendations, refer to the chapter *Planning nPartition Configurations* on page 109.

Coordinating Changes to nPartitions

When you modify nPartitions, you should perform your changes so that they occur at a time when they will not conflict with other nPartition changes in the same server complex.

The HP-UX nPartition configuration commands and the Partition Manager utility coordinate their actions by using *locks* to restrict access to portions of the server's *Complex Profile* data while they modify that data.

Commands and utilities can lock Stable Complex Configuration Data and Partition Configuration Data to ensure that only the command holding the lock can modify that portion of the Complex Profile.

In most cases, the nPartition commands and utilities will not have locking conflicts because they can complete changes quickly (within about a second), usually before any other commands attempt to modify the same portion of the server's Complex Profile data.

However, some nPartition changes involve locking parts of the Complex Profile for a longer time.

- The Partition Manager utility locks all parts of the server's Complex Profile that it may potentially modify, and it keeps them locked for as long as the associated menu items are being used.

  For example, the **Partition —> Create Partition** menu item and the **Complex —> Set Complex Name** menu item lock the Stable Complex Configuration Data portion of the server's Complex Profile. You cannot use other tools to perform any tasks that modify the Stable Complex Configuration Data (such as adding or removing cells) until the task that acquired the lock completes or is canceled.

  Likewise, the **Partition —> Modify Partition** menu item locks both the Stable Complex Configuration Data as well as the selected nPartition's Partition Configuration Data. As a result, no other tool (including another instance of Partition Manager) can add or remove cells or modify the selected nPartition until this task has completed or been canceled.

  Some tasks performed through Partition Manager also require performing a reboot for reconfig to release locks (for example, removing an active cell from an nPartition).

5551

- When *removing an active cell* from an nPartition, you must perform a reboot for reconfig (`shutdown -R`, not `-r`) of the modified nPartition to release the Complex Profile lock, regardless of whether you use `parmodify` or Partition Manager.

  You must perform the reboot for reconfig before you can add or remove other cells from nPartitions in the server complex. (The lock on the Stable Complex Configuration Data is not released in this case until the reboot for reconfig has occurred.)

- When you *add or remove cells from an active nPartition* and specify the `parmodify` command's `-B` option, the Stable Complex Configuration Data remains locked until the modified nPartition has performed a reboot for reconfig. In this situation, no further changes to cell assignments can occur until after the reboot for reconfig.

Although you can use the `parunlock` command to force-unlock any parts of a server's Complex Profile, you *should not use* this command unless the program that established the lock has abnormally terminated. Instead, if possible, you should allow the Complex Profile to be unlocked as part of the normal procedures described above. See the *parunlock* (1M) manpage for details.

5550

Rebooting to Implement nPartition Changes

Once an nPartition has booted and is active, the nPartition has a fixed set of active hardware resources. In order to establish a different set of active hardware resources for an nPartition you must reboot the nPartition, as described below.

You can add and remove cells from an active, booted nPartition; however, you only can add or remove *inactive* cells without having to reboot the nPartition.

To remove an active cell from an nPartition, or to make a newly added cell or inactive cell *active*, you must perform a reboot for reconfig of the nPartition.

The following list describes situations where you may need to reboot an nPartition to implement changes.

- Perform a reboot for reconfig (**`shutdown -R`**) of an nPartition in the following situations.
  - When you want to add one or more cells to an nPartition.

    Newly added cells initially are inactive when assigned to an nPartition. To allow the new cells to rendezvous (join the nPartition as active members), perform a reboot for reconfig.
  - When you remove one or more cells from an nPartition.

    Removing an active cell requires an nPartition reboot for reconfig, but removing an *inactive* cell *does not* require an nPartition reboot for reconfig. Inactive cells are removed immediately.
  - When you change a cell's use-on-next-boot value from "n" (no, do not use) to "y" (yes, use the cell).

    A reboot for reconfig permits the cell to rendezvous into the nPartition and become active; see below.
  - When you want to allow a currently inactive cell to become active.

    A reboot for reconfig reboots all cells, allowing them an opportunity to join (rendezvous) the nPartition as active members.

- Reset an nPartition to the ready for reconfig state (`shutdown -R -H`) to make the nPartition inactive.

  All cells in an nPartition remain inactive when the nPartition is in the ready for reconfig state; the cells do not perform a partition rendezvous.

- Perform a standard reboot (`shutdown -r`) of an nPartition in most other situations where you do not need to add or remove cells from the nPartition.

  A standard reboot causes only the *currently active* cells in an nPartition to reboot, and it does not allow any pending complex configuration changes to complete (the changes remain pending, still requiring a reboot for reconfig for them to be in effect).

  Pending changes that require a reboot for reconfig (`shutdown -R`, not a `shutdown -r`) include removing an active cell from an nPartition. The cell cannot be unassigned until its nPartition has a reboot for reconfig performed.

  Other changes, such as adding a cell to an nPartition or changing a cell's use-on-next-boot value from "n" to "y", also require performing a reboot for reconfig (`shutdown -R`, nor `-r`) to enable the inactive cell to become active.

5548

Listing the Local (Current) Partition Number

Each nPartition within a server complex has a unique number assigned to it. This **partition number** identifies the nPartition in various menus, commands, and utilities. You also can specify the partition number when performing operations on an nPartition, such as adding or removing cells or resetting an nPartition.

You can list the local partition number by using the following procedures:

- *Listing the Local nPartition Number [BCH]* on page 248
- *Listing the Local nPartition Number [HP-UX]* on page 248

Listing the Local nPartition Number [BCH]

Use the Configuration menu **PD** command to list the local partition number from the BCH interface.

Step 1. Access the Boot Console Handler (BCH) interface for the nPartition, and access the BCH Configuration menu.

Enter `CO` from the BCH Main menu to access the Configuration menu. If you are at a BCH menu other than the Main menu, enter `MA` to access the Main menu.

Step 2. From the BCH Configuration menu, enter the **PD** command to list the local nPartition's name and partition number.

```
Configuration Menu: Enter command > PD

Partition Number: 1
Partition Name: jules01

Configuration Menu: Enter command >
```

Listing the Local nPartition Number [HP-UX]

Use the **parstatus -w** command to list the partition number of the local (current) nPartition from HP-UX.

Step 1. Login to HP-UX running on the nPartition.

5547

Step 2. Issue the **parstatus -w** command to list the partition number for the local nPartition.

```
# parstatus -w
The local partition number is 0.
#
```

The parstatus -P command lists all nPartitions within the server complex, including the local nPartition.

```
# parstatus -P
[Partition]
Par                 # of  # of I/O
Num Status          Cells Chassis  Core cell  Partition Name (first 30 chars)
=== ============ ===== ======== ========== ==============================
 0  active          2      2      cab0,cell0 jules00
 1  active          2      2      cab0,cell4 jules01
#
```

Listing All Configured nPartitions

You can configure each server complex to have multiple nPartitions, which are composed of cells in the complex.

You can list all configured nPartitions in the server complex by using the following procedures:

- *Listing All nPartitions [Service Processor]* on page 250
- *Listing All nPartitions [HP-UX]* on page 251
- *Listing All nPartitions [Partition Manager]* on page 252

Listing All nPartitions [Service Processor]

Use the Command menu **CP** command to list all nPartitions in a server complex from the complex's service processor.

Step 1. Login to the service processor for the complex and enter **CM** to access the Command menu.

```
# telnet sdome-s
Trying...
Connected to sdome-s.rsn.hp.com.
Escape character is '^]'.
Local flow control off

GSP login: Accountname
GSP password: Password

....

GSP> CM
                Enter HE to get a list of available commands
GSP:CM>
```

Step 2. From the service processor Command menu, enter the **CP** command to list all configured nPartitions within the server complex.

The CP command lists each nPartition (by partition number) and indicates which cells from each cabinet are assigned to the nPartition.

In the following example the complex has two nPartitions: partition number 0 has cells 0 and 2, and partition number 1 has cells 4 and 6.

```
GSP:CM> CP

-------------------------------------------------------------------------------
Cabinet |    0    |    1    |    2    |    3    |    4    |    5    |    6    |    7
--------+---------+---------+---------+---------+---------+---------+---------+--------
 Slot   |01234567|01234567|01234567|01234567|01234567|01234567|01234567|01234567
--------+---------+---------+---------+---------+---------+---------+---------+--------
Part  0 |X.X.....|........|........|........|........|........|........|........
Part  1 |....X.X.|........|........|........|........|........|........|........

GSP:CM>
```

To the right of each partition number is a list of cells assigned to the nPartition. Assigned cells are marked with an "X". The cell's slot (0 to 7) and its cabinet number (0 or above) are listed above each cell.

You also can use the **DU** command to list *all* cells in a server complex (and other complex hardware details), including unassigned cells.

Listing All nPartitions [HP-UX]

Use the **parstatus -P** command (and **parstatus -C**, for more details) to list information about all nPartitions in a server complex from HP-UX.

From any nPartition in a complex, you can list details about all cells and nPartitions within the complex.

Step 1. Login to HP-UX running on any of the server complex's nPartitions.

You can login to HP-UX on the nPartition either by connecting with `telnet` or `rlogin`, or by logging in to its complex's service processor and accessing the nPartition's console.

Step 2. Issue the **parstatus -P** command to list brief details about all nPartitions in the server complex.

The `parstatus -P` command lists all nPartitions and shows each nPartition's number and name, the number of cells assigned to it, the number of active I/O chassis, and the nPartition's active core cell.

```
# parstatus -P
[Partition]
Par                # of  # of I/O
Num Status         Cells Chassis  Core cell  Partition Name (first 30 chars)
=== ============ ===== ======== ========== ==============================
```

SS44

```
 0  active          2      2      cab0,cell0 jules00
 1  active          2      2      cab0,cell4 jules01
#
```

While an nPartition is booting, the parstatus command cannot determine the nPartition's I/O chassis and core cell information. When this is the case parstatus does not count the I/O chassis and reports a question mark (?) for the core cell. When the nPartition has completed booting, parstatus reports all details.

Step 3. To list detailed information about all cells and nPartitions in the server complex, issue the **parstatus -C** command.

The parstatus -C command presents more detailed information about all cells and nPartitions. These details include each cell's status (active, inactive), its processor and memory configuration, its I/O chassis connections (if any), the cell's use-on-next-boot setting, and nPartition assignment.

```
# parstatus -C
[Cell]
                               CPU     Memory                                     Use
                               OK/     (GB)                               Core    On
Hardware   Actual              Deconf/ OK/                                Cell    Next Par
Location   Usage               Max     Deconf     Connected To            Capable Boot Num
========== ============ ======= ========= =================== ======= ==== ===
cab0,cell0 active core  4/0/4    2.0/ 0.0 cab0,bay0,chassis1  yes     yes  0
cab0,cell1 absent       -       -         -                   -       -    -
cab0,cell2 active base  4/0/4    2.0/ 0.0 cab0,bay1,chassis3  yes     yes  0
cab0,cell3 absent       -       -         -                   -       -    -
cab0,cell4 active core  4/0/4    2.0/ 0.0 cab0,bay0,chassis3  yes     yes  1
cab0,cell5 absent       -       -         -                   -       -    -
cab0,cell6 active base  4/0/4    2.0/ 0.0 cab0,bay1,chassis1  no      yes  1
cab0,cell7 absent       -       -         -                   -       -    -

#
```

For cells and nPartitions that have not finished booting, the parstatus command cannot determine processor, memory, or I/O details and instead reports a question mark (?) for these details.

Listing All nPartitions [Partition Manager]

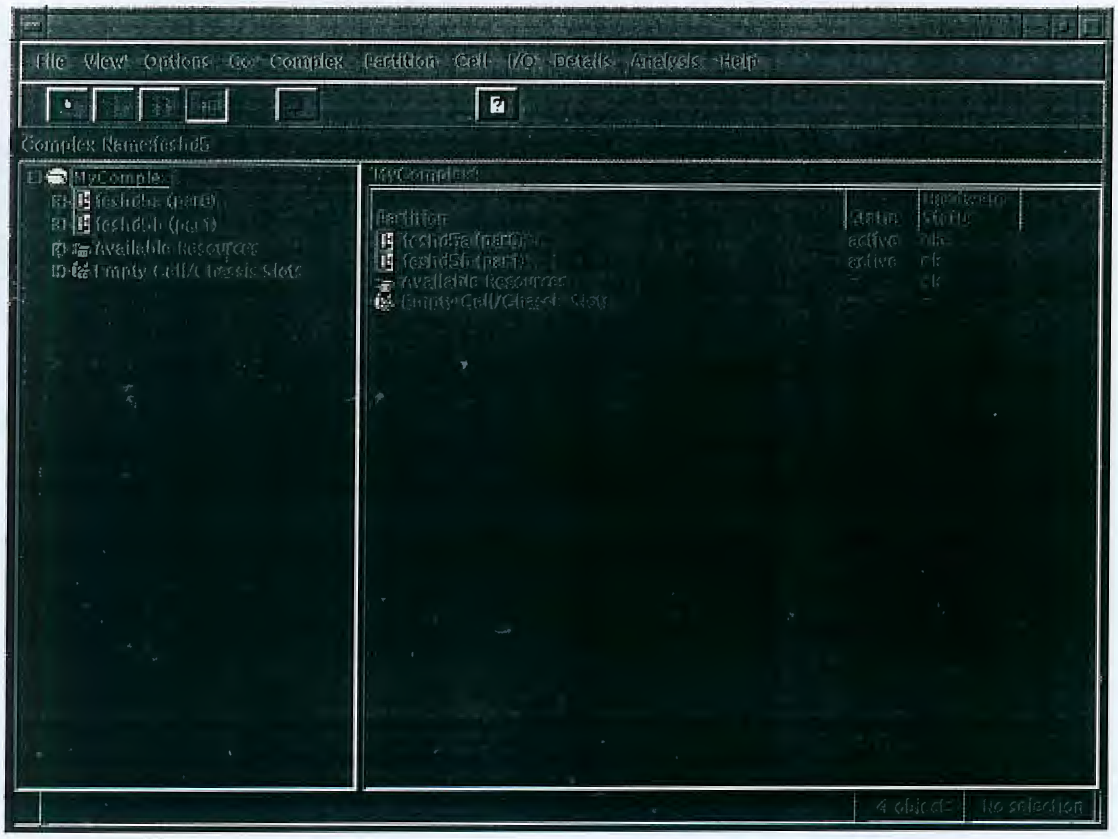
View the left side of Partition Manager primary window to see a list of all nPartitions in a server complex using Partition Manager.

Step 1. Run Partition Manager (/opt/parmgr/bin/parmgr) or access it from SAM or a Web browser.

me

SS43
21

Step 2. When the Partition Manager starts up, the left side of its primary display lists the nPartitions in the complex.



Partition	State	Hardware Status
feshd5a (par0)	active	ok
feshd5b (par1)	active	ok
Available Resources	-	ok
Empty Cell/Chassis Slots	-	-

The right side of the primary display also lists the complex's nPartitions when nothing is selected on the display's left side, or when **My Complex** is selected.

Listing Cell nPartition Assignments

Each cell in an nPartition server complex either is assigned to an nPartition, or it is unassigned (if it is an available resource).

You can list all cells and their nPartition assignments by using these procedures:

- *Listing Cell nPartition Assignments [Service Processor]* on page 254
- *Listing Cell nPartition Assignments [HP-UX]* on page 254
- *Listing Cell nPartition Assignments [Partition Manager]* on page 255

Listing Cell nPartition Assignments [Service Processor]

Use the Command menu's `CP` and `DU` commands to list all cell nPartition assignments (and other details) from the server complex's service processor.

Step 1. Login to the service processor for the complex and enter `CM` to access the Command menu.

Step 2. Enter the `CP` command to list all configured nPartitions in the server complex.

Step 3. Enter the `DU` command to list additional details (such as available core I/O) for the cells assigned to the various nPartitions in the server complex.

On HP Superdome servers, you also can use the service processor Command menu's `IO` command to list cell-to-I/O chassis connections.

Listing Cell nPartition Assignments [HP-UX]

Use the `parstatus -C` command to list all cells in a server complex and their nPartition assignments.

Step 1. Login to HP-UX running on one of the server complex's nPartitions.

Step 2. Issue the `parstatus -C` command to list all cells, any I/O chassis connections, and any nPartition assignments for the cells.

In addition to reporting the cell nPartition assignments (listed in the "Par Num" column), the parstatus -C command reports each cell's current status (absent, inactive, active core, active base) in the "Actual Usage" column.

```
# parstatus -C
[Cell]
                        CPU     Memory                              Use
                        OK/     (GB)                         Core   On
Hardware   Actual       Deconf/ OK/                          Cell   Next Par
Location   Usage        Max     Deconf    Connected To       Capable Boot Num
========== ============ ======= ========= =================== ======= ==== ===
cab0,cell0 active core  4/0/4    2.0/ 0.0 cab0,bay0,chassis1  yes     yes  0
cab0,cell1 absent       -       -         -                   -       -    -
cab0,cell2 active base  4/0/4    2.0/ 0.0 cab0,bay1,chassis3  yes     yes  0
cab0,cell3 absent       -       -         -                   -       -    -
cab0,cell4 active core  4/0/4    2.0/ 0.0 cab0,bay0,chassis3  yes     yes  1
cab0,cell5 absent       -       -         -                   -       -    -
cab0,cell6 inactive     4/0/4    2.0/ 0.0 cab0,bay1,chassis1  no      -    -
cab0,cell7 absent       -       -         -                   -       -    -

#
```

For cells that are not assigned to an nPartition, parstatus -C lists a hyphen (-) in the "Par Num" column instead of the cell's partition number. The "Connected To" column lists any I/O chassis connections for the cells, and "Core Cell Capable" lists whether core I/O is available through each the cell's I/O chassis.

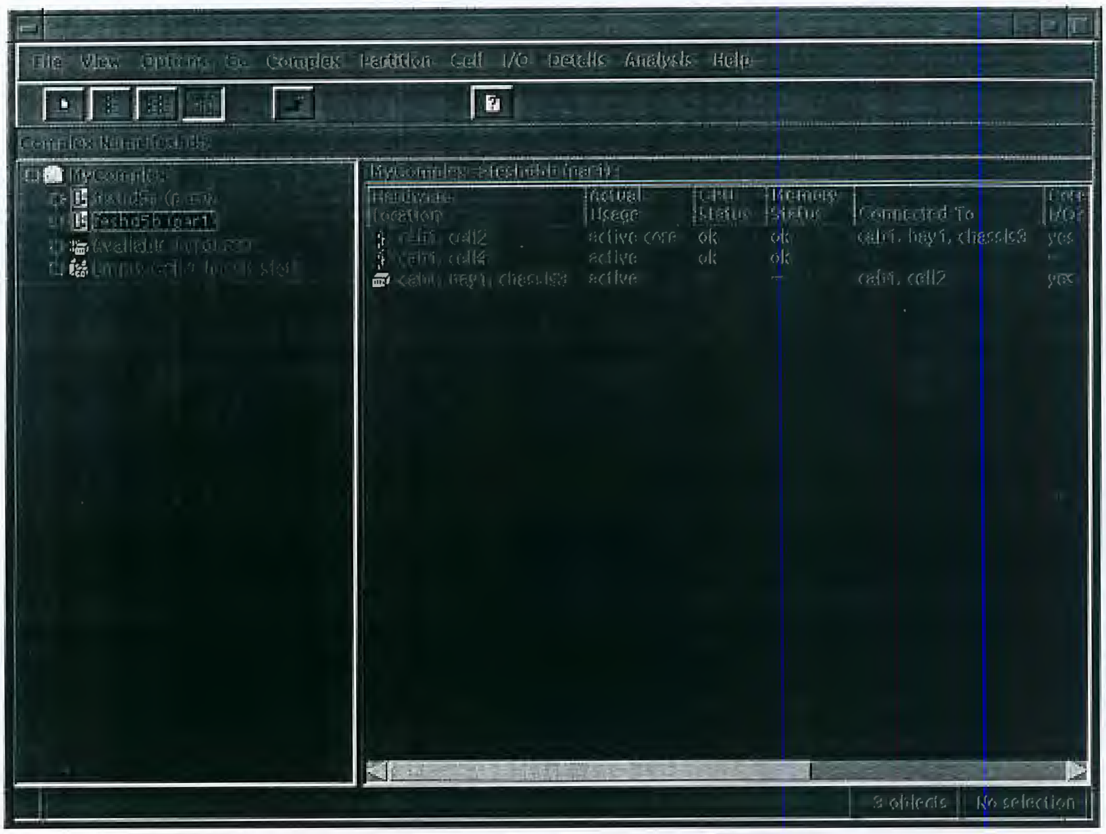
Listing Cell nPartition Assignments [Partition Manager]

Select each nPartition and Available Resources on the left side of the primary window to view all cell nPartition assignments in a server complex from Partition Manager.

Step 1. Run Partition Manager (/opt/parmgr/bin/parmgr) or access it from SAM or a Web browser.

Step 2. At the Partition Manager primary window, select each nPartition on the left side of the window to list the nPartition's cell assignments on the window's right side, or select Available Resources to list all unassigned cells.

5540



MyComplex->feshd5b (par1)

Hardware Location	Actual Usage	CPU Status	Memory Status	Connected To	Core I/O?
cab0, cell2	active core	ok	ok	cab0, bay1, chassis3	yes
cab0, cell4	active	ok	ok		–
cab0, bay1, chassis3	active		–	cab0, cell2	yes

3 objects | No selection

On the right side of the primary window, for each selected nPartition, Partition Manager lists the cell assignments and any I/O chassis connected to the cells.

5539

Creating a Genesis Partition

When you create a Genesis Partition, you establish a one-cell nPartition on the server complex. The Genesis Partition replaces all other nPartitions, and once created it is the only nPartition in the server.

The only way to create a Genesis Partition is to use the service processor Command menu's `CC` command on the server complex.

Genesis Partition Creation [Service Processor]

Use the service processor Command menu's `CC` command and `G` option to create a Genesis Partition on an HP nPartition server.

As a result of this procedure, *all existing nPartitions are destroyed* and are replaced with a single, one-cell nPartition (the Genesis Partition).

You can revert to the previous nPartition configuration—if any existed before you created the Genesis Partition—by using the `CC` command's `L` option to restore the last configuration.

Step 1. Save all current nPartition configuration details, if any nPartitions are configured in the complex.

Saving the current nPartition information provides you the details you would need to re-create all nPartitions as they currently exist.

Use the `parstatus -V -p#` HP-UX command (or an equivalent `parmgr` procedure) to save configuration details about each nPartition.

For each nPartition, enter the `parstatus -V -p#` command to display detailed information about the partition number (`-p#`) specified.

Step 2. Determine which cell will be configured as the Genesis Partition.

The cell must be connected to an I/O chassis. The I/O chassis must have a core I/O card installed, and it should have a bootable HP-UX disk (or a method for installing HP-UX and a disk onto which it can be installed).

Step 3. Ensure that all nPartitions within the complex are in the ready for reconfig (inactive) state.

538

If an nPartition is running HP-UX, you can shut down the nPartition to the ready for reconfig state by using the `shutdown -R -H` command.

Or, you can put an nPartition into the ready for reconfig state by using the BCH interface's `RECONFIGRESET` command or using the service processor Command menu's `RR` command.

Step 4. Login to the server complex's service processor (GSP or MP).

Login as a user with administrator privileges, which are required for creating a Genesis Partition.

Step 5. Enter **`CM`** to access the service processor Command menu.

Step 6. Issue the **`CC`** command, select **`G`** for Genesis Complex Profile, and specify the cabinet and cell slot for the cell that will comprise the Genesis Partition.

```
GSP:CM> CC

This command allows you to change the complex profile.

WARNING: You must shut down all Protection Domains before
executing
         this command.

G - Genesis Complex Profile
L - Last Complex Profile
    Select Profile: g

    Enter Cabinet number: 0

    Enter Slot number: 0

    Do you want to modify the complex profile? (Y/[N]) y

    -> The complex profile will be modified.
GSP:CM>
```

You can confirm that the Genesis Partition was successfully created if the `CC` command reports that the “complex profile will be modified”.

If the `CC` command reports “Sorry, command failed”, then the Genesis Partition was not created, possibly because one or more nPartitions are not at the ready for reconfig state. If this is the case, go back to *Step 3* and ensure all nPartitions are inactive at the ready for reconfig state.

5537

Step 7. Issue the BO command to boot the Genesis Partition past its ready for reconfig state and make it an active nPartition.

When a Genesis Partition is created, it remains at boot-is-blocked (in an inactive, ready for reconfig state), so you must boot it manually.

The Genesis Partition always is assigned partition number 0, because when it is created it is the first and only nPartition in the server complex.

Using the BO command to boot partition 0 will boot the Genesis Partition to its Boot Console Handler (BCH) interface.

```
GSP:CM> BO

This command boots the selected partition.

     #    Name
    ---   ----
     0)   Partition 0

    Select a partition number : 0

    Do you want to boot partition number 0,
    named Partition 0 ? (Y/[N]) y

    -> The selected partition will be booted.
GSP:CM>
```

Step 8. Access the Genesis Partition's console and configure the nPartition as appropriate and necessary.

From the service processor Command menu, enter **MA** to return to the Main menu, then enter **CO** to access the Console menu. The Genesis Partition is partition 0 and by default is named "Partition 0".

You will need to set the boot paths (PRI, ALT, and HAA), any core cell choices, the nPartition name, and other settings as appropriate. You also may need to add cells to the Genesis Partition if you want it to have more than one cell.

5536

Creating a New nPartition

In a server complex, you can create multiple nPartitions if the server has enough cells and core I/O to support the nPartitions.

You can create a new nPartition by using the following procedures:

- *Creating a New nPartition [HP-UX]* on page 260
- *Creating a New nPartition [Partition Manager]* on page 264

At least one cell in each nPartition must be connected to an I/O chassis that has core I/O attached. To boot HP-UX the nPartition also must have a boot device and any required PCI cards and devices installed.

When creating an nPartition, you should adhere to the HP nPartition requirements and guidelines. HP recommends only specific sets of nPartition configurations.

If no nPartitions exist in a server complex, you must first establish a Genesis Partition before creating other nPartitions.

Creating a New nPartition [HP-UX]

Use the **parstatus**, **parcreate**, and **parmodify** commands to create and configures a new nPartition from HP-UX.

This procedure uses parstatus to find available (unassigned) cells, uses parcreate to create an nPartition using the cells, and uses parmodify to modify the nPartition's settings and configure it for use.

One alternative to using this complete procedure is to replace steps 2–5 with a single parcreate command.

For example, the commands performed in steps 2–5 could be replaced with the following parcreate command line.

```
# parcreate -c4:base:y:ri -c6:base:y:ri -P "hostname05" -r0/4 \
> -r0/6 -b 4/0/1/0/0.9 -B
Partition Created. The partition number is : 1
#
```

5535
21

In the above alternative command line, the -B option is specified and causes the nPartition to be booted past boot-is-blocked immediately, thus making the new nPartition active. (It is booted to its BCH interface.)

Step 1. Login to HP-UX running on an existing nPartition in the server complex, and plan your nPartition configuration by selecting which cells will comprise the new nPartition.

Use the **parstatus -AC** command to list all unassigned (available) cells in the server complex.

```
# parstatus -AC
[Cell]
                        CPU     Memory                                Use
                        OK/     (GB)                          Core    On
Hardware   Actual       Failed/ OK/                           cell    Next Par
Location   Usage        Max     Failed  Connected To          Capable Boot Num
========== ============ ======= ======= ===================== ======= ==== ===
cab0,cell1 absent       -       -       -                     -       -    -
cab0,cell3 absent       -       -       -                     -       -    -
cab0,cell4 power on     4/0/4   2.0/0.0 cab 0,bay0,chassis3 yes     -    -
cab0,cell5 absent       -       -       -                     -       -    -
cab0,cell6 power on     4/0/4   2.0/0.0 cab 0,bay1,chassis1 yes     -    -
cab0,cell7 absent       -       -       -                     -       -    -

#
```

You can select any of the cells listed to create the new nPartition; only the cells that are *not "absent"* are present within the server complex.

All cells that you choose **must** meet the hardware requirements for nPartitions (for example, they all must have the same processor revision and firmware) and **should** form an HP-recommended nPartition configuration. At least one cell must have an I/O chassis with core I/O.

Step 2. After confirming that cells you have chosen would establish a valid nPartition configuration, use the **parcreate -c**... command to create a new nPartition with the cells.

When using the parcreate command, *do not* specify the -B option for this procedure.

(The -B option causes parcreate to immediately boot the newly-created nPartition past the default ready for reconfig state, thus making the nPartition active and preventing you from further modifying it.)

5530

By *not* specifying `-B`, the new nPartition can be further modified because it will remain inactive at the ready for reconfig state (until you boot it using the service processor Command menu's `BO` command).

If creating a single-cell nPartition, just use one `-c` option.

To create a multiple-cell nPartition, you should specify the `-c` option multiple times (once for each cell) issuing a single command line.

```
# parcreate -c4:base:y:ri -c6:base:y:ri
Partition Created. The partition number is : 1
#
```

When `parcreate` successfully creates a new nPartition, it reports "Partition Created" and reports the nPartition number ("partition number is...").

If parcreate detects any problems or issues when creating an nPartition, it lists them in its output. If it cannot create the nPartition, `parcreate` reports "Command failed" along with more details.

The `parcreate` command's `-c` option is as follows:

`-c` *`cell`*`:`[*`cell_type`*]`:`[*`use_on_next_boot`*]`:`[*`failure_usage`*]

This option specifies the cell ID (*`cell`*) to be assigned to the nPartition.

- The only valid *`cell_type`* value is: `base` (base cell, the default).
- The valid *`use_on_next_boot`* values for cells are:

  `y` Participate in reboot (the default).

  `n` Do not participate in reboot.
- The only valid *`failure_usage`* value is: `ri` (reactivate with interleave, the default).

For details, see the *parcreate* (1M) manpage.

Step 3. Use the **`parmodify`** command to modify the new nPartition's configuration and set the nPartition name (`-P`), boot paths (`-b`, `-s`, and `-t`), and any core cell choices (`-r`).

When using the `parmodify` command, you must use the `-p#` option to specify the partition number for the nPartition. Use the partition number that the `parcreate` command reported in *Step 2*.

5533

```
# parmodify -p1 -P "hostname05"
Command succeeded.
# parmodify -p1 -r0/4 -r0/6
Command succeeded.
# parmodify -p1 -b 4/0/1/0/0.9
Command succeeded.
#
```

When each modification takes place, parmodify reports "Command succeeded". Otherwise it reports any problems.

You can specify each configuration option on a separate command line or can combine all options into a single, longer command line.

For details on the various options for modifying nPartition settings, see the *parmodify* (1M) manpage.

Step 4. Use the **parstatus -V -p#** command to list all details about your newly created and configured nPartition.

If any configuration details should be modified, use the parmodify command before you boot the nPartition in the next step.

```
# parstatus -V -p1
[Partition]
Partition Number        :  1
Partition Name          : hostname05
Status                  : inactive
IP address              :
Prmary Boot Path        : 4/0/1/0/0.9
ALternate Boot Path     : 0/0/0/0/0/0/0/0.0.0
HA Alternate Boot Path  : 0/0/0/0/0/0/0/0.0.0
PDC Revision            : 104.1
IODCH Version           : 23664
CPU Speed               : 552 MHz
Core Cell               : ?
Core Cell Alternate     :
                0. cab0,cell4
                1. cab0,cell6
[Cell]
                        CPU     Memory                             Use
                        OK/     (GB)                       Core    On
Hardware   Actual       Failed/ OK/                        cell    Next Par
Location   Usage        Max     Failed    Connected To     Capable Boot Num
========== ============ ======= ========= ================= ======= ==== ===
cab0,cell4 inactive     4/0/4    2.0/ 0.0 cab 0,bay0,chassis3 yes     yes  1
cab0,cell6 inactive     4/0/4    2.0/ 0.0 cab 0,bay1,chassis1 yes     yes  1
....
```

5332

Step 5. Boot your newly-created nPartition past boot-is-blocked to make it active and make its BCH interface available.

Use the service processor Command menu's BO command to boot the nPartition.

Once the nPartition is booted, you can access its BCH interface through its console. Use the service processor Console menu (enter CO at the service processor Main menu).

Creating a New nPartition [Partition Manager]

Use the **Partition —> Create Partition** action to create a new nPartition using Partition Manager.

Step 1. Plan your nPartition configuration by selecting which cells will comprise the new nPartition.

All cells that you choose **must** meet the hardware requirements for nPartitions (for example, they all must have the same processor revision and firmware) and **should** form an HP-recommended nPartition configuration. At least one cell must have an I/O chassis with core I/O.

Step 2. Run Partition Manager (`/opt/parmgr/bin/parmgr`) or access it from SAM or a Web browser.

You optionally can specify the `parmgr -t create` command and options to automatically launch the **Partition —> Create Partition** action. See the *parmgr* (1M) manpage for command option details.

Step 3. Select the **Partition —> Create Partition** action to run the Partition Manager task wizard for creating a new nPartition.

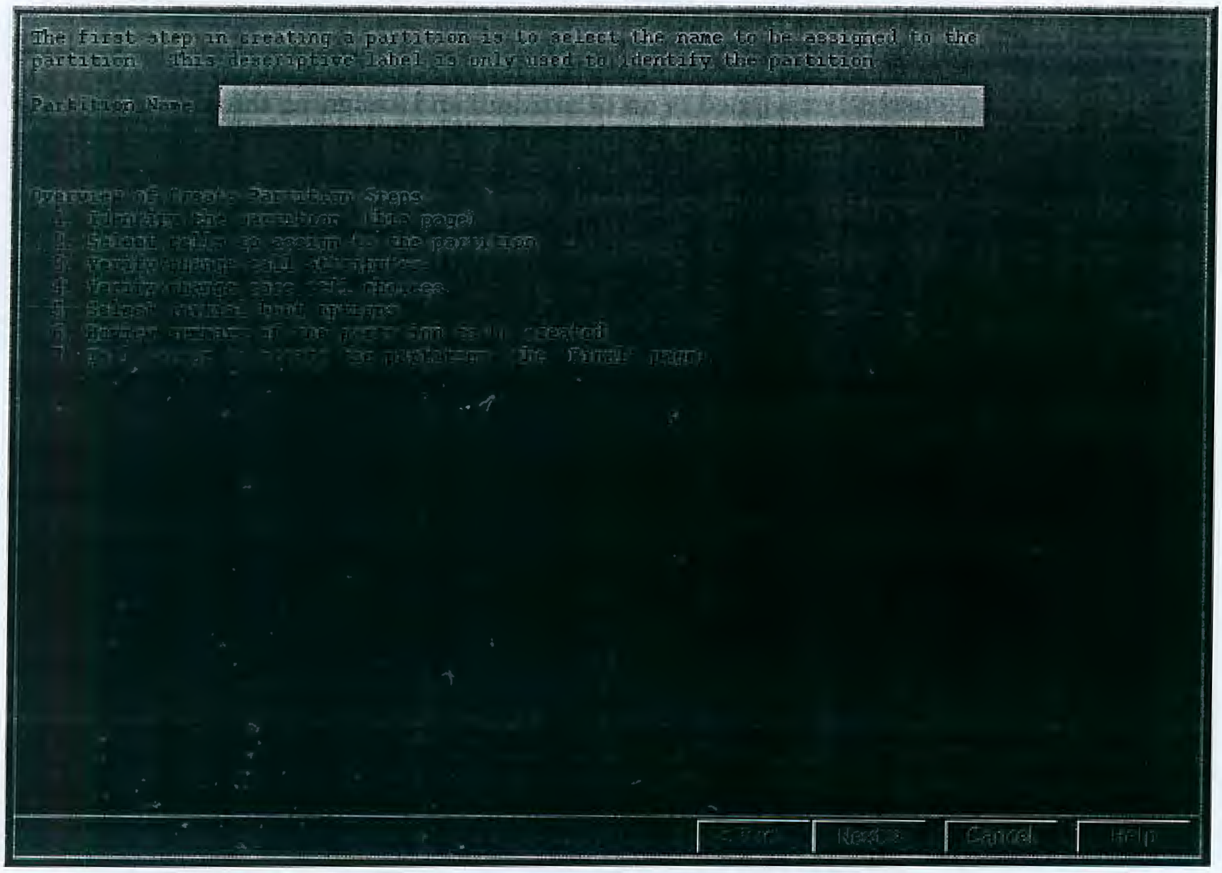
Partition Manager guides you through the steps it requires for creating a new nPartition.

You can move backward and forward through the steps by using **Next** and **Back** buttons. At the final steps, you can verify the settings you have established for the new nPartition and, if they are correct for your purposes, click the **Finish** button to create the new nPartition.

You can *cancel the new nPartition* creation at any time by clicking the **Cancel** button.

5531

The following window shows the first step and overview for Partition Manager's create **Partition —> Create Partition** action.



The first step in creating a partition is to select the name to be assigned to the partition. This descriptive label is only used to identify the partition.

Partition Name:

Overview of Create Partition Steps
1. Identify the partition (this page)
2. Select cells to assign to the partition
3. Verify/change cell attributes
4. Verify/change core cell choices
5. Select optional boot options
6. Review summary of the partition to be created
7. Finish and create the partition (the Finish page)

If you specify for Partition Manager to automatically boot the new nPartition, you can access the new nPartition's BCH interface from its console when you finish using the create partition task wizard.

Otherwise, if you *do not* specify to automatically boot the new nPartition, you must use the service processor Command menu's BO command to boot the nPartition past boot-is-blocked (inactive, ready for reconfig state) and make its BCH interface available.

SS30

Assigning (Adding) Cells to an nPartition

You can add cells to the local nPartition or to any remote nPartitions in the same server complex.

Adding cells to an nPartition involves selecting available cells (those not currently assigned to an nPartition) and assigning them to an existing nPartition. Both the selected cells and any I/O chassis connected to the cells are assigned to the designated nPartition.

You can add cells to an nPartition by using the following procedures:

- *Adding Cells to an nPartition [HP-UX]* on page 267
- *Adding Cells to an nPartition [Partition Manager]* on page 268

When adding cells to an nPartition, you should refer to the guidelines in the chapter *Planning nPartition Configurations* on page 109.

Reboot for Reconfig Guidelines for Adding Cells

In some situations, you must immediately perform a reboot for reconfig of a modified nPartition after adding cells to it.

- You **must** immediately perform a reboot for reconfig (`shutdown -R`) of an nPartition when you have added a cell to an active nPartition and you specified the `-B` option to the `parmodify` command.
- You **should** perform a reboot for reconfig of an nPartition *as soon as possible* after you have added a cell to an active nPartition and have specified a "y" use-on-next-boot value for the new cell.
- You need not perform a reboot for reconfig of an nPartition in these situations:
  - When you have added a cell to an inactive nPartition.
  - When you have added a cell with a "n" use-on-next-boot value and you did not specify the `-B` option to the `parmodify` command.

Adding Cells to an nPartition [HP-UX]

Use the `parstatus` and `parmodify` commands to add cells to an nPartition using HP-UX commands.

Step 1. Use the `parstatus -A -C` command to list all available cells (the unassigned cells) in the server complex.

Step 2. Choose one or more eligible cells from the list to add to the nPartition.

Adding the cell(s) to the nPartition should create a configuration that adheres to the hardware requirements and performance guidelines.

Step 3. Modify the nPartition by issuing the `parmodify -p# -a#...` command to add the cell.

The `-p#` option specifies the partition number (#) for the nPartition being modified.

The `-a` *`cell:type:use:fail`* option specifies the cell ID and other details for the cell to be added to the nPartition.

To add multiple cells, you can specify the `-a` option multiple times in the same command.

For example: `parmodify -p1 -a0:base:y:ri -a2:base:y:ri` adds two cells (cell ID 0 and cell ID 2) to nPartition number 1.

The `-a` option (`-a` *`cell:type:use:fail`*) specifies the following details for each cell that you add to the nPartition.

`cell` The cell to be added to the nPartition. You can specify the cell in global (*`cell`*) format or in hardware location (*`cabinet/slot`*) format.

`type` The cell type: `base` is the only supported cell type and it is the default.

`use` The cell's use-on-next-boot value: `y` or `n`. Use `y` (the default) if the cell is to be an active member of the nPartition, or use `n` if the cell is to remain an inactive member.

`fail` The cell's failure usage: `ri` (reactivate with interleave) is the only supported failure usage policy and it is the default.

SS28

You can optionally specify the `parmodify` command's `-B` option to require that the modified nPartition be rebooted.

- When you specify `-B` to modify an *inactive* nPartition, the inactive nPartition completes partition rendezvous and becomes active if possible.
- When you specify `-B` to modify an *active* nPartition, you must perform a reboot for reconfig of the nPartition before any other cell assignment changes can be made within the server complex.

The `parmodify -p1 -a0:base:y:ri -a2:base:y:ri` command adds cell 0 and cell 2 to partition number 1. This command also sets a "y" use-on-next-boot value for both cells, meaning that they will be active members of the nPartition following the next time all cells boot (for example, when reboot for reconfig is performed on the nPartition.

Because this example command does not include the `-B` option, if partition 1 were an *inactive nPartition*, it would remain inactive; if partition 1 were an *active nPartition* the new cells would be assigned, but they would remain inactive cells until a reboot for reconfig is performed.

See the *parmodify* (1M) manpage for details on all options.

Step 4. As needed, perform a reboot for reconfig (**`shutdown -R`**) on the modified nPartition.

See the *Reboot for Reconfig Guidelines for Adding Cells* on page 266 for details on when to perform a reboot for reconfig.

Adding Cells to an nPartition [Partition Manager]

Use the **Partition —> Modify Partition** action, **Add/Remove Cells** tab to add cells to an nPartition from Partition Manager.

Step 1. Run Partition Manager (`/opt/parmgr/bin/parmgr`) or access it from SAM or a Web browser.

Step 2. In the Partition Manager primary window, select the nPartition to which you want to add cells, then select the **Partition —> Modify Partition** menu item.

Step 3. In the Modify Partition window, click the **Add/Remove Cells** tab.

Step 4. Select the cells that you want to add to the nPartition from the Available Cells list, then click the **Add** button to add them to the nPartition's cell list.

If adding multiple cells, you can select multiple cells by pressing the **Control** key while clicking on the cells.

Adding the cell(s) to the nPartition should create a configuration that adheres to the hardware requirements and performance guidelines.

Step 5. After you add the new cells to the nPartition's cell list, click the **OK** button.

The cells are not actually *assigned* to the nPartition until after the next step.

Step 6. Review the information shown in the **Notes and Warnings**, the **Summary of Changes**, and the **HA Checks** tabs.

Partition Manager generates this information when it checks details of the new nPartition configuration, such as cell compatibility and various high-availability guidelines.

To cancel all nPartition changes, click the **Cancel** button in the Notes and Warnings window and then click **Cancel** in the Modify Partition window.

To proceed with adding the cell(s) to the nPartition, click **OK**.

Step 7. Once Partition Manager confirms that the "partition has been successfully modified" click the **OK** button.

The cells are assigned to the nPartition after clicking **OK** in the previous step. However, any cells you have added to an active nPartition will remain *inactive* until you perform a reboot for reconfig of the modified nPartition.

Step 8. As needed, perform a reboot for reconfig (`shutdown -R`) of the modified nPartition.

See the *Reboot for Reconfig Guidelines for Adding Cells* on page 266 for details on when to perform a reboot for reconfig.

5526

Unassigning (Removing) Cells from an nPartition

Removing a cell from an nPartition involves unassigning the cell from the nPartition to which it is assigned and, if necessary, performing a reboot for reconfig of the nPartition.

You can remove *any cell* from the local nPartition and can remove *inactive cells* from remote nPartitions in the same server complex. However, at least one core-capable cell must remain in each nPartition.

You can remove (unassign) cells from nPartitions by using these procedures:

- *Removing Cells from an nPartition [HP-UX]* on page 271
- *Removing Cells from an nPartition [Partition Manager]* on page 274

When removing cells from an nPartition, you should ensure that the modified nPartition still adheres to the hardware requirements and performance guidelines for nPartitions. Refer to the chapter *Planning nPartition Configurations* on page 109 for details.

After you remove a cell from an nPartition, the cell's I/O chassis also is removed from the nPartition. As a result, any I/O devices associated with the cell are made unavailable to the nPartition after the cell is removed.

If you want to remove the last cell in an nPartition, you must instead remove the nPartition using the `parremove` command or Partition Manager.

Once a cell is unassigned, the cell (and any I/O resources connected to the cell) is considered to be an available resource that is on the "free cell list" and can be assigned to any nPartition in the server complex.

Reboot for Reconfig Guidelines for Removing Cells

In some situations, you must immediately perform a reboot for reconfig (`shutdown -R`) of a modified nPartition after removing cells from it. Performing a required reboot for reconfig completes cell assignment changes and unlocks the server's Complex Profile.

- You **must** immediately perform a reboot for reconfig of an nPartition when you have removed an *active cell* from the nPartition.
- You **must** immediately perform a reboot for reconfig of an nPartition when you have removed a cell from an active nPartition and specified the `-B` option to the `parmodify` command.
- You need not perform a reboot for reconfig of an nPartition when you have removed an *inactive* cell from an nPartition and did not specify the `-B` option to the `parmodify` command.

In the cases where you must immediately perform a reboot for reconfig after removing a cell, *not doing so* will leave the Complex Profile locked and thus will prevent any other changes to the server complex configuration. In these cases, the reboot for reconfig is required to complete the cell assignment changes and permit other changes to occur.

Removing Cells from an nPartition [HP-UX]

Use the **`parstatus`** and **`parmodify`** commands to remove cells from an nPartition using HP-UX commands.

Step 1. List the current nPartition assignments and status for the cells you plan to remove from their assigned nPartition by issuing the **`parstatus -c#...`** HP-UX command.

Specify each cell you plan to remove with a separate `-c` option.

For example, to list details on cells 0, 1, and 2, issue the `parstatus -c0 -c1 -c2` command.

The cells must all be assigned to the same nPartition in order to remove them using a single procedure. Otherwise, if the cells are assigned to different nPartitions, you must perform this procedure separately for each nPartition.

SS24

In order to remove cells that are not assigned to the local nPartition, the cells must be *inactive* (their “Actual Usage” must be “inactive”). You can list the local nPartition by issuing the `parstatus -w` command.

To remove an *active* cell from its nPartition, you must do so when logged in to HP-UX running on the cell’s nPartition.

Step 2. Remove the cell from the nPartition to which it is assigned by using the **`parmodify -p# -d#...`** command.

Specify the partition number (`-p#`) and each cell (`-d#`) that you want to remove from the nPartition.

If removing *multiple cells* from an nPartition, specify each cell with a separate `-d#` option on the same command line (such as: `parmodify -p1 -d0 -d2...` to remove cells 0 and 2 from partition number 1).

Slightly different procedures are required for removing active cells and inactive cells. See the following information for details (*Guidelines for Removing an Active Cell* and *Guidelines for Removing an Inactive Cell*).

When you are removing multiple cells from the local nPartition, if at least one of the cells you plan to remove is currently active, then you should follow the guidelines for removing active cells.

- **Guidelines for Removing an Active Cell**

  You **should** specify the `-B` option to `parmodify` when removing an active cell from the local nPartition if you want the nPartition to become active following its reboot for reconfig.

  For example, the following command removes cell 4 from partition 0 and the `-B` option ensures that the nPartition will be active following its reboot for reconfig.

  ```
  # parmodify -p0 -d4 -B
  Cell 4 is active.
  Use shutdown -R to shutdown the system to ready for
  reconfig state.
  Command succeeded.
  #
  ```

  You **must** perform a reboot for reconfig (`shutdown -R`) after you issue the `parmodify` command to remove active cell(s) from the nPartition. (This is covered in *Step 3* that follows.)

- **Guidelines for Removing an Inactive Cell**

  When removing an *inactive* cell from an nPartition you do not need to specify the `-B` option to `parmodify` and do not need to perform a reboot for reconfig of the cell's nPartition.

  When you use `parmodify` to remove an inactive cell, the cell is immediately unassigned from its nPartition.

  If you specify the `-B` option when removing an *inactive cell* from an *inactive nPartition*, then the cell is immediately removed and the modified nPartition is booted past its inactive ready for reconfig state and becomes an active nPartition.

  For example, the following command removes cell 2 from partition 0. Because cell 2 is inactive, it is immediately unassigned.

  ```
  # parmodify -p0 -d2
  Command succeeded.
  #
  ```

Step 3. As needed, perform a reboot for reconfig (**`shutdown -R`**) of the nPartition being modified.

You **must** perform a reboot for reconfig if you have removed an *active cell* or have specified the `-B` option when modifying an *active nPartition*.

See the *Reboot for Reconfig Guidelines for Removing Cells* on page 271 for details on when to perform a reboot for reconfig.

This reboot for reconfig enables the cell removal to complete and the Complex Profile to be unlocked.

If you have removed an active cell and you did not specify the `-B` option to `parmodify`, then the nPartition will remain *inactive* in the ready for reconfig state after you perform the reboot for reconfig. To make the inactive nPartition active, use the service processor Command menu's `BO` (boot) command.

SS22

Removing Cells from an nPartition [Partition Manager]

Use the **Partition —> Modify Partition** action, **Add/Remove Cells** tab to remove cells from an nPartition using Partition Manager.

Step 1. Determine which cell(s) you want to remove from the nPartition.

The cells must all be assigned to the same nPartition in order to remove them using a single procedure. Otherwise, if the cells are assigned to different nPartitions, you must perform this procedure separately for each nPartition.

Step 2. Run Partition Manager (`/opt/parmgr/bin/parmgr`) or access it from SAM or a Web browser.

Step 3. In the Partition Manager primary window, select the nPartition from which you want to remove cells, then select the **Partition —> Modify Partition** action.

Step 4. In the Modify Partition window, click the **Add/Remove Cells** tab.

Step 5. From the "Cells in the Partition" list, select the cells that you want to remove from the nPartition. Then click the **Remove** button to move them to the Available Cells list. If removing multiple cells, you can select multiple cells by pressing the **Control** key while clicking on the cells.

Removing the cell(s) from the nPartition should create a configuration that adheres to the hardware requirements and performance guidelines.

Step 6. After you have removed the cells from the nPartition's cell list, click the **OK** button.

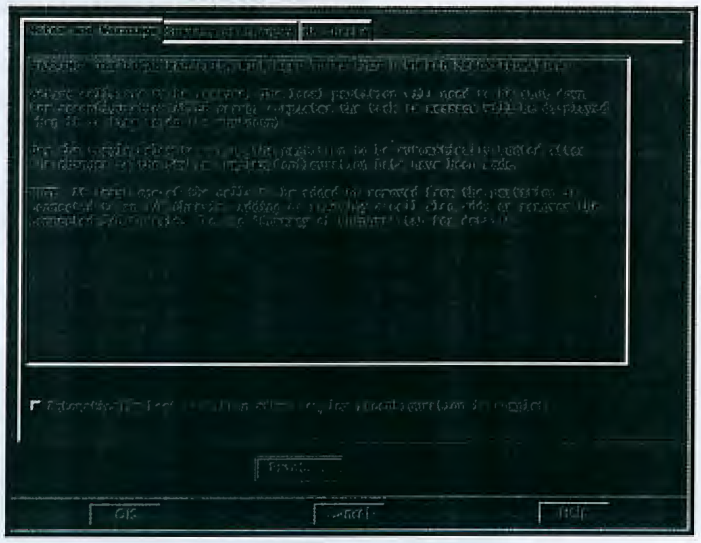
The cells are not actually *removed* from the nPartition until after the next step.

Step 7. Review the information shown in the **Notes and Warnings**, the **Summary of Changes**, and the **HA Checks** tabs.

Partition Manager generates this information when it checks details of the new nPartition configuration.

If you **must** perform a reboot for reconfig of the nPartition, such as when removing an active cell from the nPartition, then the Notes and Warnings tab provides details and options.

- If a reboot for reconfig is required, the Notes and Warnings tab has information about the reboot procedure. (See *Step 9* for details.)



- When a reboot for reconfig is required, the Notes and Warnings tab also has a check box ("Automatically boot partition") that—when selected—enables the nPartition to rendezvous and be active after the reboot for reconfig.

To cancel all nPartition changes, click the **Cancel** button in the Notes and Warnings window and then click **Cancel** in the Modify Partition window.

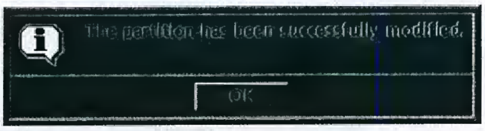
To proceed with removing the cell(s) from the nPartition, click **OK**.

Step 8. When Partition Manager confirms that the "partition has been successfully modified", review any additional information and respond as needed to the dialog box presented.

(The cells were designated to be removed from the nPartition after completing the previous step, however a reboot may be required.)

- If you have removed only *inactive* cells from the nPartition, Partition Manager provides no additional info and you can click **OK** to complete the procedure (a reboot is not needed).

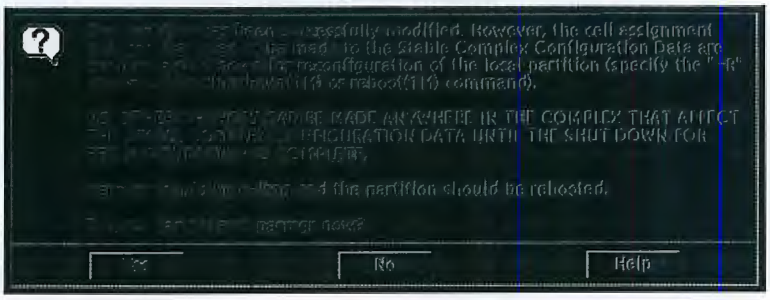
SS20
22



The partition has been successfully modified.

- If you have removed one or more *active* cells from the nPartition, then Partition Manager provides more info about performing the required reboot for reconfig of the nPartition.

  You **must** reboot the nPartition as soon as possible, so you should click the **Yes** button to exit Partition Manager and proceed with the next step of this procedure.



[illegible] been successfully modified. However, the cell assignment [illegible] made to the Stable Complex Configuration Data are [illegible] for reconfiguration of the local partition (specify the "-R" [illegible] shutdown(1M) or reboot(1M) command).

[illegible] CAN BE MADE ANYWHERE IN THE COMPLEX THAT AFFECT [illegible] CONFIGURATION DATA UNTIL THE SHUT DOWN FOR [illegible] COMPLETE.

[illegible] and the partition should be rebooted.

[illegible] manager now?

Step 9. As needed, perform a reboot for reconfig (**`shutdown -R`**) of the modified nPartition.

- If you have removed only inactive cells from an nPartition, then you *do not* need to perform a reboot for reconfig of the nPartition.

- If you have removed any active cells from the nPartition, then you **must** perform a reboot for reconfig and will have seen a detailed message about rebooting from Partition Manager (see *Steps 7 and 8*).

  After you issue the `shutdown -R` command, the nPartition performs the reboot for reconfig. If you selected the "Automatically boot partition" check box earlier in this procedure (see *Step 7*), then the nPartition is active after the reboot for reconfig and you can interact with it through its console.

If you *did not* select the "Automatically boot partition" check box, then the nPartition is inactive (at the ready for reconfig state) after the reboot for reconfig occurs. In this situation, you can make the nPartition active by using the service processor Command menu's BO command.

SS18
20

Removing (Deleting) an nPartition

You can delete (remove) any nPartition within a server complex.

The HP-UX nPartition deletion capabilities include restrictions for security reasons: you can delete only the *local nPartition* and *inactive remote* nPartitions.

You can delete an nPartition using these procedures:

- *Deleting an nPartition [HP-UX]* on page 278
- *Deleting an nPartition [Partition Manager]* on page 280

When removing the local nPartition, you must complete the procedure by issuing the **`shutdown -R -H`** command *as soon as possible* after initiating the local nPartition's removal.

Deleting an nPartition causes all of the nPartition's cells (and any I/O resources connected to the cells) to be unassigned. As a result, all of these cells become available resources that are on the "free cell list" and can be assigned to any nPartition in the server complex.

Deleting an nPartition [HP-UX]

Use the **`parremove`** command to delete an nPartition using HP-UX commands.

Step 1. Use the **`parstatus -P`** command to list all nPartitions, and check the status (active or inactive) for the nPartition you plan to remove.

To check the *local* partition number, use the `parstatus -w` command. The local nPartition always is active when it is running HP-UX.

If you are planning to remove a *remote* nPartition, check to see whether the remote nPartition is inactive.

Step 2. If a remote nPartition that you plan to remove currently is *active*, then put the nPartition into the ready for reconfig state to make it inactive.

If the remote nPartition is running HP-UX, you can shut down the nPartition to the ready for reconfig state by 1) logging in to HP-UX on the remote nPartition, 2) shutting down all applications and warning users, and 3) issuing the `shutdown -R -H` command.

5517

You also can put the nPartition into the ready for reconfig state by using the BCH interface's `RECONFIGRESET` command or the service processor Command menu's `RR` command.

Step 3. Save all current configuration details about the nPartition you plan to remove.

Use the **`parstatus -V -p#`** command to display all current configuration information related to the nPartition you plan to remove.

Save this information, as you can use it to manually recreate the nPartition if necessary at a later time.

Step 4. Remove the nPartition.

Use one of the following procedures (*Removing an Inactive Remote nPartition* or *Removing the Local nPartition*) to remove the nPartition.

- **Removing an Inactive Remote nPartition**

  1. Issue the `parremove -p#` command to remove the inactive remote nPartition, where the `-p#` option specifies the partition number. For example:

     ```
     # parremove -p1
     ```

  2. Issue the `parstatus -P` command to confirm that the nPartition was removed.

     If the nPartition was removed, it no longer is listed in the `parstatus` command's output.

- **Removing the Local nPartition**

  To remove the local nPartition (the nPartition on which you currently are issuing commands), perform the following steps.

  1. Shut down all applications and warn users. Follow the same procedures you would use if you were to reboot the nPartition.

  2. Issue the `parremove -F -p#` command, which initiates the complex profile revisions that will take place when the nPartition is removed.

     When using `parremove` to remove the local nPartition, you must specify both the `-p#` option (to specify the local partition number) and the `-F` option (to force-remove the local nPartition).

SS16

28

Note that the local nPartition remains active following the `parremove -F -p#` command, until you perform a shutdown for reconfig (`shutdown -R -H`) to complete the removal.

As soon as possible you should proceed with the shutdown for reconfig because the server Complex Profile will remain locked—and no other changes can occur—until the pending nPartition removal is completed.

3. Perform a shutdown for reconfig (`shutdown -R -H`) of the local nPartition.

   The `shutdown -R -H` command shuts down the nPartition and all cells so that the configuration changes occur and the nPartition is deleted.

After you complete the nPartition removal, the nPartition no longer exists—its configuration information has been deleted.

All cells (and associated I/O chassis) that used to be assigned to the deleted nPartition now are unassigned and can be assigned for other uses.

Deleting an nPartition [Partition Manager]

Use the **Partition —> Delete Partition** action to remove an nPartition using Partition Manager.

Step 1. Run Partition Manager (`/opt/parmgr/bin/parmgr`) or access it from SAM or a Web browser.

Step 2. In the Partition Manager primary window, select the nPartition you want to remove.

Click the nPartition's name in the list on the left side of the primary window to select the nPartition.

If you plan to remove a *remote nPartition*, then after you select the nPartition's name, all of the nPartition's hardware (listed on the right side of the primary window) should be listed as having an Actual Usage of "inactive". To remove a remote nPartition it must be inactive.

NR

Step 3. Select the **Partition —> Delete Partition** action to request that the selected nPartition be removed (deleted).

Partition Manager presents the following window to confirm whether you want to delete the selected nPartition.

You can view details about the nPartition by clicking the **Show Details** button, or cancel the deletion by clicking **Cancel**.

Step 4. Proceed with the nPartition deletion by clicking the **OK** button in the Partition Manager confirmation window.

Step 5. Perform any remaining tasks (such as a `shutdown -R -H`) as needed.

You may need to perform a shutdown for reconfig, depending on the type of nPartition you are removing (local or remote) and its state (active or inactive). Review the following list for details:

- If you are removing a *remote* nPartition that was *inactive*, the nPartition was removed immediately so this removal procedure is finished and you do not need to perform any shutdowns.

- If you attempt to remove a *remote* nPartition that is *active*, Partition Manager cannot remove the remote nPartition. You first must make the remote nPartition inactive by putting it into the ready for reconfig state.

  To put the remote nPartition in the ready for reconfig state: login to the remote nPartition and issue the `shutdown -R -H` command, or issue the BCH `RECONFIGRESET` command or the service processor `RR` command for the remote nPartition.

  After the remote nPartition is inactive, you must perform this removal procedure again using Partition Manager on the local nPartition if you want to remove the remote nPartition.

- If you are removing the *local* nPartition, Partition Manager will display the following information to you after you click **OK** to remove the nPartition.

  To complete the local nPartition's removal, you must perform a shutdown for reconfig (`shutdown -R -H`) of the local nPartition as soon as possible.

5514

Because the Complex Profile will remain locked until the local nPartition's removal is completed, no other changes can occur in the server complex until you perform the shutdown for reconfig.

After Partition Manager removes an nPartition, the nPartition no longer exists—its configuration information has been deleted.

All cells (and associated I/O chassis) that used to be assigned to the deleted nPartition now are unassigned and are available resources that can be assigned for other uses.

5573
2l

Naming and Renaming nPartitions

Each nPartition has both a partition *number* and an nPartition *name*.

The **partition name** for each nPartition can have from 1 to 64 characters, including upper- and lowercase letters; numbers; and dashes, underscores, and spaces ("-" "_" and " ").

You can customize each nPartition's name to help you distinguish among the nPartition in a server complex. (You cannot change the partition number, which is a permanent unique identifier that is automatically assigned for each nPartition in a server complex.)

You can name and rename nPartitions using these procedures:

- *Renaming an nPartition [BCH]* on page 283
- *Renaming an nPartition [HP-UX]* on page 284
- *Renaming an nPartition [Partition Manager]* on page 285

Partition names are displayed (along with partition numbers) in various reports and menus provided by the service processor, Boot Console Handler (BCH), and the HP-UX nPartition tools. Note that some utilities display only the first 30 characters of nPartition names.

Renaming an nPartition [BCH]

Use the Configuration menu `PD` command to check and sets the local nPartition's name from the BCH interface.

Step 1. Login to the service processor for the server complex in which the nPartition resides.

Step 2. Access the nPartition's console.

From the service processor Main menu, enter `CO` to access the console menu and select the nPartition.

If necessary, type `^ecf` (**Control-e c f**) to get write access for the console.

Note that if the nPartition is booted to HP-UX, you should instead use the HP-UX command method of modifying the nPartition name.

Step 3. Access the BCH interface's Configuration menu.

From the Main menu, enter **CO** to access the Configuration menu.

If at another BCH menu, enter `MA` to access the Main menu, then enter `CO` for the Configuration menu.

Step 4. At the BCH Configuration menu, use the **`PD`** command to check and set the local nPartition's name.

Enter `PD` to check the current name, or enter `PD` *`New Name`* to set the nPartition's name to the new name. No quotation marks are needed when specifying the new name.

```
Configuration Menu: Enter command > PD

Partition Number: 1
  Partition Name: Partition 1
Configuration Menu: Enter command >

Configuration Menu: Enter command > PD My New Name

  Partition Name: My New Name
Configuration Menu: Enter command > PD

Partition Number: 1
  Partition Name: My New Name
Configuration Menu: Enter command >
```

Renaming an nPartition [HP-UX]

Use the **`parmodify -p# -P`** ***`name`*** command to set the nPartition name for nPartitions using HP-UX commands.

Step 1. List the current nPartition states and names using the `parstatus -P` command.

This shows all nPartitions, their current status (active or inactive), and their partition numbers and nPartition names.

Step 2. Use the `parmodify -p# -P` *name* command to set the nPartition name for any of the nPartitions in the server complex.

Specify both the partition number (`-p#`) and the new name for the nPartition (`-P` *name*). If the nPartition name contains spaces then quotation marks must surround the name.

SS 21

```
# parmodify -p1 -P "New Name"
Command succeeded.
#
```

You can list the nPartition's new name by using the `parstatus -p#` command or `parstatus -P`.

Renaming an nPartition [Partition Manager]

Use the **Partition —> Modify Partition** action, **General** tab to name and rename nPartitions using Partition Manager.

Step 1. Run Partition Manager (`/opt/parmgr/bin/parmgr`) or access it from SAM or a Web browser.

Step 2. In the Partition Manager primary window, select the nPartition whose name you want to change.

Click the nPartition's name in the list on the left side of the primary window to select the nPartition.

Step 3. Select the **Partition —> Modify Partition** action, and access the **General** tab.

The nPartition name is listed—and can be edited—in the Partition Name field in the **General** tab.

Step 4. Edit the nPartition's name in the Partition Name field, and click **OK** when done editing the name (or click **Cancel** to cancel any changes).

Step 5. Review any Notes and Warnings that Partition Manager presents, and click **OK** to implement the name change (or click **Cancel** to cancel the change).

If there are any important notes or warnings, Partition Manager presents them in the window before completing the changes.

When the name change is complete, Partition Manager presents a final dialog box confirming that the nPartition was successfully modified.

Me

SS10

Setting and Checking Cell Attributes

Each cell assigned to an nPartition has *use-on-next-boot* and *failure usage* attributes that determine how the cell is used within the nPartition.

You can list and set cell attributes by using these procedures:

- *Setting Cell Attributes [BCH]* on page 287
- *Setting Cell Attributes [HP-UX]* on page 289
- *Setting Cell Attributes [Partition Manager]* on page 292

Each cell's use-on-next-boot and failure usage attribute settings establish the following behaviors for the cell:

- **Use-on-Next-Boot**

  The use-on-next-boot setting for each cell indicates whether the cell will be used (active) the next time the cell's nPartition is booted.

- **Failure Usage**

  The failure usage setting (called the "Failure Mode" in Partition Manager) for each cell indicates whether the cell will be used, if possible, if any processors or memory fail during the cell's self-tests.

NOTE Currently, only one failure usage setting is supported: *reactivate with interleave* (`ri`).

The reactivate-with-interleave setting allows a cell to actively join its nPartition following processor or memory failures during the cell's self tests. The cell joins its nPartition if at least one processor and any valid amount of memory passes self tests. Any of the cell's components that fail (processors or memory) are not available to the nPartition.

After changing a cell's attributes, the new attribute settings are used starting the next time the nPartition and cells are rebooted.

5509
21

Setting Cell Attributes [BCH]

Use the Configuration menu **CELLCONFIG** command to list and set a cell's use-on-next-boot setting from the BCH interface.

From the BCH interface you can modify only cell use-on-next-boot settings.

Step 1. Login to the complex's service processor, access the nPartition's console, and access the BCH interface.

From the nPartition console, you access the nPartition's BCH interface. If the nPartition is not at the BCH interface, you must either boot the nPartition or shut down HP-UX to return to the BCH interface.

Step 2. Access the BCH Configuration menu by entering **CO** from the BCH Main menu.

If you are at a BCH menu other than the Main menu, enter MA to return to the Main menu and then enter CO to access the Configuration menu.

Step 3. From the BCH Configuration menu, use the **CELLCONFIG** command to list or set each cell's use-on-next-boot setting.

To list the use-on-next-boot settings for all cells in the nPartition, issue the CELLCONFIG command with no arguments.

```
Configuration Menu: Enter command > CELLCONFIG

  Cell Configuration Data for Partition
 ----------------------------------------
  Configured Set   : 0x0000000000000050
  Deconfigured Set: 0x0000000000000000
  Free Cell Set    : 0xffffffffffffffaa

       Cab/
 Cell  Slot  Cell State  Configuration Status
 ----  ----  ----------  --------------------
   4   0/4      Alive        Configured
   6   0/6      Alive        Configured

Configuration Menu: Enter command >
```

To change the use-on-next-boot setting for a cell, issue the CELLCONFIG command with arguments: CELLCONFIG *cell* [ON|OFF]

S508

For example, CELLCONFIG 6 OFF sets the use-on-next-boot setting for cell 6 to OFF. This causes the cell to be inactive (not rendezvous and thus not be used) the next time the nPartition boots.

```
Configuration Menu: Enter command > CELLCONFIG 6 OFF

 Are you sure you want to DECONFIGURE cell 6 for next boot?
(y/[n]) >> y
 Cell 6 will be disabled during next reboot.

Configuration Menu: Enter command >
```

Step 4. Reboot the nPartition to use the cells' new use-on-next-boot settings.

If you have changed any cell use-on-next-boot settings for the nPartition, you should reboot the nPartition in either of two ways:

- Use the BCH interface's REBOOT command to perform a reboot.

  If you have only changed cell configurations from ON to OFF, then perform a reboot using the REBOOT command. Any cells set to not be used will still be assigned to the nPartition but will not be used (will not rendezvous) in the nPartition.

- Use the BCH interface's RECONFIGRESET command to put the nPartition in the ready for reconfig state, then use the service processor Command menu's BO command to boot the nPartition.

  If you have changed any cell from OFF ("n", do not use on next boot) to ON ("y", use the cell on next boot), then you must perform these two tasks; this resets and reconfigures the nPartition and boots it.

SS07

BCH

```
Configuration Menu: Enter command > RECONFIGRESET
Reset the partition for reconfiguration of Complex Profile ...
```

Service Processor (GSP or MP)

```
GSP:CM> BO

This command boots the selected partition.

     #    Name
    ---   ----
     0)   jules00
     1)   jules01

    Select a partition number: 1

    Do you want to boot partition number 1? (Y/[N]) y

    -> The selected partition will be booted.
GSP:CM>
```

Setting Cell Attributes [HP-UX]

Use the **parstatus** and **parmodify -p# -m#...** commands to list and set the use-on-next-boot and failure usage settings for cells using HP-UX commands.

Step 1. Login to HP-UX running on the nPartition.

You can login to HP-UX on the nPartition either by connecting with `telnet` or `rlogin`, or by logging in to its complex's service processor and accessing the nPartition's console.

Connecting through the service processor allows you to maintain nPartition console access after HP-UX has shut down.

Step 2. From the HP-UX command line, use the `parstatus` command to list the use-on-next-boot and failure usage attribute settings for cells in the server complex.

You can list and modify any cell's settings from HP-UX running on any nPartition in the server complex.

Use either `parstatus -C` or `parstatus -V -c#` to list the cell attribute settings. The following examples and text describe both these commands.

- A use-on-next-boot value of "yes" means the cell will be active as part of the nPartition the next time the nPartition boots.

SS06

"Yes" is equivalent to a BCH cell configuration value of ON and "no" is equivalent to OFF.

- A failure usage setting of "activate" (equivalent to "ri") indicates that the cell is set to reactivate with interleave in the event of any failure during the cell's self test.

Use the `parstatus -C` command to list the use-on-next-boot setting for all cells, which is shown in the "Use On Next Boot" column.

```
# parstatus -C
[Cell]
                          CPU     Memory                                Use
                          OK/     (GB)                          Core    On
Hardware   Actual         Deconf/ OK/                           Cell    Next Par
Location   Usage          Max     Deconf    Connected To        Capable Boot Num
========== ============ ======= ========= =================== ======= ==== ===
cab0,cell0 active core  4/0/4    2.0/ 0.0 cab0,bay0,chassis1  yes     yes  0

cab0,cell2 active base  4/0/4    2.0/ 0.0 cab0,bay1,chassis3  yes     yes  0
cab0,cell3 absent       -       -         -                   -       -    -
cab0,cell4 active core  4/0/4    2.0/ 0.0 cab0,bay0,chassis3  yes     yes  1
cab0,cell5 absent       -       -         -                   -       -    -
cab0,cell6 active base  4/0/4    2.0/ 0.0 cab0,bay1,chassis1  no      yes  1
cab0,cell7 absent       -       -         -                   -       -    -

#
```

To list a specific cell's failure-usage and use-on-next boot settings, issue the `parstatus -V -c#` command and specify the cell number.

```
# parstatus -V -c2
[Cell]
Hardware Location        : cab0,cell2
Global Cell Number       : 2
Actual Usage             : active base
Normal Usage             : base
Connected To             : cab0,bay1,chassis3
Core Cell Capable        : yes
Firmware Revision        : 6.0
Failure Usage            : activate
Use On Next Boot         : yes
Partition Number         : 0

....

Memory OK     : 2.00 GB
Memory Deconf : 0.00 GB

#
```

5505
21

Step 3. To modify a cell's use-on-next-boot and failure usage attribute settings, use the `parmodify -p# -m#...` command and specify the cell's new settings.

Specify both the `-p` (partition number) and `-m` (modify cell) options when using `parmodify`. The following example modifies cell 2 to not be used the next time its nPartition (partition number 0) boots.

```
# parmodify -p0 -m2:base:n:ri
Command succeeded.
#
```

The `parmodify` command's `-m` option is as follows:

```
    -m cell:[cell_type]:[use_on_next_boot]:[failure_usage]
```

This option specifies the cell ID (*cell*) whose settings are modified using the following arguments.

- The only valid *cell_type* value is base (base cell).
- The valid *use_on_next_boot* values for cells are:

`y`	Participate in reboot (the default).
`n`	Do not participate in reboot.

- The only valid *failure_usage* value for cells is `ri` (reactivate and interleave).

For details, see the *parmodify* (1M) manpage.

Step 4. If you have modified a cell's attribute settings, you must reboot the nPartition to which the cell is assigned for the settings to be used.

Rebooting the cell's nPartition allows the nPartition to use each cell's new attribute settings.

- If a cell's use-on-next-boot setting is changed from "n" (do not use) to "y" (use), you must perform a reboot for reconfig of the cell's nPartition by using the `shutdown -R` command.
- Otherwise, if the cell use-on-next-boot settings are only changed from "y" to "n" then you can perform a standard reboot using the `shutdown -r` command.

SS04

Setting Cell Attributes [Partition Manager]

Use the **Partition —> Modify Partition** action, **Change Cell Attributes** tab to list and set the configurable cell attributes using Partition Manager.

Step 1. Run Partition Manager (`/opt/parmgr/bin/parmgr`) or access it from SAM or a Web browser.

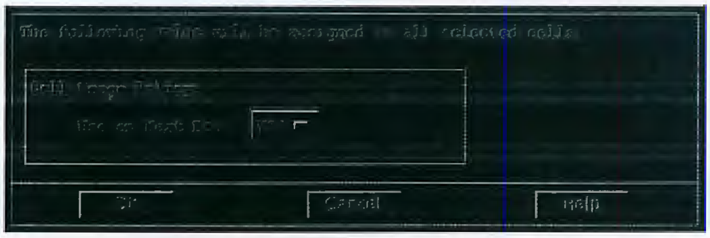
Step 2. In the Partition Manager primary window, select the nPartition whose cell attributes you want to change.

Click the nPartition's name in the list on the left side of the primary window to select the nPartition.

Step 3. Select the **Partition —> Modify Partition** action, and click the **Change Cell Attributes** tab.

Step 4. Highlight the cell whose attributes you want to modify, click the **Modify Cell** button, and configure the cell attributes as desired.

You can modify the settings for multiple cells at once by selecting all desired cells (press **Control** while clicking on the cells) before clicking the **Modify Cell** button.



The following values will be assigned to all selected cells:

Cell Usage Policy

Use on Next Boot: Yes

Configure the cell attributes in the window, and then click **OK** to apply the modified attributes or **Cancel** to cancel any changes.

Step 5. If you have modified any cell attributes, when you return to the **Change Cell Attributes** tab you can click **OK** to apply the changes or click **Cancel** to cancel them.

Review any Notes and Warnings that Partition Manager presents, then click **OK** to proceed or **Cancel** to cancel the changes.

If the cell attribute changes are implemented, Partition Manager presents a final confirmation that the nPartition was successfully modified.

Step 6. If you have modified a cell's attribute settings, you must reboot the nPartition to which the cell is assigned for the settings to be used.

Rebooting the cell's nPartition allows the nPartition to use each cell's new attribute settings.

- If a cell's use-on-next-boot setting is changed from "no" (do not use) to "yes" (use), you must perform a reboot for reconfig of the cell's nPartition by using the `shutdown -R` command.
- Otherwise, if the cell use-on-next-boot settings are only changed from "yes" to "no" then you can perform a standard reboot using the `shutdown -r` command.

5502

Setting and Checking nPartition Core Cell Choices

The **core cell choice** settings for an nPartition are optional preferences that establish which cells in the nPartition are preferred to be selected as the core cell for the nPartition.

You can list and set an nPartition's core cell choices by using these procedures:

- *Setting nPartition Core Cell Choices [BCH]* on page 295
- *Setting nPartition Core Cell Choices [HP-UX]* on page 296
- *Setting nPartition Core Cell Choices [Partition Manager]* on page 297

NOTE

You do not need to specify core cell choices for a valid core cell to be chosen.

By default on HP Superdome and HP rp8400 server, system firmware selects the lowest numbered eligible cell as an nPartition's active core cell. By default on HP rp7405/rp7410 servers, cell 1 is selected as the core cell.

NOTE

You should specify only *core-capable* cells as core cell choices. A cell must have an I/O chassis with core I/O attached to be eligible to be chosen as the core cell.

S501

Setting nPartition Core Cell Choices [BCH]

Use the Configuration menu `COC` command to set the core cell choices for an nPartition using the nPartition's BCH interface.

Step 1. Access the BCH menu for the nPartition whose core cell choices you wish to set.

Step 2. Access the BCH Configuration menu for the nPartition.

From the BCH Main menu, enter `CO` to enter the Configuration menu.

Step 3. Issue the `COC` command to check current core cell choice preferences.

Entering COC with no arguments lists all core cell choice preferences.

Step 4. Issue the `COC` command *with arguments* to set or change the nPartition's core cell choice preferences.

The COC command syntax is: COC *`choice cell`*, where *`choice`* is 0–3 (with 0 being the highest-priority choice) and where *`cell`* is the cell ID.

For example, `COC 0 2` sets the most preferred core cell choice to be cell ID 2. Likewise, `COC 1 4` sets the next (second-highest priority) core preference to be cell ID 4.

Use the HELP COC command for other details about the COC command.

Step 5. [*Optional*] If you have changed the setting for the highest-priority core cell choice (choice 0) and you want the cell you have specified to become the active core cell, then issue the BCH menu's REBOOT command.

Even if you do not perform this step, the new core cell choice settings will be used the next time the nPartition is rebooted.

5500

Setting nPartition Core Cell Choices [HP-UX]

Use the **parstatus** and **parmodify** commands to list and set the core cell choices for an nPartition using HP-UX commands.

Step 1. Issue the **parstatus -V -p#** command to list the nPartition's current core cell choices and core cell use.

The parstatus -V -p# command list detailed status, including the current active core cell ("Core Cell"), and any core cell choice settings (the "Core Cell Alternate" listings, if any).

```
# parstatus -V -p0
[Partition]
Partition Number         : 0
Partition Name           : jules00
Status                   : active
IP address               : 0.0.0.0
Primary Boot Path        : 0/0/2/0/0.13.0
Alternate Boot Path      : 0/0/2/0/0.0.0
HA Alternate Boot Path   : 0/0/2/0/0.14.0
PDC Revision             : 6.0
IODCH Version            : 23664
CPU Speed                : 552 MHz
Core Cell                : cab0,cell0
Core Cell Alternate [1]: cab0,cell0
Core Cell Alternate [2]: cab0,cell2

....

                                      Core Connected  Par
Hardware Location   Usage             IO   To         Num
=================== ============ ==== ========== ===
cab0,bay0,chassis1  active            yes  cab0,cell0 0
cab0,bay1,chassis3  active            yes  cab0,cell2 0

#
```

The core cell choice preferences are listed by parstatus as the "Core Cell Alternate" settings with "1" being the highest priority and "2" through "4" as the lower priority core cell choices.

The parstatus core cell choice listings (1 through 4) directly correspond to the BCH core cell choice listings (0 through 3).

Step 2. Modify the nPartition's core cell choices using the **parmodify -p# -r#...** command.

5199

You can modify the core cell choices for the local nPartition or any remote nPartition in the server complex.

Use the following command: `parmodify -p# -r# -r#...`

Specify the partition number (`-p#`) and the cell ID (`-r#`) for all cells you wish to designate as core cell choices.

```
# parmodify -p0 -r2 -r0
Command succeeded.
#
```

The order in which you list the cells is the order in which the nPartition's core cell choices are established; the first cell listed is the first preferred core cell (choice 1), and the subsequent cells are lower-priority core cell choices (choices 2 through 4, if specified).

Step 3. [*Optional*] If you wish to immediately use the new core cell choice settings, reboot the nPartition whose core cell choices you have changed.

Even if you do not reboot now, the new core cell choices will be used the next time the nPartition is rebooted.

You can issue the `shutdown` command with the `-r` option to reboot the nPartition and use the new core cell choice settings. (You *do not* need to perform a reboot for reconfig of the nPartition.)

If you have modified an *inactive remote* nPartition, use the service processor Command menu's `BO` command to boot the remote nPartition; the designated core cell choices will be used to select the active core cell.

Setting nPartition Core Cell Choices [Partition Manager]

Use the **Partition —> Modify Partition** action, **Cell Cell Choices** tab to set the core cell choices for an nPartition using Partition Manager.

Step 1. Run Partition Manager (`/opt/parmgr/bin/parmgr`) or access it from SAM or a Web browser.

Step 2. In the Partition Manager primary window, select the nPartition whose core cell choices you want to change.

Click the nPartition's name in the list on the left side of the primary window to select the nPartition.

Step 3. Select the **Partition —> Modify Partition** action, and click the **Cell Cell Choices** tab.

Step 4. Modify the core choice setting for each cell whose core choice priority you want to revise.

Highlight the cell whose core cell choice you want to configure, select the desired choice priority (1st, 2nd, none, etc.) from the Core Cell Choice pop-up list, and click the **Modify** button to modify the priority.

Step 5. Click the **OK** button when done changing the core choice priorities (or click **Cancel** to not revise any priorities).

Review any Notes and Warnings that Partition Manager presents, then click **OK** to proceed or **Cancel** to cancel the changes.

If the cell choice priority changes are implemented, Partition Manager presents a final confirmation that the nPartition was successfully modified.

The new core cell choice priorities will be used the next time the nPartition is rebooted.

5497

Reassigning (Moving) a Cell to a Different nPartition

To move a cell from one nPartition to another nPartition in the same server complex, use the high-level procedure described here.

This high-level procedure involves:

1. Removing (unassigning) the cell from its original nPartition.
2. Performing a reboot for reconfig (`shutdown -R`) of the original nPartition, if needed.
3. Adding (assigning) the cell to the new nPartition.
4. Performing a reboot for reconfig (`shutdown -R`) of the cell's new nPartition.

Be aware that this procedure modifies the hardware configurations of both nPartitions involved.

You should *adhere to the hardware requirements and performance guidelines* when removing the cell from its original nPartition *and* when adding it to its new nPartition.

When you remove a cell from an nPartition, any I/O connected to the cell also is removed from the nPartition. As a result, any I/O devices associated with the cell are made unavailable to the nPartition.

CAUTION

Moving a cell that has an attached I/O chassis from one nPartition to another is effectively the same as moving the associated I/O devices from one computer to another.

All precautions you would take when moving I/O devices from one computer to another must be taken in this situation.

For example, LVM volume groups that are being moved from one nPartition to another must be exported from their original nPartition *before the cell or I/O chassis is moved*. For details see the *vgexport* (1M) manpage and *Managing Systems and Workgroups*.

S496

Reassigning (Moving) a Cell to a Different nPartition

The following high-level procedure moves a cell to a different nPartition.

You can perform these steps using either HP-UX commands or Partition Manager.

Step 1. See the procedure *Unassigning (Removing) Cells from an nPartition* on page 270 to remove the cell that you want to move to the other nPartition.

As part of this step, you perform a reboot for reconfig (`shutdown -R`) of the nPartition to which the cell is originally assigned.

As a result of this step, the cell is unassigned (on the "free cell list" of available resources) so is is available to be assigned to the other nPartition in the next step.

Step 2. See the procedure *Assigning (Adding) Cells to an nPartition* on page 266 to assign the cell you made available in *Step 1* to its new nPartition.

This step also requires that you perform a reboot for reconfig (`shutdown -R`) of the nPartition to which the cell is being added.

Following the reboot for reconfig, the cell is available (assigned and active) in the new location.

5495

Restoring a Complex Profile

You can restore a previous Complex Profile configuration, which effectively allows you to undo your last nPartition configuration change.

Restoring the previous Complex Profile allows you to revert to the previous complex configuration—including the nPartition configurations—that existed before you made your last change.

NOTE Because restoring a prior Complex Profile requires shutting down all nPartitions to an inactive ready for reconfig state, you should use this procedure only when absolutely necessary.

Restoring a Complex Profile [Service Processor]

Use the Command menu `CC` command and `L` option to restore the prior complex configuration that existed before you made your last nPartition configuration change.

Step 1. Ensure that all nPartitions within the server complex are inactive at the ready for reconfig state.

You can put each nPartition into the ready for reconfig state by using the `shutdown -R -H` command, the BCH interface's `RECONFIGRESET` command, or using the service processor Command menu's `RR` command.

Step 2. Login to the server complex's service processor, and enter `CM` to access the Command menu.

Login as a user with administrator privileges, which are required for restoring the previous complex profile configuration.

Step 3. Issue the `CC` command, select Last Complex Profile (`L`), and confirm that you want to modify the Complex Profile configuration.

```
GSP:CM> CC

This command allows you to change the complex profile.

WARNING: You must either shut down the OSs for reconfiguration or
         execute the RR (reset for reconfiguration) command for all
         partitions before executing this command.
```

```
    G - Build genesis complex profile
    L - Restore last complex profile
        Select profile to build or restore: L

    Do you want to modify the complex profile? (Y/[N]) y

    -> The complex profile will be modified.
GSP:CM>
```

Step 4. Confirm that the nPartition cell assignments are what you intended to establish.

Use the service processor Command menu's **CP** command to display the current complex profile configuration.

```
GSP:CM> CP

--------------------------------------------------------------------------------
Cabinet |    0    |    1    |    2    |    3    |    4    |    5    |    6    |    7
--------+---------+---------+---------+---------+---------+---------+---------+--------
 Slot   |01234567|01234567|01234567|01234567|01234567|01234567|01234567|01234567
--------+---------+---------+---------+---------+---------+---------+---------+--------
 PD  0  |X.X.....|........|........|........|........|........|........|........
 PD  1  |....X.X.|........|........|........|........|........|........|........
 PD  2  |.X.X....|........|........|........|........|........|........|........
 PD  3  |.....X.X|........|........|........|........|........|........|........

GSP:CM>
```

If the nPartition cell assignments are not what you intended—that is, if you prefer the nPartition configuration you had before you restored the existing nPartition configuration—you can repeat this procedure to restore the configuration you had before beginning the procedure.

One level of undo is provided by the service processor Command menu's CC command. This allows you to undo your last nPartition change, and undo your undo.

Step 5. Issue the BO command to boot any nPartitions you want to make active.

After you use the CC command, all nPartitions still are in a boot-is-blocked ready for reconfig state and thus are *inactive* nPartitions.

You can use the Command menu's BO command to boot the nPartitions past boot-is-blocked to make the nPartitions active.

Unlocking Complex Profiles

This section describes how you can force-unlock portions of the nPartition Complex Profile data

CAUTION Do not force-unlock complex profile data except in extremely rare cases following nPartition or server crashes.

Improperly force-unlocking complex profiles can result in the loss of pending configuration changes to nPartitions and the server complex.

Under normal circumstances you do not need to manually unlock the Complex Profile. The commands, utilities, and related procedures handle all locking and unlocking.

In some situations, you must perform a reboot for reconfig (`shutdown -R`) of a modified nPartition in order to complete an nPartition reconfiguration and unlock the changed portion of the Complex Profile. (For example, when removing an active cell from an nPartition you must perform a reboot for reconfig.)

HP-UX provides the `parunlock` command to force-unlock parts of a server's Complex Profile in situations where the normal procedures and utilities have failed.

The service processor (GSP or MP) also provides the `RL` command for resetting Complex Profile locks.

SU92
21

7 Listing and Managing Server Hardware

This chapter covers the tools and procedures for listing details about the hardware assigned to nPartitions. This chapter also covers getting information about server hardware, and managing the hardware resources in nPartitions and their server complexes.

For an introduction to nPartition servers and hardware features, refer to the chapter *nPartition System Overviews* on page 31.

Tools for Listing and Managing Hardware

You can use several software tools to list server hardware details and manage the hardware in a server complex. These tools have features that overlap for some tasks, but each tool also has unique features.

The tools for listing and managing system hardware are:

- **Service Processor (GSP or MP) menus**

  Service processor menus provide a complex-wide service interface that can allow access to all hardware and nPartitions.

NOTE

The service processor in HP servers is sometimes called the Management Processor (MP) and sometimes the Guardian Service Processor (GSP).

Regardless of the name, the service processor in these servers provides approximately the same features and performs essentially the same role.

Throughout this document, the term “service processor” refers to both the MP and GSP service processors.

  Hardware management features include the service processor Command menu’s `DU`, `ID`, `PE`, `PS`, and `SYSREV` commands.

- **Boot Console Handler (BCH) interfaces**

  The BCH interface is the method for interacting with an nPartition before it has booted HP-UX.

  Hardware management features include the BCH interface’s Configuration menu, Interface menu, and Service menu.

- **HP-UX Commands**

  HP-UX commands allow you to manage and monitor nPartitions and hardware within a server complex from HP-UX running on any of the server’s nPartitions.

  Hardware management features include the `parstatus`, `frupower`, `fruled`, and `rad` commands, among many others.

- **Partition Manager** (`/opt/parmgr/bin/parmgr`)

  Partition Manager provides a graphical interface for managing and monitoring nPartitions and hardware within a server complex.

  Hardware management features include menus and windows that list details about cells, I/O chassis, and PCI I/O card slots in the server complex.

- **System Administration Manager** (SAM, `/usr/sbin/sam`)

  The SAM graphical interface (GUI) provides an alternate way to launch Partition Manager as a SAM area.

  SAM also provides a Peripheral Devices area, which has a Cards subarea that is the recommended method for managing PCI I/O cards and PCI slots.

  The **Peripheral Devices —> Cards** area includes error checking and resource analysis not available from the HP-UX command line.

Powering Server Cabinets On and Off

You can power on and power off the cabinets within a server complex either by using the main power switch on the front of the cabinet, or by using the service processor Command menu.

You can use the following procedures:

- *Powering Server Cabinets On and Off [Power Switch]* on page 309
- *Powering Server Cabinets On and Off [Service Processor]* on page 310

When powering off a cabinet, you turn off 48-volt power to the cabinet thus causing all cells and all I/O chassis to power off, and causing most fans to turn off.

CAUTION

When you power on or off HP Superdome 64-way compute cabinets, you must power off and power on cabinet 0 and cabinet 1 in such a way that *both cabinets are off* for an overlapping interval.

If either Superdome 64-way cabinet is powered off then powered on while the other cabinet remains on, then communications between the two cabinets is lost.

CAUTION

Before powering off system hardware, you first must check whether it is being used.

The cabinet power switch and the service processor Command menu's `PE` command *do not check* whether system hardware is in use before powering it off.

Changes in cabinet power status *do not* affect the standby power that supplies system utilities such as the service processor (GSP or MP) and keeps some fans running. These utilities and fans can receive power as long as standby power is enabled.

The way in which standby power is enabled and disabled differs for various HP server models. On HP Superdome servers, standby cabinet power is switched using the power breakers on the rear of the cabinet. On HP rp7405/rp7410 and HP rp8400 servers, standby power is enabled through the power cords connecting to the inputs on the rear of the cabinet.

Powering Server Cabinets On and Off [Power Switch]

Use the Virtual Front Panel to check status, and then use the cabinet power switch to manage a cabinet's 48-volt power with the cabinet hardware.

Step 1. Login to the system's service processor and access the Virtual Front Panel for the system.

From the service processor Main menu, enter `VFP` to access the Virtual Front Panel menu, then enter `S` to access the "system VFP" that displays the current status for all nPartitions.

Step 2. Check the VFP status to see whether any cabinet hardware is running HP-UX.

Any nPartition whose state is "HP-UX heartbeat" is running HP-UX and thus should not have its hardware powered off until after HP-UX is shut down.

Type `^b` (**Control-b**) to exit the VFP.

Step 3. Shut down HP-UX running on any cabinet hardware that you plan to power off.

Step 4. Confirm that nobody else is using or servicing the cabinet hardware you plan to power on or off.

You should both physically inspect the hardware, and check whether others are remotely accessing the system's service processor (using the Command menu's `WHO` command).

Step 5. Access the cabinet hardware and flip the power switch (located on the cabinet's front) to the on or off position in order to power the cabinet on or off.

S486

Powering Server Cabinets On and Off [Service Processor]

Use the Virtual Front Panel, and the use the Command menu **PE** command to turn a cabinet's 48-volt power on or off from the service processor (GSP or MP).

Step 1. Login to the system's service processor and access the Virtual Front Panel for the system.

From the service processor Main menu, enter **VFP** to access the Virtual Front Panel menu, then enter **S** to access the "system VFP" that displays the current status for all nPartitions.

Step 2. Check the VFP status to see whether any cabinet hardware is running HP-UX.

Any nPartition whose state is "HP-UX heartbeat" is running HP-UX and thus should not have its hardware powered off until after HP-UX is shut down.

Step 3. Shut down HP-UX running on any cabinet hardware that you plan to power off.

Step 4. Confirm that nobody else is using or servicing the cabinet hardware you plan to power on or off.

You should both physically inspect the hardware, and check whether others are remotely accessing the system's service processor (using the Command menu's **WHO** command).

Step 5. Access the system's service processor Command menu, issue the **PE** command, then select the cabinet to power on or power off.

From the service processor Main menu, enter **CM** to access the Command menu. To exit the Command menu enter **MA**.

When using the `PE` command enter **B** to power on or off a cabinet; specify the cabinet number; and then enter **ON** (power on), **OFF** (power off), or **Q** (quit without changing the power status).

```
GSP:CM> PE

This command controls power enable to a hardware device.

    B - Cabinet
    C - Cell
    I - IO Chassis
        Select Device: b
```

```
Enter cabinet number: 1

The power state is ON for Cabinet 1.
In what state do you want the power? (ON/OFF)
```

Powering Cells and I/O Chassis On and Off

This section covers *cell* and *I/O chassis* power management procedures, which allow you to control power for cells and I/O chassis from remote locations, without physically accessing the system hardware.

You can use the following procedures:

- *Powering Cells and I/O Chassis On and Off [Service Processor]* on page 313
- *Powering Cells and I/O Chassis On and Off [HP-UX]* on page 314
- *Powering Cells and I/O Chassis On and Off [Partition Manager]* on page 316

NOTE

On HP nPartition systems, *powering on* a cell also powers on any I/O chassis attached to the cell, and *powering off* a cell also powers off any I/O chassis attached to the cell.

Powering on or off an I/O chassis connected to a powered-on cell *causes the cell to reset* if the cell located and mapped the I/O chassis during its cell boot process.

The `frupower` command and Partition Manager permit you to power on or off *inactive* cells and I/O chassis that are assigned to the current nPartition or are not assigned to any nPartition.

The service processor Command menu's `PE` command permits you to power on or off any hardware in the complex, including active cells and I/O chassis. The `PE` command does not check the current usage of components.

5483

21

Powering Cells and I/O Chassis On and Off [Service Processor]

Use the Command menu **PE** command to power on and power off cells, I/O chassis, and cabinets from the service processor interface (GSP or MP).

CAUTION When using the service processor Command menu's PE command to power on or off hardware, you should be certain to *specify the correct component* to power on or off.

The PE command *does not check* whether the hardware is actively being used.

You can manage the power for all components within the system complex using the service processor Command menu's PE command, regardless of any nPartition assignment or the status (active or inactive) for the hardware components.

Step 1. Login to the system's service processor and access the Command menu.

From the service processor Main menu, enter **CM** to access the Command menu. To exit the Command menu enter **MA**.

Step 2. Issue the **PE** command and specify the type of hardware whose power you want to turn on or turn off.

You can manage power to cells, I/O chassis, and cabinets.

Step 3. Specify the hardware device to power on or power off.

The service processor *does not check* whether the specified component is currently being used.

- **Cabinets**—When you power on or off a cabinet, the firmware also powers on or off all cells and I/O chassis in the cabinet.
- **Cells**—When you power on or off a cell, the firmware also powers on or off any I/O chassis attached to the cell.

  When specifying a cell, you indicate both the *cabinet number* and the *slot* in which the cell resides.

5982

- **I/O Chassis**—When you power off an I/O chassis from the service processor Command menu, the system firmware *resets the cell* attached to the I/O chassis (if the cell located and mapped the I/O chassis during its cell boot process).

  When specifying an I/O chassis, you indicate the cabinet, bay, and chassis numbers to identify it.

In the following example, the service processor powers off cell 2 in cabinet 0.

```
GSP:CM> PE

This command controls power enable to a hardware device.

    B - Cabinet
    C - Cell
    I - IO Chassis
        Select Device: c

    Enter cabinet number: 0
    Enter slot number: 2

    The power is ON for the Cell in Cabinet 0, Slot 2.
    In what state do you want the power for the
    Cell in Cabinet 0, Slot 2? (ON/OFF) OFF

GSP:CM>
```

Powering Cells and I/O Chassis On and Off [HP-UX]

Use the **`frupower -o -c#`** and **`frupower -f -c#`** commands to power on and power off cells (and their associated I/O chassis) from HP-UX.

NOTE

You can use the `frupower` command to power on or off *inactive cells* that are either assigned to the local nPartition or are not assigned to an nPartition.

You cannot power off active cells or power on or off cells assigned to a remote nPartition when using `frupower`.

To power on or off an I/O chassis using `frupower`, do so by power cycling the cell to which it is connected.

Step 1. Login to HP-UX running on one of the system's nPartitions.

To manage a cell's power, you must login to the nPartition to which the cell is assigned. If the cell is not assigned to an nPartition, you can manage its power from *any* nPartition.

Step 2. Use the `frupower` command to turn on or turn off the cell's power.

Specify the **`frupower -f -c#`** command to *power off* a cell. (`-c#`). This also powers off any I/O chassis connected to the cell.

Specify the **`frupower -o -c#`** command to *power on* a cell (`-c#`). This also powers on any I/O chassis connected to the cell.

The following example shows several sample `frupower` commands and their results.

```
# frupower -f -c0
Error: Can not power off active cell 0.
# frupower -f -c2
# frupower -o -c2
# frupower -f -c6
Error: Cell 6 belongs to partition 1.  Can not power off cell.
#
# frupower -f -i0/1/1
Error: I/O chassis 0/1/1 is attached to a powered-on free
cell 4.  Please power off the free cell.
#
```

In the above example, cell 0 is active and thus cannot be powered off using `frupower`. Cell 2 is inactive and is powered off (`frupower -f -c2`) and then powered back on (`frupower -o -c2`). Cell 6 is assigned to a remote nPartition (partition number 1) and thus cannot be powered off. I/O chassis 0/1/1 is attached to cell 4, so to power it off cell 4 must be powered off.

Powering Cells and I/O Chassis On and Off [Partition Manager]

Use the **Cell —> Power On Cell** action, or **Cell —> Power Off Cell** action, to power on and power off cells (and their associated I/O chassis) from Partition Manager.

NOTE You can use Partition Manager to power on or off *inactive cells* that are assigned to the local nPartition.

You cannot power off active cells or power on or off cells assigned to a remote nPartition when using Partition Manager.

To power on or off an I/O chassis using Partition Manager, do so by power cycling the cell to which it is connected.

Step 1. Run Partition Manager (`/opt/parmgr/bin/parmgr`) or access it from SAM or a Web browser.

Step 2. Select the nPartition that contains the cell you want to power on or off.

Partitions are listed on the left side of the Partition Manager primary window.

The cells and I/O chassis assigned to the nPartition are listed on the right side of the primary window once the nPartition is selected.

Step 3. Select the cell whose power you want to turn on or off.

Step 4. Select the **Cell —> Power On Cell** menu item, or select the **Cell —> Power Off Cell** menu item.

Power Status for Hardware Components

You can use system software to check power status for the following components from remote locations:

- Cabinets
- Bulk Power Supplies and Power Boards
- Cell Boards
- I/O Chassis
- Individual PCI Slots

NOTE Cabinet power details and power supply details are specific to each server model. For example, HP Superdome servers and HP rp8400 server have different power configurations and requirements.

You can use the following procedures:

- *Determining Hardware Power Status [Service Processor]* on page 318
- *Determining Hardware Power Status [HP-UX]* on page 320
- *Determining Hardware Power Status [Partition Manager]* on page 322

S478

Determining Hardware Power Status [Service Processor]

Use the Command menu **PS** command to check power status for cabinets, bulk power supplies and power boards, cells, and core I/O from the service processor.

Step 1. Login to the system's service processor and enter **CM** to access the Command menu.

Step 2. Issue the service processor Command menu's **PS** command.

The PS command can list detailed information—including power status—for components within the system complex.

The PS command summarizes all cabinets, cells, and core I/O cards, and prompts you to specify which hardware device you want information about.

```
GSP:CM> PS

This command displays detailed power and hardware configuration status.

The following GSP bus devices were found:

|  8 |     |  *  |  *  |               |  *   *  |  *   *  |         |        |
You may display detailed power and hardware status for the following items:

    B - Cabinet (UGUY)
    C - Cell
    G - GSP
    I - Core IO
        Select Device:
```

Step 3. Specify the cabinet whose hardware and power status you want to check.

For each cabinet (B), the PS command reports detailed information that includes the power status for *all components* within the cabinet, including:

- **Cabinet Power**—Whether the 48-volt cabinet power switch is on or off, whether cabinet power is enabled, and details about power boards and bulk power supplies.
- **Cell Power**—Whether power is enabled and on for all cells within the cabinet.
- **Core I/O Card Power**—Whether power is enabled and on for all core I/O cards within the cabinet.

For system complexes that have multiple cabinets, you must check details for each cabinet separately.

You also can use the `PS` command to check individual cell (`C`) or core I/O (`I`) hardware and power status.

The following example shows cabinet power details for cabinet 0 of an SD64000 model Superdome server.

```
 Select Device: b

    Enter cabinet number: 0

HW status for SD64000 compute cabinet #0: NO FAILURE DETECTED

5476

Determining Hardware Power Status [HP-UX]

Use the `parstatus -B`, `parstatus -V -b#`, `frupower -d -C`, `frupower -d -I`, or `rad -q` command to check the power status for system hardware from HP-UX.

For details on these HP-UX commands, see the online manpages for *parstatus* (1M), *frupower* (1M), and *rad* (1M).

Step 1. Login to HP-UX running on one of the system's nPartitions.

To check the power status for PCI card slots, you must login to the *local nPartition* where their PCI card cage resides.

You can check the power status for cabinets, cells, and I/O chassis from *any nPartition*.

Step 2. Issue the HP-UX commands to check the power status for the system components of interest to you.

- **Cabinet Power**—Use the `parstatus -V -b#` command to check cabinet power status for the specified cabinet (`-b#`), or use the `parstatus -B` command for brief power status for all cabinets.

  The `parstatus` command gives details about each cabinet's bulk power supplies and power boards, as well as details about cabinet fans and blowers.

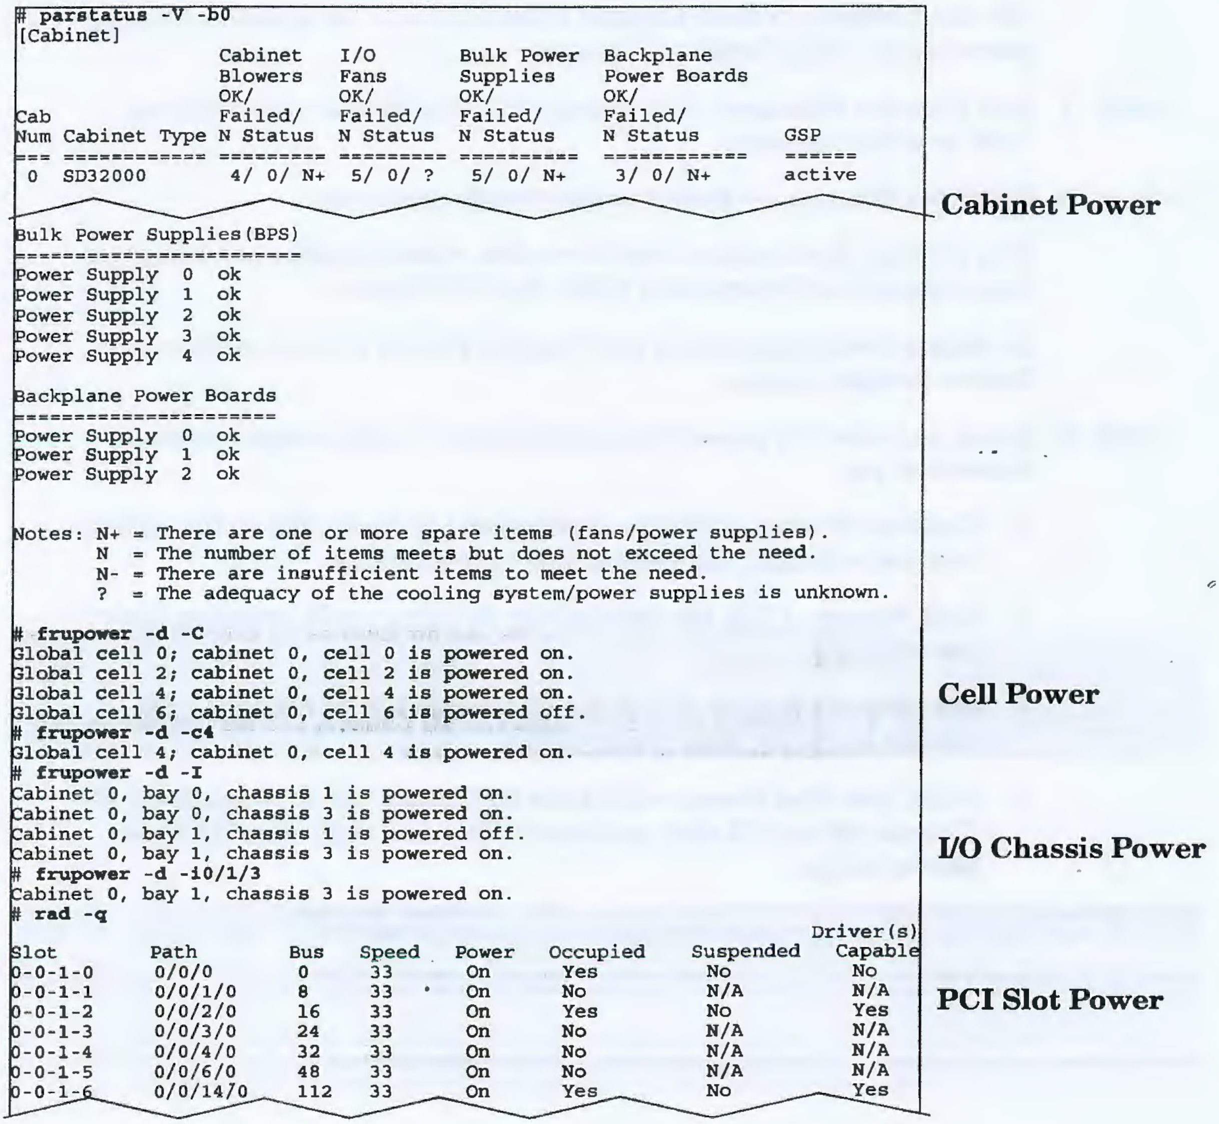
- **Cell Power**—Use the `frupower -d -C` command to list cell power status for all cells, or use the `frupower -d -c#` command to list power status for a specific cell (`-c#`).

- **I/O Chassis Power**—Use the `frupower -d -I` command for power status for all I/O chassis, or use the use `frupower -d -i#/#/#` command to list details for a specific I/O chassis (*`cabinet/bay/chassis`*)

- **PCI Card Slot Power**—Use the `rad -q` command and option to list details including PCI card slot power for all PCI card slots within the local nPartition.

  The `rad` command lists information for the local nPartition only.

The following example output shows power details for an HP Superdome system's cabinet, cells, I/O chassis, and PCI slots, as presented by various HP-UX commands.



```
# parstatus -V -b0
[Cabinet]
                  Cabinet   I/O       Bulk Power  Backplane
                  Blowers   Fans      Supplies    Power Boards
                  OK/       OK/       OK/         OK/

```

Determining Hardware Power Status [Partition Manager]

Use the **Complex —> Show Complex Details** menu to list system hardware power status using Partition Manager.

Step 1. Run Partition Manager (`/opt/parmgr/bin/parmgr`) or access it from SAM or a Web browser.

Step 2. Select the **Complex —> Show Complex Details** menu item.

This displays the Complex Details window, which has tabs providing info for cabinets (the General tab), Cells, and I/O Chassis.

To update the information in the Complex Details window, click the the **Rescan Complex** button.

Step 3. Select and view the power status information for the components of interest to you.

- **Cabinet Power**—Click the **Cabinet Info** tab for details on the system complex's cabinet, including cabinet power status.
- **Cell Power**—Click the **Cells** tab for details on cells including their power status.
- **I/O Chassis Power**—Click the **I/O Chassis** tab for details on I/O chassis including their power status.
- **PCI Card Slot Power**—Click the **I/O Chassis** tab, then select the I/O Chassis whose PCI slots you want to list, and then click the **Show Details** button.

Turning Attention Indicators (LEDs) On and Off

HP's nPartition systems provide **attention indicators (LEDs)** to help you to visually select and confirm which hardware you want to perform operations on. Attention indicators are amber (orange) lights.

Table 7-1 on page 324 lists attention indicator meanings and LED states (off, blinking, and on). These states and meanings adhere to the PCI Hot-Plug specification.

You can control the attention indicators for various hardware components by using the following procedures:

- *Turning Attention LEDs On and Off [HP-UX]* on page 325
- *Turning Attention LEDs On and Off [Partition Manager]* on page 327

NOTE On HP Superdome servers, the attention indicator behavior has changed since the original HP-UX 11i release.

Starting with the June 2001 HP-UX 11i release, the HP-UX command and utility behavior is to blink attention indicators (rather than light them to a steady-on state, as was the original behavior).

As a result, HP Superdome servers upgrading to the June 2001 or later release will exhibit the new, blinking behavior (see Table 7-1 on page 324) when cell and I/O chassis attention indicators are enabled.

In cases where some nPartitions are running the original HP-UX 11i release and others are running a more recent release, *both behaviors* (the original "steady-on" behavior and the "PCI Hot-Plug" behavior) may be exhibited—possibly within the same server complex.

Table 7-1 lists the meanings for the various attention indicator states. When all of a system's components are functioning and no service operations are occurring, every attention indicator should be turned off. (HP Superdome cabinet number LCDs remain lit or blinking when cabinet power is on.)

Table 7-1 **Attention Indicator (LED) States and Meanings**

Attention Indicator State	Meaning
OFF	Not selected.
BLINKING	Selected to be used in a service operation.
ON	*Supported for PCI card slot LEDs only.* Service required, problems have been identified with the component.

LEDs for Hardware Components

You can control (turn off, blink, and/or turn on) attention indicators for the following hardware components.

- **Cell LEDs**

  Each cell or cell slot has its own attention indicators.

  — On HP *Superdome servers*, each cell's attention indicator is located on the server cabinet hardware below the cell's slot, just to the right of the cell slot's power LED.

  — On HP *rp7405 / rp7410 and rp8400 servers*, each cell's attention indicator is located on the cell hardware, to the outside of the cell's power LEDs.

- **I/O Chassis LEDs**

  On HP *Superdome servers* only, each I/O chassis has a attention indicator, which is located on the cabinet above the I/O chassis.

- **PCI Card Slot LEDs**

  On *all* HP nPartition systems, each PCI card slot has an attention indicator that you can use to select the card slot. You can view a PCI card slot's attention indicator when accessing the card cage.

S471

On HP *rp7405 / rp7410 and rp8400 servers* only, you also can view each PCI slot's attention indicator beneath the corresponding slot, on the cabinet's external chassis at the rear of the server cabinet.

- **Cabinet Number LCDs**

  On HP *Superdome servers* only, each cabinet has a cabinet number LCD that serves as the cabinet's attention indicator.

NOTE

The **cabinet "attention" light** on HP Superdome, HP rp8400, and HP rp7405/rp7410 servers is not user-controllable.

The cabinet "attention" light automatically turns on when one or more alert level 6 (or higher) chassis codes has been recorded in the error logs and has not yet been read. This light automatically turns off when a user enters the service processor (GSP or MP) chassis logs viewer.

Turning Attention LEDs On and Off [HP-UX]

Use the **`fruled -o...`**, **`fruled -f...`**, or **`rad -f...`** command to manage attention indicators by turning them on, off, or blinking them from HP-UX.

Step 1. Login to HP-UX running on one of the system's nPartitions.

You can manage cabinet, cell, and I/O chassis attention indicators from HP-UX on *any nPartition*. To manage PCI slot attention indicators, you must access HP-UX in the *local nPartition* to which the PCI slot's chassis is assigned.

Step 2. Use the `fruled` command or the `rad` command to manage (turn on, off, or blink) the attention indicator for a system hardware component.

From HP-UX you can manage LEDs for the following hardware components:

- **Cells**—Use `fruled` to blink or turn off a cell's attention indicator.

  — Turn Off: The **`fruled -f -c#`** command *turns off* the attention indicator for the specified cell (`-c#`). To turn off all cell attention indicators use the **`fruled -f -C`** command.

S470

  - Blink: The **`fruled -o -c#`** command *blinks* the attention indicator for the specified cell (`-c#`).

- **I/O Chassis**—Use `fruled` to blink or turn off HP Superdome I/O chassis attention indicators.

  Specify the I/O chassis using *`cabinet/bay/chassis`* notation (#/#/#).

  - Turn Off: The **`fruled -f -i#/#/#`** command *turns off* the attention indicator for the specified I/O chassis (`-i#/#/#`). To turn off all I/O chassis attention indicators use the **`fruled -f -I`** command.
  - Blink: The **`fruled -o -i#/#/#`** command *blinks* the attention indicator for the specified I/O chassis (`-i#/#/#`).

- **Cabinet Numbers**—Use `fruled` to blink or not-blink (keep lit) the cabinet number LCD for an HP Superdome cabinet.

  - Not-Blink: The **`fruled -f -b#`** command *stops blinking* (keeps it lit) the cabinet number LCD for the specified cabinet (`-b#`).
  - Blink: The **`fruled -o -b#`** command *blinks* the cabinet number LED for the specified cabinet (`-b#`).

- **PCI Card Slots**—Use `rad` to turn on, off, or blink the attention indicator for a PCI card slot.

  Specify the PCI slot using *`cabinet-bay-chassis-slot`* (#-#-#-#) notation.

  - Turn Off: The **`rad -f off`** ***`slot`*** command *turns off* the attention indicator for the specified PCI card slot (*`slot`*).
  - Blink: The **`rad -f attention`** ***`slot`*** command *blinks* the attention indicator for the specified PCI card slot (*`slot`*).
  - Turn On: The **`rad -f on`** ***`slot`*** command *turns on* the attention indicator for the specified PCI card slot (*`slot`*).

For details see the *fruled* (1) manpage or the *rad* (1M) manpage.

The following example turns off and blinks various attention indicators on an HP Superdome system, including cell, I/O chassis, PCI slot, and cabinet LEDs.

5469
20

`# fruled -f -C`
`# fruled -f -I`
	Turn off all cell and I/O chassis attention

`# fruled -o -c0 -c2 -c4`
`# fruled -o -i0/0/1 -i0/0/3`
`# fruled -o -b0`
	Blink attention indicators for cells 0, 2, and 4 and I/O chassis 0/0/1 and 0/0/3. *Blink* the cabinet number LCD for

`# fruled -f -C`
`# fruled -f -I`
`# fruled -f -b0`
	Turn off all cell and I/O chassis attention indicators and *stop blinking* the cabinet number LED.

`# rad -f attention 0-0-1-2`
`# rad -f off 0-0-1-2`
`#`
	Blink the attention indicator for PCI slot 2 in cabinet 0, bay 0, chassis 1. Then *turn off* the same PCI slot's attention

Turning Attention LEDs On and Off [Partition Manager]

Use the **Cell —> Light Cell LED** action, the **I/O —> Light I/O Chassis LED** action, or the **I/O —> Light Chassis and Slot LEDs** action to manage a hardware component's attention indicator by blinking it and turning it off from Partition Manager.

Step 1. Run Partition Manager (`/opt/parmgr/bin/parmgr`) or access it from SAM or a Web browser.

Step 2. In Partition Manager's primary window, select the nPartition to which the hardware component (cell, I/O chassis, or PCI slot) is assigned, or select Available Resources if the component is not assigned.

Step 3. Select the hardware component whose attention indicator you want to blink, then select the appropriate menu item to blink the LED.

You can manage LEDs for the following hardware components:

- **Cells**—Select the cell in Partition Manager's primary window, then select the **Cell —> Light Cell LED** menu item.

5468

This menu item *blinks* the selected cell's attention indicator. On HP Superdome servers this *also blinks* the cabinet number LCD for the cabinet in which the cell resides.

- **I/O Chassis**—Select the I/O chassis in Partition Manager's primary window, then select the **I/O —> Light I/O Chassis LED** menu item.

  On HP Superdome servers this menu item *blinks* the attention indicator for the selected I/O chassis, and *also blinks* the cabinet number LCD for the cabinet in which the I/O chassis resides.

- **PCI Card Slots**—Double-click the PCI slot's I/O chassis in Partition Manager's primary window, then select the PCI slot listed in the I/O chassis window, and then select the **I/O —> Light Chassis and Slot LEDs** menu item.

  This menu item blinks the selected PCI card slot's attention indicator.

  On HP Superdome servers, this also blinks the I/O chassis attention indicator and blinks the cabinet number LCD.

Step 4. Click the **OK** button in the window to *turn off* the attention indicator for the hardware component you selected.

On HP Superdome servers, this *also turns off* any I/O chassis attention indicator and *stops blinking* any cabinet number LCD changed by this procedure.

Listing Cell Processor and Memory Configurations

You can determine the processor and memory configurations for cells in a server complex by using software tools and utilities.

Table 7-2 on page 330 lists the processor version info (HVERSIONs) that is reported by the procedures given in this section.

You can list processor and memory details using the following procedures:

- *Listing Cell Processors and Memory [Service Processor]* on page 331
- *Listing Cell Processors and Memory [BCH]* on page 333
- *Listing Cell Processors and Memory [HP-UX]* on page 334
- *Listing Cell Processors and Memory [Partition Manager]* on page 335

SU66
2

Table 7-2 Processor (CPU) Versions for Cells

Cell's Operating CPU Frequency	HVERSION for HP rp7405/rp7410 and rp8400 Servers	HVERSION for HP Superdome Servers
PA8600 — 552 MHz	—	`0x5c70`
PA8700 — 650 MHz	`0x5e60`	`0x5d70`
PA8700 — 750 MHz	`0x5e40`	`0x5e70`
PA8700 — 875 MHz	`0x5eb0`	`0x5ea0`

PA-RISC Processor HVERSIONs

Table 7-2 lists the processor HVERSION numbers that are reported for nPartitions and cells. These are hexadecimal numbers. HP Superdome processor HVERSIONs differ from rp7405/rp7410 and rp8400 HVERSIONs. See the procedures that follow for info on listing HVERSIONs.

NOTE

The HVERSION indicates the current operating frequency for processors in cells, but does not necessarily indicate the processor hardware revisions.

For a cell that is assigned to an nPartition, the processor HVERSION is based on the *operating frequency of the monarch cell* in the nPartition to which the cell is assigned.

Likewise, for a cell not assigned to an nPartition, the reported HVERSION refers to the *operating frequency of the cell.*

All processors in a cell operate at the same frequency, and all cells in an nPartition must operate at the same frequency. Different nPartitions in a server can operate at different frequencies.

Listing Cell Processors and Memory [Service Processor]

Use the Command menu `PS` command to list cell processor and memory configurations using the service processor Command menu.

Step 1. Login to the system's service processor and enter `CM` to access the Command menu.

You can check processor and memory details for any cell in the complex from the service processor.

Step 2. Issue the `PS` command and specify the cell whose processor and memory details you want to view.

The `PS` command reports details for the cell including its processor configuration (CPU population) and its memory configuration (DIMM population).

For the cell *memory configuration* details, the `PS` command displays each populated DIMM and identifies it using its rank notation (0A–0D, 1A–1D, and so on).

The following example shows details for cell 0 in cabinet 0, which has four processors (0–3) and four DIMMs installed (0A–0D).

5464

```
GSP:CM> PS

This command displays detailed power and hardware configuration status.

You may display detailed power and hardware status for the following items:

    B - Cabinet (UGUY)
    C - Cell
    G - GSP
    I - Core IO
        Select Device: c

    Enter cabinet number: 0
    Enter slot number: 0

HW status for Cell 0 in cabinet 0: NO FAILURE DETECTED

Power status: on, no fault
Boot is not blocked; PDH memory is shared
Cell Attention LED is off
RIO cable status: connected
RIO cable connection physical location: cabinet 0, IO bay 1, IO chassis 3
Core cell is cabinet 0, cell 0

PDH status LEDs:  ****
                             CPUs
                           0 1 2 3
          Populated        * * * *
          Over temperature

S463

Listing Cell Processors and Memory [BCH]

Use the Information menu **PR** and **ME** commands to list cell processor and memory configurations from an nPartition's BCH interface.

Using the BCH interface, you can check these details only for the active cells in the local nPartition.

Step 1. Access the BCH interface for the nPartition to which the cell is assigned, and access the BCH Information menu.

From the BCH Main menu, enter **IN** to access the BCH Information menu. (If you are not at the BCH Main menu, enter **MA** to go to the Main menu.)

Step 2. From the BCH Information menu, list the processor or memory status for all cells by issuing the **PR** and **ME** commands.

- **Processor status**—Use the **PR** command to report details about all processors on all active cells in the nPartition.
- **Memory status**—Use the **ME** command to report details about all active cells' memory configurations.

  The ME command summarizes memory (DIMM) details for each ranks of memory. Each rank is a set of 4 DIMMs.

These BCH commands do not report details for inactive cells.

```
Information Menu: Enter command > PR

Listing Cell Processors and Memory [HP-UX]

Use the **parstatus** command with various options to list cell processor and memory configurations from HP-UX.

You can check these details for any cell in the complex.

Step 1. Login to HP-UX running on any of the system's nPartitions.

You can list processor and memory details from any nPartition.

Step 2. Issue the `parstatus` command to view cell hardware details including processor and memory configurations.

Use any of the following `parstatus` commands to view cell hardware information:

- **parstatus -V -c#**

  List detailed processor and memory configuration information for the specified cell.

- **parstatus -C**

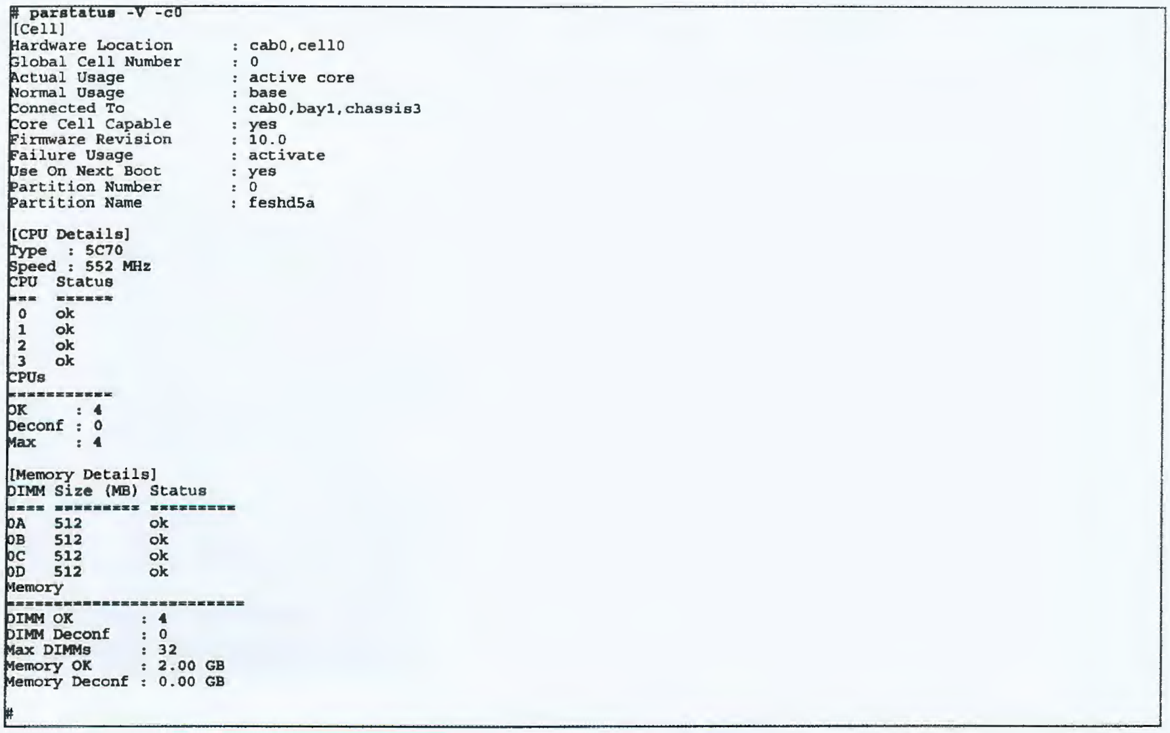
  List brief processor and memory information for all cells in the entire complex.

- **parstatus -V -p#**

  List brief processor and memory information for all cells assigned to the specified nPartition.

SU64
21

The following example shows the `parstatus -V -c0` command's output. This presents detailed processor and memory info for cell 0 in cabinet 0.



```
# parstatus -V -c0

#
```

Listing Cell Processors and Memory [Partition Manager]

Use the **Cell —> Show Cell Details** action, **CPUs/Memory** tab to list cell processor and memory details from Partition Manager.

Step 1. Run Partition Manager (`/opt/parmgr/bin/parmgr`) or access it from SAM or a Web browser.

Step 2. On the left of the primary window, select the nPartition to which the cell is assigned, or select Available Resources if the cell is unassigned.

Step 3. On the right of the primary window, select the cell whose processor and memory details you want to list, then select the **Cell —> Show Cell Details** menu item.

Step 4. Click the **CPUs/Memory** tab to list the selected cell's processor and memory configurations.

Deconfiguring Cells, Processors, and Memory

You can **deconfigure (make inactive) a cell** that is assigned to an nPartition by setting its use-on-next-boot value to "n" (do not use). This causes the cell to remain assigned to the nPartition, but the cell will be inactive the next time its nPartition boots, meaning the cell's resources will not be used.

You also can **deconfigure processors and memory** from any cell that is assigned to an nPartition. This causes the deconfigured processors or memory to not be available for use by the cell or its nPartition.

Whenever you configure or deconfigure cells, processors, or memory, *you must reboot the corresponding nPartition* for the configuration change to take effect.

You can use the following procedures:

- *Deconfiguring Cells, Processors, and Memory [BCH]* on page 337
- *Deconfiguring Cells, Processors, and Memory [HP-UX]* on page 339
- *Deconfiguring Cells, Processors, and Memory [Partition Manager]* on page 340

Deconfiguring Cells, Processors, and Memory [BCH]

Use the Configuration menu `CELLCONFIG` or `CPUCONFIG` command, or Service menu `DIMMDEALLOC` command, to configure and deconfigure cells, processors, and memory from the BCH interface.

Step 1. Access the BCH interface for the nPartition whose cells, processors, or memory you want to configure or deconfigure.

Step 2. To change *cell or processor* configurations, access the Configuration menu. To change *memory* configurations, access the Service menu.

To access the Configuration menu, enter `CO` at the BCH interface's main menu. To access the Service menu enter `SER`.

Step 3. Configure or deconfigure the cell, processors, or memory.

5461

You *cannot* deconfigure the last cell, processor, or DIMM rank. Cells must have at least one configured processor or DIMM rank, and nPartitions must have at least one configured cell.

- **Cells**

  From the Configuration menu, use the `CELLCONFIG` command to configure or deconfigure a cell in the nPartition.

  `CELLCONFIG # OFF` deconfigures the cell (#) by setting its use-on-next-boot value to "n" (do not use).

  `CELLCONFIG # ON` configures the specified cell (#) by setting its use-on-next-boot value to "y" (use the cell).

  Enter **`HELP CELLCONFIG`** for details.

- **Processors**

  From the Configuration menu, use the `CPUCONFIG` command to configure or deconfigure a processor on a cell in the nPartition.

  `CPUCONFIG` ***`cell cpu`*** **`OFF`** deconfigures the specified processor (*cpu*) on the specified cell (*`cell`*).

  `CPUCONFIG` ***`cell cpu`*** **`ON`** configures the specified processor on the cell

  Enter **`HELP CPUCONFIG`** for details.

- **Memory**

  DIMMs operate in ranks of four. Each rank is numbered (0, 1, 2, and so on) and the DIMMs in the rank are lettered (A to D). For example, rank 0 includes DIMMs 0A, 0B, 0C, and 0D.

  From the Service menu, use the `DIMMDEALLOC` command to configure or deconfigure memory on a cell in the nPartition.

  When you deallocate a DIMM, *all other DIMM's in the rank also will not be used* the next time the nPartition boots.

  `DIMMDEALLOC` ***`cell dimm`*** **`OFF`** deconfigures the specified DIMM (*dimm*) on the cell (*`cell`*) indicated.

  `DIMMDEALLOC` ***`cell dimm`*** **`ON`** configures the specified DIMM on the cell.

5460

For example, `DIMMDEALLOC 0 1B OFF` sets DIMM 1B on cell 0 to be deallocated the next time the nPartition boots, and as a result all other DIMMs in the same rank (1A, 1C, and 1D) also will not be used.

Enter **`HELP DIMMDEALLOC`** for details.

Step 4. Reboot the nPartition using the **`REBOOT`** command.

Whenever changing cell, processor, or memory configurations you must reboot the corresponding nPartition to allow the configuration changes to take place.

Deconfiguring Cells, Processors, and Memory [HP-UX]

Use the **`parmodify -p# -m#::[y|n]:`** command to configure or deconfigure (makes inactive) cells from the HP-UX command line.

Step 1. Login to HP-UX on the nPartition whose cell you want to configure or deconfigure.

Step 2. Issue the **`parstatus -C`** command to list all cells, their nPartition assignments, their actual (current) usage, and their use-on-next-boot values.

Step 3. Issue the **`parmodify -p# -m#::[y|n]:`** command to configure or deconfigure the specified cell (`-m#`) from the nPartition (`-p#`).

The **`parmodify -p# -m#::n:`** command deconfigures the specified cell (`-m#`). This sets the cell's use-on-next-boot value to "n" (do not use).

The **`parmodify -p# -m#::y:`** command configures the specified cell to be used. This sets the cell's use-on-next-boot value to "y" (use the cell).

The partition number (`-p#`) you specify must be the local nPartition number, which you can list using the `parstatus -w` command.

Step 4. Reboot the nPartition using the **`shutdown -R`** command.

You must reboot the partition to allow the new use-on-next-boot values to take effect.

The `shutdown -R` command performs a reboot for reconfig for the nPartition, which allows *all cells* to reboot, including any currently inactive cells in the nPartition.

Deconfiguring Cells, Processors, and Memory [Partition Manager]

Use the **Partition —> Modify Partition** menu, **Change Cell Attributes** tab to configure and deconfigure (makes inactive) cells using Partition Manager.

Step 1. Run Partition Manager (`/opt/parmgr/bin/parmgr`) or access it from SAM or a Web browser.

Step 2. Select the nPartition whose cell configuration you want to modify, then select the **Partition —> Modify Partition** menu item.

Step 3. Click the **Change Cell Attributes** tab.

Step 4. Select the cell whose configuration you want to modify, then click the **Modify Cell(s)** button.

Step 5. In the Modify Cell Attributes window, set the cell's use-on-next-boot value, then click the **OK** button.

To configure the cell to be used set use-on-next-boot to "yes".

To configure the cell *to not* be used set use-on-next-boot to "no".

Step 6. Exit Partition Manager, then reboot the corresponding nPartition using the **`shutdown -R`** command.

You must reboot the nPartition whose use-on-next-boot cell values you changed to allow the new use-on-next-boot values to take effect.

Listing the Server Product Number and Serial Number

You can list the *product number* and the *serial number* for your server complex by using software commands and utilities.

You can use the following procedures:

- *Listing Product and Serial Numbers [Service Processor]* on page 341
- *Listing Product and Serial Numbers [BCH]* on page 342
- *Listing Product and Serial Numbers [HP-UX]* on page 343
- *Listing Product and Serial Numbers [Partition Manager]* on page 343

Listing Product and Serial Numbers [Service Processor]

Use the Command menu **ID** command to list the system complex's product number and serial number from the service processor.

Step 1. Login to the system's service processor and enter **CM** to access the Command menu.

Step 2. Issue the service processor Command menu's **ID** command to display the system complex information, including the product and serial numbers.

Step 3. Type **n** (or type **q**) to *not modify* the system complex information that was displayed.

```
GSP:CM> ID

This command allows you to change certain fields in the Stable complex
configuration portion of the complex profile.

Retrieving the stable complex configuration portion of the complex profile.

    GSP modifiable stable complex configuration data fields.
    Model String           : 9000/800/SD64000
    Complex System Name    : feshd5
    Complex Serial Number  : USR2024FP1

```

```
    Do you want to modify any of this information? (Y/[N]) n

    -> No fields modified.
GSP:CM>
```

Listing Product and Serial Numbers [BCH]

Use the Information menu **CID** command to list the system complex's product number and serial number from the BCH interface.

Step 1. Access the BCH interface for any nPartition in the complex.

You can list the complex's product number and serial number from any nPartition in the server.

Step 2. Access the BCH Information menu by entering **IN** from the BCH Main menu.

If you are at a BCH menu other than the Main menu, enter `MA` to go to the Main menu and then enter `IN` to access the Information menu.

Step 3. From the BCH Information menu, use the **CID** command to list the complex's ID information, including the product number and serial number.

The `CID` BCH command (also: `ComplexID`) displays information that is stored as part of the server's Stable Complex Configuration Data.

```
Information Menu: Enter command > CID

COMPLEX ID INFORMATION

                 Complex Name: feshd4
                 Model String: 9000/800/SD16000
      Original Product Number: A5201A
       Current Product Number: A5201A
                Serial Number: USR2025FP2
                Enterprise ID: 0x2020202020202020

Checking Blower and Fan Status

You can remotely check the operating status of a server complex's blowers and fans by using software commands and utilities.

NOTE Different HP server and cabinet models have different blower and fan configurations.

You can use the following procedures:

- *Checking Fan Status [Service Processor]* on page 345
- *Checking Fan Status [HP-UX]* on page 346
- *Checking Fan Status [Partition Manager]* on page 347

Checking Fan Status [Service Processor]

Use the `PS` command's "Cabinet" option to check fan and blower status from the service processor Command menu.

Step 1. Login to the complex's service processor and enter `CM` to access the Command menu.

Step 2. Issue the `PS` command, select the "Cabinet" option, and specify the cabinet number whose fan status you want to check.

SYS2
21

```
Fan 3  ok

I/O Fans
=============
Fan 0  ok
Fan 1  failed
Fan 2  ok
Fan 3  ok
Fan 4  ok

Bulk Power Supplies(BPS)
=======================
Power Supply  0  ok
...
```

Checking Fan Status [Partition Manager]

Use the **Complex —> Show Complex Details** menu, **Power/Cooling** tab to list fan status from Partition Manager.

Step 1. Run Partition Manager (`/opt/parmgr/bin/parmgr`) or access it from SAM or a Web browser.

Step 2. Select the **Complex —> Show Complex Details** menu item.

This displays the Complex Details window.

Step 3. Click the **Power/Cooling** tab to view the panel that has information about the status of the blowers and fans in the complex.

SUS1

Complex Health Analysis of a Server

You can quickly check for hardware problems in an nPartition server by using Partition Manager's "Analyze Complex Health" feature.

This feature scans the server complex and uses problem detectors to check the operating status of cells, I/O chassis, fans and blowers, and power supplies.

Partition Manager automatically performs this task when you launch the application; if any problems are detected then the complex health analysis is displayed before Partition Manager's primary window.

Analyzing Server Complex Health [Partition Manager]

Use the **Complex —> Analyze Complex Health** action to quickly check a server complex's operating status from Partition Manager.

Step 1. Run Partition Manager (`/opt/parmgr/bin/parmgr`) or access it from SAM or a Web browser.

Step 2. Select the **Complex —> Analyze Complex Health** action.

Partition Manager displays a window that reports the hardware analysis results. To re-analyze the server's health click the **Refresh** button.

5449

Listing the Cabinets in a Server Complex

You can list all cabinets in a server complex by using software commands and utilities, which allow you to determine the complex's cabinet configuration from a remote location.

You can use the following procedures:

- *Listing Cabinets [Service Processor]* on page 350
- *Listing Cabinets [HP-UX]* on page 351
- *Listing Cabinets [Partition Manager]* on page 351

Listing Cabinets [Service Processor]

Use the Command menu DU command to list all cabinets in the server complex using the service processor.

Step 1. Login to the server's service processor and enter CM to access the Command menu.

Step 2. Issue the DU command to list all cabinets in the server complex.

```
GSP:CM> DU

 1   SD64000       4/ 0/ N+  5/ 0/ ?    5/ 0/ N+     3/ 0/ N+      none

Notes: N+ = There are one or more spare items (fans/power supplies).
       N  = The number of items meets but does not exceed the need.
       N- = There are insufficient items to meet the need.
       ?  = The adequacy of the cooling system/power supplies is unknown.

#
```

Listing Cabinets [Partition Manager]

Use the **Complex —> Show Complex Details** menu, **Cabinet Info** panel to list the cabinets in a server complex from Partition Manager.

Step 1. Run Partition Manager (/opt/parmgr/bin/parmgr) or access it from SAM or a Web browser.

Step 2. Select the **Complex —> Show Complex Details** menu item, then click the **Cabinet Info** panel.

5487

Listing the nPartitions in a Server

You can list details about the nPartitions defined in a server complex, including the partition numbers, nPartition names, and the cells assigned to the nPartitions.

You can use the following procedures:

- *Listing nPartitions [Service Processor]* on page 352
- *Listing nPartitions [HP-UX]* on page 353
- *Listing nPartitions [Partition Manager]* on page 353

Listing nPartitions [Service Processor]

Use the Command menu **CP** command to list all nPartitions from the service processor.

Step 1. Login to the server's service processor and enter **CM** to access the Command menu.

Step 2. Issue the service processor Command menu's **CP** command to list all nPartitions defined in the server complex.

The CP command lists the partition number (Part 0, Part 1, and so on) for each nPartition and lists which cells are assigned to each nPartition.

```
GSP:CM> CP

--------------
Cabinet | 0  |
--------+----+
 Slot   |0123|
--------+----+
Part  0 |*...|
Part  1 |.*..|

GSP:CM>
```

5446

Listing nPartitions [HP-UX]

Use the **parstatus -P** command to list a server's nPartitions from HP-UX.

Step 1. Login to HP-UX running on any of the server's nPartitions.

You can list all nPartitions from any nPartition in the server.

Step 2. Issue the **parstatus -P** command and option to list all nPartitions and their current status.

```
# parstatus -P
[Partition]
Par                 # of  # of I/O
Num Status          Cells Chassis  Core cell  Partition Name (first 30 chars)
=== ============ ===== ======== ========== ===============================
 0  active          2       2      cab0,cell0 jules00
 1  active          2       2      cab0,cell4 jules01
#
```

Listing nPartitions [Partition Manager]

View the left side of the primary window to see a display of all nPartitions in the server from Partition Manager.

Step 1. Run Partition Manager (/opt/parmgr/bin/parmgr) or access it from SAM or a Web browser.

Step 2. Access Partition Manager's primary window, and view the list of nPartitions shown on the window's left side.

Each nPartition is listed separately. Also listed here are the server's Available Resources, which are not assigned to any nPartition.

5445

Naming or Renaming a Server Complex

You can assign a name for each server complex in order to better identify the complex as you work with it.

Several commands and utilities display the server complex name as part of their output and interfaces. For example, some nPartition commands and Partition Manager list the complex name.

The server complex name only serves as a helpful identifier; changing the name does not affect the way in which commands and utilities interact with the complex.

You can use the following procedures:

- *Renaming a Server Complex [Service Processor]* on page 354
- *Renaming a Server Complex [Partition Manager]* on page 355

The server complex name is stored as part of the server's complex profile (part of its "stable complex configuration" data).

NOTE Each server complex name has up to 20 characters, which can include upper- and lowercase letters; numbers; and dashes, underscores, periods, and spaces (“-” “_” “.” and “ ”).

Renaming a Server Complex [Service Processor]

Use the Command menu `ID` command to list and modify the server complex name from the service processor.

Step 1. Login to the server's service processor and enter `CM` to access the Command menu.

Step 2. Issue the service processor Command menu's `ID` command to list the complex's name.

The `ID` command lists some of the current server complex's "stable complex configuration" data, including the complex name.

```
GSP:CM> ID

This command allows you to change certain fields in the Stable complex
configuration portion of the complex profile.

Retrieving the stable complex configuration portion of the complex profile.

    GSP modifiable stable complex configuration data fields.
    Model String             : 9000/800/SD64000
    Complex System Name      : feshd5
    Complex Serial Number    : USR2024FP1
    Original Product Number: A5201A
    Current Product Number : A5201A
    Enterprise Id            :

    Do you want to modify any of this information? (Y/[N])
```

Step 3. Specify whether you want to modify the complex profile, including its name.

You should only modify the “complex system name”. Do not change the model string, serial number, or other details used by commands, utilities, and licensing tools.

To cancel the changes at any time, enter **q** to quit the `ID` command without modifying the complex profile data.

Renaming a Server Complex [Partition Manager]

Use the **Complex —> Set Complex Name** action to rename a server complex using Partition Manager.

Step 1. Run Partition Manager (`/opt/parmgr/bin/parmgr`) or access it from SAM or a Web interface.

Step 2. Select the **Complex —> Set Complex Name** menu item.

Step 3. Enter the complex’s new name in the pop-up window.

The pop-up window shows the current complex name. If no name was previously assigned, the default name is “MyComplex”.

Step 4. Click **OK** to set the new name or click **Cancel** to keep the previously assigned name.

S4U3

Checking for Power Supply Failures

From remote locations, you can check the operating status of power supplies by using software commands and utilities.

Different HP server and cabinet models have different supply requirements and configurations.

You can use the following procedures:

- *Checking Power Supply Status [Service Processor]* on page 356
- *Checking Power Supply Status [HP-UX]* on page 356
- *Checking Power Supply Status [Partition Manager]* on page 358

Checking Power Supply Status [Service Processor]

Use the Command menu **PS** command's "Cabinet" option to check power status from the service processor.

Step 1. Login to the complex's service processor and enter **CM** to access the Command menu.

Step 2. Issue the **PS** command, select the "Cabinet" option, and specify the cabinet number whose power status you want to check.

Checking Power Supply Status [HP-UX]

Use the `parstatus -B` or `parstatus -V -b#` command to list the status of power supplies from HP-UX.

Step 1. Login to HP-UX running on any of the system's nPartitions.

You can check power details from HP-UX running on any nPartition.

Step 2. Issue the `parstatus -B` command for a brief summary of all cabinets including power status, or issue the `parstatus -V -b#` command for detailed power status for a specific cabinet (`-b#`) whose details you want to view.

S442

- The `parstatus -B` command summarizes the power status for all cabinets in the system complex.
- The `parstatus -V -b#` command displays a detailed status (“ok” or “failed”) for all power supplies in the specified cabinet (`-b#`).

The following example shows power supply details for cabinet number 0, which has one failed bulk power supply (Power Supply 3).

```
# parstatus -V -b0
[Cabinet]
                 Cabinet   I/O       Bulk Power  Backplane
                 Blowers   Fans      Supplies    Power Boards
                 OK/       OK/       OK/         OK/
Cab              Failed/   Failed/   Failed/     Failed/
Num Cabinet Type N Status  N Status  N Status    N Status      GSP
=== ============ ========= ========= ==========  ============  ======
 0  SD32000       4/ 0/ N+  5/ 0/ ?   3/ 1/ N     3/ 0/ N+     active

Cabinet Blowers
===============
Fan 0  ok
Fan 1  ok
Fan 2  ok
Fan 3  ok

I/O Fans
==============
Fan 0  ok
Fan 1  ok
Fan 2  ok
Fan 3  ok
Fan 4  ok

Bulk Power Supplies(BPS)
========================
Power Supply  0  ok
Power Supply  1  ok
Power Supply  3  failed
Power Supply  4  ok

Backplane Power Boards
======================
Power Supply  0  ok
Power Supply  1  ok
Power Supply  2  ok

Notes: N+ = There are one or more spare items (fans/power supplies).
       N  = The number of items meets but does not exceed the need.
```

```
N- = There are insufficient items to meet the need.
?  = The adequacy of the cooling system/power supplies is unknown.

#
```

Checking Power Supply Status [Partition Manager]

Use the **Complex —> Show Complex Details** action, **Power/Cooling** tab to list power status from Partition Manager.

Step 1. Run Partition Manager (`/opt/parmgr/bin/parmgr`) or access it from SAM or a Web browser.

Step 2. Select the **Complex —> Show Complex Details** menu item.

This displays the Complex Details window.

Step 3. Click the **Power/Cooling** tab to bring up the panel that contains information about the status of the power supplies in the complex.

5440

Checking for Memory DIMM Failures

You can list cell memory configurations and check for memory DIMM failures using software tools and utilities.

You can use the following procedures:

- *Checking Memory Status [HP-UX]* on page 359
- *Checking Memory Status [Partition Manager]* on page 361

Checking Memory Status [HP-UX]

Use the **parstatus -V -c#** command to list a cell's memory status, including any DIMM failures, from HP-UX.

Step 1. Login to HP-UX running on any of the system's nPartitions.

You can check memory details for any cell from any nPartition.

Step 2. Issue the **parstatus -V -c#** command to list detailed information about the specified cell (-c#).

The detailed information parstatus reports includes a list of all DIMMs (memory modules) installed on the cell, and the status of each DIMM.

Any memory listed as "failed" either has failed self-tests or has been software deconfigured by the Boot Console Handler (BCH) Service menu's DIMMDEALLOC command.

NOTE For any DIMM that fails or is deallocated, *all other DIMMs in the same rank also are deallocated*. All four DIMMs within the same rank must pass self-test and must be allocated for the rank to be made available for use by the cell and its nPartition.

In the following example, eight DIMMs (0A–0D and 1A–1D) are installed and are available ("ok") for use by the cell's nPartition.

```
# parstatus -V -c0
[Cell]
Hardware Location        : cab0,cell0
```

SU39

```
Global Cell Number      : 0
Actual Usage            : active core
Normal Usage            : base
Connected To            : cab0,bay0,chassis1

....

[CPU Details]
Type  : 5E70
Speed : 750 MHz
CPU  Status
===  ======
 0   ok
 1   ok
 2   ok
 3   ok
CPUs
===========
OK      : 4
Deconf  : 0
Max     : 4

[Memory Details]
DIMM Size (MB) Status
==== ========= =========
0A   512       ok
0B   512       ok
0C   512       ok
0D   512       ok
1A   512       ok
1B   512       ok
1C   512       ok
1D   512       ok
Memory
=========================
DIMM OK         : 8
DIMM Deconf     : 0
Max DIMMs       : 32
Memory OK       : 4.00 GB
Memory Deconf   : 0.00 GB

#
```

In the above example, if any DIMM had failed its status would be “failed” and all other DIMMs in its rank (for instance, rank 0 or rank 1) also would be listed as failed.

5438

Any one or more of the failed DIMMs might have been software deallocated or might have failed self tests. In either case, all DIMMs in the rank automatically are deallocated when any of the rank's DIMMs fails or is deallocated.

Checking Memory Status [Partition Manager]

Use the **Cell —> Show Cell Details** action, **CPUs/Memory** tab to list a cell's memory status, including any DIMM failures, from Partition Manager.

Step 1. Run Partition Manager (/opt/parmgr/bin/parmgr) or access it from SAM or a Web browser.

Step 2. On the left of the primary window, select the nPartition to which the cell is assigned, or select Available Resources if the cell is unassigned.

Step 3. On the right of the primary window, select the cell whose memory details you want to list, then select the **Cell —> Show Cell Details** menu item.

Step 4. Click the **CPUs/Memory** tab to display the status of memory modules (DIMMs) for the cell.

5437

Checking for Processor Failures

You can list cell processor configuration, including any processor failures, using software tools and utilities.

You can use the following procedures:

- *Checking Processor Status [HP-UX]* on page 362
- *Checking Processor Status [Partition Manager]* on page 363

Checking Processor Status [HP-UX]

Use the **`parstatus -V -c#`** command to list a cell's processor status, including any failures, from HP-UX.

Step 1. Login to HP-UX running on any of the system's nPartitions.

You can check processor details for any cell from any nPartition.

Step 2. Issue the **`parstatus -V -c#`** command to list detailed information about the specified cell (`-c#`).

The detailed information `parstatus` reports includes a list of all processors (CPUs) installed on the cell, and the status of each CPU.

Any processors listed as "failed" either have failed self-tests or have been software deconfigured by the Boot Console Handler (BCH) Configuration menu's `CPUCONFIG` command.

```
# parstatus -V -c5
[Cell]
Hardware location        : cab0,cell5
Global Cell Number       : 5
Actual Usage             : active base
Normal Usage             : base
Connected To             : -
Core Cell Capable        : no
Firmware Revision        : 32.5
Failure Usage            : activate
Use On Next Boot         : yes
Partition Number         : 0
Partition Name           : betty
```

5436

```
[CPU Details]
Type  : 23664
Speed : 552 MHz
CPU  Status
===  ======
 0   ok
 1   failed
 2   ok
 3   failed
CPUs
===========
OK      : 2
Failed  : 2
Max     : 4

....
```

Checking Processor Status [Partition Manager]

Use the **Cell —> Show Cell Details** menu, **CPUs/Memory** tab to list processor details and any failures using Partition Manager.

Step 1. Run Partition Manager (`/opt/parmgr/bin/parmgr`) or access it from SAM or a Web browser.

Step 2. On the left of the primary window, select the nPartition to which the cell is assigned, or select Available Resources if the cell is unassigned.

Step 3. On the right of the primary window, select the cell whose processor details you want to list, then select the **Cell —> Show Cell Details** menu item.

Step 4. Click the **CPUs/Memory** tab to display the processors installed in the selected cell and list the status for each processor.

5435

S434

8 Online Add and Replacement (OLAR) of PCI Cards

This chapter presents background information and procedures for performing PCI I/O card *online addition and replacement* (OLAR) on HP's nPartition servers.

The main procedures for adding and replacing PCI cards are:

- *Online Addition (OLA) for a PCI Card* on page 383
- *Online Replacement (OLR) for a PCI Card* on page 389

See the sections that follow for info on tools, requirements, limitations, and other PCI card OLAR details.

For an introduction to I/O hardware on nPartition servers, refer to the chapter *nPartition System Overviews* on page 31.

Also refer to the book *Configuring HP-UX for Peripherals* for further details on configuring PCI cards and related devices.

Overview of PCI Card Online Addition and Replacement (OLAR)

HP-UX 11i supports online addition and replacement (OLAR) of PCI I/O cards on HP nPartition systems. *Without rebooting* HP-UX running on an nPartition, you can add or replace PCI cards whose device drivers support OLAR.

The HP-UX PCI card OLAR features allow for:

- *Adding a new PCI card* without affecting other components of the system and *without* requiring a system reboot.

  This procedure is presented in *Online Addition (OLA) for a PCI Card* on page 383.

- *Replacing an existing PCI card* without affecting other components of the system and *without* requiring a system reboot.

  This procedure is presented in *Online Replacement (OLR) for a PCI Card* on page 389.

nPartition System OLAR Notes

The core I/O cards in HP nPartition servers are *not supported* for online addition or replacement.

On HP rp7405/rp7410 servers, two PCI card slots (chassis 0, slot 1 and chassis 1, slot 8) are dedicated for use by a combination SCSI/LAN card. This SCSI/LAN card is supported for online addition or replacement.

On HP rp7405/rp7410 and rp8400 servers, the PCI card slot latches must be used in conjunction with PCI card OLAR procedures when HP-UX is running. When a card slot latch is open, the slot is powered off and the slot is made accessible for card addition or replacement.

See the chapter *nPartition System Overviews* on page 31 and the section *PCI Card Slot Latches and Doorbells* on page 376 for other I/O hardware details.

5432

OLAR Tools and Interfaces

This section discusses the tools available for performing online card addition and replacement tasks. Also given here are example uses of some of the commonly used OLAR commands and interfaces.

The primary tools for performing PCI card OLAR tasks are the System Administration Manager utility (SAM, `/usr/sbin/sam`) and Partition Manager (`/opt/parmgr/bin/parmgr`).

NOTE Always use SAM or Partition Manager when performing card addition and replacement tasks, because these tools perform critical resource analysis and properly execute all scripts and commands in the correct sequences.

The `/usr/bin/rad` command and other utilities also can provide useful OLAR-related information.

Details on the OLAR tools and interfaces are given in Table 8-1.

Table 8-1 Tools and Interfaces for PCI Card Online Addition and Replacement (OLAR)

OLAR Tool/Interface	Description
System Administration Manager (SAM)	`/usr/sbin/sam` SAM provides both a graphical user interface (GUI) and an equivalent text-based terminal interface. To perform OLAR tasks from SAM, enter the **Peripheral Devices > Cards** area, which gives a listing of all PCI cards currently available in the local nPartition. When you select a slot or path from this list, items in the **Actions** menu enable you to perform OLAR-related tasks on the selection.

SU31

Table 8-1 **Tools and Interfaces for PCI Card Online Addition and Replacement (OLAR) (Continued)**

OLAR Tool/Interface	Description
Partition Manager	`/opt/parmgr/bin/parmgr` Partition Manager's interface is exclusively a GUI. In addition to supporting nPartition administration tasks, Partition Manager has complete support for PCI card OLAR. To perform OLAR tasks from Partition Manager, select and "open" an I/O chassis in the primary window, which gives a listing of all PCI cards in the selected I/O chassis. When you select a slot or path from this list, items in the **I/O** menu enable you to perform OLAR-related tasks on the selection. Note that when using Partition Manager you can add or replace cards in the *local* nPartition's active I/O chassis only.
`/usr/bin/rad`	The `rad` command is a command-line interface for performing some OLAR tasks and getting system PCI card and driver status information for the local nPartition. HP recommends you perform online card add or replace tasks using SAM or Partition Manager—not `rad`. However, the `rad` command can be useful for listing status, getting additional slot or card details, and for independently managing card slot attention indicators (LEDs). The `rad` command reports *the default speed/frequency* for PCI slots when they are not occupied. When a slot is occupied with a card the `rad` command reports *the operating speed/frequency* for the card and slot. See *Example Uses of Common rad Commands* on page 370 for other details.

S430

Table 8-1 Tools and Interfaces for PCI Card Online Addition and Replacement (OLAR) (Continued)

OLAR Tool/Interface	Description
Scripts in the directory `/usr/sbin/olrad.d/`	Each OLAR-capable card's driver(s) may have associated scripts in the `/usr/sbin/olrad.d/` directory. Each driver's script accepts the following command-line arguments: the *`action`* to perform and *`path`* for the slot for which the action is performed. The SAM and Partition Manager utilities automatically run these scripts, as needed, when performing PCI card online addition or replacement tasks. Normally, the driver OLAR scripts *are not invoked manually* by administrators. These scripts' actions include various preface–, prepare–, and post-replace tasks and post-add tasks.
I/O Chassis Hardware	Hardware in each I/O chassis includes PCI card slots, card slot dividers, and power and attention indicators (LEDs) for each slot. HP rp7405/rp7410 and rp8400 servers also have PCI card slot latches. Note that the I/O chassis locations and other features of I/O chassis hardware differ in the various HP nPartition server models. Refer to the chapter *nPartition System Overviews* on page 31 and the section *PCI Card Slot Latches and Doorbells* on page 376 for nPartition I/O hardware details.
`/usr/lib/libolrad.1`	The `libolrad` library is used by the `rad` command and other utilities such as SAM and Partition Manager to support PCI card slot inquiry and online addition and replacement tasks.

5429

Example Uses of Common rad Commands

This section gives summaries and examples uses of common `rad` commands and options.

Table 8-2 **rad Command Commonly Used Options**

Command	Description
`rad -q`	Displays the status of all OLAR-capable slots in the *local* nPartition. Only displays slots in currently active I/O chassis.
`rad -N` *`path`*	Lists the slot ID for the specified hardware path (*`path`*). The `rad -N` command gives info for OLAR-capable slots only.
`rad -f` *`flag slot`*	Sets the attention indicator (LED) for the specified slot. The accepted *`flag`* arguments: on, `attention`, and `off`, where `attention` flashes the specified slot's LED, and on and `off` turn the LED steady-on or off.
`rad -c` *`slot`*	Displays the device information for all functions/interfaces at the specified slot.

See the *rad* (1M) manpage for complete details.

Example 8-1 **Commonly Used rad Commands for nPartition I/O Details and Card Add/Replace Tasks**

- **`rad -q`**

  To list basic slot, path, card, and driver details, use the `rad -q` command.

  The `rad -q` command lists all PCI card slots in the local nPartition, the corresponding hardware paths, and the current status of all slots and drivers.

```
# rad -q
                                                                    Driver(s)
Slot        Path        Bus   Speed   Power   Occupied    Suspended  Capable
0-0-0-1     0/0/8/0     64    33      On      No          N/A        N/A
0-0-0-2     0/0/10/0    80    33      On      No          N/A        N/A
0-0-0-3     0/0/12/0    96    33      On      Yes         No         Yes
0-0-0-4     0/0/14/0    112   33      On      No          N/A        N/A
0-0-0-5     0/0/6/0     48    33      On      Yes         Yes        Yes
0-0-0-6     0/0/4/0     32    33      On      No          N/A        N/A
```

5428

```
0-0-0-7      0/0/2/0      16     33      On      No        N/A        N/A
0-0-0-8      0/0/1/0      8      33      On      No        N/A        N/A
#
```

- **`rad -N`** ***`path`***

  To determine which card slot corresponds to a hardware path, use the `rad -N` *`path`* command.

  The `rad -N` *`path`* command lists the card slot used by the device whose hardware path you specify. The slot is reported in *cabinet-bay-chassis-slot* format.

```
# rad -N 0/0/6/0/0.6.0
0-1-3-5
#
```

- **`rad -f`** ***`flag slot`***

  To flash, turn on, or turn off a PCI slot's attention indicator (LED) use the `rad -f` *`flag slot`* command.

```
# rad -f attention 0-1-3-1
# rad -f off 0-1-3-1
#
```

- **`rad -c`** ***`slot`***

  To list device information about a card use the `rad -c` *`slot`* command.

  The `rad -c` *`slot`* command lists details for all interfaces in a card, including the hardware path(s), driver name(s), and vendor and revision details.

```
# rad -c 0-1-3-5
Path                   :0/0/6/0/0
Name                   :c720
Device_ID              :000f
Vendor_ID              :1000
Subsystem_ID           :0000
Subsystem_Vendor_ID    :0000
Revision_ID            :4
Class                  :010000
Status                 :0200
Command                :0156

Bridge                 :No
Capable_66Mhz          :No
Power_Consumption      :75

#
```

S427

Requirements for OLAR Operations

To perform a card *addition* or card *removal-and-replacement* operation, the following system requirements must be met:

- The add or replace operation **must** be supported on the system hardware.

  All HP nPartition servers support PCI card OLAR.

- The replacement PCI card **must** be identical to the original card.

  When performing a card replacement task, you must use a replacement card that: uses the *same driver*, is manufactured by the *same vendor*, and is the *same hardware revision* as the original card being replaced.

  Use the `rad -c` *`slot`* command to list detailed driver, vendor, and revision information for a card in the specified slot.

- The PCI card's driver **must** support OLAR.

  Some PCI card drivers do not support OLAR.

  Use the `rad -q` command's output to check whether an existing PCI card's driver is capable of being suspended and resumed for card OLAR operations.

  Both SAM and Partition Manager also indicate in the "Status" column whether an existing PCI card's driver supports OLAR. All card slots except those listed as "not OLAR-able" are valid for online PCI card add or replace tasks.

- The card's driver **must** be loaded in the currently running HP-UX kernel.

  For online *addition*, the driver must be present in the kernel to support the new card.

  For online *replacement*, the replacement card must use the same revision of the driver as the original card.

  Use the SAM utility's **Kernel Configuration > Drivers** area to list all currently loaded drivers.

- The PCI slot **must** have firmware that supports OLAR.

  On all HP nPartition servers, the I/O firmware supports OLAR.

5426

- The card **must** fit into the slot.

  On all nPartition servers, all PCI card slots can accept PCI cards keyed as universal cards.

  However, in nPartition server I/O chassis the PCI card slots also are physically keyed to accept cards that either are keyed as 5-volt cards or keyed as 3.3-volt cards.

  See the chapter *nPartition System Overviews* on page 31 for details on I/O slot capabilities.

- The resources supported by the card **must not** be critical for the server's continued operation.

  Resources that do not have a defined failover are considered to be "critical resources" that cannot be replaced online.

  For example, the following cards may be considered critical resources: cards that connect to disks for active filesystems, or a LAN card that provides the network port used by the current instance of SAM.

  You could replace a SCSI card used by a disk with an active filesystem, if the filesystem were mirrored on a different disk supported by a second SCSI card. In this case LVM could automatically failover to the mirrored disk, thus allowing you to perform an online replacement of the original SCSI card.

NOTE The core I/O cards on HP nPartition servers *are not* supported for online addition or replacement (OLAR) operations.

5425

PCI Card OLAR Considerations

This section discusses two issues of possible concern when performing PCI card OLAR tasks: card slot power domains, and multi-function cards.

Power Domains

Each **power domain** consists of all the PCI card slots that are powered on or off together as a unit.

On HP nPartition servers *each slot is in its own power domain*, which allows each slot to power on or off without affecting any other slots.

Both SAM's and Partition Manager's OLAR procedures automatically check the effects of OLAR operations on the slots in a power domain. However, in all nPartition servers each slot's power is independent.

To list all slots in a power domain, use the **`rad -a`** ***`slot`*** command. For example, the following `rad` command output indicates that slot 0-1-3-5 is in its own power domain.

```
# rad -a 0-1-3-5
0-1-3-5
#
```

Multi-Function Cards

A **multi-function card** provides more than one function in a single PCI card that occupies one slot. For example: a dual-SCSI PCI card has two SCSI ports, and a combination SCSI/LAN PCI card has both a SCSI port and a LAN port. Such cards allow a single PCI card slot to provide services that otherwise would require two or more PCI cards.

A multi-function card has a separate hardware path for each function, and has a separate driver bound at each hardware path.

Both SAM's and Partition Manager's OLAR procedures automatically check for critical resources at all hardware paths of multi-function cards. These utilities also suspend and resume all drivers bound to multi-function cards as required for OLAR purposes.

To list all functions provided by a PCI card slot, use the **rad -h** ***slot*** command. For example, the following rad command lists all hardware paths associated with slot 0-1-3-8 (cabinet 0, bay 1, chassis 3, slot 8).

```
# rad -h 0-1-3-8
0/0/11/0/0
0/0/11/0/1
#
```

As the above example shows, slot 0-1-3-8 has two functions, one at each of the hardware paths listed.

To list all drivers bound to a multi-function card, use the **rad -c** ***slot*** command.

To list additional details about a multi-function card, use the **ioscan -H** ***path*** command and specify only the first three fields (*cell/SBA/LBA*) of the card's hardware path.

On HP nPartition servers, each card slot has its own local bus adapter (LBA) that is shared by all ports on the card that occupies the slot. For example, the following ioscan command lists two SCSI ports that are provided by the card at hardware path 0/0/11.

```
# ioscan -H 0/0/11
H/W Path        Class                       Description
=======================================================
0/0/11                 ba                   Local PCI Bus Adapter (782)
0/0/11/0/0                    ext_bus       SCSI C896 Ultra2 Wide LVD
0/0/11/0/0.7                     target
0/0/11/0/0.7.0                      ctl     Initiator
0/0/11/0/1                    ext_bus       SCSI C896 Ultra2 Wide LVD
0/0/11/0/1.7                     target
0/0/11/0/1.7.0                      ctl     Initiator
#
```

PCI Card Slot Latches and Doorbells

NOTE This section applies only to HP rp7405/rp7410 and rp8400 servers.

This section introduces two features of HP rp7405/rp7410 and rp8400 server I/O chassis: PCI card slot latches and PCI card slot doorbell buttons.

PCI Card Slot Latches

Both HP rp7405/rp7410 and rp8400 servers have slot latches for all PCI card slots; each PCI card slot has its own latch.

Each PCI card slot latch can enable or disable power to its card slot and, when closed, the latch can secure a PCI card in place. These slot latches are accessible when you have removed the top cover from an HP rp7405/rp7410 or rp8400 server chassis.

Card slot latches are used both for *offline* PCI card procedures and for *online* PCI card procedures.

When a PCI slot latch is open, the slot is powered off.

When a PCI slot latch is closed, the slot can have power enabled. However, note that when a slot's latch is closed the slot's power can be disabled as part of a PCI card OLAR procedure from SAM or Partition Manager, or as a manual operation performed from the HP-UX command-line or from a service processor (GSP or MP) command.

NOTE When HP-UX is running in the nPartition to which an I/O chassis belongs, you should use SAM or Partition Manager procedures to prepare a PCI card slot before opening or closing the slot's latch.

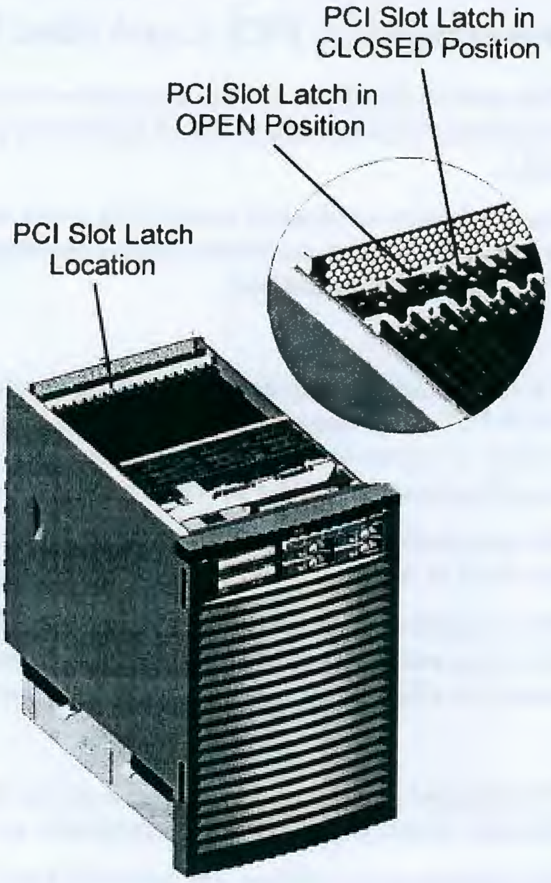
Otherwise you may encounter unpredictable results.

Figure 8-1 on page 377 shows positions of PCI card slot latches. While an HP rp8400 server is shown in Figure 8-1, HP rp7405/rp7410 card slot latches are available in the same location and operate identically.

5422

21

Figure 8-1 **PCI Card Slot Latches (HP rp7405/rp7410 and rp8400)**



PCI Slot Latch in CLOSED Position
PCI Slot Latch in OPEN Position
PCI Slot Latch Location

PCI Card Slot "Doorbells"

NOTE

This section applies only to HP rp7405/rp7410 and rp8400 servers.

The "doorbell" buttons currently have no functions. Pressing a card slot doorbell button has no impact on system operations.

On both HP rp7405/rp7410 and rp8400 servers, access to the doorbell buttons is prevented by a plastic covering.

The PCI card slot doorbell buttons are provided for future expanded functionality.

5421

21

Determining PCI Card Slot Locations

This section describes how to determine which PCI card slot is used by a filesystem, network interface, or hardware path (such as a boot device path).

You may want to identify which PCI cards are used by critical and non-critical system resources when planning for card replacement or nPartition reconfiguration.

NOTE While you can use the manual techniques described here to help identify which PCI cards support critical system resources, you should rely on the critical resource analysis that SAM and Partition Manager perform for a complete analysis of the services a card provides.

You can perform SAM or Partition Manager critical resource analysis for any card in an nPartition's active I/O chassis.

When performing a *card replacement* action, both SAM and Partition Manager automatically check for any critical system resources that would be affected by taking the card offline.

The manual procedures described here use the `rad -N` *`path`* command to identify which PCI card slot corresponds to the specified hardware path.

The following procedures are provided here:

- *Determining a Network Interface's PCI Card Slot* on page 379
- *Determining a Filesystem's PCI Card Slot* on page 379
- *Determining a Boot Device Path's PCI Card Slot* on page 380

To determine the actual physical location of a PCI card slot, based on the *cabinet-bay-chassis-slot* format that the `rad` command lists, refer to the chapter *nPartition System Overviews* on page 31 for an introduction to nPartition I/O hardware.

5420

Determining a Network Interface's PCI Card Slot

This procedure determines which PCI card slot is used by a network interface.

Step 1. At the HP-UX command line, enter the **/usr/sbin/lanscan** command to list the local nPartition's LAN devices and status.

Step 2. Enter the **rad -N *path*** command, and specify the hardware path (*path*) for the network interface whose card slot information you want.

The rad command displays the hardware slot for the network interface's card, in *cabinet-bay-chassis-slot* format.

Example 8-2 Example of Determining a Network Interface's PCI Card Slot

```
# lanscan
Hardware Station        Crd Hdw   Net-Interface  NM  MAC       HP-DLPI DLPI
Path     Address        In# State NamePPA        ID  Type      Support Mjr#
0/0/0/1/0 0x0010832754E0 0   UP    lan0 snap0     1   ETHER     Yes     119
# rad -N 0/0/0/1/0
0-1-3-0
#
```

The above output indicates that the card is installed in cabinet 0, bay 1, chassis 3, slot 0 (0-1-3-0).

Determining a Filesystem's PCI Card Slot

This procedure determines which PCI card slot is used by a filesystem.

Step 1. At the HP-UX command line, enter the **bdf -l** command to list the local filesystems for the local nPartition.

Step 2. For the filesystem of interest, enter the following command:

/usr/sbin/lvdisplay -v -k *lvolume* | grep dev

Where *lvolume* is the device path of the filesystem's logical volume, as was displayed in the bdf command output.

Step 3. Enter the **/usr/sbin/lssf *pvolume*** command, and specify the physical volume path (*pvolume*) as was reported by the lvdisplay command.

For example: lssf /dev/dsk/c0t5d0, for a filesystem whose physical volume is c0t5d0.

S419

Step 4. Enter the **rad -N *path*** command and specify the hardware path (*path*), which lssf reported as the "address" of the filesystem's physical volume.

The rad command displays the hardware slot for the filesystem's card, in *cabinet-bay-chassis-slot* format.

Example 8-3 **Example of Determining a Filesystem's PCI Card Slot**

This example determines which PCI card (0-1-3-5) supports the /stand filesystem.

```
# bdf -l
Filesystem          kbytes    used    avail %used Mounted on
/dev/vg00/lvol3     143360   42571    94743   31% /
/dev/vg00/lvol1    1025617   45445   877610    5% /stand
/dev/vg00/lvol8     512000  225212   269124   46% /var
/dev/vg00/lvol7    1015808  719619   277730   72% /usr
/dev/vg00/lvol4    1048576   77997   909975    8% /tmp
/dev/vg00/lvol6     794624  566033   214349   73% /opt
/dev/vg00/lvol5      20480    1190    18086    6% /home
# lvdisplay -vk /dev/vg00/lvol1 | grep dev
LV Name                     /dev/vg00/lvol1
VG Name                     /dev/vg00
   /dev/dsk/c0t5d0    256        256
# lssf /dev/dsk/c0t5d0
sdisk card instance 0 SCSI target 5 SCSI LUN 0 section 0 at address 0/0/6/0/0.5.0
/dev/dsk/c0t5d0
# rad -N 0/0/6/0/0.5.0
0-1-3-5
#
```

Determining a Boot Device Path's PCI Card Slot

This procedure determines which PCI card slot is used by an nPartition's boot path variable (such as PRI, HAA, or ALT).

Step 1. Issue the **/usr/sbin/parstatus -V -p# | grep Path** command, and specify the local nPartition's partition number (-p#).

This command displays the boot path variable settings for the nPartition.

To determine the local partition number, enter the parstatus -w command.

Step 2. Issue the **rad -N *path*** command and specify the hardware path (*path*) of the boot path variable of interest.

The rad command displays the hardware slot corresponding to the boot path, in *cabinet-bay-chassis-slot* format.

Example 8-4 Example of Determining a Boot Device Path's PCI Card Slot

```
# parstatus -w
The local partition number is 0.
# parstatus -V -p0 | grep Path
Primary Boot Path        : 0/0/6/0/0.6.0
Alternate Boot Path      : 0/0/6/0/0.5.0
HA Alternate Boot Path : 2/0/14/0/0.6.0
# rad -N 0/0/6/0/0.6.0
0-1-3-5
#
```

5477

Checklist for Preparing for PCI Card OLAR

This section reviews the items that you must check when adding or replacing a PCI card.

Most of the items in the following checklist are incorporated into the card addition and replacement procedures that follow.

- ☐ Review and follow all server power and safety guidelines and any related guidelines for rack operation. Also follow all site safety, maintenance, and operating procedures.
- ☐ Use proper static protection and follow all site ESD procedures.
- ☐ If *adding* a PCI card:
  - — Ensure card's required driver(s) are loaded into the currently running kernel before adding the new card.
  - — Check the target slot's frequency and power capabilities, and ensure that they match new card's requirements before adding the card.
- ☐ If *replacing* a PCI card:
  - — Check to be certain the card's driver is OLAR-capable.
  - — Be certain that the replacement card uses the same driver(s) as the original card.
  - — Be certain that the replacement card is made by the same vendor and has the same revision ID as the original card.
  - — Be certain that the replacement card operates at the same voltage and same bus frequency as the original card.
  - — Label all cables connected to the original card—or at least note their connections—before removing them.

    After replacing the card, ensure the cable are connected identically to the replacement card.
- ☐ If *replacing a networking card*, check the system (user) impact of taking the card offline before beginning to replace it.
- ☐ If *replacing a defective card*, properly label/mark the card after removing it from its slot to indicate that the card is not operational.

5416

21

Online Addition (OLA) for a PCI Card

This section describes the procedure for adding a new PCI card on an HP nPartition server while HP-UX remains online and running.

WARNING **When performing this procedure you must follow all server power and safety guidelines and any related guidelines for rack operation. Also follow all site safety, maintenance, and operating procedures.**

Failure to do so can result in personal injury or equipment damage.

PCI Card Online Addition with SAM or Partition Manager

This procedure adds a new PCI I/O card to an empty slot in an nPartition server while HP-UX remains running.

You can use either the System Administration Manager (SAM) or Partition Manager tool to perform the main steps of this procedure.

CAUTION You must follow all site static-protection requirements to avoid damaging equipment when using this procedure.

Step 1. Login to HP-UX running on the nPartition where the card that will be added is to be installed.

You must login as `root` to perform this procedure.

Step 2. Launch either SAM or Partition Manager, if it is not yet running.

You can use either application when performing this procedure.

To run SAM, enter **`/usr/sbin/sam`** from the command line. You can run SAM in either graphical (GUI) or text-only terminal mode.

To run Partition Manager either enter **`/opt/parmgr/bin/parmgr`** from the command line or click the **Partition Manager** icon in the main SAM area.

S415

Step 3. Access the list of the local nPartition's PCI card slots from SAM or Partition Manager.

To list cards in SAM, access the **Peripheral Devices > Cards** area.

To list cards in Partition Manager, select the local nPartition in the primary window, then select and open the I/O chassis where the new card will be installed.

Step 4. Identify the card slot where the new PCI card will be installed, and confirm that the slot can support the card.

You can identify the card slot using SAM's **Cards** window or Partition Manager's list of cards in its primary window. The target card slot must be available (the "Description" column for the slot is "empty slot").

You also can use the `rad -q` command to confirm that the target card slot is available (the "Occupied" column for the slot is "No").

NOTE

The **Show I/O Slot Details** option in SAM and Partition Manager displays the *default* bus speed for the selected slot, although all slots are capable of operating at either 33 MHz or 66 MHz.

When the slot "Power Available" listed is 65535 watts, the indication is that slot power details are unavailable to the utility.

See the chapter *nPartition System Overviews* on page 31 for details on the types of physical card keying the PCI card slots support.

Step 5. Confirm that the device driver(s) required by the card are installed in the HP-UX kernel currently running on the nPartition.

You can view currently loaded drivers using the SAM (`/usr/sbin/sam`) utility's **Kernel Configuration—>Drivers** area.

Step 6. [*Optional*] Confirm the physical location of both the server and the PCI card slot.

Perform the following tasks:

A. Set the card slot's attention indicator to flash in order to help you locate the slot.

5414

In SAM, select (highlight) the slot, then select the **Actions —> Light I/O Slot LED** menu item. SAM flashes the selected PCI card slot's LED.

In Partition Manager, select (highlight) the slot, then select the **I/O —> Light Chassis and Slot LEDs** menu item. Partition Manager flashes the selected PCI card slot's LED, and on HP Superdome servers also flashes the corresponding I/O chassis LED and cabinet number LCD.

From the HP-UX command line, you can issue the **`rad -f attention`** ***`slot`*** command to flash the PCI card slot's attention indicator (LED).

B. Locate the server, and view the PCI card slot attention indicators. The LED for the specified card slot should be flashing.

C. After locating the server and card slot, turn off the card slot LED.

In SAM or Partition Manager, click the **OK** button to return the attention indicators to their normal state.

From the HP-UX command line you can issue the **`rad -f off`** ***`slot`*** command to turn off the PCI card slot's attention indicator.

This step is optional, but performing it is recommended to confirm that the actual location is known and accessible.

Step 7. Begin the online PCI card addition procedure.

- To initiate online card addition in SAM, select the **Actions—>Add** menu item.

  Then select (highlight) the slot where the card will be installed, and click the **OK** button.

- To initiate online card addition in Partition Manager, select (highlight) the slot where the card will be installed, and then select the **I/O—>Add Card** menu item.

Step 8. Review the results of the critical resource analysis for the slot.

The first lines of the analysis indicate whether the card addition can or cannot proceed. For example:

```
Critical Resource Analysis for slot 0-1-3-8:
No affected resources found.
```

Step 9. Click either the **Cancel** or **OK** button.

To *cancel* the card addition procedure click the **Cancel** button.

To *continue* the card addition procedure click the **OK** button. This proceeds to power off the card's slot and flash the card's attention indicator (LED).

If you are proceeding with the card addition using Partition Manager on an HP Superdome server, Partition Manager also flashes the corresponding I/O chassis LED and cabinet number LCD.

Step 10. Review the information presented in the **Insert Card** screen.

This screen lists the actions that SAM or Partition Manager has already performed, and describes how you can cancel the card addition.

CAUTION *Complete all steps* required for installing the new PCI card before clicking the **OK** button to bring the card online.

Details for installing the new card are covered in the steps that follow.

Step 11. Locate the PCI card slot that has been prepared for the card addition procedure.

As needed, open or remove any cabinet panels or bezels in order to view the I/O chassis and card slot.

The card slot's attention indicator (LED) will be *flashing* and slot power will be *off*.

Step 12. Ensure you have direct physical access to the I/O chassis.

For example, if adding a PCI card to a Superdome I/O expansion cabinet, you must remove the I/O bay's front covers and then carefully slide the I/O chassis out from its bay/rack.

Step 13. Remove the top cover from the I/O chassis.

Loosen the cover's thumb screws, pull the cover forward, then lift and remove the cover and safely set it aside.

On HP rp7405/rp7410 and rp8400 servers, the I/O chassis cover also is the server cabinet top cover.

Step 14. Confirm the location of the card slot where the new PCI card will be installed.

At this point, all attention and power indicators (LEDs) for the card slot are visible. The light bars on the card slot's divider should indicate that the slot is powered off and its attention LED is flashing.

Each slot divider corresponds to the *PCI card slot to its immediate right* (when viewing the I/O chassis by facing the card slots with the top up).

Step 15. On HP rp7405/rp7410 and rp8400 servers, flip the card slot latch to its open position.

When open, the latch is parallel to the back edge of the chassis.

Step 16. Place the new card in the slot.

Slide the card in the slot, and ensure it is properly aligned. Press firmly on the card until it is fully seated in the card slot.

Step 17. On HP rp7405/rp7410 and rp8400 servers, flip the card slot latch to its closed position.

When closed, the latch is parallel to the card slot divider.

If the latch will not close, the card might not be completely seated in its slot. In this situation, you can either press firmly on the card until it is seated, or lift the slot divider to release the card and then realign and reseat the card.

Step 18. Connect all cables to the new card to establish the desired configuration.

Step 19. Replace the top of the I/O chassis, and restore all front covers and bezels to their original locations.

Replace the I/O chassis cover and firmly push it back into place before tightening all thumb screws.

Also, as needed, carefully slide all racked equipment back into place before replacing any additional covers and bezels. Close any cabinet or rack doors.

Step 20. In the SAM or Partition Manager **Insert Card** window, click the **OK** button.

Clicking **OK** indicates that the new card has been installed.

At this point, the card slot is powered on, the slot attention indicator is turned off, and the driver(s) for the card are started to bring the card online.

If the new card is not detected in the slot, SAM or Partition Manager indicates this and presents a window indicating the problem. This gives you an opportunity to check the new card's installation and then click **Yes** to re-try the card online addition, or click **No** to cancel the operation.

Online Replacement (OLR) for a PCI Card

This section describes the procedure for replacing a PCI card on an HP nPartition server while HP-UX remains online and running.

WARNING **When performing this procedure you must follow all server power and safety guidelines and any related guidelines for rack operation. Also follow all site safety, maintenance, and operating procedures.**

Failure to do so can result in personal injury or equipment damage.

PCI Card Online Replacement with SAM or Partition Manager

This procedure replaces a PCI I/O card in an nPartition server while HP-UX remains running.

You can use either the System Administration Manager (SAM) or Partition Manager tool to perform the main steps of this procedure.

CAUTION You must follow all site static-protection requirements to avoid damaging equipment when using this procedure.

Step 1. Login to HP-UX running on the nPartition where the card that will be replaced is currently installed.

You must login as `root` to perform this procedure.

Step 2. Launch either SAM or Partition Manager, if it is not yet running.

You can use either application when performing this procedure.

To run SAM, enter **`/usr/sbin/sam`** from the command line. You can run SAM in either graphical (GUI) or text-only terminal mode.

S409

To run Partition Manager either enter `/opt/parmgr/bin/parmgr` from the command line or click the **Partition Manager** icon in the main SAM area.

Step 3. Access the list of the local nPartition's PCI cards from SAM or Partition Manager.

To list cards in SAM, access the **Peripheral Devices > Cards** area.

To list cards in Partition Manager, select the local nPartition in the primary window, then select and open the I/O chassis where the card that will be replaced is currently installed.

Step 4. Identify the card's slot location and confirm that the card can be replaced online.

Perform the following tasks:

A. View the list of currently available PCI card slots in the local nPartition.

This card list is shown in SAM's **Cards** window or in Partition Manager's primary window.

B. Identify the slot where the card that will be replaced is currently installed.

The "Description" column indicates the type of card in the slot.

C. Confirm that the driver for the PCI card slot supports OLAR procedures.

The "State" column indicates "not OLAR-able" if the card *cannot* be replaced online, otherwise online replacement of the card is supported.

Step 5. [*Optional*] Confirm the physical location of both the server and the PCI card slot.

Perform the following tasks:

A. Set the card slot's attention indicator to flash in order to help you locate the slot.

In SAM, select (highlight) the slot, then select the **Actions —> Light I/O Slot LED** menu item. SAM flashes the selected PCI card slot's LED.

In Partition Manager, select (highlight) the slot, then select the **I/O —> Light Chassis and Slot LEDs** menu item. Partition Manager flashes the selected PCI card slot's LED, and on HP Superdome servers also flashes the corresponding I/O chassis LED and cabinet number LCD.

From the HP-UX command line, you can issue the `rad -f attention slot` command to flash the PCI card slot's attention indicator (LED).

B. Locate the server, and view the PCI card slot attention indicators. The LED for the specified card slot should be flashing.

C. After locating the server and card slot, turn off the card slot LED.

In SAM or Partition Manager, click the **OK** button to return the attention indicators to their normal state.

From the HP-UX command line you can issue the `rad -f off slot` command to turn off the PCI card slot's attention indicator.

This step is optional, but performing it is recommended to confirm that the actual location is known and accessible before the card's services are suspended.

Step 6. Select the PCI card to be replaced from the card list displayed by SAM or Partition Manager.

Highlight the card in the list. If you are replacing a multi-function card, you only need to highlight any one of the hardware paths in the slot.

For a multi-function (multi-port) card, SAM and Partition Manager list one entry per port, with each port having the same slot number in the "Slot" column and a unique path in the "Hardware Path" column.

Step 7. Begin the online replacement procedure for the selected card.

To initiate online card replacement in SAM, select the **Actions—>Replace** menu item.

To initiate online card replacement in Partition Manager, select the **I/O—>Replace Card** menu item.

Both of these menu items initiate the same processes, beginning with an analysis of any resources provided by the selected card.

Step 8. Review all results from the critical resource analysis of the card.

5407
38

The first lines of the analysis indicate whether the card replacement can or cannot proceed. For example:

```
Critical Resource Analysis for slot 0-1-3-8:
No affected resources are in use.
```

If the card resource analysis determines that the card cannot be taken offline, this result is indicated with a "critical" message such as the following output.

```
CRITICAL: Affected resources are essential for system
operation.
The operation cannot proceed.
```

For a multi-function card, SAM and Partition Manager list the analysis results for all ports on the card.

CAUTION

Review *all parts* of the critical resource analysis report to determine whether to continue or cancel an online card replacement procedure.

Even when the analysis indicates that "no affected resources are in use", continuing the card replacement procedure will take the card offline and will halt any services the card provides.

For example, replacing a networking card causes any network connections the card provides to be suspended or terminated.

Step 9. Click either the **Cancel** or **OK** button.

To *cancel* the card replacement procedure click the **Cancel** button. This cancels the procedure and returns to the list of PCI cards. After you click **Cancel** *you must not perform the remaining steps* in this procedure.

To *continue* the card replacement procedure click the **OK** button. This proceeds to suspend the card's driver(s), power off the card's slot, and flash the card's attention indicator (LED).

Step 10. Review the information presented in the **Replace Cards** screen.

This screen lists the actions that SAM or Partition Manager has already performed to take the selected card offline.

CAUTION *Complete all steps* required for replacing the selected PCI card before clicking the **OK** button to bring the card back online. Details for removing and replacing the card are covered in the steps that follow.

NOTE Clicking the **Cancel** button on the **Replace Cards** screen causes the card to *remain offline*: the card slot remains powered off and the card driver(s) remain suspended. The card slot attention indicator is turned off.

Because the card's slot power remains off, you still can replace the card.

To bring a card back online, select the card and then choose the **Actions—>Bring On-line** menu item in SAM or the **I/O—>Bring Card On-line** menu item in Partition Manager.

Step 11. Locate the PCI card slot that has been taken offline for the card removal procedure.

As needed, open or remove any cabinet panels or bezels in order to view the I/O chassis and card slot that contains the PCI card to be replaced.

The card slot's attention indicator (LED) will be *flashing* and slot power will be *off*.

Step 12. Ensure you have direct physical access to the I/O chassis.

For example, if replacing a PCI card from a Superdome I/O expansion cabinet, you must remove the I/O bay's front covers and then carefully slide the I/O chassis out from its bay/rack.

Step 13. Remove the top cover from the I/O chassis.

Loosen the cover's thumb screws, pull the cover forward, then lift and remove the cover and safely set it aside.

On HP rp7405/rp7410 and rp8400 servers, the I/O chassis cover also is the server cabinet top cover.

Step 14. Locate the PCI card that is to be replaced, note all cable connections to the card, and if needed label any unmarked cables. Save all notations for future reference.

S405

At this point, all attention and power indicators (LEDs) for the card slot are visible. The light bars on the replacement card's slot divider should indicate that the slot is powered off and its attention LED is flashing.

Each slot divider corresponds to the *PCI card slot to its immediate right* (when viewing the I/O chassis by facing the card slots with the top up).

Step 15. Disconnect all cables from the PCI card to be replaced.

Carefully set the cable ends aside where they will not obstruct work or be damaged.

Step 16. On HP rp7405/rp7410 and rp8400 servers, flip the card slot latch to its open position.

When open, the latch is parallel to the back edge of the chassis.

Step 17. Lift the card slot divider to release the PCI card from its slot.

Pull firmly on the slot divider's "handle" until the card becomes unseated. The correct slot divider is indicated by its LED states.

Step 18. Remove the card from its slot and set the card aside.

You may need to label the removed card to indicate it is defective.

Step 19. Place the replacement card in the slot.

Slide the card in the slot, and ensure it is properly aligned. Press firmly on the card until it is fully seated in the card slot.

Step 20. On HP rp7405/rp7410 and rp8400 servers, flip the card slot latch to its closed position.

When closed, the latch is parallel to the card slot divider.

If the latch will not close, the card might not be completely seated in its slot. In this situation, you can either press firmly on the card until it is seated, or lift the slot divider to release the card and then realign and reseat the card.

Step 21. Reconnect all cables to the new card to match their prior attachments to the original card.

Step 22. Replace the top of the I/O chassis, and restore all front covers and bezels to their original locations.

Replace the I/O chassis cover and firmly push it back into place before tightening all thumb screws.

Also, as needed, carefully slide all racked equipment back into place before replacing any additional covers and bezels. Close any cabinet or rack doors.

Step 23. In the SAM or Partition Manager **Replace Card** window, click the **OK** button.

Clicking **OK** indicates that the card has been removed and replaced with a new card.

At this point, the card slot is powered back on, the slot attention indicator is turned off, and the driver(s) for the card are resumed to bring the card online.

However, if SAM or Partition Manager cannot bring the replacement card online then you may need to perform additional steps, as directed the SAM or Partition Manager user interface.

9 Processor Instant Capacity on Demand (iCOD)

This chapter covers using Hewlett-Packard's processor iCOD (Instant Capacity on Demand) product on nPartitions.

iCOD is an *optional* software product that enables you to instantly increase or adjust processing power within nPartitions. As you need more or fewer processors, you use iCOD tools to adjust the number of activated processors in the nPartition.

Two varieties of iCOD software and contracts are available from HP: iCOD Purchase and iCOD Utility (pay per use). Both are described in this chapter.

NOTE Using both Processor Sets (Psets) and iCOD simultaneously is supported for iCOD Purchase Version 5.0 and higher only.

NOTE For HP Superdome nPartitions running the HP virtual partitions software, only iCOD Purchase Version 5.0 and higher is supported.

5401

Introduction to Processor iCOD on nPartitions

HP's iCOD product is available for both nPartition servers and non-partitionable HP servers. This document covers iCOD issues that are unique to nPartition systems.

See the *Instant Capacity on Demand (iCOD) and Pay Per Use (PPU) User's Guide for Version B.04.x* and the *Instant Capacity on Demand (iCOD) User's Guide for Version B.05.00* for complete information about iCOD on all supported platforms.

iCOD is an *optional* product that includes an iCOD software bundle and a corresponding system contract with Hewlett-Packard, which determine the type of billing for processors you activate and use.

Billing for iCOD-activated processors is calculated on a complex-wide basis: the total number of activated iCOD processors in all nPartitions.

HP nPartition systems support two varieties of iCOD:

- **iCOD Purchase**

  iCOD Purchase enables you to instantly activate and purchase *additional* processors as your needs increase.

- **iCOD Utility (PPU: Pay Per Use)**

  iCOD Utility supports instantly increasing and decreasing the number of activated processors, for billing on a *pay per use* basis.

All nPartitions in a server complex either must run the same iCOD variety (purchase or utility) or not run iCOD. If you configure iCOD Utility for one nPartition then you also must configure all other nPartitions with iCOD Utility. HP recommends (but does not require) that you configure iCOD Purchase for all nPartitions if you configure any nPartition with iCOD Purchase.

You cannot configure nPartitions with both iCOD Utility and iCOD Purchase in the same server complex.

5400

iCOD Features for nPartitions

HP's iCOD Purchase and iCOD Utility products have some different features and behaviors on nPartition servers than iCOD on other non-partitionable systems.

The following list covers some of these unique features.

- iCOD on each nPartition is managed locally and independently.

  iCOD commands affect and list iCOD settings for the *local* nPartition (the nPartition where the commands are run).

  While there is one iCOD license for the entire server complex, iCOD processors are activated and deactivated independently for each nPartition. Each nPartition has its own settings for iCOD contact, notification, and processor configuration purposes.

- Passwords are not required for activating and deactivating iCOD processor on nPartitions.

  On nPartition servers under either iCOD contract (iCOD Purchase or iCOD Utility) you can perform all tasks that change the iCOD processor configuration for an nPartition.

  On non-partitionable systems an HP service password is required for some iCOD processor deactivation tasks.

- Both varieties of iCOD support "load balancing" processors across nPartitions in the same server complex.

  When using either iCOD Purchase or iCOD Utility, you can instantly adjust each nPartition's number of activated processors as system loads demand and maintain the same total number of activated processors in the complex.

  For example, you can deactivate processors in one underused nPartition and activate the same number of processors in another, more heavily used nPartition to load balance using the same number of processors.

  This load balancing does not change any nPartition cell assignments. Each nPartition keeps the hardware assigned to it while iCOD software in each nPartition either activates or deactivates processors.

5399

iCOD Issues for Managing nPartitions

iCOD introduces several new issues for managing nPartitions. The following list describes some of these new management issues for nPartition systems that have iCOD configured:

- At least one iCOD processor must be activated for each active cell in an nPartition.

  For example, a three-cell nPartition with iCOD must have at least three activated iCOD processors, and the iCOD software ensures that each cell has a processor activated.

- The maximum number of activated processors in an nPartition is the iCOD "requested active processors" setting.

  However, if the number of active cells is *greater than* the number of "requested active processors" then the iCOD software activates more processors than were requested: one processor is activated for each active cell in the nPartition.

- Only processors on active cells can be activated by iCOD.

  Inactive cells in an nPartition cannot have processors activated by iCOD in the nPartition. To activate processors on inactive cells, you first must make the cells active.

- Activating and deactivating processors can potentially affect software packages that rely on certain processor IDs to be present, such as certain processor set (Pset) configurations. Refer to the chapter *Processor Sets (Psets) on nPartitions* on page 419 for details.

  Likewise, changing the number of activated processors may have implications for managing software that is licensed on a per-processor basis.

- Adding or removing cells in an nPartition with iCOD does not necessarily increase or decrease the number of activated processors in the nPartition.

  The iCOD software activates the requested number of processors for an nPartition as long as the nPartition has enough configured processors to satisfy the request.

  Adding a cell to an nPartition increases the total processors and the number of configured processors in the nPartition. However, if the requested number of processors remains the same for the nPartition then the same number of activated iCOD processors are available after performing a reboot for reconfig to make the newly added cell active.

For example, in a two-cell nPartition that has six of its eight processors activated with iCOD, adding another four-processor cell brings the total processors to 12. However, the iCOD software keeps the number of activated processors at six (no change). (Other of the new cell's resources—such as memory and I/O—are made available for use in the nPartition.)

Likewise, removing a cell from an nPartition reduces the total processors and the number of configured processors in the nPartition. If enough processors remain available then the requested number of iCOD processors are activated.

When not enough processors are configured, the iCOD software activates as many processors as possible and the number of activated processors is less than the number of "requested active processors".

The sections that follow give more details for managing iCOD on nPartitions.

Tools for Managing iCOD Processors

The HP Instant Capacity on Demand (iCOD) product includes the following commands for managing iCOD settings and processor configurations. This same set of commands is used for both the iCOD Purchase and iCOD Utility products.

For details on these commands, see the *icod_modify* (1M), *icod_notify* (1M), and *icod_stat* (1M) manpages.

- `/usr/sbin/icod_modify`

  The `icod_modify` command allows you to activate and deactivate iCOD processors. This command also lets you change system contact information and apply a software license to use iCOD.

  The `-a` option activates processors and `-d` deactivates processors.

- `/usr/sbin/icod_notify`

  The `icod_notify` command allows you to request that an iCOD asset report be delivered by e-mail, and allows you to turn on or off e-mail notification of iCOD configuration changes.

  The `-n` option turns on or off automatic change notification e-mail.

- `/usr/sbin/icod_stat`

  The `icod_stat` command displays iCOD status and configuration information as well as iCOD processor usage details.

  The `-p` option gives complex-wide iCOD Purchase details on nPartition systems. The `-u` option displays the iCOD change record, listing the changes from oldest to newest.

When using the iCOD commands to activate and deactivate processors or update contact and notification details, you affect the iCOD configuration and settings for the *local nPartition* only. While some iCOD settings are stored in complex profile data, many iCOD settings are stored on disk in the iCOD configuration file (/etc/.iCOD_data). As a result, you may need to check and adjust iCOD configuration settings when booting from different disks.

When you license iCOD (by using the `icod_modify -l...` command) you can do so from *any nPartition* in the server complex. This licenses iCOD for all nPartitions in the server, and only one license is needed for the entire complex.

5395

iCOD Requirements for nPartition Servers

HP's iCOD software has the following requirements and restrictions for using and managing iCOD processors in an nPartition server complex.

- Each nPartition server complex can *optionally* be under either an iCOD Purchase contract or a pay per use (iCOD Utility) contract.

  In a server complex that is under one of these contracts, the appropriate software **must** be installed in the complex's nPartitions to support the contract.

  HP *does not* support mixing iCOD Purchase and iCOD Utility nPartitions in the same server complex.

- nPartition servers that are under an iCOD Utility contract (a pay per use "PPU" contract) **must** have iCOD Utility software installed and running on *every* HP-UX instance in the complex.

NOTE

Where multiple devices are configured for an nPartition (for example, the PRI, HAA, and ALT boot paths), each device must have iCOD Utility software installed. This applies to nPartition servers under a PPU (iCOD Utility) contract.

- Each nPartition that is under an iCOD Purchase contract **must** have iCOD Purchase software installed to enable additional processors to be activated (or to deactivate processors).

  In an iCOD Purchase complex, you *do not* have to install iCOD Purchase software on the nPartitions that are *not* under an iCOD Purchase contract. However, in this situation HP recommends that all nPartitions have iCOD Purchase software installed to allow administrators to perform "load balancing" across nPartitions.

NOTE

All potential boot disks for nPartitions with iCOD processors must have the iCOD Purchase software installed, including any alternate boot devices. This applies to nPartition servers under an iCOD Purchase contract.

5394
20

- For the iCOD software to activate processors, the processors **must** be *configured* processors on *active* cells that are *assigned* to the local nPartition

  Processors that are deconfigured cannot be activated by iCOD; they first must be configured (for example, by using the BCH Configuration menu's `CPUCONFIG` command).

  Cells that are inactive cannot have processors activated by iCOD. Each cell first must boot and complete "partition rendezvous" before it can contribute resources to the nPartition to which it is assigned.

  Likewise, cells that are unassigned cannot have processors activated by iCOD. Each cell must be assigned to an nPartition and must be an active member of its nPartition before its resources can be used.

5393

Installing and Configuring iCOD on nPartitions

NOTE This section describes iCOD software install and configuration for an nPartition server complex.

You also must establish a contract with HP for either iCOD Purchase or iCOD Utility (pay per use) to properly use this software product.

Software bundles for iCOD Purchase and iCOD Utility are available on the Support Plus media and at the `http://software.hp.com` Web site.

For complete details on installing and using iCOD software, refer to the *Instant Capacity on Demand (iCOD) and Pay Per Use (PPU) User's Guide for Version B.04.x* and the *Instant Capacity on Demand (iCOD) User's Guide for Version B.05.00*.

The following procedure gives an overview of initially installing and configuring iCOD Purchase or iCOD Utility on an nPartition server complex.

iCOD Installation and Configuration

Step 1. Install the appropriate iCOD software bundle on all required nPartitions in the server complex.

On nPartition server complexes that have iCOD Purchase contracts, you must install the iCOD Purchase software on those nPartitions in the complex that have iCOD processors. (For greater flexibility in load balancing iCOD processors HP recommends installing iCOD Purchase software on all nPartitions.)

On nPartition servers that have iCOD Utility (pay per use) contracts, you must install the iCOD Utility software on *every* nPartition in the complex.

If you expect to boot an nPartition from different devices—even on rare occasions—you must install the appropriate iCOD software bundle on all potential boot devices (such as the devices at the PRI, HAA, and ALT boot paths).

5392

Step 2. [*An HP service representative must perform this step.*]

Validate the server complex as an iCOD server.

Step 3. Configure `sendmail` so that it can send e-mail to an HP mail server that is outside of your company's firewall.

HP iCOD software sends encrypted e-mail from the local nPartition running iCOD to HP for billing purposes and to request licensing information. Details on `sendmail` configuration are in the user's guide for iCOD.

You must configure `sendmail` on all nPartitions that have iCOD software installed. On nPartitions with multiple boot devices, configure `sendmail` for each boot device.

Step 4. Configure the iCOD contact information for each nPartition that has iCOD software installed, using the `icod_modify -c...` command.

This specifies the person who will receive iCOD licensing e-mail from HP and iCOD configuration change notices. For example:

```
# icod_modify -c "Joe Doe":joe@company.com:555-5555
```

On nPartitions with multiple boot devices, configure the the iCOD contact information for each boot device, in case alternate devices (such as HAA or ALT) are booted.

Step 5. [*This step needs to be performed only once for the entire server complex.*]

Request a license by issuing the `icod_notify` command (with no options) in any nPartition that has iCOD, `sendmail`, and the contact information configured.

The `icod_notify` command sends an iCOD asset report to HP and to the iCOD contact and `root` for the nPartition. After HP receives the asset report a confirmation e-mail, which contains the iCOD license key, is sent to the iCOD contact.

Apply the license for iCOD by issuing the `icod_modify -l...` command. For example:

```
# icod_modify -l AABBCCDD
```

where *AABBCCDD* is the iCOD license key given in the confirmation e-mail. You only need to apply the iCOD license once for the entire server complex.

5391

Step 6. Use iCOD features: list iCOD statistics with `icod_stat` and, when required, activate or deactivate processors.

To list iCOD configuration details for the local nPartition, use the `icod_stat` command (with no options).

For an nPartition complex that has iCOD Purchase configured for multiple nPartitions, you also can use the `icod_stat -p` command to display iCOD processor usage statistics for all nPartitions in the server complex. (The `-p` option does not give more information for iCOD Utility configurations or for non-nPartition configurations.)

See *Procedures for Changing Processor iCOD Configurations on nPartitions* on page 409 for details on managing an nPartition's iCOD processors.

Ne

5390

Procedures for Changing Processor iCOD Configurations on nPartitions

This section covers the following procedures for changing the iCOD configuration on nPartitions. These procedures apply for both iCOD Purchase and iCOD Utility software and contracts.

- *Activating and Deactivating Processors with iCOD* on page 410

  This procedure (using the icod_modify -a... or icod_modify -d... command) activates or deactivates processors in an nPartition with iCOD.

- *Setting the Total Number of Requested Active Processors* on page 411

  This procedure (using the icod_modify -s... command) sets the total number of requested active processors for an nPartition with iCOD software installed and configured.

- *Load Balancing Processors across nPartitions with iCOD* on page 412

  This procedure (using both the icod_modify -d... and icod_modify -a... commands) adjusts the balance of activated processors across two nPartitions in the same server complex: deactivate processors in one nPartition and activate the same number of processors in another nPartition.

- *iCOD Contract Changes for an nPartition Server Complex* on page 413

  This procedure describes how to change your existing iCOD contract to either iCOD Purchase or iCOD Utility by contacting HP sales or support representatives.

- *Removing iCOD Software and Functionality from nPartitions* on page 414

  This procedure describes how to remove iCOD software and functionality from an nPartition server complex after completing your iCOD purchasing and contract obligations.

5389

NOTE The following nPartition changes also can cause iCOD software to activate a different number or set of the nPartition's processors: adding and removing cells from an nPartition, making cells active or inactive, or configuring or deconfiguring processors from cells in the nPartition.

Activating and Deactivating Processors with iCOD

This procedure (using the `icod_modify -a...` or `icod_modify -d...` command) activates or deactivates processors in an nPartition with iCOD.

NOTE Activating or deactivating processors can affect your billing for iCOD services.

On systems with HP processor set (Pset) software installed: *newly activated* processors are assigned to the default Pset, and deactivated processors are removed from the Pset to which they were assigned.

HP's iCOD software selects processors for activation or deactivation by following the appropriate processor installation order for the machine type. The iCOD utilities select processors based on their *physical location* in the server (not their HP-UX CPU IDs).

For example, on HP Superdome servers the processor install order for each cell is: first processor slot 0, then slots 3, 1, and 2.

As a result, all active cells in a Superdome nPartition always have processor 0 activated because a minimum of one processor must be activated per cell. Then, as needed to meet the iCOD "requested active processors" number for the nPartition, each cell's "processor 3" slot is activated, then each cell's "processor 1" slot, and finally the "processor 2" slots.

Step 1. Login to the nPartition in which you will be activating or deactivating processors.

You can activate or deactivate processors in only the *local* nPartition (the nPartition in which you issue the `icod_modify` command).

5388
2l

Step 2. Issue the `icod_modify` command with either the `-a #` option (to activate # processors) or `-d #` option (to deactivate # processors).

You must include the following details after the `-a` or `-d` option. This information is recorded in the nPartition's iCOD change log.

`[`*`description`*`]:`*`user_name`*`:`*`mgr_name`*`:`*`mgr_email`*`:`*`mgr_phone`*

These details provide an optional description of the change, the name of the user/person making the change, and the authorizing manager, manager's e-mail address, and manager's phone number.

For example, to activate two processors (`-a 2`):

```
# icod_modify -a 2 "two CPUs added":Ann:Joe:jdoe@comp.com:555-5555
```

In the next example, one processor is deactivated (`-d 1`):

```
# icod_modify -d 1 "one less CPU":Ann:Joe:jdoe@comp.com:555-5555
```

See also the *icod_modify* (1M) manpage for details.

Step 3. As desired, issue the `icod_stat` command to list the new processor configuration details for the local nPartition.

Setting the Total Number of Requested Active Processors

This procedure (using the **`icod_modify -s...`** command) sets the total number of requested active processors for an nPartition with iCOD software installed and configured.

Performing this procedure can increase or decrease the number of activated processors in an nPartition.

NOTE Activating or deactivating processors can affect your billing for iCOD services.

On systems with HP processor set (Pset) software installed: *newly activated* processors are assigned to the default Pset, and deactivated processors are removed from the Pset to which they were assigned.

Step 1. Login to the nPartition in which you will be activating or deactivating processors.

S387

You can activate or deactivate processors in only the *local* nPartition (the nPartition in which you issue the `icod_modify` command).

Step 2. Issue the `icod_modify -s...` command and specify the number of processors to be activated.

You must include the following details after the `-s` option. This information is recorded in the nPartition's iCOD change log.

[*description*]:*user_name*:*mgr_name*:*mgr_email*:*mgr_phone*

For example, the following command sets the number of "requested active processors" to 10, which may increase or decrease the number of activated processors in the nPartition (depending on the number of processors available before the command is issued).

```
# icod_modify -s 10 "activate 10 CPUs total":Ann:Joe:jdoe@comp.com:555-5555
```

See also the *icod_modify* (1M) manpage for details.

Step 3. As desired, issue the `icod_stat` command to list the new processor configuration details for the local nPartition.

Load Balancing Processors across nPartitions with iCOD

This procedure (using both the **`icod_modify -d...`** and **`icod_modify -a...`** commands) adjusts the balance of activated processors across two nPartitions in the same server complex: deactivate processors in one nPartition and activate the same number of processors in another nPartition.

NOTE

After "load balancing" processors across nPartitions, each nPartition still has the same cells and processors assigned to it.

However, this procedure reduces the number of activated processors in the first nPartition and increases (by the same amount) the number of activated processors in the second nPartition.

This procedure does not affect your billing for iCOD services *if*: the total number of activated processors in the complex does not change *and* the operations are not performed by HP service representatives.

Both nPartitions must have iCOD software installed and configured.

Also, both nPartitions must have enough activated or deactivated processors to accommodate the reduction or increase in processors.

Step 1. Login to the first nPartition and deactivate the number of processors you plan to activate in the second nPartition.

See the procedure *Activating and Deactivating Processors with iCOD* on page 410, and use the `icod_modify -d...` command to deactivate the processors.

If HP processor set (Pset) software is installed, deactivating processors removes the corresponding CPU IDs from the Pset to which they were assigned.

Step 2. Login to the second nPartition and activate the same number of processors you deactivated in the previous step.

See the procedure *Activating and Deactivating Processors with iCOD* on page 410 and use the `icod_modify -a...` command to activate the processors.

If HP processor set (Pset) software is installed, the newly-activated processors are assigned to the local nPartition's default Pset.

iCOD Contract Changes for an nPartition Server Complex

This procedure describes how to change your existing iCOD contract to either iCOD Purchase or iCOD Utility by contacting HP sales or support representatives.

Changing the type of iCOD contract for a server complex will affect your billing for iCOD services.

Step 1. Contact your HP sales or support representatives and request an iCOD contract and software change.

Changing the type of iCOD contract and software will require that an HP service representative alter the iCOD software configuration for all nPartitions affected by the change.

For nPartitions that have multiple boot devices (such as PRI, HAA, and ALT), HP iCOD software bundles on every boot device must be updated.

5385

Step 2. Consider any software licensing issues or nPartition system configuration issues that you must address when changing from iCOD Purchase to iCOD Utility (pay per use) or vice versa.

For example, some nPartitions may have different sets of processors activated as a result of the change. Or, in the case of a pay per use (iCOD Utility) contract, the set of activated processors in each nPartition may change on an ongoing basis.

Such changes could potentially affect HP processor set (Pset) configurations, or the configuration of HP Process Resource Manager (PRM) or HP Workload Manager (WLM) software.

Removing iCOD Software and Functionality from nPartitions

This procedure describes how to remove iCOD software and functionality from an nPartition server complex after completing your iCOD purchasing and contract obligations.

For more details, see the *Instant Capacity on Demand (iCOD) and Pay Per Use (PPU) User's Guide for Version B.04.x* and the *Instant Capacity on Demand (iCOD) User's Guide for Version B.05.00*.

Step 1. Confirm that all processors in all nPartitions in the server complex are activated and purchased.

All processors in the complex are activated when: for every nPartition the "requested active processors" equals the "total processors". You can check this by issuing the `icod_stat` command in each nPartition.

If you have a server complex that is under an iCOD Purchase contract, you also must have paid the enablement fee for all processors. Confirm this with your HP sales or service representative.

If your server complex is under an iCOD Utility (pay per use) contract, you must check with your HP sales or service representative to determine if you have met all contract requirements.

Step 2. After confirming with HP that you have completed all requirements, use the `swremove` command to uninstall the iCOD Purchase or iCOD Utility bundle.

5384

You must remove the bundle from every nPartition that no longer is under contract. In the case of iCOD Utility contracts this involves removing the bundles from all nPartitions.

On nPartitions where iCOD software is installed on multiple boot devices (such as PRI, HAA, and ALT) you should remove the bundle from all devices.

See the iCOD documentation and the *swlist* (1M) and *swremove* (1M) manpages for details.

5383

Managing iCOD Utility (Pay Per Use) on nPartitions

This section describes several methods of managing processor resources for a server complex that is under a pay per use (iCOD Utility) contract.

If your server complex is under an iCOD Utility contract then you are billed for *all activated* processors in the whole nPartition server complex.

The pay per use iCOD Utility contract enables you to manage processor resources in the complex in such a way that you only pay for the amount of processor resources that you actually require.

When you have processors in an nPartition complex that you do not need, you can exclude those processors from billing by *deactivating* processors, by making processors *inactive*, or by *deconfiguring* processors.

These three methods of excluding processors from pay per use billing are discussed here. See the *Deactivated Processors*, *Inactive Processors*, and *Deconfigured Processors* sections that follow.

Tips for Pay Per Use Processor Management

- The recommended method for activating and deactivating processors on nPartitions is to use the `icod_modify` command. This command instantly increases or decreases the number of available processor resources in the nPartition without requiring a reboot.

  For example, if an nPartition is underused—as when most of the nPartition's processors are constantly idle—you could deactivate unneeded processors by using the `icod_modify -d...` command.

- When an entire nPartition in a complex is unused you can exclude that nPartition's processors from billing by making the nPartition inactive.

  For example, if an nPartition is not running HP-UX but is "just sitting at the BCH interface" you could reset the nPartition to the ready for reconfig state by using the BCH `RECONFIGRESET` command to make the nPartition inactive. (When an nPartition is running HP-UX, using the `shutdown -R -H` command makes the nPartition inactive.)

When an nPartition is inactive, all its cells and processors are inactive and cannot be used until the nPartition is booted (using the GSP or MP Command menu's BO command).

- Individual cells that are *inactive* are not billed for iCOD Utility purposes, because all processors on inactive cells also are inactive.

  This includes unassigned cells, as well as cells that have not participated in "partition rendezvous" for their assigned nPartition (for example: newly-added cells or cells that had a "n" use-on-next-boot value when the nPartition last booted).

Deactivated Processors

A **deactivated processor** is one that has been "turned off" by the nPartition's iCOD software, perhaps as a result of the `icod_modify -d...` command. Deactivated processors can be activated instantly by using the `icod_modify -a...` command.

The iCOD software selects which processors are activated and deactivated and chooses processors based on their physical locations.

For details, see the procedures in *Activating and Deactivating Processors with iCOD* on page 410.

Inactive Processors

An **inactive processor** is a processor that is in an inactive cell and thus is at a boot is blocked (BIB) state.

The following examples describe situations where both cells and processors are inactive (and thus are not subject to iCOD Utility billing):

- All processors on a cell that is not assigned to an nPartition are inactive.
- All processors on a cell that did not participate in "partition rendezvous" for its nPartition are inactive.

  You can make a cell inactive either by unassigning it from an nPartition, or by setting the cell's use-on-next-boot value to "n" (meaning: do not use the cell) and rebooting the cell's nPartition.
- All processors on cells that are assigned to an inactive nPartition are inactive.

  You can make all processors in an nPartition inactive by resetting the nPartition to the ready for reconfig state. In an inactive nPartition, all cells are inactive and thus all processors on cells in the nPartition are inactive.

3381

> To put an nPartition in the inactive, ready for reconfig state: if HP-UX is running use the `shutdown -R -H` command, or if at the Boot Console Handler (BCH) interface use the `RECONFIGRESET` command.

None of an inactive cell's resources (processors, memory, or any I/O connected to the cell) are available for use in an nPartition. For the cell's processors and other hardware resources to be used, the cell must be *assigned* and *active* in an nPartition.

Deconfigured Processors

A **deconfigured processor** is a processor that has been made unavailable for use by its nPartition through settings enabled by Boot Console Handler (BCH) menu commands.

You can deconfigure processors using the BCH Configuration menu's `CPUCONFIG` command. Also use this command to configure processors that have been deconfigured.

Using BCH commands to configure and deconfigure processors requires rebooting the nPartition in which the processors reside. For this reason deconfiguring processors is *not the recommended method* of making processors inactive for iCOD purposes.

Instead, the recommended method is to deactivate processors using the `icod_modify -d...` HP-UX command, which can instantly make processors deactivated and activated without rebooting.

S380

10 Processor Sets (Psets) on nPartitions

This chapter describes how to use and manage processor sets (Psets) on nPartition systems.

Using Psets, you can create multiple independent processor groups in an nPartition. Each Pset has its own processors, schedules, and attributes. Because Psets are dynamic, you can create, modify, and destroy Psets instantly as your system needs demand.

HP's processor set software is an *optional* package that is free for all HP-UX 11i systems and is available at the `http://software.hp.com` Web site.

The same Pset features are available on all HP-UX 11i systems, including both non-partitionable systems and nPartitions servers.

On nPartition servers, however, you should be aware of the nPartition system configuration issues that can affect your use of processor sets. This chapter covers special configuration issues for Psets in nPartition environments.

NOTE Using both Processor Sets (Psets) and iCOD simultaneously is supported for iCOD Purchase Version 5.0 and higher only.

S379

Introduction to Psets

HP's processor set (Pset) product is an optional software package that runs on any HP-UX 11i system, including all nPartition servers. The Pset software package is free and is available from the **`http://software.hp.com`** Web site.

Each processor set (Pset) is a group of active processors that functions as an independent *scheduling allocation domain*. When the Pset software is installed, you can establish multiple Psets in a single HP-UX system.

By dividing the active processors in an nPartition into multiple Psets, you can provide processor resource isolation for applications that run in each Pset. Each application only has access to the processors assigned to the Pset in which it runs.

You can dynamically create and reconfigure Psets using the `psrset` command or HP's Process Resource Manager (PRM). You also can launch each thread or process to run in a specific Pset and can manually migrate threads and processes to different Psets while they run.

Thread and Process Pset Bindings

In systems where Pset software is installed, every thread and process is bound to only one Pset at a time.

Applications are not migrated to different Psets unless you have configured PRM to do so, or if you manually bind a process to a different Pset using the `psrset` command.

HP-UX load balancing occurs within each Pset. Because load balancing does not occur across Psets, processors in one Pset can potentially be oversubscribed while processors in another Pset are nearly idle. This is an aspect of the processor resource isolation that Psets provide.

Both real-time and time-share schedulers are supported for processor sets and each Pset has its own schedulers. So, for example, real-time processes in one Pset only contend for processors in the Pset in which they are running.

Use of the HP-UX gang scheduler is supported only in the default Pset (processor set ID 0), as of the current Pset software release. See the *gang_sched* (7) manpage or the *mpsched* (1) manpage for details on using gang scheduling.

HP-UX Processor Numbering and Availability on nPartitions

The HP-UX operating system number processors from 0 to n-1, where n is the number of configured processors on active cells in an nPartition.

Each physical processor is not necessarily given the same logical HP-UX processor ID each time the nPartition is booted. HP-UX processor IDs are assigned on a first-come first-numbered basis. As a result, even if an nPartition's processor configuration does not change, the correlations from physical processors to logical HP-UX processor IDs may change when HP-UX is rebooted in the nPartition.

This list gives details on how processors are available and numbered by HP-UX running on nPartitions.

- The following processors are *numbered* and are *available*: processors that are configured, reside on active cells, and (if HP's iCOD software is configured) are activated by iCOD.
- Processors that are *deconfigured* are not available and are not numbered by HP-UX.

  For deconfigured processors to be available they first must be configured using the nPartition's Boot Console Handler (BCH) interface.

  For details refer to the chapter *Listing and Managing Server Hardware* on page 305.
- Processors on *inactive cells* are not available and are not numbered by HP-UX. The cells must be active and must have configured processors in order to contribute processors to the nPartition.
- Processors that have been *deactivated* by HP's Instant Capacity on Demand (iCOD) software *are* numbered by HP-UX but are not available to be used until they are activated by iCOD.

  This means that when iCOD has deactivated one or more processors, some processors were numbered by are not listed in output displayed by commands such as `mpsched -s`, `top`, or `sar`.

  For example, the `mpsched` output below shows that processors 1, 2, 5, 6 and possibly others are deactivated. (To view more iCOD details use `icod_stat`.) Refer to the chapter *Processor Instant Capacity on Demand (iCOD)* on page 397 for details.

  ```
  # mpsched -s
  System Configuration
  =====================
  Locality Domain Count: 1
  ```

5377

```
Processor Count       : 5

Domain     Processors
------     ----------
0          0   3   4   7   8
#
```

The System Default Pset

When Pset software is installed, a *system default Pset* always exists that gives all users access to the processors assigned to it. The default Pset is Pset 0, which always has at least processor ID 0 assigned to it.

All processors are initially assigned to the default Pset until you configure processors to belong to other Psets.

When a Pset is destroyed or when a processor is removed from a Pset, the processors involved are assigned back to the default Pset.

Pset Attributes and Access Permissions

Each Pset has attributes that configure the Pset's behavior in various situations. These attributes also include "owner, group, and others" access permissions similar to traditional HP-UX file permissions. The default Pset's attributes cannot be changed, but all other Psets can have their attributes adjusted as needed.

Users who have write access for a Pset can modify *some* of the Pset's attributes, including attributes other than the access permissions. Each Pset's owner can modify the Pset's access permissions.

The following users can modify *all aspects* of all non-default Psets in a system: `root`, `superuser`, and users who belong to a group that has the `PSET` privileged capability. These users can modify all Pset attributes, modify all Pset processor assignments, and can create and destroy Psets.

The `PSET` privileged capability is established for a group by issuing the `setprivgrp` command. For example, `setprivgrp mygrp PSET` applies this privilege (and no other privileges) to the "mygrp" group. See the *setprivgrp* (1M) manpage for details.

Pset Boot-Time Configuration

When HP-UX boots on an nPartition that has Pset software installed, by default all processors are assigned to the default Pset: Pset 0.

You can have multiple Psets established at boot time either by creating HP-UX startup scripts that configure Psets, or by configuring Psets through PRM and having PRM establish configurations at boot time.

Pset Binding and Inheritance

Child threads and processes inherit the Pset bindings of their parents.

So, for example, when a process creates child processes, the children are are launched into the same Pset as the parent.

By using the Pset programming interface you can have more control over the Pset locations where threads and processes are spawned and run.

Using PRM on nPartitions with Psets

The HP Process Resource Manager product enables you to create and manage Psets through its graphical interface.

PRM provides the ability to maintain Pset configurations across system reboots. It also has the ability to assign (isolate) memory to Psets, thus giving Psets memory isolation as well as processor resource isolation.

PRM software refers to Psets that it tracks using PRM IDs or names, rather than using Pset IDs. PRM may modify Psets and cause them to be renumbered while managing Psets. Thus, if you use the `psrset -i` command while PRM has configured Psets, you may notice this renumbering of Pset IDs.

Note that if you have used PRM to assign specific processor IDs to Psets in the system, all specified processor IDs *must be present* for PRM to be able to load and establish the Pset configurations. Otherwise, when specified processors are not present, PRM cannot create the Psets.

You can help avoid this potential problem by not specifying processor IDs and instead specifying the *number of processors* for PRM to configure in each Pset.

This processor availability issue can prevent PRM from loading Pset configurations when iCOD software in an nPartition has *deactivated* one or more of the specified processors.

PRM also may be prevented from loading Pset configurations when any of the following has occurred in an nPartition: *deconfiguring* processors (at the BCH interface), *unassigning* a cell from an nPartition, or making one or more of an nPartition's cells *inactive*.

For details on managing PRM, see the PRM online help or *HP Process Resource Manager User's Guide*. Also see the *psrset* (1M) manpage for details on using the `-f` option while PRM is managing Psets.

Programming Interface for Psets

For details on the Pset programming interface, see the following HP-UX manpages: *pset_assign* (2), *pset_bind* (2), *pset_create* (2), *pset_ctl* (2), *pset_destroy* (2), *pset_getattr* (2), *pset_setattr* (2).

53>5

Tools for Managing and Using Psets

This section lists several tools for managing Psets.

For details, see these manpages: *psrset* (1M), *xprm* (1), *prmconfig* (1), *mpsched* (1), *rtsched* (1), *sar* (1M), *setprivgrp* (1M), and *getprivgrp* (1).

- `/usr/sbin/psrset`

  This command provides the main command-line interface for Psets.

- HP Process Resource Manager (PRM):
  `/opt/prm/bin/xprm` and
  `/opt/prm/bin/prmconfig`

  These commands provide graphical (`xprm`) and command-line (`prmconfig`) interfaces to PRM, which has built-in support for Psets.

- `/usr/bin/mpsched`

  This command provides a method for launching and managing time-share processes and threads, allowing for processor binding and unbinding, enabling gang scheduling, and inquiring about system and process attributes.

- `/usr/bin/rtsched`

  This command provides a method of launching real-time threads and processes.

- `/usr/sbin/sar`

  This command reports system activity, including Pset activity when the `-p` *`pset`* option or `-P` option is specified.

  For example, `sar -u -M -P 5` gives a snapshot of system processor use over a five second period, and because `-P` is specified Pset assignments are included.

- `/usr/sbin/setprivgrp` and
  `/usr/bin/getprivgrp`

  The `setprivgrp` command sets privileged capabilities for a specified group. When issuing this command, you must list all privileged capabilities that are to be applied for the group. For example: `setprivgrp mygrp PSET RTSCHED` grants special Pset and real-time scheduling capabilities to the members of the "mygrp" group.

To remove privileged capabilities for a group, issue the `setprivgrp` command with no capabilities specified (for example: `setprivgrp mygrp`).

The `getprivgrp` command reports privileged capabilities for the user issuing the command.

5373

Procedures for Managing Psets

This section lists only the psrset command-line procedures for managing Psets.

The common Pset tasks briefly given here are:

- *Listing Pset Configurations* on page 426
- *Creating a New Pset* on page 426
- *Destroying (Deleting) a Pset* on page 427
- *Assigning (Reassigning) Processors to Psets* on page 427
- *Unassigning (Removing) Processors from Psets* on page 427
- *Configuring Pset Attribute Values* on page 427
- *Setting Pset Access Permissions* on page 428
- *Running Programs in a Pset* on page 429
- *Binding Threads and Processes to a Pset* on page 429

Also see the *psrset* (1M) manpage for details, or see *Example Uses of Psets* on page 430 for command output and examples.

For details on support for Psets in HP Process Resource Manager (PRM) refer to the book *HP Process Resource Manager User's Guide* or the PRM online help.

Listing Pset Configurations

Step 1.

```
/usr/sbin/psrset -i
```

This lists all Psets defined in the system including the processors assigned to each and the owner, access permissions, and attributes for the Psets.

Creating a New Pset

Step 1.

```
/usr/sbin/psrset -c [processor_list]
```

where *processor_list* is an optional list of processors that are assigned to the newly created Pset.

S372

Destroying (Deleting) a Pset

Step 1.

```
/usr/sbin/psrset -d [pset_list | all]
```

where you specify either `all` (to delete all Psets) or a list of the Psets to be deleted (*`pset_list`*).

When you delete a Pset, the Pset's ID no longer exists and all processors assigned to the Pset are assigned to the default Pset. Deleting all Psets (`psrset -d all`) causes all processors to be assigned to the default Pset (Pset ID 0), which then is the only Pset in the system.

The user issuing this command must have write permission for the Psets that are deleted.

Assigning (Reassigning) Processors to Psets

Step 1.

```
/usr/sbin/psrset -a pset_id processor_list
```

where *`pset_id`* is the Pset to which the processors specified in *`processor_list`* are assigned.

The user issuing this command must have write permission for both the Pset specified by *`pset_id`* and the Pset(s) to which the processors in *`processor_list`* are assigned.

Unassigning (Removing) Processors from Psets

Step 1.

```
/usr/sbin/psrset -r processor_list
```

where *`processor_list`* is the list of processors that will be removed from their current Psets and assigned to the default Pset.

The user issuing this command must have write permission for the Pset(s) to which the processors in *`processor_list`* are assigned.

Configuring Pset Attribute Values

To configure access permissions (OWNID, GRPID, PERM) you must have root or superuser access or membership in a group that has PSET privileged capabilities.

537

You cannot modify attributes for Pset ID 0.

Step 1. `/usr/sbin/psrset -t pset_id attr_name=attr_value`

where *pset_id* is the Pset whose attribute(s) will be configured.

Each attribute (*attr_name*) is set to the corresponding value (*attr_value*) specified.

Attributes include OWNID, GRPID, PERM, and others listed in the *psrset* (1M) manpage.

Step 2. `/usr/sbin/psrset [-n | -F] pset_id`

where *pset_id* is the Pset for which external I/O interrupts are either enabled (-n) or disabled (-F).

When configuring attributes other than access permissions, the user issuing these commands must have write permission for the Psets specified.

Setting Pset Access Permissions

Step 1. Use the psrset command's -t option, as described in *Configuring Pset Attribute Values* on page 427.

To configure access permissions (OWNID, GRPID, PERM), you must have root or superuser access or membership in a group that has PSET privileged capabilities.

Specify the PERM attribute and corresponding value to set access permissions.

```
/usr/sbin/psrset -t pset_id PERM=p1p2p3
```

where *pset_id* is the Pset and *p1p2p3* is the set of access permissions for the Pset owner (*p1*), Pset group (*p2*), and others (*p3*).

Each access permission (owner, group, and others) is a number from 0–7 to indicate execute (x), write (w), and/or read (r) permissions.

0=no permissions, 1=x, 2=w, 3=xw, 4=r, 5=xr, 6=wr, 7=xwr

Execute allows running programs in the Pset, write allows changing the Pset configuration, and read allows reading the Pset configuration.

For example “PERM=754” gives the Pset owner execute, write, and read permissions; gives members of the Pset’s group execute and read permissions; and gives other users only read permission.

You also can specify attributes and values to change the owner (OWNID) and group (GRPID) for the Pset.

Running Programs in a Pset

Step 1. `/usr/sbin/psrset -e pset_id command [arguments]`

where *pset_id* is the Pset in which the specified *command* will be executed.

As needed, specify *arguments* to list any command-line options or arguments for the command.

The user issuing this command must have execute permission for the Pset in which the command is run.

Binding Threads and Processes to a Pset

Step 1. `/usr/sbin/psrset -b pset_id pid_list`

where *pset_id* is the Pset in which the specified process IDs (*pid_list*) will be bound.

The user issuing this command must have execute permission for both the original and new Psets in which the process ID executes.

Example Uses of Psets

NOTE

These examples show the use of processor sets (Psets) on an HP Superdome server that also has HP Instant Capacity on Demand (iCOD) “pay per use” software installed.

Uses of the optional HP iCOD software commands are noted in the text accompanying the examples.

For iCOD management information, refer to the chapter *Processor Instant Capacity on Demand (iCOD)* on page 397.

The following Pset examples are given in this section.

- *Listing, Creating, and Using Psets* on page 430
- *Destroying a Pset and Reassigning Processors* on page 432
- *Example of Running and Binding Programs in Psets* on page 434
- *Managing Pset Permissions and Attributes* on page 436

Example 10-1 Listing, Creating, and Using Psets

Initially this nPartition has only one Pset: the default Pset, which is Pset 0.

```
# psrset -i
PSET         0
SPU_LIST     0    1    2    3    4    5    6    7    8    9    10   11
OWNID        0
GRPID        0
PERM         755
IOINTR       ALLOW
NONEMPTY     DFLTPSET
EMPTY        FAIL
LASTSPU      DFLTPSET

#
```

S368

The icod_modify command sets the total number of processors to four. As the psrset -i command shows, this reduces the number of processors that are available and assigned to Psets. Note that processor IDs (listed in the SPU_LIST) are *not sequentially numbered* because several processors have been deactivated by the iCOD software.

```
# icod_modify -s 4 "set to 4":Ann:Joe:jdoe@comp.com:555-5555

4 processors are now active.

NOTE:    Verify that HP and 3rd party software licenses are upgraded
         to take into account the number of active processors.

# psrset -i
PSET         0
SPU_LIST     0     3     4     8
OWNID        0
GRPID        0
PERM         755
IOINTR       ALLOW
NONEMPTY     DFLTPSET
EMPTY        FAIL
LASTSPU      DFLTPSET

#
```

Create a new Pset using processor IDs 4 and 8, using the psrset -c... command. Then list all Psets using the psrset -i command.

```
# psrset -c 4 8
successfully created pset 2
successfully assigned processor 4 to pset 2
successfully assigned processor 8 to pset 2
# psrset -i
PSET         0
SPU_LIST     0     3
OWNID        0
GRPID        0
PERM         755
IOINTR       ALLOW
NONEMPTY     DFLTPSET
EMPTY        FAIL
LASTSPU      DFLTPSET

PSET         2
SPU_LIST     4     8
OWNID        0
GRPID        3
PERM         755
IOINTR       ALLOW
```

536

```
NONEMPTY     DFLTPSET
EMPTY        FAIL
LASTSPU      DFLTPSET

#
```

Example 10-2 Destroying a Pset and Reassigning Processors

List the local nPartition's Pset configuration using the `psrset -i` command. There are three Psets: the default Pset 0, Pset 10, and Pset 11.

```
# psrset -i
PSET         0
SPU_LIST     0     1     2     3     4
OWNID        0
GRPID        0
PERM         755
IOINTR       ALLOW
NONEMPTY     DFLTPSET
EMPTY        FAIL
LASTSPU      DFLTPSET

PSET         10
SPU_LIST     9     10    11
OWNID        0
GRPID        3
PERM         755
IOINTR       ALLOW
NONEMPTY     DFLTPSET
EMPTY        FAIL
LASTSPU      DFLTPSET

PSET         11
SPU_LIST     5     6     7     8
OWNID        0
GRPID        3
PERM         755
IOINTR       ALLOW
NONEMPTY     DFLTPSET
EMPTY        FAIL
LASTSPU      DFLTPSET

#
```

Destroy Pset 10 because it is no longer needed. Its processors (9, 10, and 11) are assigned back to the default processor set (Pset 0). Then list the new Pset configurations using the `psrset -i` command.

5366

```
# psrset -d 10
successfully destroyed pset 10
# psrset -i
PSET         0
SPU_LIST     0    1    2    3    4    9    10   11
OWNID        0
GRPID        0
PERM         755
IOINTR       ALLOW
NONEMPTY     DFLTPSET
EMPTY        FAIL
LASTSPU      DFLTPSET

PSET         11
SPU_LIST     5    6    7    8
OWNID        0
GRPID        3
PERM         755
IOINTR       ALLOW
NONEMPTY     DFLTPSET
EMPTY        FAIL
LASTSPU      DFLTPSET

#
```

Assign processors 4 and 9 to Pset 11 using the `psrset -a...` command. Then list the new Pset configurations using `psrset -i`, which shows the processor assignments for all Psets (Pset 0 and Pset 11).

```
# psrset -a 11 4 9
successfully assigned processor 4 to pset 11
successfully assigned processor 9 to pset 11
# psrset -i
PSET         0
SPU_LIST     0    1    2    3    10   11
OWNID        0
GRPID        0
PERM         755
IOINTR       ALLOW
NONEMPTY     DFLTPSET
EMPTY        FAIL
LASTSPU      DFLTPSET

PSET         11
SPU_LIST     4    5    6    7    8    9
OWNID        0
GRPID        3
PERM         755
IOINTR       ALLOW
NONEMPTY     DFLTPSET
EMPTY        FAIL
```

5365

```
LASTSPU      DFLTPSET

#
```

Example 10-3 Example of Running and Binding Programs in Psets

List the current Pset configuration for the local nPartition. Two Psets are configured: Pset 0 and Pset 2.

Note that processor ID 10 is not active in this nPartition (because iCOD software has deactivated it).

```
# psrset -i
PSET         0
SPU_LIST     0    2    9
OWNID        0
GRPID        0
PERM         755
IOINTR       ALLOW
NONEMPTY     DFLTPSET
EMPTY        FAIL
LASTSPU      DFLTPSET

PSET         2
SPU_LIST     1    3    4    5    6    7    8    11
OWNID        0
GRPID        3
PERM         755
IOINTR       ALLOW
NONEMPTY     DFLTPSET
EMPTY        FAIL
LASTSPU      DFLTPSET

#
```

Use the mpsched command to run the “potato” program and bind it to processor ID 2. Then use the psrset -q... command to list the Pset binding for “potato” (process ID 10368); “potato” is bound to Pset 0.

```
# mpsched -c 2 ./potato -n 7
Pid 10368: bound to processor 2 using the default process launch policy
Threads = 7
tid = 2  cpu = 2
tid = 3  cpu = 2
tid = 4  cpu = 2
tid = 5  cpu = 2
tid = 6  cpu = 2
tid = 7  cpu = 2
tid = 1  cpu = 2
```

```
# psrset -q 10368
PID  10368         PSET  0
#
```

Use the psrset -b... command to change the Pset binding for “potato” to Pset 2. Then use psrset -q... to confirm that it is bound to Pset 2, and use the mpsched -q... command to check its processor binding.

```
# psrset -b 2 10368
successfully bound pid 10368 to pset 2
# psrset -q 10368
PID  10368         PSET  2
# mpsched -q -p 10368
Pid 10368: bound to processor 3 using the default process launch policy
#
```

Use the sar command to list the current nPartition’s processor usage, including Pset details. Note that processor ID 3 in (Pset 2) is heavily loaded by the “potato” program.

```
# sar -u -M -P 1

HP-UX feshd5a B.11.11 U 9000/800    10/23/01

00:17:11    pset     cpu    %usr    %sys    %wio   %idle
00:17:12       0       0       0       0       7      92
               2       1       0       0      10      90
               0       2       0       0       8      92
               2       3     100       0       0       0
               2       4       0       0       4      96
               2       5       0       0       8      92
               2       6       0       0       7      93
               2       7       0       0       9      91
               2       8       0       0       5      95
               0       9       0       1       9      90
               2      11       0       0       8      92
                  system       9       0       7      84
#
```

Use the mpsched -u... command to *unbind* the “potato” program (process ID 10368) from processor ID 3, to allow the program’s threads to migrate to other processors in the Pset to which it is bound.

Then use sar to list the local nPartition’s current processor usage, including all processor and Pset details.

Since the “potato” program was unbound from processor 3, its threads were able to migrate to the other processors in the Pset to which it “potato” is bound (Pset 2).

S363

All processors in Pset 2 are being used fairly heavily, while processors in Pset 0 are 100% idle. This is due to Pset processor resource isolation: by default each program only uses processors in the Pset in which it is run. (The Pset programming interface can override this default to launch threads and processes in other Psets, given the right conditions.)

```
# mpsched -u -p 10368
Pid 10368: not bound using the default process launch policy
# sar -u -M -P 1

HP-UX feshd5a B.11.11 U 9000/800    10/23/01

00:24:26     pset     cpu     %usr     %sys     %wio    %idle
00:24:27        0       0        0        0        0      100
                2       1      101        0        0        0
                0       2        1        0        0      100
                2       3      101        0        0        0

#
```

Example 10-4 Managing Pset Permissions and Attributes

This example modifies Pset owner, group, and access permissions; lists various Pset details; and includes other sample Pset uses by various users on the system.

Use psrset -i to list the current Pset configuration for the local nPartition. Three Psets are configured: Pset 0, Pset 7, and Pset 8.

```
# psrset -i
PSET         0
SPU_LIST     0    1    2    3    4    5
OWNID        0
GRPID        0
PERM         755
IOINTR       ALLOW
NONEMPTY     DFLTPSET
EMPTY        FAIL
LASTSPU      DFLTPSET
```

5362
21

```
PSET          7
SPU_LIST      9     10    11
OWNID         0
GRPID         3
PERM          755
IOINTR        ALLOW
NONEMPTY      DFLTPSET
EMPTY         FAIL
LASTSPU       DFLTPSET

PSET          8
SPU_LIST      6     7     8
OWNID         0
GRPID         3
PERM          755
IOINTR        ALLOW
NONEMPTY      DFLTPSET
EMPTY         FAIL
LASTSPU       DFLTPSET

#
```

Modify the group setting for Pset 8 to be group ID 20. Also use `psrset -t...` to modify the permissions for Pset 8. Setting the permissions to 774 allows the owner (`root`) and users in group ID 20 (the group named `users`) to execute, write, and read Pset 8; all others can only read details about the Pset's configuration.

```
# psrset -t 8 GRPID=20
# psrset -t 8 PERM=774
#
```

Using the `psrset -t...` command, change the owner for Pset 7 to user ID 103 (the user named ann).

```
# psrset -t 7 OWNID=103
#
```

Now ann uses the `id` command to list the user ID and group memberships for her user account. She then lists the current Pset configuration for the local nPartition.

The ann user account gives her execute and read access to Pset 0, ownership of Pset 7 (including execute, write, and read access), and execute, write, and read access for Pset 8.

She (ann) is considered one of the "others" (access permissions 5) for Pset 0, the owner (user ID 103, with access permissions 7) for Pset 7, and a group member (group ID 20, access permission 7) for Pset 8.

S361

```
ann $ id
uid=103(ann) gid=20(users) groups=102(prog)
ann $ psrset -i
PSET        0
SPU_LIST    0    1    2    3    4    5
OWNID       0
GRPID       0
PERM        755
IOINTR      ALLOW
NONEMPTY    DFLTPSET
EMPTY       FAIL
LASTSPU     DFLTPSET

PSET        7
SPU_LIST    9    10   11
OWNID       103
GRPID       3
PERM        755
IOINTR      ALLOW
NONEMPTY    DFLTPSET
EMPTY       FAIL
LASTSPU     DFLTPSET

PSET        8
SPU_LIST    6    7    8
OWNID       0
GRPID       20
PERM        774
IOINTR      ALLOW
NONEMPTY    DFLTPSET
EMPTY       FAIL
LASTSPU     DFLTPSET

ann $
```

Because ann is the owner for Pset 7, she has authority to modify the Pset's user, group, and access permissions attributes.

Using the `psrset -t...` command, ann sets the group for Pset 7 to 102 (the group named prog). Another `psrset -t...` command sets access permissions for Pset 7 to 770, which gives the owner (ann) and prog group members access to execute, write, and read the Pset. All others have no permissions to use or read Pset 7.

```
ann $ psrset -t 7 GRPID=102
ann $ psrset -t 7 PERM=770
ann $
```

Now ann assigns processor ID 8 to Pset 7, using the `psrset -a...` command.

Processor 8 was assigned to Pset 8, but ann can reassign it because she has write permission for Pset 8 (she is a member of group ID 20, which has execute, write, and read permissions).

Likewise, ann can assign the processor to Pset 7 because she has write permissions there (she is the owner, and has execute, write, and read permissions).

Then ann lists the new configurations for Pset 7 and Pset 8 using the `psrset -i 7 8` command.

```
ann $ psrset -a 7 8
successfully assigned processor 8 to pset 7
ann $ psrset -i 7 8
PSET         7
SPU_LIST     8     9     10    11
OWNID        103
GRPID        102
PERM         770
IOINTR       ALLOW
NONEMPTY     DFLTPSET
EMPTY        FAIL
LASTSPU      DFLTPSET

PSET         8
SPU_LIST     6     7
OWNID        0
GRPID        20
PERM         774
IOINTR       ALLOW
NONEMPTY     DFLTPSET
EMPTY        FAIL
LASTSPU      DFLTPSET

ann $
```

Now a different user in the same nPartition attempts to list and use the new Pset configurations.

This user, `joe`, lists his user ID and the IDs for the groups to which he belongs, and then lists all Pset configurations using the `psrset -i` command. Note that because `joe` does not have read permission for Pset 7, he cannot view its attribute values (he is not the owner or a member of the Pset's group, so as one of the "others" he has no permissions).

535a

```
joe $ id
uid=102(joe) gid=20(users)
joe $ psrset -i
PSET          0
SPU_LIST      0     1     2     3     4     5
OWNID         0
GRPID         0
PERM          755
IOINTR        ALLOW
NONEMPTY      DFLTPSET
EMPTY         FAIL
LASTSPU       DFLTPSET

PSET          7
SPU_LIST      8     9     10    11
psrset: no privileges for query operation on this pset

PSET          8
SPU_LIST      6     7
OWNID         0
GRPID         20
PERM          774
IOINTR        ALLOW
NONEMPTY      DFLTPSET
EMPTY         FAIL
LASTSPU       DFLTPSET

joe $
```

When `joe` uses the `psrset -e 7...` command to attempt to execute the “potato” program in Pset 7, he cannot because he does not have execute permission in the Pset.

However, when `joe` uses the `psrset -e 8...` command to execute “potato” in Pset 8 the program is run in that Pset. He can run programs in Pset 8 because he is a member of group ID 20 and members of that group have execute, write, and read permission for the Pset.

```
joe $ psrset -e 7 ./potato
psrset: no privileges to perform operation
joe $ psrset -e 8 ./potato
Threads = 2
tid = 1  cpu = 6
tid = 2  cpu = 7
...
```

S358

11 Virtual Partitions (vPars) Management on nPartitions

This chapter describes how to create, configure, and manage HP's virtual partitions within an nPartition (hard partition) system environment. Each virtual partition can boot a single instance of the HP-UX B.11.11 operating system.

The HP **virtual partitions (vPars)** software is an *optional* feature that you can use to further subdivide a server's resources into multiple, smaller virtual machines through software partitioning.

By configuring multiple virtual partitions within an nPartition, you can boot multiple instances of HP-UX B.11.11 in a single nPartition.

For detailed tasks for configuring virtual partitions within an nPartition, see *Procedures for Managing Virtual Partitions on HP nPartition Servers* on page 475.

NOTE This chapter describes the current A.02.02 vPars software release, which supports HP rp7405/rp7410, HP rp8400, and HP Superdome servers.

For an introduction to nPartition features, refer to the chapter *nPartition System Overviews* on page 31.

Also refer to the book *Installing and Managing HP-UX Virtual Partitions (vPars)* for more details about HP's vPars software.

S33

Introduction to Managing Virtual Partitions on nPartitions

Figure 11-1 shows how an nPartition can boot vPars software from its BCH interface, thus enabling one or more virtual partitions to run HP-UX B.11.11 on a subset of the nPartition's active hardware.

Figure 11-1 **Overview of HP Virtual Partitions (vPars) in an nPartition**

nPartition Boot Console Handler (BCH)
Active Cells
Inactive Cell
nPartition's Assigned Hardware
HP nPartition Service Processor (GSP or MP)

Virtual Partition Hardware

On HP nPartition servers, each virtual partition is assigned a subset of its nPartition's hardware. Only the *active hardware assigned to the local nPartition* can be used by virtual partitions within the nPartition.

Hardware that is assigned to remote nPartitions and hardware that is inactive cannot be used by virtual partitions in the local nPartition.

Each virtual partition runs its own instance of HP-UX and has its own dedicated hardware resources. You can reconfigure virtual partitions and can dynamically reallocate certain processors among virtual partitions in the local nPartition, but you cannot share resources across virtual partitions or across nPartitions.

The hardware assigned to each virtual partition includes: processors (CPUs), memory, and input/output busses. Each I/O bus can have a PCI card installed and devices attached.

Each virtual partition should be assigned at least one I/O bus (LBA) that has a boot device with HP-UX B.11.11 and the vPars software product installed. An I/O bus with a network interface card also should be assigned to each virtual partition to support networking. See *vPars Requirements and Recommendations* on page 454 for more details.

vPars Software, Booting, and Consoles

Running virtual partitions in an nPartition involves installing the HP-UX virtual partitions software product, configuring one or more virtual partitions, and then booting the vPars monitor (`/stand/vpmon`) on the nPartition and loading/booting HP-UX on each of the virtual partitions.

By booting the `/stand/vpmon` virtual partitions monitor instead of the `/stand/vmunix` HP-UX kernel, an nPartition provides an additional boot loader specifically for virtual partitions.

Each nPartition can be configured to automatically boot virtual partitions, and virtual partitions can individually be configured to be booted manually or automatically. See *Procedures for Managing Virtual Partitions on HP nPartition Servers* on page 475 for details.

Only one vPars monitor is booted per nPartition. All virtual partitions in an nPartition share the same console device: the nPartition's console. See *Virtual Partition Console and Log Use on nPartition Servers* on page 465 for details.

5355

vPars HP-UX B.11.11 Kernel

The vPars software installation builds a relocatable, vPars-enabled HP-UX B.11.11 kernel and installs patches, commands, and vpmon to support the vPars software environment. See *Installing and Configuring vPars on nPartition Servers* on page 472 for details.

You can load and run a vPars-enabled HP-UX B.11.11 kernel in both vPars environments and non-vPars environments. You *do not* need to reconfigure a vPars-enabled kernel for non-vPars use.

nPartition and vPars Performance

In general in HP nPartition virtual partitions environments, HP-UX B.11.11 and application *performance is nearly equivalent* to the performance given by a non-vPars nPartition that has the same hardware and software resources and configuration.

Also see the document *HP-UX Virtual Partitions Ordering and Configuration Guide* for more virtual partitions performance info.

The main performance factor for virtual partitions running in nPartitions is the underlying nPartition's hardware configuration: the cells and corresponding processors, memory, and I/O assigned to and actively used in the nPartition.

As in non-vPars nPartition environments, all memory is interleaved across all active cells in the nPartition when virtual partitions are running in an nPartition. Also on all HP nPartition servers, each processor has its own runway bus for communication to memory and I/O.

As a result, the locations (hardware paths) of processors assigned to a virtual partition *do not* affect performance. In general all processors have the same memory latency when accessing any significant amount of memory in an nPartition.

The rest of this chapter covers requirements, guidelines, procedures, and tools for using virtual partitions on HP nPartition-capable servers.

5354

Configuring Virtual Partition Resources and Attributes

When creating or reconfiguring a virtual partition, you manage **resources and attributes** that determine the virtual partition's configuration and capabilities.

Each virtual partition has three types of resources: `cpu`, `io`, and `mem`, which specify processor(s), I/O, and memory allocated exclusively for the virtual partition.

The virtual partition resource configuration determines which hardware is dedicated for the virtual partition's use, by indicating hardware paths, quantities, and limits.

Each virtual partition also has three types of attributes: general attributes, hardware attributes, and boot attributes.

NOTE To modify most virtual partition *hardware* resources or attributes, you must ensure that the virtual partition being modified is in a "Down" state.

Also note that some virtual partition attributes are required and some are optional.

See the *vparmodify* (1M) and *vparresources* (5) manpages for details.

The following list includes details and command-line options for setting virtual partition attributes. Also see the *vparcreate* (1M) and *vparmodify* (1M) command manpages.

- **Virtual Partition General Attributes**

  The **general virtual partition attributes** include the *name* of the virtual partition and the `static` attribute.

  The *name* attribute (`-p` and `-P`) defines the virtual partition's name, which you use when referencing or managing the virtual partition using commands.

5353

The *static* attribute (-S) defines whether the virtual partition can be reconfigured. See *Dynamic and Static Virtual Partitions* on page 461 for details.

- **Virtual Partition Hardware Resource Attributes**

  Virtual partition hardware resource attributes include specifications for the processors, I/O, and memory that are dedicated for use by the virtual partition.

  You can add (-a), delete (-d), and modify (-m) virtual partition hardware resources and attributes.

  Also see the *vparresources* (5) manpage for details.

  Descriptions of processor (cpu), I/O (io), and memory (mem) virtual partition hardware resource attributes are in the following list.

  — Processors (cpu) resources — You can specify the following attributes for processors:

  The *path* of one or more processors that are bound to the virtual partition. For example, to set the processor at hardware path 0/10 to be bound to the virtual partition:

  ```
  # vparmodify -p name -m cpu:0/10
  ```

  A *minimum* and *maximum* number of processors allowed in the virtual partition. For example, to set the minimum number of processors to 2 and the maximum to 4 processors:

  ```
  # vparmodify -p name -m cpu:::2:4
  ```

  The *total* number of processors in the virtual partition. For example, to set the total number of processors to 6:

  ```
  # vparmodify -p name -m cpu::6
  ```

  — Input/Output (io) — You can optionally specify boot, altboot, and other attributes for each I/O device path assigned to a virtual partition.

  The boot attribute specifies the primary (PRI) boot device path for the virtual partition, which is stored in the vPars database (vpdb) and is separate from the nPartition boot device path settings.

The altboot attribute specifies the alternate (ALT) boot device path for the virtual partition, which also is separate from nPartition boot settings.

For example, to set the specified virtual partition's PRI boot device path to 0/0/6/0/0.5 (the corresponding nPartition's PRI path is *not* changed, however):

```
# vparmodify -p name -m io:0/0/6/0/0.5:boot
```

— Memory (mem) — You can specify the total (-m mem::*size*) memory *size* in MBytes for a virtual partition, and can increase (-a) or decrease (-d) the amount of memory,

As needed, the specified *size* is rounded up to a 64 MByte boundary.

For example, to configure a virtual partition to have 2 GBytes (2048 MBytes) of memory allocated:

```
# vparmodify -p name -m mem::2048
```

NOTE

HP recommends that you *only specify the total amount of memory* to be allocated for each virtual partition. On all supported HP virtual partition systems there is no benefit to specifying the base and range for memory.

Each nPartition's memory is interleaved across all active cells in the nPartition and thus all useful ranges of virtual partition memory will span all cells.

- **Virtual Partition Boot Attributes**

  Virtual partition boot attributes include the *autoboot* setting, the *kernel path* attribute, the *boot options* attribute, and *io resources* attributes.

  The *autoboot* attribute (-B) determines whether a virtual partition is booted (-B auto) or not booted (-B manual) when the virtual partition is reset. This attribute also affects virtual partition boot behavior when the vPars monitor is loaded with the vpmon -a option or when the vparload -auto command is issued from the MON> prompt.

The *`kernel path`* attribute (`-b`) specifies the path of the vPars-enabled HP-UX B.11.11 kernel that is to be booted when the virtual partition is loaded. By default the `/stand/vmunix` kernel on the boot device is used.

The *`boot options`* attribute (`-o`) specifies the options that are applied when the virtual partition's HP-UX B.11.11 kernel is booted. These boot options are equivalent to the secondary system loader options described in the *hpux* (1M) manpage.

You can use the *`io resources`* attributes (`-a io...`, `-m io...`) to designate primary (PRI) and alternate (ALT) boot device paths for a virtual partition, as explained in *Virtual Partition Hardware Resource Attributes* on page 446.

5350

Tools for Managing Virtual Partitions on nPartition Servers

The main tools for virtual partitions administration are the HP-UX vPars commands and the Virtual Partition Manager (`vparmgr`) utility.

This section briefly lists these and other tools and commands you can use for managing virtual partitions on HP nPartition servers.

- **HP-UX Virtual Partitions Commands**

  The HP-UX vPars commands create, modify, and provide status and configuration info about the virtual partitions in the *currently active* vPars database (`/stand/vpdb`), or any other accessible vPars database that you specify.

  The vPars commands list status or modify configuration details for virtual partitions in the local nPartition. They cannot modify or list info about virtual partitions running in remote nPartitions.

  Using all vPars commands requires `root` permission.

  In most cases the vPars commands are used after you have booted one or more virtual partitions in an nPartition. However, you also can use some vPars commands when you have booted HP-UX in a non-vPars nPartition environment, such as when initially configuring virtual partitions.

  See the *vpartition* (5) manpage for a list and descriptions of the vPars commands, including `vparstatus`, `vparcreate`, `vparmodify`, `vparboot`, `vparreset`, and others.

- **Virtual Partition Manager (`vparmgr`) Utility**

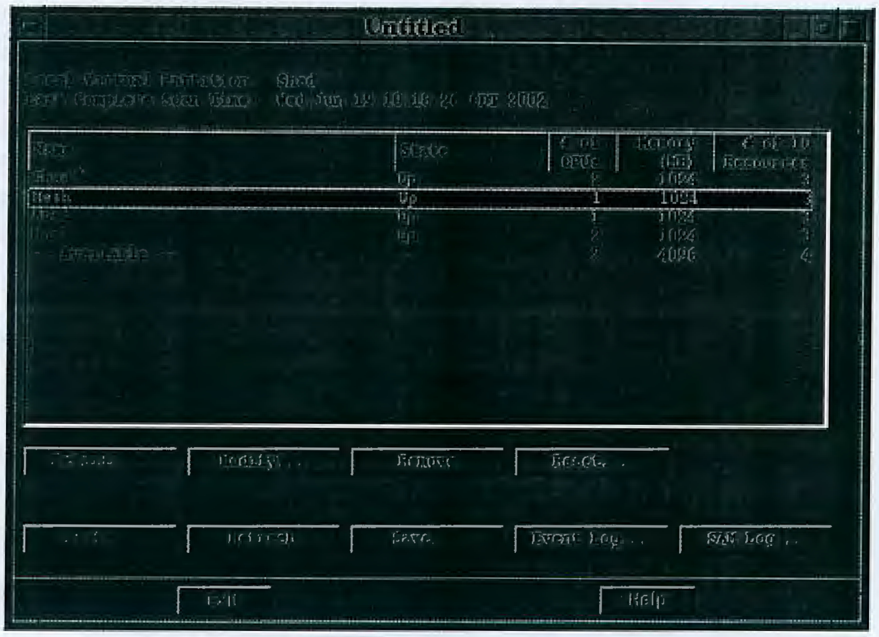
  The Virtual Partition Manager utility provides a graphical interface to the HP-UX vPars commands. Using Virtual Partition Manager, you can perform virtual partitions administration tasks from HP-UX running on a virtual partition. You cannot use Virtual Partition Manager when HP-UX is booted in non-vPars mode.

NOTE The Virtual Partition Manager utility *is not installed* as part of the virtual partitions software product installation. Instead, you must install Virtual Partition Manager separately, as described in the the book *Installing and Managing HP-UX Virtual Partitions (vPars)*.

Using the Virtual Partition Manager utility requires `root` permission.

Because Virtual Partition Manager is an X window graphical utility, you must set and export the virtual partition system's DISPLAY environment variable before launching `vparmgr`. The DISPLAY variable specifies where (which X server) the system displays X windows. You also must use the `xhost` command on the X server (your local system) to grant access for the virtual partition system to display windows on the X server. See the *X* (1) and *xhost* (1) manpages for details.

The following window is the Virtual Partition Manager utility's status window, which is the first window displayed after any alert messages. This window lists the status of all virtual partitions defined in the current vPars database as well as general details about available resources.



```
Untitled

Local Virtual Partition:    Shad

```

Virtual Partition Manager has online help that you can view at any time by clicking the **Help** button, which displays info in a separate Web browser. You also can view Virtual Partition Manager help from a Web browser by issuing the following command:

```
/opt/netscape/netscape file:/opt/webadmin/vparmgr/help/C/overview.html
```

See the online help for complete details on using the Virtual Partition Manager.

All Virtual Partition Manager tasks also can be performed using the HP-UX vPars commands, which are described in the *vpartition* (5) manpage.

- HP-UX nPartition Commands: parstatus and Others

  The parstatus command can list nPartition status info as well as details about hardware assigned to the local nPartition and other hardware throughout the entire nPartition server complex.

  See the *parstatus* (1) manpage for details.

  The other HP-UX nPartition commands, such as parmodify, also are supported when running HP-UX in a virtual partition on an nPartition. Likewise the Partition Manager tool is supported.

3342

- HP-UX `setboot` Command

  The HP-UX `setboot` command affects the current virtual partition's boot settings (stored in its `/stand/vpdb`) when you use it in a virtual partition environment.

  When used in a *non-vPars* nPartition environment, the `setboot` command affects the local nPartition's boot settings. The nPartition boot device paths are stored in the nPartition's Partition Configuration Data portion of the server's Complex Profile.

- Tools for Boot Device AUTO File Management

  HP-UX commands to set (`mkboot`) and list (`lifcp`) a device's AUTO file: **`mkboot -a`** ***`STRING`*** **`/dev/dsk/...`** and **`lifcp /dev/dsk/...:AUTO -`**

  ISL commands to list (`hpux show...`) and set (`hpux set...`) an AUTO file: **`hpux show autofile`** and **`hpux set autofile`** ***`STRING`***

  vPars monitor (`MON>`) command to list an AUTO file: **`getauto`**

  See the *mkboot* (1M), *lifcp* (1), and *hpux* (1M) manpages.

- HP nPartition Virtual Front Panel (VFP)

  The nPartition VFP indicates the boot status for all cells and virtual partitions in the nPartition. As long as at least one virtual partition is running HP-UX the VFP will display an HP-UX "heartbeat".

  For details, refer to the chapter *Using Console and Service Processor Interfaces* on page 125.

- HP nPartition Console and Virtual Partition Consoles

  Each nPartition console provides access to BCH for the nPartition, allows you to boot HP-UX or the vPars monitor on an nPartition, and permits access to all virtual partition console interfaces in the nPartition.

  For details, see *Virtual Partition Console and Log Use on nPartition Servers* on page 465.

- HP vPars Monitor (`vpmon`) Commands

  At the vPars monitor (`MON>`) prompt enter **`?`** or the **`help`** command to list all available vPars monitor commands.

5346

The vPars monitor commands include: `reboot` (reboot the nPartition), `vparload` (load/boot one or more virtual partitions), `scan` (scan and list all active hardware in the local nPartition), `log` (list recent history from the vPars monitor's event log), and other commands.

The vPars monitor's `MON>` prompt is available when the nPartition's monarch processor is not assigned to a virtual partition that has been loaded/booted.

- HP nPartition Service Processor (GSP or MP) Commands

  Service processor commands that reboot or reset an nPartition affect all virtual partitions within the nPartition.

  For details, refer to the chapter *Using Console and Service Processor Interfaces* on page 125.

- HP nPartition Server Chassis Log Viewer (SL)

  HP virtual partitions-related details that are accessible as chassis logs include the HP-UX "heartbeat" emitted when HP-UX is running on each virtual partition. Otherwise, all vPars-specific event logs are stored in the vPars event log.

  For details, see the section *Virtual Partition Console and Log Use on nPartition Servers* on page 465.

5345

vPars Requirements and Recommendations

HP offers the following requirements and recommendations for configuring virtual partitions in HP nPartition environments.

Additional recommendations for avoiding obstacles to loading/booting virtual partitions are in *Fault-Tolerant Virtual Partition Configurations for nPartitions* on page 457.

NOTE See the *HP-UX Virtual Partitions Ordering and Configuration Guide* for the latest requirements.

Configuration Requirements and Recommendations for Virtual Partitions

❑ The following software releases, or later, **must** be installed for complete vPars support on HP nPartition-capable servers:

— Any HP-UX B.11.11 release (December 2000 or later).

— The A.02.02 virtual partitions software product.

— The Partition Manager B.11.11.01.05 product, which must be installed *before* the A.02.02 vPars software is installed.

— The Superdome SMS Software V1.2 release (including firmware).

❑ Each nPartition in which virtual partitions are configured **must** have *no more than* eight cells assigned to it, and all the nPartition's cells **must** reside in the same cabinet.

❑ Each nPartition **must** have *no more than* eight virtual partitions configured.

If you require more than eight virtual partitions in the same HP nPartition complex, configure the virtual partitions in multiple nPartitions.

❑ Hardware to be used by virtual partitions within an nPartition **must** be *assigned* to the local nPartition and must be *active* hardware.

Because each nPartition only provides access to the hardware that is assigned to and active within the local nPartition, any virtual partitions in the nPartition are limited to using this same set of currently available nPartition hardware.

Adding or removing hardware from an nPartition changes the local set of hardware that is available to virtual partitions in the nPartition. Likewise, making nPartition hardware inactive makes it unavailable to virtual partitions.

- ❑ At least one processor **must** be bound to each virtual partition.

  Only bound processors can handle I/O interrupts. Other processors in the virtual partition can be either bound or unbound.

- ❑ A multiple of 64 MBytes of memory **must** be assigned to each virtual partition.

  When you specify the memory size of each virtual partition, the commands involved automatically round the memory assignment upward as required to a 64-MByte boundary.

  Memory in HP nPartitions is interleaved across all active cells in the local nPartition. As a result the memory used by each virtual partition may physically reside on all active cells in the nPartition where the virtual partitions exist.

- ❑ Each virtual partition **must** have at *least one* I/O bus (LBA) assigned to it.

  On HP nPartition servers, each LBA corresponds to a PCI card slot in an I/O chassis attached to an active cell in the local nPartition.

  For I/O slot details, see the section *Planning Virtual Partition Configurations for HP nPartition Servers* on page 467.

- ❑ Each virtual partition **must** have at least one bootable disk accessible through a PCI card in one of the I/O busses assigned to the virtual partition.

  The bootable disk must have both HP-UX B.11.11 and the HP virtual partitions software package installed.

- ❑ The HP processor pay per use (PPU, or iCOD Utility) product is *not yet supported for virtual partitions* and **must not** be installed or configured for nPartition systems running vPars.

5343

The HP processor Instant Capacity on Demand (iCOD Purchase) release B.05.00 software may be installed and used with vPars software on HP nPartition-capable servers.

A future release of iCOD Utility (pay per use) also will support processor capacity on demand for nPartition servers running vPars.

□ Each virtual partition **should** have at least one LAN card or port available through one of the I/O busses assigned to the virtual partition.

The LAN port is required if HP-UX networking is to be supported.

HP recommends that, for best performance, you do not configure HP-UX lan0 to use the nPartition's Core I/O LAN (on HP Superdome servers, the LAN at hardware path *cell*`/0/0/1/0`).

The HP Superdome Core I/O card is a PCI-1x card that possibly provides lower performance than a comparable PCI-2x or PCI-4x card.

□ If you require that a virtual partition not be reconfigured then you **should** set the virtual partition to be "static". For details, see *Dynamic and Static Virtual Partitions* on page 461.

The next section gives detailed guidelines for creating fault-tolerant virtual partition configurations on nPartitions.

5338

Dynamic and Static Virtual Partitions

Each virtual partition has a static/dynamic attribute that determines whether resource changes can be made to the virtual partition.

A **static virtual partition** cannot have any modifications made to its resource profile. This means that the virtual partition's processor, memory, and I/O characteristics and assignments cannot be changed, even if the virtual partition is not running (in a "Down" state).

A **dynamic virtual partition** can have its resource profile changed through the use of the `vparmodify` command.

To toggle between the `static` and `dynamic` virtual partition attribute settings, use the `vparmodify` command's `-S` option:

```
vparmodify -p vpname -S static
```

```
vparmodify -p vpname -S dynamic
```

You also can toggle this attribute between `dynamic` and `static` in a single command. For example, the following command sets the virtual partition named "Shad" to be dynamic, then modifies its total number of CPUs, then sets the virtual partition to be static.

```
# vparmodify -p Shad -S dynamic -m cpu::3 -S static
```

See the *vparmodify* (1M) manpage for details.

Note that some resource changes require that the virtual partition not only be dynamic but also be in a "Down" state.

For example, changing I/O attributes or adding and removing processors may be possible while a dynamic virtual partition is running, but changing memory or I/O assignments requires a virtual partition to be both *dynamic* and *down*.

To check virtual partition static/dynamic attribute settings, use `vparstatus`.

```
# vparstatus
[Virtual Partition]
                                                                    Boot
Virtual Partition Name            State Attributes Kernel Path              Opts
============================== ===== ========== ========================= =====
Shad                              Down  Dyn,Manl   /stand/vmunix
Mesh                              Up    Stat,Manl  /stand/vmunix            boot
```

```
[Virtual Partition Resource Summary]
                                                     CPU     Num        Memory (MB)
                                            CPU    Bound/    IO    # Ranges/

```

5336

Virtual Partition Configuration Data on nPartitions

This section covers configuration data issues related to using virtual partitions in nPartitions.

Virtual partition configuration data by default is stored in the `/stand/vpdb` file, although you can specify that another file be used as the vPars database.

When you have multiple virtual partitions booted (in an "Up" state) on an nPartition, the vPars databases for all booted virtual partitions are kept coherent; any changes to virtual partition configurations are saved in each of the booted virtual partition's databases.

Virtual partition configuration data *is not* stored in the nPartition complex profile data. As a result, virtual partition changes do not affect nPartition configurations.

The following list describes some issues related to managing both nPartition and virtual partitions configuration data in an nPartition.

- Boot Paths for Virtual Partitions and nPartitions

  Each nPartition's boot path variables (PRI, HAA, ALT) are stored in the nPartition's profile data.

  The virtual partition boot device paths (PRI, ALT) are stored in the vPars configuration database.

  The `parmodify` and `parstatus` commands always can report and modify nPartition boot device path details.

  When one or more virtual partitions is booted in an nPartition, the `setboot` command affects the *current virtual partition's* boot paths and settings.

  When HP-UX is booted in a *non-vPars nPartition*, the `setboot` command and others affect the local nPartition.

- Virtual Partition Configuration Data Coherency

  Only the vPars configuration database (`/stand/vpdb`) residing on each virtual partition's currently booted device's filesystems is updated to reflect any changes.

Any booted virtual partition that has multiple boot devices (such as `boot` and `altboot`) can have one current and one outdated copy of virtual partition data.

For example: when a virtual partition boots from its ALT device path and has a config change, and then the virtual partition's nPartition reboots and loads `/stand/vpmon` from the same virtual partition's PRI device path, then as a result the latest virtual partition config changes are not used (but they still reside on the virtual partition's ALT device). Instead, in this example, the `/stand/vpdb` vPars database on the virtual partition's PRI device is used for configuring the nPartition's virtual partitions.

5334

Virtual Partition Console and Log Use on nPartition Servers

On HP nPartition-capable servers, each nPartition has its own console and its own console log that stores a record of recent console activity.

When an nPartition has one or more virtual partitions booted, the nPartition console serves as the console for all virtual partitions loaded/booted in the nPartition.

NOTE

To switch among virtual partition console interfaces, type **Control-a** when accessing the corresponding nPartition console.

In the following example, the user of the nPartition console repeatedly types **Control-a** to cycle through the available virtual partition consoles.

```
feshd3a / Shad [HP Release B.11.11] (see /etc/issue)
Console Login:
Control-a
[Mesh]
Control-a
[Abed]
Control-a
[Danl]
Control-a
[Shad]
Control-a
[Mesh]
```

The above example starts with console access to the virtual partition named "Shad", then switches to the "Mesh" virtual partition console, "Abed" console, "Danl" console, and then back to the "Shad" and finally the "Mesh" virtual partition console.

The service processor (GSP or MP) console log stores nPartition console output, including BCH output and HP-UX `/dev/console` for nPartitions.On nPartition server running virtual partitions, all virtual partitions in the nPartition emit their `/dev/console` output to the nPartition console. Thus, when HP-UX B.11.11 is running in multiple virtual partitions in an nPartition, the nPartition console will display `/dev/console` output for more than one instance of HP-UX.

The nPartition console log also records vPars monitor (vpmon, MON> prompt) output for its nPartition, because the vPars monitor interface is accessed and displayed through the virtual partition's nPartition console.The vpmon event logs file—which is viewable from the `vparstatus -e` command or the vPars monitor's `log` command—only records virtual partition events. It does not record any nPartition chassis codes.The server chassis logs—which are viewable from the service processor (GSP or MP) Show Chassis Log menu—record nPartition and server complex hardware events. nPartition chassis logs do not record virtual partition configuration or virtual partition-specific load/boot events.However, as in non-vPars nPartition environments, the chassis logs do record HP-UX "heartbeat" events and related timeout counter details.

The vPars monitor prompt (MON>) is shared by all virtual partitions in the same nPartition and gives access to commands for loading/booting virtual partitions, displaying virtual partition and system info, reviewing event log history, and performing other tasks.

If multiple nPartitions in a server are running virtual partitions, each nPartition has its own vPars monitor, just as each nPartition runs its own instance of Boot Console Handler (BCH).

S332

Planning Virtual Partition Configurations for HP nPartition Servers

You can use this section to help plan the virtual partition configurations you will establish in nPartitions.

This section covers the following topics:

- *Virtual Partition Hardware Paths* on page 468
- *Listing Available nPartition Hardware Resources* on page 469
- *Virtual Partition Configuration Planning* on page 470

Also see the book *Installing and Managing HP-UX Virtual Partitions (vPars)* for other virtual partition planning info.

S33

Virtual Partition Hardware Paths

You may need to reference the following hardware path info for HP nPartition-capable servers when planning virtual partition configurations.

Figure 11-2 **HP nPartition Hardware Paths for Virtual Partition Configurations**

Processor (CPU) Hardware Paths

cell/10
cell/11
cell/12
cell/13

For all nPartition hardware paths, *cell* is the global cell number (0–15).

HP Superdome — PCI Card Slot Hardware Paths

Slot	11	10	9	8	7	6	5	4	3	2	1	0
Path (LBA)	*cell*/0/8	*cell*/0/9	*cell*/0/10	*cell*/0/11	*cell*/0/12	*cell*/0/14	*cell*/0/6	*cell*/0/4	*cell*/0/3	*cell*/0/2	*cell*/0/1	*cell*/0/0

HP rp7405/rp7410 and HP rp8400 — PCI Card Slot Hardware Paths

Slot	1	2	3	4	5	6	7	8
Path (LBA)	*cell*/0/8	*cell*/0/10	*cell*/0/12	*cell*/0/14	*cell*/0/6	*cell*/0/4	*cell*/0/2	*cell*/0/1

5330

Listing Available nPartition Hardware Resources

This section presents how you can list all available hardware resources in an nPartition server.

The following are common methods of listing available hardware:

- **`vparstatus -A`** lists the available processor, I/O, and memory resources in the local nPartition. This command lists the hardware that has not yet been assigned to any virtual partition.

  Note that `vparstatus -A` command lists processors and I/O using a form of the hardware path notation where a period (`.`) separates each hardware path field rather than a slash (`/`).

- **`ioscan`** lists the assigned and active hardware in the local nPartition or the current virtual partition.

  When HP-UX is booted in a *non-vPars* environment, `ioscan` lists all all active hardware in the local nPartition.

  When HP-UX is booted in a virtual partition, `ioscan` lists only the I/O devices assigned to the current virtual partition and lists processors on active cells in the local nPartition (but it *does not* list bound processors in other virtual partitions).

  Note that `ioscan` can list some processors that are not assigned to the current virtual partition, including unbound processors assigned to other virtual partitions.

- **`mpsched -s`** lists only the assigned and active processors in the current virtual partition or nPartition.

  Note, however, that `mpsched -s` lists the HP-UX CPU IDs for processors, not their hardware paths.

- **`parstatus -C`** lists the configurations of all cells in an HP nPartition-capable server complex, including the number of processors, amount of memory, I/O chassis connections, current usage status, and nPartition assignment.

Also refer to the chapter *Listing and Managing Server Hardware* on page 305 for details.

5329

Virtual Partition Configuration Planning

Table 11-1 is for planning virtual partition attributes and resource assignments.

For each virtual partition, you **must** specify: a virtual partition name, at least one bound CPU, at least one I/O slot, a PRI boot path, and enough memory to boot HP-UX. The *default virtual partition attributes* establish a dynamic configuration that manually boots the `/stand/vmunix` kernel with no boot options.

The “Host Info” column in Table 11-1 includes configuration details for HP-UX networking (the hostname, IP, gateway, and so on).

Also see *Configuring Virtual Partition Resources and Attributes* on page 445.

5328

Table 11-1 Configuration Planning Table for a Virtual Partition

Virtual Partition Name and Host Info	Attributes (* = Default)	Processor Resources	Input/Output Resources	Memory Resources
Virtual Partition Name: ______________	Configuration: Static *or* Dynamic*	Min: _____	Boot Path (PRI): __/0/__/__/__.__ *Note: also must assign the LBA.*	Size (MBytes): _________ *Note:* *1024 MBytes = 1 GByte*

DNS IP: ___.___.___.___ Domain: ______________				

Installing and Configuring vPars on nPartition Servers

This section covers information on installing the vPars software product onto disks that will be used for booting HP-UX on a virtual partition that is loaded in an nPartition.

After a boot disk has both HP-UX and the vPars software product installed, the disk can be booted to be used in either virtual partition or non-vPars environments.

The vPars software install process can occur when you have booted HP-UX from each disk so that HP-UX is running in a non-vPars environment.

You also can install *both* the HP-UX and vPars software simultaneously on a virtual partition when its nPartition is running in vPars mode. To do this issue the `vparboot -p` *`vpname`* `-I...` command from a different virtual partition in the same nPartition to load/boot the virtual partition from an Ignite-UX server. For details see the *vparboot* (1M) manpage or the vPars install documentation listed below.

NOTE The HP vPars software product must be installed on *every boot device* that will be used by virtual partitions. Each virtual partition must have a boot disk where HP-UX B.11.11 and the vPars software product are installed.

NOTE Before installing the HP vPars software product on an nPartition, you must install the Partition Manager B.11.11.01.05 product (or a later Partition Manager release).

For the latest Partition Manager software, see the **`http://software.hp.com`** Web site.

vPars Software Installation for an HP nPartition

This procedure gives a high-level overview of a process for manually installing HP's virtual partitions software product on an nPartition's disks.

The book *Read Before Installing HP-UX Virtual Partitions* has important information you should read before performing this procedure. Also refer to the book *Installing and Managing HP-UX Virtual Partitions (vPars)*.

Step 1. Boot HP-UX on the nPartition using the boot device that will be the primary (PRI) boot device for one of the nPartition's virtual partitions.

Step 2. Install the HP virtual partitions software product on the booted device.

As part of the vPars software installation, the nPartition is rebooted and a new `/stand/vmunix` HP-UX kernel is built.

Step 3. Create the first virtual partition on the device onto which you have installed the vPars software product.

NOTE Only perform this step for the boot disk from which `/stand/vpmon` will be loaded. Do not perform this step for other boot disks.

Other boot disks are automatically updated with copies of the vPars database as needed.

To complete this step, first boot HP-UX from the device, and then use the `vparcreate` and `vparmodify` commands to create the first virtual partition for the nPartition.

Creating the first virtual partition establishes a vPars database (`/stand/vpdb`) for the nPartition.

You can assign each virtual partition resources that are part of the *local* nPartition. Only hardware that is *assigned* to the local nPartition and is *active* can be used by the virtual partitions within the nPartition.

By default the `vparcreate`, `vparmodify`, and `vparstatus` commands use the `/stand/vpdb` file. Although the vPars monitor is not running as you perform this step, these commands will read and write to `/stand/vpdb` if you do not specify a different vPars database file using the `-D` option.

If you want to create multiple virtual partitions within an nPartition you can do so as part of this step, by issuing a `vparcreate` command for each new virtual partition within the local nPartition.

You also can create any additional virtual partitions later, after you have booted the vPars monitor and loaded/booted HP-UX B.11.11 on the first virtual partition.

Step 4. Issue the **`shutdown -r`** command to reboot HP-UX on the nPartition and return to the nPartition's BCH interface.

As needed, interrupt the autoboot process to interact with the nPartition at the BCH interface.

Step 5. Install the vPars software product on each remaining boot device that is to be used to boot HP-UX on one of the nPartition's virtual partitions.

For each virtual partition boot device, you can boot HP-UX from the device in non-vPars mode and then install the vPars software product on the device.

An alternate install method is to load/boot HP-UX on the first virtual partition, and then simultaneously install HP-UX and vPars software on other virtual partitions by using the the `vparboot -p` *`vpname`* `-I...` command. See the *vparboot* (1M) manpage.

You must install both HP-UX and the vPars software for every virtual partition. For example, if you plan to have three virtual partitions in an nPartition then you need at least three boot devices with HP-UX and vPars software installed.

If you intend to have multiple boot disks for a virtual partition—for example, a PRI device and an ALT device—then you need to install HP-UX and the vPars software product on *both* the PRI and ALT devices for the virtual partition.

5324

Procedures for Managing Virtual Partitions on HP nPartition Servers

This section has procedures for performing typical virtual partitions configuration and management tasks on HP nPartition-capable servers.

The following virtual partitions procedures are covered here:

- *vPars Management: Creating a New Virtual Partition in an nPartition* on page 477
- *vPars Management: Deleting a Virtual Partition from an nPartition* on page 481
- *vPars Management: Modifying Virtual Partition Attributes in nPartition Environments* on page 483
- *vPars Management: Listing Virtual Partition Status from an nPartition* on page 485
- *vPars Management: Booting HP-UX B.11.11 on Virtual Partitions in an nPartition* on page 487
- *vPars Management: Rebooting or Shutting Down Virtual Partitions in an nPartition* on page 495
- *Configuring Virtual Partition Autoboot* on page 498

NOTE

The procedures described here use the HP-UX virtual partitions commands and *not* the graphical Virtual Partition Manager utility.

You can perform all tasks in this section with either the commands or Virtual Partition Manager. For info on the Virtual Partition Manager graphical utility see its online help or see the section *Tools for Managing Virtual Partitions on nPartition Servers* on page 449.

See the section *Installing and Configuring vPars on nPartition Servers* on page 472 for details on installing vPars software on nPartition systems.

Also see the section *Managing nPartitions from a Virtual Partition* on page 506 for issues you should be aware of when you perform nPartition config tasks from a vPars environment.

S323

The book *Installing and Managing HP-UX Virtual Partitions (vPars)* also has detailed virtual partitions management information.

Creating a New Virtual Partition

This section gives details on how to create a new virtual partition.

NOTE Before creating a virtual partition you should already have planned how the local nPartition's resources will be assigned to the virtual partitions running in the local nPartition.

See the section *Planning Virtual Partition Configurations for HP nPartition Servers* on page 467 for info on planning virtual partitions configurations for use in nPartitions.

vPars Management: Creating a New Virtual Partition in an nPartition

This procedure creates a new virtual partition from HP-UX running in a virtual partition on an nPartition.

The book *Installing and Managing HP-UX Virtual Partitions (vPars)* also has detailed virtual partitions information.

Step 1. Login to HP-UX running on one of the virtual partitions within an nPartition.

Step 2. Complete all virtual partition resource planning and confirm that the resources are available for the new virtual partition you intend to create.

See the section *Planning Virtual Partition Configurations for HP nPartition Servers* on page 467 for planning details.

Issue the **vparstatus -A** command to list the processors, memory, and I/O busses that are not yet assigned to any virtual partition.

The vparstatus -A command should list all hardware you plan to assign to the new virtual partition. If any hardware you planned to assign is not available then you must either must revise your plans or unassign or otherwise make the hardware available.

```
# vparstatus -A
[Unbound CPUs (path)]:  0.13
                        1.11
                        1.12
                        1.13
                        2.10
```

                                 2.0.6
                                 2.0.8
                                 2.0.9
                                 2.0.10
                                 2.0.11
                                 2.0.12
                                 2.0.14

[Unbound memory (Base  /Range)]:  0x0/64
                (bytes) (MB)      0x8000000/6080
[Available memory (MB)]:  6144
#
```

Step 3. Issue the **vparcreate -p...** command to create the new virtual partition and as needed use **vparmodify -p...** to further configure the new virtual partition.

When using the `vparcreate` command you *must specify* the name for the new virtual partition (`-p` *vpname*).

You also should specify the resources that are to be assigned for exclusive use by the virtual partition, including processor (`-a cpu...`) memory (`-a mem...`) and input/output (`-a io...`) resources.

You also can include other virtual partition attributes and settings (such as the autoboot setting) as part of the vparcreate command that establishes the new virtual partition.

```
# vparcreate -p Mesh -a mem::2048 -a io:2/0/14 -a io:2/0/0 -B manual -S dynamic
-a io:2/0/14/0/0.6:BOOT -a cpu:2/10
#
```

To further modify the virtual partition, issue the vparmodify command after vparcreate has created the new virtual partition.

For other details on creating and configuring virtual partitions see the section *Configuring Virtual Partition Resources and Attributes* on page 445.

Step 4. Issue the **vparstatus** command to list the configuration and boot status for the newly created virtual partition.

For detailed virtual partition information, use the **vparstatus -v -p...** command.

If you need to change any of the new virtual partition's configuration details, use the **vparmodify** command.

```
# vparstatus
[Virtual Partition]
                                                                          Boot

S318

Deleting a Virtual Partition

This section describes the procedure for deleting a virtual partition and related issues you may encounter.

NOTE The virtual partition you delete *must* be in a "Down" state.

You can delete virtual partitions that are defined in the currently active vPars database (vpdb) used by the *local* nPartition.

You also can delete virtual partitions from an alternate vPars database that you specify using the `vparremove` command's `-D` *`database`* option.

You *cannot* modify or delete vPars configuration info from inaccessible vPars databases, such as those on currently unused boot disks. (Currently unused boot disks include: disks assigned to a virtual partition that is not in an "Up" state; or disks not currently booted by a virtual partition such as the ALT boot device for a virtual partition that has booted its PRI device.)

vPars Management: Deleting a Virtual Partition from an nPartition

This procedure deletes a virtual partition's configuration info from the currently active vPars database.

Also see the book *Installing and Managing HP-UX Virtual Partitions (vPars)* for virtual partition management info.

Step 1. Login to HP-UX running on one of the virtual partitions in an nPartition.

Step 2. Issue the **vparstatus** command to list the current boot status and high-level configuration information for all virtual partitions defined in the currently active vPars database (vpdb) used by the local nPartition

```
# vparstatus
[Virtual Partition]
                                                                    Boot
Virtual Partition Name         State Attributes Kernel Path         Opts
============================== ===== ========== =================== =====
Shad                           Up    Dyn,Auto   /stand/vmunix
Mesh                           Down  Dyn,Manl   /stand/vmunix       boot

[Virtual Partition Resource Summary]
                                                  CPU    Num       Memory (MB)
```

S317

```
                                   CPU     Bound/    IO   # Ranges/
Virtual Partition Name           Min/Max  Unbound   devs  Total MB     Total MB
============================== =============== ==== ====================
Shad                               2/  8    2    0     7    0/   0          2048
Mesh                               2/ 12    2    0     3    0/   0             0
#
```

Step 3. Issue the **vparremove -p *vpname*** command to delete the specified virtual partition (*vpname*) and then issue the **vparstatus** command to list the new configuration status.

You can delete only virtual partitions that are in a “Down” state, as reported by the vparstatus command (see the example in the previous step).

See the *vparremove* (1M) manpage for details.

```
# vparremove -p Mesh
Remove virtual partition Mesh? [n]  y
#
# vparstatus
[Virtual Partition]
                                                                          Boot
Virtual Partition Name          State Attributes Kernel Path              Opts
============================== ===== ========== ========================= =====
Shad                            Up    Dyn,Auto   /stand/vmunix

[Virtual Partition Resource Summary]
                                          CPU     Num        Memory (MB)
                                   CPU     Bound/    IO   # Ranges/
Virtual Partition Name           Min/Max  Unbound   devs  Total MB     Total MB
============================== =============== ==== ====================

#
```

5316

Modifying Virtual Partition Configuration Attributes

This section describes how to add or remove resources from a virtual partition, and how to change a virtual partition's attribute settings.

Many virtual partition hardware resource changes require that the virtual partition being modified *is not running* (not in an "Up" state).

vPars Management: Modifying Virtual Partition Attributes in nPartition Environments

This procedure describes how to modify a virtual partition's attributes and resource configuration.

Step 1. Login to HP-UX running on one of the virtual partitions in an nPartition, or login to HP-UX running in non-vPars mode on an nPartition.

You can modify virtual partition attributes from HP-UX running in a virtual partition.

You also can modify vPars database configurations when you have booted HP-UX in non-vPars mode. By default the `vparcreate`, `vparmodify`, and `vparstatus` commands use the `/stand/vpdb` file.

To modify a vPars database other than the `/stand/vpdb` file, use the `-D` option to specify its location.

Step 2. Issue the **vparstatus** command to list the current status of the virtual partition you plan to update.

For detailed info on a virtual partition use the `vparstatus -v -p...` command.

```
# vparstatus
[Virtual Partition]
                                                                           Boot
Virtual Partition Name         State Attributes Kernel Path                Opts
============================== ===== ========== ========================== =====
Shad                           Up    Dyn,Manl   /stand/vmunix
Mesh                           Up    Dyn,Manl   /stand/vmunix              boot

[Virtual Partition Resource Summary]
                                           CPU     Num       Memory (MB)
                                  CPU     Bound/    IO   # Ranges/
Virtual Partition Name          Min/Max  Unbound   devs  Total MB    Total MB
==============================  ================   ====  ====================
```

5315

```
Shad                                     2/  8     2   6      7    0/  0          2048
Mesh                                     2/ 12     2   6      3    0/  0          2048
#
```

Step 3. Issue the **vparmodify -p...** command to modify the specified virtual partition.

See the section *Configuring Virtual Partition Resources and Attributes* on page 445 for descriptions of the virtual partitions configuration options.

Also see the *vparmodify* (1M) manpage for details.

For example, the following commands set the virtual partition named "Mesh" to be configured for autoboot; configure "Shad" to have 4 processors; and configure "Mesh" to have 12 processors:

```
# vparmodify -p Mesh -B auto
# vparmodify -p Shad -m cpu::4
# vparmodify -p Mesh -m cpu::12
```

Step 4. Issue the vparstatus command to list the new status for the virtual partition you modified in the previous step.

You can make further changes to the virtual partition by issuing additional vparmodify commands.

```
# vparstatus
[Virtual Partition]
                                                                                Boot
Virtual Partition Name         State Attributes Kernel Path                     Opts
============================== ===== ========== ========================= =====
Shad                           Up    Dyn,Manl   /stand/vmunix
Mesh                           Up    Dyn,Auto   /stand/vmunix                   boot

[Virtual Partition Resource Summary]
                                          CPU     Num        Memory (MB)
                                 CPU    Bound/    IO    # Ranges/
Virtual Partition Name         Min/Max  Unbound  devs   Total MB     Total MB
============================== ================ ==== ====================
Shad                             2/  8    2   2     7    0/  0          2048
Mesh                             2/ 12    2  10     3    0/  0          2048
#
```

5314

Listing the Status for Virtual Partitions

This section covers methods for listing the status of virtual partitions in an nPartition.

You can list virtual partition status details from HP-UX running on a virtual partition. You also can list vPars database details for nPartitions that are not booted in vPars mode.

In addition to the procedure listed below, you can list limited virtual partition status info from the vPars monitor (the MON> prompt) by using the vparinfo monitor command.

vPars Management: Listing Virtual Partition Status from an nPartition

This procedure lists the boot status and configuration details for virtual partitions that are defined in an nPartition.

Step 1. Login to HP-UX running on any of the virtual partitions in the nPartition.

Step 2. Issue the **vparstatus** command for details about virtual partitions.

You can list the status for all virtual partitions, a specific virtual partition, or the vPars monitor's event log.

- To list a summary that includes the status for all currently defined virtual partitions, issue the **vparstatus** command with no arguments or options.
- To list detailed information about a specific virtual partition, issue the **vparstatus -v -p** ***vpname*** command.
- To display history from the vPars monitor's event log issue the **vparstatus -e** command.

  The vPars monitor event log details are available only when the nPartition is booted in vPars mode.

```
# vparstatus
[Virtual Partition]
                                                                          Boot
Virtual Partition Name          State Attributes Kernel Path              Opts
============================== ===== ========== ========================= =====

S312

Booting HP-UX on Virtual Partitions

This section provides a procedure for loading and booting HP-UX on a virtual partition that is running in an nPartition.

As part of the virtual partition boot process, you will boot the `/stand/vpmon` vPars monitor from the nPartition BCH interface instead of booting the `/stand/vmunix` HP-UX kernel.

From the vPars monitor (the `MON>` prompt) running on an nPartition, you can load one or more virtual partitions. Each virtual partition then can boot a single instance of the HP-UX kernel.

Before performing this procedure, review the following list for an overview of situations you may encounter when loading and booting virtual partitions on an nPartition server.

- If one or more virtual partitions already has loaded/booted HP-UX on the nPartition, you can load/boot additional virtual partitions from HP-UX running on one of the existing virtual partitions.

  In this situation, you can issue the `vparboot` command to load other virtual partitions; see the *vparboot* (1M) manpage for details.

  However, you can only load virtual partitions that are defined in the currently active vPars configuration database, which typically is the `/stand/vpdb` file on the same boot device where `/stand/vpmon` was booted.

- If HP-UX is booted in non-vPars mode on an nPartition, you must shut down HP-UX on the nPartition and from the nPartition's BCH interface boot the `/stand/vpmon` vPars monitor before loading any virtual partitions.

These above situations also are addressed in the following procedure.

vPars Management: Booting HP-UX B.11.11 on Virtual Partitions in an nPartition

This procedure describes how to boot HP-UX on one or more virtual partitions in a single nPartition.

Also refer to the chapters *An Overview of nPartition Boot and Reset* on page 161 and *Booting and Resetting nPartitions* on page 197 for details on booting nPartitions.

Step 1. Login to the service processor (GSP or MP) for the server where the virtual partitions will be booted.

Step 2. Access the console for the nPartition in which the virtual partitions will boot HP-UX.

From the service processor main menu enter **CO** to access the nPartition console menu, and select the nPartition in which you will boot the virtual partitions.

```
GSP> CO

        Partitions available:

          #    Name
        ---    ----
          0)   feshd4a
          1)   feshd4b
          Q)   Quit

        Please select partition number: 0
```

Step 3. Access HP-UX or the BCH interface for the nPartition, and if needed reboot the instance of HP-UX running on the nPartition.

When accessing the nPartition console, if you can interact with a BCH command prompt such as the following:

```
Main Menu: Enter command or menu >
```

then you can proceed to the next step and *skip the rest of this step*.

If you cannot interact with a BCH menu or HP-UX login prompt or command line, then the nPartition might be booting or might be hanged.

You can use the server's Virtual Front Panel (VFP) to check the nPartition's current boot state. Refer to the chapter *Using Console and Service Processor Interfaces* on page 125 for details.

Otherwise, if HP-UX is running in the nPartition, first check to see whether HP-UX booted in vPars-mode or non-vPars mode.

Enter the **vparstatus -w** command, and determine the current nPartition boot state:

- If `vparstatus` reports `Error: Virtual partition monitor not running` then the nPartition is *not running vPars*.

  Enter `shutdown -r` to reboot the nPartition and as needed interrupt the autoboot process to access the nPartition's BCH interface.

After entering the `shutdown` command and accessing the BCH interface you can *proceed with the next step.*

- If `vparstatus` reports `The current virtual partition is...` then the nPartition is *running one or more virtual partitions.*

NOTE

This note applies only when an nPartition is running one or more virtual partitions.

Because at least one virtual partition already has loaded/booted HP-UX on the nPartition, you should check whether the virtual partition you wish to boot already is loaded, or whether the virtual partition can be loaded without rebooting HP-UX.

From HP-UX running on the virtual partition, enter the `vparstatus` command.

If the virtual partition you wish to load/boot *is not listed* in the `vparstatus` output, you may need to reboot the nPartition and its virtual partitions and you can *proceed with the rest of this step and procedure.*

If the virtual partition you wish to load/boot is listed, then check its boot state. If the virtual partition is "Up" then it *already has loaded / booted* HP-UX. If the virtual partition is "Down" then you can load/boot it using the `vparboot` command (see the *vparboot* (1M) manpage). In either of these two cases you can *skip the rest of this procedure.*

If you are certain that you need to reboot the nPartition and its virtual partitions, proceed with the rest of this step.

To access BCH, shut down HP-UX on all virtual partitions and reset the virtual partition.

See the procedure *Rebooting or Shutting Down Virtual Partitions* on page 494 for complete details on shutting down HP-UX on all virtual partitions and returning to the BCH interface. You must shut down and halt (`shutdown -h`) HP-UX in each virtual partition, and then at the vPars monitor's `MON>` prompt enter the `reboot` command to reset the nPartition. When the nPartition resets all active cells in the

S309

nPartition are reset; after the cells reset you should interrupt the nPartition's autoboot process if needed and then access the BCH interface.

Once you have access to the BCH interface proceed with the next step.

Step 4. From the BCH interface enter the **`BOOT`** ***`device`*** command, where *`device`* is the disk where the desired vPars configuration database (the `/stand/vpdb` file) resides.

When using the `BOOT` command you can specify a boot path variable (for example, `BOOT PRI`) or a hardware path for the boot device (for example, `BOOT 0/0/1/0/1.3`).

In addition to having the vPars database (vpdb), the device must have both HP-UX B.11.11 and the vPars software product installed.

Step 5. Instruct BCH to stop the boot process at the ISL prompt by entering **`y`** at the "Do you wish to stop" prompt.

```
Do you wish to stop at the ISL prompt prior to booting? (y/n)
>> y
```

If the boot device's AUTO is set to boot `/stand/vpmon` then you can instead enter `n` (for "do not stop at ISL") and have the nPartition proceed to boot the vPars monitor automatically.

However, you must direct the ISL/SSL interfaces to load `/stand/vpmon` if the boot device's AUTO file *does not contain* the string `hpux boot /stand/vpmon`.

You can check the AUTO file contents from the ISL prompt by entering the `hpux show autofile` command. By default the AUTO file is set to `hpux`, which loads the `/stand/vmunix` kernel.

See *Configuring Virtual Partition Autoboot* on page 498 for details on configuring a boot device's AUTO file.

Step 6. As necessary, from the ISL interface enter the **`hpux boot /stand/vpmon`** command to boot the vPars monitor (vpmon) on the local nPartition.

```
ISL> hpux boot /stand/vpmon

Boot
: disk(0/0/6/0/0.5.0.0.0.0.0;0)/stand/vpmon
565248 + 156368 + 16872200 start 0x23000
```

S308

```
Welcome to VPMON (type '?' for a list of commands)

MON>
```

If you stopped at the ISL interface, you must perform this step.

You do not need to perform this step if the boot device AUTO file is set to `hpux boot /stand/vpmon` and you did not stop at the ISL prompt in the previous step.

Step 7. At the vPars monitor's MON> prompt, enter the **vparinfo** command to list details about the virtual partitions currently defined in the vPars database (vpdb).

Especially note the list of virtual partitions that the `vparinfo` command displays as the "Names of the partitions in the database".

```
MON> vparinfo

Resources not assigned to any partition
-------------------------------------
0           0xfffffffffc000000       1       0   TYPE=14   SV_MODEL=170
0/0         0xffffff808000000        1       0   TYPE= 7   SV_MODEL= 12
0/0/0       0xffffff804000000        1       0   TYPE=13   SV_MODEL= 10
0/0/1       0xffffff804002000        1       0   TYPE=13   SV_MODEL= 10

....

Names of the partitions in the database:
----------------------------------------

Shad
Mesh

Available Free Memory: 0 MB

Available MEM RANGE: 0x0000000000000000-0x00000000ffffffff (4194304 Kb)
MON>
```

To see detailed information about a particular virtual partition you can use the `vparinfo` *vpname* command, where *vpname* is the virtual partition's name. This detailed information includes the resources assigned to the virtual partition and other details such as the virtual partition boot path(s) and the virtual partition's autoboot setting.

Step 8. From the vPars monitor's MON> prompt, use the **vparload** command load/boot HP-UX on a virtual partition.

S307

You can specify any of the following vparload commands at the vPars monitor MON> prompt:

- To load/boot HP-UX on *all virtual partitions* that are defined in the current vPars configuration database, enter: **vparload -all**
- To load/boot HP-UX on *a single virtual partition*, enter: **vparload -p *vpname***

  where *vpname* is the name of the virtual partition, as reported by the vparinfo command in the previous step.
- To load/boot HP-UX only on *the autoboot-enabled virtual partitions*, enter: **vparload -auto**

  This command loads only the virtual partitions that have the autoboot attribute configured (the boot attribute is set to auto).

The following example shows the virtual partition named “Shad” being loaded from the vPars monitor prompt and booting HP-UX.

```
MON> vparload -p Shad
[MON] Booting Shad...
[MON] Console client set to Shad
[MON] Console server set to Shad

[Shad]

[MON] Shad loaded

```

Step 9. Login to HP-UX running in the virtual partition you loaded/booted in the previous steps of this procedure.

Because the *nPartition console is shared by all virtual partitions* within the nPartition, you should login using a method other than the system console login for most virtual partition access purposes.

Use the `telnet` command or another remote login method to access HP-UX running on the virtual partition.

After you login to a virtual partition running on an nPartition, you can list the current virtual partition using `vparstatus -w`, and can list the local nPartition's partition number using the `parstatus -w` command.

```
# vparstatus -w
The current virtual partition is Shad.
# parstatus -w
The local partition number is 0.
#
```

S305

Rebooting or Shutting Down Virtual Partitions

This section describes how to reboot HP-UX in a virtual partition and how to shut down all virtual partitions running in an nPartition.

After shutting down all virtual partitions in an nPartition you can reboot the vPars monitor to reset the nPartition and, after resetting, make the nPartition's BCH interface available.

NOTE

The nPartition *reboot for reconfig* and *ready for reconfig state* involve methods of resetting an nPartition that require additional considerations not covered in this section.

See the section *Managing nPartitions from a Virtual Partition* on page 506 for details and procedures to perform a *reboot for reconfig* or to shut down an nPartition to a *ready for reconfig state* when one or more virtual partitions is running in the nPartition.

When you reboot (`shutdown -r`) HP-UX running in a virtual partition, HP-UX will automatically attempt to reboot on the virtual partition *if* the virtual partition is configured for autoboot *and* none of the other virtual partitions in the same nPartition have initiated a reboot for reconfig or a shutdown to the ready for reconfig state.

You can interrupt the virtual partition autoboot process when accessing the virtual partition's console interface through its nPartition's console.

When you halt (`shutdown -h`) HP-UX running in a virtual partition the virtual partition shuts down to a "Down" state and HP-UX does not reboot. After you have halted a virtual partition you can load/boot HP-UX on the virtual partition using the `vparboot` command from HP-UX running on any of the other virtual partitions in the same nPartition. Also see the procedure *vPars Management: Booting HP-UX B.11.11 on Virtual Partitions in an nPartition* on page 487 for other methods and details.

To shut down *all virtual partitions* in an nPartition, login to each virtual partition through its console and halt HP-UX (`shutdown -h`). Then from the vPars monitor's `MON>` prompt you can enter `reboot` to exit the vPars monitor and reset the nPartition's active cells.

S304

vPars Management: Rebooting or Shutting Down Virtual Partitions in an nPartition

The following procedure is for performing a normal reboot (`shutdown -r`) or a shutdown-and-halt (`shutdown -h`) in a virtual partition that is running in an nPartition.

This procedure also describes how to halt all virtual partitions in an nPartition and return to the nPartition's BCH interface.

Step 1. Login to HP-UX running on the virtual partition that you want to shutdown or reboot.

You can login to the virtual partition remotely by using the `telnet` command or another remote login command, or can login through the virtual partition's console.

If you plan to *shut down all virtual partitions* in the nPartition, you should gain console login access to the virtual partitions.

You also will need virtual partition console access for this procedure if you must interrupt the virtual partition's HP-UX autoboot process.

To access the virtual partition's console, first login to the service processor (GSP or MP) for server where the virtual partition's nPartition resides and then access the nPartition's console. As needed, in the nPartition console type **Control-a** to switch among the virtual partition consoles.

Step 2. Enter the **`vparstatus -w`** command to confirm that you are logged into the virtual partition that you want to shut down.

You also can check the virtual partition's autoboot setting by using the `setboot` or the `vparstatus` command.

```
# vparstatus -w
The current virtual partition is Shad.
# setboot
Primary bootpath : 0/0/6/0/0.5.0
Alternate bootpath : 0/0/6/0/0.6.0

Autoboot is ON (enabled)
Autosearch is ON (enabled)

Note: The interpretation of Autoboot and Autosearch has changed
for
```

5303

```
systems that support hardware partitions. Please refer to the
manpage.
#
```

Step 3. From HP-UX running in the virtual partition you want to shut down, enter the **shutdown** command with the appropriate command-line options.
If shutting down *all virtual partitions* in the nPartition, use **shutdown -h**.

To shut down and halt HP-UX on the virtual partition, enter the **shutdown -h** command along with any additional command-line options you need.

To shut down HP-UX on the virtual partition and allow the virtual partition to autoboot HP-UX if it is configured to do so, enter the **shutdown -r** command along with any additional options you need.

See the *shutdown* (1M) manpage for complete details about all options.

Step 4. If you are shutting down *all virtual partitions* in the nPartition, type **Control-a** to switch to the next virtual partition's console login prompt, login to the virtual partition, and then repeat *Step 2* and *Step 3* to shut down HP-UX in the virtual partition.

Typing **Control-a** switches among the virtual partition consoles that are available through an nPartition's console, when one or more virtual partitions are loaded/booted in the nPartition.

NOTE When you type **Control-a** repeatedly in the nPartition console and remain at the vPars monitor (`MON>` or `[MON]`), then no virtual partitions are loaded or booted in the nPartition.

Step 5. If you are shutting down *all virtual partitions* in the nPartition, then after you have halted HP-UX running in each virtual partition in the nPartition you can reset the nPartition by entering the **reboot** command from the `MON>` prompt.

The vPars monitor `reboot` command resets all active cells in the nPartition.

S302

After the cells have reset and completed self-tests, the cells participate in partition rendezvous, form an nPartition, and finally the nPartition's BCH interface is made available through the nPartition console.

If the nPartition is configured to autoboot, you can interrupt the autoboot process by typing any key at the appropriate time when accessing the nPartition's console.

If autoboot is configured for an nPartition, you will see a message similar to the following in the nPartition's console during the nPartition reset process.

```
Attempting to boot using the primary path.
-------------------------------------------------------------

 To discontinue, press any key within 10 seconds.
```

530

Configuring Virtual Partition Autoboot

This section describes how you can configure an nPartition to automatically boot the virtual partitions Monitor and to also boot all virtual partitions that have autoboot configured.

For details on automatically booting HP-UX in *non-vPars mode* on an nPartition, refer to the chapter *Booting and Resetting nPartitions* on page 197.

As the following procedure describes, setting up the virtual partitions autoboot process involves first configuring the nPartition's boot device paths and path flags to boot the device where the current vPars database resides, then configuring that boot device's AUTO file to specify that the vPars monitor be loaded with the `-a` option, and finally configuring the virtual partitions that you want load automatically to have their boot attribute set to auto.

vPars Management: Configuring Virtual Partition Boot Settings

This procedure configures an nPartition to autoboot the vPars monitor (`MON>` prompt) and also automatically load/boot the virtual partitions that have autoboot configured.

Step 1. From the nPartition's BCH interface, configure the nPartition to automatically boot the device where the current vPars database and vPars monitor resides.

First configure one of the nPartition's boot path variables (PRI, HAA, or ALT) to reference the device where the current vPars database (`/stand/vpdb`) resides.

Then configure the nPartition's path flags to boot the chosen device path.

Refer to the chapter *Booting and Resetting nPartitions* on page 197 for details on nPartition autoboot, including device path and path flag configuration.

Step 2. Boot HP-UX in *non-vPars mode* from the device you configured in the previous step.

From the BCH interface, issue the BOOT command and specify the boot path variable you set in the previous step. For example: `BOOT HAA` to boot the HAA device path.

Step 3. Login to HP-UX and configure the chosen boot device's AUTO file.

S300

After HP-UX has booted in non-vPars mode on the nPartition, login as root, use the lvdisplay command to list device file for the boot device, and then use the mkboot command to configure the boot device's AUTO file. You also can use the lifcp command to display the contents of the AUTO file.

For example, the following mkboot command sets the AUTO file for the /dev/dsk/c1t5d0 device, and the lifcp command displays the contents of the device's AUTO file.

```
# mkboot -a "hpux boot /stand/vpmon -a" /dev/dsk/c1t5d0
# lifcp /dev/dsk/c1t5d0:AUTO -
hpux boot /stand/vpmon -a
#
```

The vpmon -a option specifies to automatically load/boot all virtual partitions that have autoboot configured when the vPars monitor is loaded.

Also see the example *Autoboot Configuration Example for Virtual Partitions (vPars)* on page 500 for more example.

Step 4. From HP-UX check all virtual partition boot attributes and reconfigure any boot attributes to establish the virtual partitions autoboot configuration you desire.

Use the vparstatus command to list details about all virtual partitions, including boot attributes. Note that when you issue this command when HP-UX is booted in non-vPars mode, the command presents configuration info based on the /stand/vpdb vPars database.

Then as needed use the vparmodify command to reconfigure any boot attributes. For example, the following command sets the virtual partition named "Mesh" to automatically load/boot HP-UX when possible.

```
# vparmodify -p Mesh -B auto
```

Each virtual partition that you want to boot automatically must have its boot attribute set to auto.

Step 5. Reboot the nPartition, and as desired observe its boot progress from the nPartition's Virtual Front Panel or its console.

The result of this nPartition reboot is to automatically load/boot the virtual partitions that you have configured for autoboot.

5299

Issue the **shutdown -r** command to shut down HP-UX and reboot the nPartition.

When the nPartition reboots to its BCH interface, it will proceed to boot the device path you specified using nPartition boot paths and path flags. The nPartition then will execute the device's AUTO file contents that you specified, to load the /stand/vpmon vPars monitor. Finally, because the vPars monitor is invoked with the -a option, it will automatically load/boot all virtual partitions that have autoboot configured.

Example 11-1 **Autoboot Configuration Example for Virtual Partitions (vPars)**

In this example, the user first confirms that the vPars database (/stand/vpdb) and vPars monitor (/stand/vpmon) are in the /stand directory and thus can be referenced and booted.

The bdf command displays the logical volume associated with the /stand directory, and the the lvdisplay command then displays the device file associated with the logical volume.

```
# ls /stand/vp*
/stand/vpdb    /stand/vpmon
# bdf /stand
Filesystem          kbytes    used   avail %used Mounted on
/dev/vg00/lvol1     512499   71581  389668   16% /stand
# lvdisplay -vk /dev/vg00/lvol1 | grep dev
LV Name                      /dev/vg00/lvol1
VG Name                      /dev/vg00
   /dev/dsk/c1t5d0    128        128
#
```

The first lifcp command that follows displays the original contents of the boot device's AUTO file. Originally, this device is configured with the AUTO file default, hpux, which invokes the hpux loader with no options and thus the /stand/vmunix kernel would be booted.

The mkboot command that follows sets the AUTO file contents so that the hpux loader will boot the /stand/vpmon vPars monitor with the -a option. Issuing the lifcp command again shows the new contents of the device's AUTO file.

```
# lifcp /dev/dsk/c1t5d0:AUTO -
hpux
# mkboot -a "hpux boot /stand/vpmon -a" /dev/dsk/c1t5d0
# lifcp /dev/dsk/c1t5d0:AUTO -
hpux boot /stand/vpmon -a
#
```

S298

Next the user issues the vparstatus command to list the current settings for the virtual partitions defined in the /stand/vpdb file. Because the vparstatus command is issued when the local nPartition is booted in non-vPars mode, the command lists info based on the vpdb file rather than the vPars monitor (which is not running).

```
# vparstatus
vparstatus: Warning: Virtual partition monitor not running, Requested resources
shown.
[Virtual Partition]
                                                                          Boot
Virtual Partition Name         State Attributes Kernel Path               Opts
============================== ===== ========== ========================= =====
Shad                           N/A   Dyn,Manl   /stand/vmunix
Mesh                           N/A   Dyn,Manl   /stand/vmunix

[Virtual Partition Resource Summary]
                                           CPU    Num        Memory (MB)
                                  CPU     Bound/   IO   # Ranges/

==============================  ================  ====  ====================
Shad                              2/  3    2   0     6    0/  0         2048
Mesh                              1/  2    1   1     6    0/  0         1024
#
```

In this example both virtual partitions, named “Shad” and “Mesh”, originally are configured to be booted manually, as shown in the previous vparstatus command output: the boot attribute for each is listed as “Manl” (manual).

Next the vparmodify command reconfigures the boot attribute for the virtual partition named “Mesh” to auto.

After changing the boot attribute, issuing the vparstatus command shows updated info about “Mesh” and lists its boot attribute as “Auto” (auto).

```
# vparmodify -p Mesh -B auto
# vparstatus -p Mesh
vparstatus: Warning: Virtual partition monitor not running, Requested resources
shown.
[Virtual Partition]
                                                                          Boot
Virtual Partition Name         State Attributes Kernel Path               Opts

============================  ========  =======  ====  =================
Mesh                             1/  2     1   1      6   0/  0        1024
#
```

This example nPartition now is configured so that when the nPartition reboots it will automatically boot from a device that will automatically load a vPars monitor, which then will automatically load/boot the virtual partition named “Mesh”.

In this example’s next step the user reboots the nPartition by issuing the `shutdown -r` command.

```
# shutdown -r

SHUTDOWN PROGRAM
06/26/02 17:57:23 CDT
Waiting a grace period of 60 seconds for users to logout.
Do not turn off the power or press reset during this time.

Broadcast Message from root (console) Wed Jun 26 17:58:23...
SYSTEM BEING BROUGHT DOWN NOW ! ! !

Do you want to continue? (You must respond with 'y' or 'n'.):   y

/sbin/auto_parms: DHCP access is disabled (see /etc/auto_parms.log)

     System shutdown in progress
     ___________________________

     Stopping OpC agent processes (opcagt). .................... OK
     Stop CDE login server ..................................... OK
```

Because the nPartition is booted in non-vPars mode, the `shutdown -r` command shuts down HP-UX and resets the nPartition’s active cells.

After the cells boot and the nPartition reaches its BCH interface, the autoboot process begins.

The following example output shows that the nPartition automatically boots the primary (PRI) boot device path, whose AUTO file is configured to load the vPars monitor and automatically load/boot the virtual partitions whose boot attribute is auto.

The end result of this example nPartition shutdown-and-reboot is that the nPartition has loaded/booted the virtual partition named “Mesh”.

```

In this example, the nPartition has completed the reboot and autoboot process and has automatically loaded/booted the virtual partition named “Mesh”, which has its boot attribute set to auto.

As the following output shows, when the user logs in to HP-UX running on the virtual partition, the vparstatus and parstatus commands report that the *current virtual partition* is “Mesh”, the *local nPartition* is partition number 0, and the virtual partition named “Shad” is in a “Down” state. Shad was not automatically loaded/booted because its boot attribute is set to manual (listed as “Manl” in the output below).

Managing nPartitions from a Virtual Partition

This section covers the nPartition management issues that are unique to virtual partition environments.

NOTE

In virtual partition environments, you can apply the same nPartition configuration tools and principles that you use in non-vPars environments—but you *must take additional steps* to perform a reboot for reconfig of an nPartition that has more than one virtual partition loaded/booted.

The procedures in this section address the minor differences in performing nPartition reconfiguration and reboot for reconfig processes when using virtual partitions in an nPartition.

The following procedures are covered in this section:

- *vPars Management: Determining if an nPartition is Running vPars* on page 507
- *vPars Management: Performing a Reboot for Reconfig or Shutdown to Ready for Reconfig from a Virtual Partition* on page 510
- *vPars Management of nPartitions: Adding and Removing nPartition Cells from a Virtual Partition* on page 513
- *vPars Management of nPartitions: Reconfiguring nPartition Attributes from a Virtual Partition* on page 518

Also refer to the chapter *Managing nPartitions* on page 243 for complete nPartition management procedures.

Virtual partition configuration procedures are covered in the section *Procedures for Managing Virtual Partitions on HP nPartition Servers* on page 475.

5292

Determining if an nPartition is Running vPars

This section gives you several methods for determining if an nPartition has loaded/booted HP-UX in or more virtual partitions. For example, typing **Control-a** at the nPartition console, or using the `vparstatus` command.

vPars Management: Determining if an nPartition is Running vPars

Step 1. Login to the service processor (GSP or MP) for the server where the nPartition resides, and access the nPartition's console. From the main menu, enter `CO` for the console menu and select the nPartition's console.

Step 2. At the nPartition's console, determine the current boot state.

The nPartition's current console prompt, if any, provides the first clue about the boot state:

- If you can interact with a BCH command prompt such as the following:

  ```
  Main Menu: Enter command or menu >
  ```

  Then the nPartition has not booted HP-UX or any virtual partitions.

- If you can interact with a vPars monitor prompt (`MON>`) then the nPartition has *at least* booted the `/stand/vpmon` vPars monitor.

  It is possible that one or more virtual partitions also are loaded/booted.

- If you can interact with the HP-UX console login prompt or the HP-UX command line then you still need to determine if HP-UX has booted in a vPars or in non-vPars mode.

If the nPartition console does not have any interactive prompt or command line, then you can use the Virtual Front Panel to help determine if the nPartition is in the process of booting/resetting or if HP-UX has hanged.

Step 3. When the nPartition's console gives access to the vPars monitor or HP-UX, use additional techniques to determine how many (if any) virtual partitions are loaded/booted.

5291

You can type **Control-a** to switch among the virtual partition consoles. Each time you type **Control-a** the name of the current virtual partition or monitor ([MON]) is displayed in the console window.

If HP-UX is running, login as root and issue the **vparstatus -w** command to list the current virtual partition's name. The **vparstatus** command with no options lists all virtual partitions.

Example 11-2 Checking if Virtual Partitions are Running on an nPartition

The following examples show different nPartition boot states on systems that have the HP vPars software installed.

In the following example, the vPars monitor has booted on the nPartition but virtual partitions have not yet been loaded or booted. Typing **Control-a** repeatedly did not switch to any virtual partitions—only the monitor ([MON]) is running.

```
MON>
Control-a
 [MON]
Control-a
 [MON]
Return
MON>
```

In the following example, HP-UX is running on the nPartition. Although the vPars software is installed, the nPartition is running in non-vPars mode. The vPars monitor is not running, indicating that /stand/vmunix was booted from BCH, not the /stand/vpmon vPars monitor.

```
# vparstatus
vparstatus: Error: Virtual partition monitor not running.
#
```

Finally, in the following example, HP-UX is running on a virtual partition in the nPartition. The current virtual partition is "Shad" and it is the only loaded/booted virtual partition in the nPartition: the other virtual partition named "Mesh" is in a "Down" state.

```
# vparstatus -w
The current virtual partition is Shad.
# vparstatus
[Virtual Partition]
                                                                   Boot
Virtual Partition Name        State Attributes Kernel Path              Opts
============================== ===== ========== ========================= =====
Shad                          Up    Dyn,Manl   /stand/vmunix
Mesh                          Down  Dyn,Manl   /stand/vmunix              boot
```

5290

```

5289

Reboot for Reconfig or Shutdown to *Ready for Reconfig* from a Virtual Partition

This section describes how to perform a *reboot for reconfig* and how to shut down an nPartition to the *ready for reconfig* state on nPartitions that are running HP-UX one or more virtual partitions.

A **reboot for reconfig** resets all cell in the nPartition, performs any nPartition reconfigurations, and reboots the nPartition to its BCH interface and allows the nPartition to autoboot, if it is configured to autoboot.

A shut down to the **ready for reconfig state** resets all cell in the nPartition, performs any nPartition reconfigurations, and then holds all cells at a boot-is-blocked state, which makes the nPartition *inactive*.

Refer to the chapter *Booting and Resetting nPartitions* on page 197 for complete details.

vPars Management: Performing a *Reboot for Reconfig* or Shutdown to *Ready for Reconfig* from a Virtual Partition

This procedure covers how to perform a *reboot for reconfig* of an nPartition that is running virtual partitions.

This procedure also describes how to reset an nPartition to a *ready for reconfig* state, for an nPartition that is running vPars.

Step 1. Login to HP-UX running on any of the nPartition's virtual partitions.

Step 2. Issue the **parstatus -w** command to list the local nPartition's partition number, and confirm that you are logged into the virtual partition on the nPartition you want to reboot.

Step 3. Issue the **vparstatus** command to list details about all virtual partitions currently defined in the local nPartition.

Check the command's output to determine whether a reboot for reconfig or a shutdown to ready for reconfig already has been initiated from one of the virtual partitions in the nPartition.

The following note in the `vparstatus` output is presented when either type of reconfig shutdown has been initiated.

S288

```
Note:  A profile change is pending.  The hard partition must be
rebooted to complete it.
```

If this note is presented, then in all other virtual partitions at an "Up" or "Load" or "Boot" state issue the **shutdown -r** command and *skip the next step*.

Step 4. Issue the **shutdown** command with the options appropriate for the type of reboot you want to perform.

You can perform a reboot for reconfig or reset the nPartition to the ready for reconfig (inactive) state.

Use either of the following lists for details.

To perform the *reboot for reconfig* of the local nPartition:

- First issue the **shutdown -R** command in the *current* virtual partition.
- Then in all other virtual partitions at an "Up" or "Load" or "Boot" state, issue the **shutdown -r** command.

  Any virtual partitions in a "Load" or "Boot" state must be shut down *after* they finish loading/booting HP-UX.

  If the nPartition has only one virtual partition—or if all other virtual partitions are in a "Down" or "Shut" state—you do not need to shut down other virtual partitions.

To reset the nPartition to a *ready for reconfig (inactive)* state:

- First issue the **shutdown -R -H** command in the *current* virtual partition.
- Then in all other virtual partitions at an "Up" or "Load" or "Boot" state, issue the **shutdown -r** command.

  Any virtual partitions in a "Load" or "Boot" state must be shut down *after* they finish loading/booting HP-UX.

  If the nPartition has only one virtual partition—or if all other virtual partitions are in a "Down" or "Shut" state—you do not need to shut down other virtual partitions.

Step 5. Monitor the nPartitions boot state by using its Virtual Front Panel. You can access the VFP from the service processor (GSP or MP) main menu.

Refer to the chapter *An Overview of nPartition Boot and Reset* on page 161 for boot status details.

S287

5286

Adding or Removing nPartition Cells from a Virtual Partition

This section describes how you can add cells and remove cells from an nPartition that is running HP-UX in one or more virtual partitions.

See *vPars Management of nPartitions: Reconfiguring nPartition Attributes from a Virtual Partition* on page 518 for details on reconfiguring other nPartition attributes, such as boot paths or the nPartition name, from a virtual partition.

Complete nPartition configuration procedures are given in the chapter *Managing nPartitions* on page 243.

vPars Management of nPartitions: Adding and Removing nPartition Cells from a Virtual Partition

This procedure covers how to add and remove cells from an nPartition that is running the HP virtual partitions software product.

In this procedure, you make changes to the *local* nPartition from HP-UX running in a virtual partition in the nPartition.

For details on modifying remote nPartitions, or nPartitions not currently running vPars, refer to the chapter *Managing nPartitions* on page 243.

NOTE

After *removing* one or more cells from an nPartition, any virtual partitions defined within the nPartition may need to be reconfigured if they explicitly used processor or I/O resources on the removed cell(s).

The vPars software product automatically adjusts virtual partition configurations as needed to account for any expected hardware that is unavailable; as a result, *the vPars database may automatically be changed* after a cell is made inactive or is removed from its nPartition.

After *adding* one or more cells to an nPartition, to use the resources on the new cell(s) you also must modify the nPartition's virtual partition configurations. For example, for a virtual partition to bind the new cell's processors or use any attached I/O slots you must add the resource to the virtual partition by using the `vparmodify` command or the Virtual Partition Manager utility.

5285

Likewise, after an nPartition's inactive cell is made active you also must modify the nPartition's virtual partition configurations to explicitly use the cell's processor or I/O resources.

The following procedure initiates an nPartition cell assignment change from HP-UX running on one virtual partition (using parmodify or Partition Manager) and then *if required* performs a reboot for reconfig of the nPartition.

Step 1. Login to HP-UX running on one of the virtual partitions in the nPartition you want to reconfigure.

You must login as root to perform this procedure.

Step 2. List the local nPartition's partition number to confirm that you are logged into the nPartition you want to modify.

Issue the **parstatus -w** command or use an equivalent Partition Manager procedure to determine the local partition number.

Step 3. Issue the **vparstatus -w** command to list the current virtual partition's name, and then issue the **vparstatus** command (with no options) to list all virtual partitions defined in the local nPartition.

```
# parstatus -w
The local partition number is 0.
# vparstatus -w
The current virtual partition is Shad.
#
# vparstatus
[Virtual Partition]
                                                                   Boot
Virtual Partition Name         State Attributes Kernel Path         Opts
============================== ===== ========== ========================= =====
Shad                           Up    Dyn,Manl   /stand/vmunix
Mesh                           Down  Dyn,Manl   /stand/vmunix             -iS

[Virtual Partition Resource Summary]
                                          CPU     Num        Memory (MB)
                                 CPU      Bound/   IO    # Ranges/
Virtual Partition Name         Min/Max  Unbound  devs  Total MB     Total MB
============================== ================ ==== ====================
Shad                             2/  8    2   2     7    0/   0         2048
Mesh                             2/  8    2   2     3    0/   0         2048
#
```

5284

After you add or remove a cell from the local nPartition, *if required* you will initiate the nPartition's reboot for reconfig from the *current virtual partition only* and will initiate a normal reboot (`shutdown -r`) from all other "Up" (loaded/booted) virtual partitions in the nPartition.

Step 4. Request that the cell(s) be added or removed from the local nPartition.

Use the `parmodify` command or Partition Manager to initiate the cell addition or removal. For detailed information on adding or removing the cell see the following list:

- You should adhere to HP's nPartition requirements and guidelines when adding or removing cells from an nPartition; refer to the chapter *Planning nPartition Configurations* on page 109.
- For details on adding or removing a cell from an nPartition, refer to the chapter *Managing nPartitions* on page 243.

After you have used the `parmodify` command or Partition Manager to modify the local nPartition's configuration, proceed with the next step.

Step 5. Determine if the local nPartition must be shut down to perform a *reboot for reconfig*.

The cell addition and removal procedures referenced in the previous step describe the situations where a reboot for reconfig of the local nPartition is required.

You **must** perform a reboot for reconfig if you removed an *active* cell or you specified the `-B` option to the `parmodify` command. You also **should** perform a reboot for reconfig if you added a cell with a "y" use-on-next-boot value.

You **do not** need to perform a reboot for reconfig if you removed an inactive cell (and did not specify the `-B` option) or if you added a cell with a "n" use-on-next-boot value (and did not specify the `-B` option).

Step 6. *Only if required* to complete the nPartition configuration change, perform a reboot for reconfig of the local nPartition.

First issue the **vparstatus** command to list the state (such as "Up" or "Down") of all virtual partitions in the local nPartition.

```
# vparstatus
[Virtual Partition]
                                                                    Boot
Virtual Partition Name        State Attributes Kernel Path          Opts
```

5283

```
============================== ===== ========== ========================= =====
Shad                           Up    Dyn,Manl   /stand/vmunix
Mesh                           Load  Dyn,Manl   /stand/vmunix             boot

[Virtual Partition Resource Summary]
                                              CPU     Num        Memory (MB)
                                       CPU   Bound/    IO    # Ranges/
Virtual Partition Name               Min/Max Unbound  devs  Total MB    Total MB
==============================      ================  ====  ====================
Shad                                   2/  8   2    0     7    0/   0         2048
Mesh                                   2/ 12   2    0     3    0/   0         2048
#
```

To perform the reboot for reconfig of the local nPartition:

- First issue the **`shutdown -R`** command in the *current* virtual partition.
- Then in all other virtual partitions that are at an "Up" or "Load" or "Boot" state, issue the **`shutdown -r`** command.

  Any virtual partitions in a "Load" or "Boot" state must be shut down *after* they finish loading/booting HP-UX.

  If the nPartition has only one virtual partition—or if all other virtual partitions are in a "Down" or "Shut" state—you do not need to shut down other virtual partitions.

For details see *vPars Management: Performing a Reboot for Reconfig or Shutdown to Ready for Reconfig from a Virtual Partition* on page 510.

After you issue the above `shutdown` commands, HP-UX on the virtual partitions is shut down and the vPars monitor is automatically rebooted.

Because a reboot for reconfig is a *reset of the nPartition hardware*, any virtual partitions that are configured for autoboot do not do so at this time. Instead, the nPartition boot process takes place—including the configured nPartition autoboot behavior (defined by the nPartition's Path Flag settings).

As the reboot for reconfig occurs, *all cells* assigned to the nPartition will reset, any cell assignment changes for the nPartition will occur, and the cells will proceed to perform their self tests.

After the nPartition's cells complete self tests the partition rendezvous can occur and then the nPartition's BCH interface is initiated. If the nPartition is configured to autoboot, then that will occur; otherwise, the BCH interface is made available through the nPartition console interface.

To load/boot all virtual partitions, you can use the normal virtual partition boot methods. See the section *Booting HP-UX on Virtual Partitions* on page 487 for details.

5281

Reconfiguring nPartition Attributes from a Virtual Partition

This section describes how you can modify nPartition attributes from HP-UX running in a virtual partition in the same server as the nPartition.

For details on changing nPartition cell assignments from a virtual partition, see *vPars Management of nPartitions: Adding and Removing nPartition Cells from a Virtual Partition* on page 513.

NOTE

When one or more virtual partitions is loaded/booted on an nPartition, the `setboot` command *affects the current virtual partition's boot settings* and *does not* affect the local nPartition's boot settings.

In this situation, instead use the `parmodify` command to configure nPartition boot device paths from HP-UX.

nPartition configuration data is stored as part of the server Complex Profile and is separate from virtual partition configuration data, which typically is stored in the `/stand/vpmon` file on disk.

For complete nPartition configuration procedures, refer to the chapter *Managing nPartitions* on page 243. Also refer to the chapter *Booting and Resetting nPartitions* on page 197 for boot-related configuration tasks.

vPars Management of nPartitions: Reconfiguring nPartition Attributes from a Virtual Partition

This section covers the configuration of nPartition attributes other than cell assignments, when performing the nPartition configuration from HP-UX running in a virtual partition.

When performing this procedure you *do not* need to perform any reboots.

Step 1. Login to HP-UX running on any virtual partition within the nPartition whose attributes you wish to reconfigure.

Some changes, such as cell attribute changes, require that you initiate the reconfiguration from the local nPartition to which the cell is assigned. When the nPartition is running multiple virtual partitions, you can login to any of the virtual partitions on the local nPartition.

Step 2. Use the **parstatus** command or Partition Manager to list the nPartition's current configuration status.

Step 3. Use the **parmodify** command or Partition Manager to modify the nPartition's configuration. (Do not use the `setboot` command.)

For example, `parmodify -p0 -P NewName` changes nPartition number 0 to be named "NewName".

For other details, refer to the chapter *Managing nPartitions* on page 243.

Typographic Conventions

We use the following typographical conventions:

audit (5) — An HP-UX manpage. *audit* is the name and *5* is the section in the *HP-UX Reference*. On the web and on the Instant Information CD, it may be a hot link to the manpage itself. From the HP-UX command line, enter “`man audit`” or “`man 5 audit`” to view the manpage. See *man* (1).

Book Title — The title of a book. On the web and on the Instant Information CD, it may be a hot link to the book itself.

Emphasis — Text that is emphasized.

Emphasis — Terms defined for the first time or text that is strongly emphasized.

`ComputerOut` — Text displayed by the computer.

`Command` — A command name or qualified command phrase.

`Computer` — `Computer font` indicates literal items displayed by the computer. For example: `file not found`

`Filename` — Text that shows a filename and/or filepath.

`UserInput` — Commands and other text that you type.

`Variable` — The name of a variable that you may replace in a command or function or information in a display that represents several possible values.

`[ ]` — The contents are optional in formats and command descriptions.

`{ }` — The contents are required in formats and command descriptions. If the contents are a list separated by `|`, you must choose one of the items

`. . .` — The preceding element may be repeated an arbitrary number of times.

`|` — Separates items in a list of choices.

1 Introducing Ignite-UX

This chapter introduces you to the features and uses of Ignite-UX:

- About this guide.
- Ignite-UX overview.
- Solving problems with Ignite-UX.

About This Guide

This guide describes installing, configuring and using Ignite-UX to facilitate installing and recovering HP-UX on HP computer systems in your computing environment.

This guide is written for experienced HP-UX systems administrators who are responsible for setting up and maintaining HP-UX workstations and servers. They must be familiar with installing HP computer hardware and software, upgrading software, applying patches and troubleshooting system problems. Ignite-UX will help them install new systems and maintain existing ones with less effort than when using individual install and update tools.

Web papers included here

This guide replaces Ignite-UX information in the *Installing HP-UX 11.0 and Updating from HP-UX 10.x to 11.0* guide previously supplied with HP-UX 11.0 media. This guide also includes information from the following papers available on the Ignite-UX web site:

- *Ignite-UX Startup Guide for System Administrators.*
- *Ignite-UX Network System Recovery.*
- *Customized Install Media.*
- *Ignite-UX FAQ*, as of March 2002 (check the web for newer versions).

Documentation and Training

Check the Ignite-UX web site often for announcements, updates to the *Ignite-UX FAQ*, and to download the latest version of Ignite-UX:

`http://software.hp.com/products/IUX`

Details about recent changes to Ignite-UX are in the *Ignite-UX Release Notes* located on the web site or in the directory */opt/ignite/share/doc/release_note*.

Additional information is available on these web pages:

- Ignite-UX and Mirrored disks

Ignite-UX training

HP offers a 3-day classroom course on Ignite-UX for the experienced HP-UX system administrator. For details, classes scheduled in your area, and class registration, go to:

`www.hp.com/education/courses/h1978s.html`

9

Ignite-UX Commands and Online Documentation

Ignite-UX provides online information in the `/opt/ignite/share/doc/` directory. Also see these Ignite-UX manpages:

Table 1-1

Ignite-UX Manpage	Description
ignite (5)	Ignite clients remotely from the Ignite-UX screen and provides an overview of all Ignite-UX commands.
instl_adm (1M) *instl_adm* (4)	Manage Ignite-UX config files.
instl_combine (1M), *make_medialif* (1M)	Construct custom, bootable install media.
instl_dbg (1M)	Debug config files.
instl_bootd (1M)	Boot protocol server for Ignite-UX client.
bootsys (1M)	Reboot and install systems using Ignite-UX.
make_bundles (1M)	Package SD bundles into an SD Depot.
make_depots (1M)	Creates SD depots from media.
make_boot_tape (1M)	Create a system boot tape.
make_net_recovery (4)	Create recovery archives on a network system.
make_tape_recovery (1M)	Create recovery tapes. Replaces `make_recovery` available beginning with Ignite-UX A/B 3.2.
check_recovery (1M)	Check recovery tape status since last `make_*_recovery`.
make_sys_image (1M)	Create golden system images.
make_config (1M)	Generate config files for installing software in SD bundles.

Table 1-1 **(Continued)**

Ignite-UX Manpage	Description
manage_index (1M)	Manage the INDEX file.
setup_server (1M)	Perform Ignite-UX client-server administration tasks.
add_new_client (1M)	Construct and populate a client directory without requiring a reboot.

Ignite-UX Overview

Ignite-UX addresses your need to perform system installations and deployment, often on a large scale. With Ignite-UX, you can:

- Create and reuse standard system configurations.
- Archive a standard system configuration and use that archive to replicate systems.
- Create customized processes to allow interactive and unattended installs.
- More-easily recover your operating system (OS) and applications after crashes and hardware failures.

After running an Ignite-UX install session, you have a working HP-UX client system.

Ignite-UX release versions

Ignite-UX is an HP-UX 10.*x*, 11.0, and 11i product, including 11i v1.6 which supports **Itanium Processor Family** (IPF) systems, that facilitates installing and configuring HP-UX systems. Ignite-UX releases are available to install the HP-UX 10.01, 10.10, 10.20, 11.0 and 11i releases on client systems.

Ignite-UX server software is currently available in these versions:

- HP-UX 10.01, 10.10, 10.20 — version A.3.7.95
- HP-UX 11.0 and 11i— version B.4.0 or later

An Ignite-UX B.*x* server runs on HP-UX 11.0 and 11i and can install HP-UX 10.20, 11.0, and 11i OS and applications on target systems. An Ignite-UX A.*x* server runs on HP-UX 10.*x* and can only install HP-UX 10.*x* software on target systems.

Be sure to check the Ignite-UX web site often for announcements and information on new Ignite-UX releases.

Ignite-UX Features

Client/server control

Ignite-UX install sessions for multiple targets can be controlled from a single server in a true client/server model. A graphical user interface (GUI) called the **Ignite-UX screen** helps you manage multiple, simultaneous install sessions. Alternatively, you can run a single install session from the target system if that is more convenient. A single install server can serve multiple HP-UX releases.

Easy-to-use GUI

The Ignite-UX screen uses tabbed dialogs for task navigation. In addition, a wizard mode is available for the novice.

Multi-sourced installations

You could install your base from one SD depot, a set of patches from another depot, and the applications you want from a third depot all in one session.

Multiple archive formats

In addition to supporting SD software sources, Ignite-UX supports tar, cpio, and pax archives. Tools are provided to help you create a **golden system image** if you wish to install from an archive.

Custom installations

It is easy to create a system that is ready to go as soon as the install session completes. Many of the tasks typically done as separate steps after an install are now incorporated into the Ignite-UX installation process. Ignite-UX allows you to specify what kernel parameters you want set and what user-supplied scripts you would like to run as part of the session. Many different script hooks are provided so you can add your own customizations (during and after the installation). Also, the host and networking information which must normally be supplied at first boot can be specified at install-time. You can:

- Create a configuration for your particular needs, save it, and then quickly apply that configuration to multiple install targets.
- Set up a configuration and then install it on a target machine with no further user interaction. This can be done in both the initial installation and the re-installation cases.
- Scan a system and produce a report detailing what hardware is present, how the disks are used, what kernel modifications have been made, and what software has been loaded. This report can be customized to meet your needs.
- Construct your own customized bootable install/recovery media using the `make_medialif` command.

System recovery

You have consistent, reliable recovery in the event of a catastrophic failure of the system disk or root volume group using either the `make_tape_recovery` or `make net recovery` command.

Support for ServiceControl Manager

Ignite-UX supports installing HP-UX client systems in an HP ServiceControl Manager environment. See the *ServiceControl Manager Installation and Configuration* guide for more details.

Solving Problems with Ignite-UX

Once you have an Ignite-UX server installed and configured for your environment, you'll find that it can help you solve many common installation and recovery problems.

One-step installation

Once you configure a system with a **common configuration** that you want **pushed** to other systems, use Ignite-UX to either manually or automatically Ignite-UX each client system. This common configuration can include any supported HP-UX 10.*x*, 11.0, or 11i OS, plus you can add any required patches and applications. This configuration can be bundled into an OS archive, either on the Ignite-UX server or any system in your environment. You can also **pull** bits from an Ignite-UX server and install the client locally. These processes are explained in Chapters 2 through 5.

Re-install HP-UX or apply patches quickly

You can quickly re-install the OS on an existing system after repair from either an OS archive or SD depots and apply patches. See Chapter 6, Installing Patches with Ignite-UX,and Chapter 7, Using Golden System Images, for details.

Scanning a system

With Ignite-UX, you can easily scan a system, or all systems in your environment, to see what hardware is present, how the disks are used, what kernel modifications have been made and what software has been loaded. See Chapter 5, "Installing HP-UX with Ignite-UX on Clients from a Server," on page 73.

Automate installations

Using Ignite-UX's configuration files allow you to completely automate the OS installation process on any systems in your environment, as explained in Chapter 9, "Automating Installations."

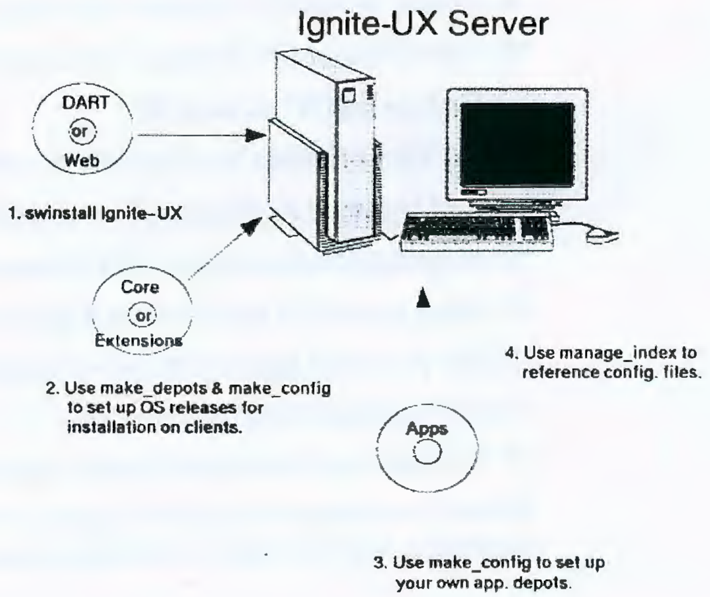
Quick system recovery

In addition to OS archives for initial installations, you can create recovery archives on tape (access from a drive on the client) or on any system in your environment (access via the network). See Chapter 11, System Recovery, for details.

2 Installing and Administering an Ignite-UX Server

This chapter describes installing and configuring an Ignite-UX server.

For on-line information about the Ignite-UX server after it has been installed, see the /opt/ignite/share/doc/ directory and the *ignite* (5) manpage.



Ignite-UX Server
DART
or
Web
1. swinstall Ignite-UX
Core
or
Extensions
2. Use make_depots & make_config to set up OS releases for installation on clients.
Apps
3. Use make_config to set up your own app. depots.
4. Use manage_index to reference config. files.

Installation Overview

Ignite-UX functions as a client-server application. Much of the server configuration will be performed for you in the Ignite-UX installation process, but there are also some separate steps you must take after installation. Tools are supplied to help you complete the server configuration.

Installing Ignite-UX will take care of most server configuration tasks. This can also be done outside Ignite-UX by using either the `setup_server` command as a simple interface or by using the Ignite-UX screen, as explained in this chapter.

Installation tasks

The tasks required to set up an Ignite-UX server are:

"A: Obtain Ignite-UX Software" on page 27

"B: Install Ignite-UX Software" on page 28

"C: Update PATH" on page 29

"D: Set Up or Update the Software Source" on page 29

"E: Add Optional Applications" on page 31

"F: Installing Minimal Ignite-UX Filesets" on page 32

"G: Start Ignite-UX for the First Time" on page 33

"H: Set an Initial Ignite-UX Server Configuration" on page 34

"I: Starting Ignite-UX" on page 36

"J: Configuring Server and Session Options" on page 40

Before proceeding to install an Ignite-UX server, review the server's hardware, software and networking requirements explained next.

Ignite-UX Hardware Requirements

IMPORTANT

NFS Diskless functionality *is not supported* on HP-UX 11.0 and later versions. Do not update your server to HP-UX 11.0 or later versions if you intend to operate that server as a NFS Diskless server.

Server requirements

You will need the following to install an Ignite-UX server:

- **Computer** — A Series 700/800 system running HP-UX 10.0, 10.10, 10.20, 11.0 or 11i. See Ignite-UX version requirements in"Ignite-UX release versions" on page 18.
- **Memory** — Ignite-UX requires 64MB minimum on each server and client. Your HP support engineer can assist in determining the proper amount of RAM.
- **Source Device** — Make sure that your system has an appropriate source (CD-ROM, DVD, DDS drive or LAN card). Ensure that tape drive heads are clean.
- **Disk Drive** — A server needs at least one hard-disk drive with at least the following capacities (`swinstall` performs an analysis of disk space needed prior to loading the software):
  — Generally, 2 GB or more for a usable system, 2.2 GB if on HP-UX 11.0 and 4GB if on HP-UX 11i.
  — Ignite-UX will be loaded under the directory `/opt/ignite`. The data files Ignite-UX creates will be placed under `/var/opt/ignite`. Ignite-UX installation will require approximately 105MB of disk space. You will probably need additional space available under `/var/opt/ignite` for archive and software depot storage.
- **tftp** — Ignite-UX will transfer some of its files using tftp. The minimum directories needed by tftp are set up in the `/etc/inetd.conf` file. Others may need to be added if you place configuration scripts in non-standard locations.
- An additional X11 display server (workstation, X-terminal, PC running an X server, etc). This can be the same system as above.

  - A separate graphics display may be required if a Series 800 Ignite-UX server is being used. Or:
  - The display can be redirected to another X-windows system by setting the DISPLAY environment variable. For example, in the Korn Shell or Posix Shell, enter:

    ```
    export DISPLAY=system_name:0.0
    ```

- Product media or link to the web to load Ignite-UX and any software depots you plan to distribute to target systems.
- Client and server must be on the same subnet if you plan to do the initial boot of the client over the network. A **boot-helper** system can be used to get between subnets and the bootsys command also works between subnets. See Appendix B, "Using a Boot-Helper System," on page 261.

NOTE You can boot over the network only from an Ethernet interface.

Installing an Ignite-UX Server

A: Obtain Ignite-UX Software

Via Media and the Web

Ignite-UX is available from these sources in standard Software Distributor (SD) depot format:

- Application CD-ROM or DVD (if specified when ordering) supplied with HP-UX 10.20, 11.0 and 11i OS media.
- An HP-UX 11i CD1 or DVD (if specified when ordering).
- HP's Software Depot:

  `http://software.hp.com/products/IUX`

  Be sure to obtain the correct Ignite-UX version for your system:

  — For HP-UX 11.0 and 11i, download and install Ignite-UX version B.*x*.

  — For HP-UX 10.20, download and install Ignite-UX version A.*x*.

An Ignite-UX version B.*x* server can install HP-UX 10.20 and 11.0/11i OS and applications on target systems. An Ignite-UX version A.*x* server can only install HP-UX 10.*x* software on target systems.

You may load one or more of the individual `Ignite-UX-1x-xx` bundles onto your system to set up a new Ignite-UX server for installing only that HP-UX version on other systems. That is, you can choose to load a release-specific bundle, such as `Ignite-UX-10-20` for HP-UX 10.20, or an entire bundle such as `B5724AA_APZ`.

IMPORTANT

Do not install individual Ignite-UX server bundles to update an existing Ignite-UX Server. Instead, install the complete bundle for your OS, for example, B5724AA_APZ for HP-UX 10.20. To update yours server to HP-UX 11i, also consider using the new `update-ux` command, as explained in the guide supplied with HP-UX 11i OE media.

Via ftp

You can also access HP's SD Depot via ftp, however this access is "blind"; the `ls` command is not available in the `/ftp` directory. Follow these steps:

Step 1. Log on anonymously to HP's Software Depot:

```
ftp www.software.hp.com
```

Step 2. Move to the `swdepot` directory and get the software bundles you need:

```
ftp> cd /dist/swdepot
ftp> get file_name.tar
```

file_name examples for HP-UX 10.20 servers are:

`ignite_10.01.tar, ignite_10.10.tar, ignite_10.20.tar, ignite_all.tar`

file_name examples for HP-UX 11.0/11i servers are:

`ignite11_10.01.tar, ignite11_10.10.tar, ignite11_10.20.tar, ignite11_11.00.tar, ignite11_ALL.tar`

B: Install Ignite-UX Software

Each software bundle contains the Ignite-UX tools plus the data files required for support of the particular HP-UX release indicated by the bundle name. If you do not wish to load the entire Ignite-UX bundle, see "F: Installing Minimal Ignite-UX Filesets" on page 32.

Step 1. If needed, remove NetInstall. Ignite-UX replaces the capability previously supplied by the NetInstall bundle that came with HP-UX releases 10.01, 10.10 and 10.20. (A system cannot be configured as a server for both NetInstall and Ignite-UX.) Loading any of the Ignite-UX software bundles will give an error until you either remove the NetInstall bundle or touch the `/tmp/okay_to_remove_net_install` file.

Step 2. Once the application CD containing Ignite-UX has been mounted or you have downloaded the Ignite-UX bundle from the web, use `swinstall` to load the desired Ignite-UX bundle(s). You can load the entire product, or you can load only a single Ignite-UX depot if you plan on only using Ignite-UX to install a single release, such as HP-UX 10.20, on client systems. For example, if the Applications CD is mounted at `/cdrom` and you want to load the support for installing HP-UX 10.20 clients onto an HP-UX 10.20 server system, enter:

```
swinstall -s /cdrom Ignite-UX-10-20
```

Or, if you want to install the entire Ignite-UX 11.0 product on an HP-UX 11.0 or 11i server from a software depot on your network located at, say, *hpfclc.fc.hp.com:/release/Ignite-UX*, enter:

```
swinstall -s hpfclc.fc.hp.com:/release/Ignite-UX \
B5725AA_APZ
```

Step 3. After loading Ignite-UX bundle(s), unmount and remove the media and mount the media/drive, if needed, to load the Core software.

C: Update PATH

In your login scripts, add `/opt/ignite/bin` to your default search path:

`export PATH=${PATH}:/opt/ignite/bin` for ksh

or

`set_path = (${path} /opt/ignite/bin` for csh

D: Set Up or Update the Software Source

Ignite-UX allows many options for installing software on target systems. The basic option is to install all software from SD depots on the server. This step describes setting up the software to install on the server.

If you plan to use both SD sources and non-SD sources (tar, cpio, or pax), consider each individually:

For SD OS software

Follow these steps to make an SD source available to Ignite-UX:

Step 1. If you do not already have disk depots, create one using the make_depots command. For example, to create the necessary disk depots that correspond to the HP-UX 10.20 Core CD-ROM or the HP-UX DVD, enter:

```
make_depots -r B.10.20 -s /dev/dsk/c0t0d0
```

This assumes that the CD-ROM or DVD is connected at: /dev/dsk/c0t0d0 and creates one or more depots in the directory: /var/opt/ignite/depots/Rel_B.10.20

Step 2. If you used make_depots as described above to create your depots, use the make_config command to create Ignite-UX config files for each of the depots you plan to use:

```
make_config -r B.10.20
```

This command will create config file for all depots found in the /var/opt/ignite/depots/Rel_B.10.20 directory. It will also add these config files to all INDEX entries for the HP-UX 10.20 release. Skip the next step.

Step 3. If you did not use make_depots to create your depots, run make_config and point it at a specific depot. For example:

```
make_config -s server:/depot_700 \
-c /var/opt/ignite/data/Rel_B.10.20/core_700
```

Now add a reference to the INDEX file:

```
manage_index -a -f /var/opt/ignite/data/Rel_B.10.20/core_700
```

See the *ignite* (5) manpage for further examples.

For non-SD OS software

You will need to create a unique config file that represents the non-SD operating system software. Samples of config files that do a core archive can be found in: /opt/ignite/data/examples/

After copying this file and making edits to it as instructed in the comments contained in the file, you can use the manage_index tool to insert a reference to this configuration in the /var/opt/ignite/INDEX file. Use of configuration files is described in Chapter 3, “Using Configuration Files,” on page 49.

E: Add Optional Applications

If you have other SD-packaged software that you would like to have installed on target clients and want to have the software made available for selection in the Ignite-UX interface, run the make_config and manage_index commands on those depots.

For SD application software

Run the following commands for each depot you plan to load SD software from during the installation. The make_config command only handles SD software which is packaged in bundle form. (All HP-supplied software is packaged in this form. See the *make_bundles* (1M)manpage for information on making SD bundles in an SD depot.)

For example, to make compiler depot bundles available, as root enter:

```
/opt/ignite/bin/make_config\ -s hpfcxxx.hp.com:\
/depots/compiler \
-c /var/opt/ignite/data/Rel_B.10.20/compilers_cfg
```

```
/opt/ignite/bin/manage_index \
-a -f /var/opt/ignite/data/Rel_B.10.20/compilers_cfg
```

Replace the depot server name (in this example: hpfcxxx.hp.com) with the server you have the SD software on. Note that the depot server can be a different system from the Ignite-UX server.

TIP

Rerun the make_config command each time new software is added or modified in the depots.

The make_config command constructs Ignite-UX config files which correspond to SD depots. When an SD depot is used as part of the Ignite-UX process, it must have a config file which describes the contents of the depot to Ignite-UX. This command can automatically construct such a config file, when it is given the name of an SD depot to operate on. This command should be run when adding or changing a depot which will be used by Ignite-UX.

The manage_index command manipulates the /var/opt/ignite/INDEX file. This utility is primarily called by other Ignite-UX tools but can also be called directly.

For non-SD application software

If the source is not an SD depot, the `make_config` command is not applicable. You will need to create a unique config file that references the non-SD software. A sample of a config file that does a non-core archive can be found in: `/opt/ignite/data/examples/noncore.cfg`

NOTE

Do not attempt to use non-core OS archives (such as layered applications) that contain files that get loaded in: `/var/adm/sw/*` Delivering files in this directory in this method may corrupt the SD database.

Step 1. Copy this file to: `/var/opt/ignite/data/Release/configx` Then make the changes to the copy in that directory.

Step 2. After copying and editing this file, use `manage_index` to insert a reference to the copy of the configuration in: `/var/opt/ignite/INDEX`

F: Installing Minimal Ignite-UX Filesets

Depending on what you are using Ignite-UX for, you may be able to reduce the disk space usage by not loading the full product. Below is a list of typical usages and a list of what parts of Ignite-UX you need. If you are not concerned with disk space, just load the bundle(s) for the HP-UX releases you support.

For all cases, the `Ignite-UX.IGNT-ENG-A-MAN` fileset can be omitted or removed if you do not want on-line documentation.

- **Ignite-UX server to install HP-UX on clients**— Load the `Ignite-UX-`*xx-yy* bundle(s) for each HP-UX release (*xx-yy*) which you plan to install onto clients. You can omit the `Ignite-UX.OBAM-RUN` fileset if your server is HP-UX 11i or later and you don't plan on using `make_net_recovery` for HP-UX 10.*x* clients.
- **Ignite-UX server to support network recovery for clients**— You will need the full Ignite-UX-*xx-yy* bundle for each version of HP-UX that your clients are running.
- **Using only make_tape_recovery command:** — You only need these filesets:
  - — `Ignite-UX.RECOVERY`
  - — `Ignite-UX.BOOT-KERNEL`

`Ignite-UX.FILE-SRV-`*`release`* where:

`release` is the HP-UX release of the system you are running

— `Ignite-UX.MGMT-TOOLS`

- **Using only make_net_recovery on a client** —.The filesets a client needs will normally be pushed out by Ignite-UX to each client from the depot created by the `pkg_rec_depot` command. These are the only filesets required for `make_net_recovery` on the client:

  ```
  Ignite-UX.RECOVERY
  Ignite-UX.MGMT-TOOLS
  ```

- **A network boot-helper system** — To setup a system on a remote subnet that is used just to allow a client to do a network boot and then contact a remote Ignite-UX server, all you need is `Ignite-UX.MinimumRuntime`. See “Setting Up the Boot-Helper” on page 262.

G: Start Ignite-UX for the First Time

To start Ignite-UX, as root enter:

```
/opt/ignite/bin/ignite
```

You will get a warning screen stating no clients exists as this is the first time that `ignite` has been invoked. This is normal since you do not have any clients waiting.

If you get this error message:

```
ERROR: This machine is not an NFS server (no nfsd running).
The -n option will not be processed.
```

the Ignite-UX server is not currently on the NFS server. The Ignite-UX server must be an NFS server. Exit Ignite-UX and make the Ignite-UX server an NFS server before continuing. You can do this by using SAM, or by editing `/etc/rc.config.d/nfsconf` to set `NFS_SERVER=1` and rebooting. If you do not get the above error, Ignite-UX has modified your `/etc/exports` file to include the `/var/opt/ignite/clients` directory:

```
exportfs -v
/var/opt/ignite/clients -anon=2
```

This directory is exported to allow remote root users to write to the client's directory. This is required for proper Ignite-UX operations. You may need to export additional directories. For example, if you use NFS to transfer your archive, it must be NFS accessible.

A quick tour

After you have Ignite-UX up and running, you will see the Welcome screen and then the Ignite screen. When you have booted each client you will see an icon representing it on the Ignite-UX screen:

- Click once on a client icon to select it for further actions.
- Double-click the client icon to get a Client Status screen.
- Right-click a client icon to get an Actions menu similar to the pull-down **Actions** menu.

To learn more about the server, step through the quick tutorial. To get started, select:

Actions –> **Run Tutorial/Server Setup** and click **Tutorial and Demo**

For more information on these screens, see Chapter 4, "Installing HP-UX with Ignite-UX on Clients Locally," on page 63.

H: Set an Initial Ignite-UX Server Configuration

Follow these steps to complete the initial server configuration:

Step 1. Select: **Options** –> **Server Configuration**

Step 2. Select the **Server Options** tab.

If needed, modify the Server Options to match the following:

- Default Configuration: (your selection)
- Default Printer: (select a default printer to be used by Ignite-UX)
- Client Timeouts: `40` (the number of minutes delay before the Ignite-UX server will inform the administrator of a network problem or client failure)
- Run client installation UI on: `server` (most administration of the install process to be performed only on the Ignite-UX server)

Step 3. Select: **Add Booting IP Address**

During the install process, the clients need to do a network boot from the Ignite-UX server. In order to do this, the clients need to be given a temporary IP address.

Under **Booting Clients**, enter an initial range of available IP addresses. This example allows Ignite-UX to perform 20 simultaneous installations:

```
15.2.73.1        15.2.73.20
```

This IP address is only used when booting over the network during the initial transfer of the kernel to the client. You may only need one or two addresses depending on how many systems do network boots at the same time. For more information see the *instl_bootd* (1M) manpage. If you need to change these addresses later, you will need to edit: `/etc/opt/ignite/instl_boottab`

Permanent IP addresses are distributed via DHCP Services.

Unless you are familiar with DHCP services, for this exercise, do not modify the "DHCP Class ID" or the "DHCP Addresses Temporary" field. The DHCP service is only used for client configurations which do not have predefined system hostnames and IP addresses.

Provide a range of available "permanent" IP addresses. These can only be supplied once here in Ignite-UX. After the initial definition, use SAM's **Networking and Communications** –> **Bootable Devices** area. For example, we use these IP addresses in our network:

```
15.2.73.21       15.2.73.40
```

Step 4. Select: **Options** –> **Server Configurations** –> **Session Options**

Verify that only these options are set:

```
Confirm new clients
Show the welcome screen for the install server
```

You may wish to de-select **Ask for customer information**, as this installation information is geared to HP and HP distributor-partner manufacturing.

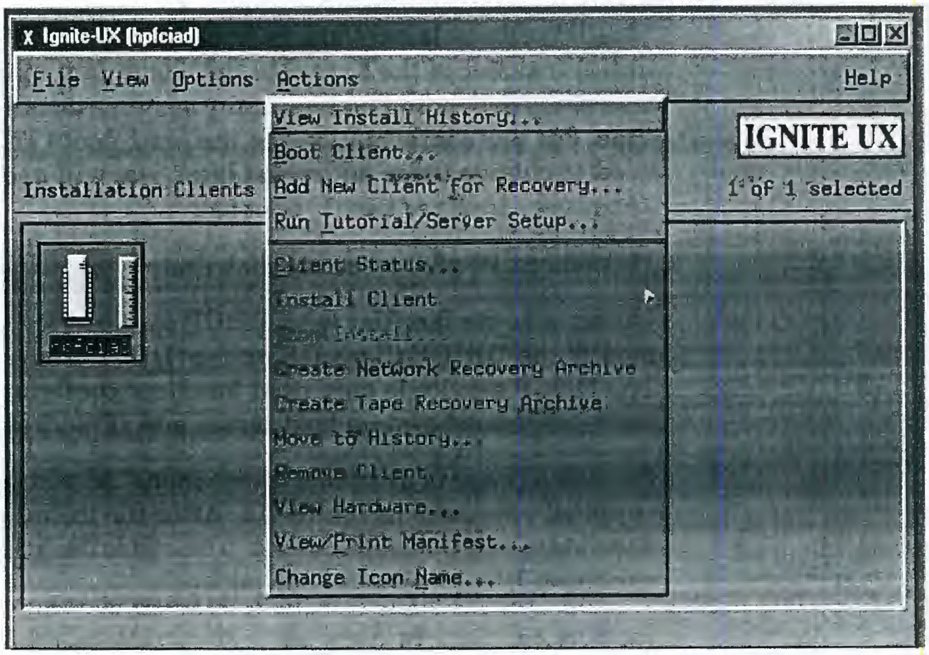
I: Starting Ignite-UX

To start `ignite` on the Ignite-UX server, as root enter:

```
/opt/ignite/bin/ignite
```

Client/server screen

After the Welcome screen is acknowledged by clicking **OK**, Ignite-UX displays its client/server screen as in the following:



Ignite-UX displays each system's installation status via the colored border around each system icon:

- **Green** — OS completely installed, booted and running.
- **Red** — Partially installed or installation stopped. The light blue installation indicator shows the relative progress.
- **No color** — OS not installed.

Client icons represent all booted systems and those systems that can be used for recovery systems. These systems are known to Ignite-UX via `/var/opt/ignite/clients`. If a client is not yet running an OS, see the booting procedure at the end of this chapter. If the client is already running an OS, this can be accomplished remotely by selecting **Actions -> Boot Client**

Actions menu

Select a client (click its icon) and select the **Actions** menu to review available actions for that client:

- **View Install History** — Lists details of all successfully installed clients.
- **Boot Client** — Allows you to boot the selected client.
- **Add New Client for Recovery** — Allows you to identify a client to be recovered.
- **Run Tutorial/Server Setup** — Displays the Welcome screen and you can choose to run the **Tutorial and Demo** or **Server Setup** options.
- **Client Status** — Allows you to see the status of a given client, see "Review client status" on page 39 for more information.
- **Install Client** — Starts the HP-UX installation process for the selected client. This process is explained in Chapter 5, "Installing HP-UX with Ignite-UX on Clients from a Server.".
- **Stop Install**— Stops the install process on the selected client. You can now reboot or halt the client.
- **Create Network Recovery Archive** — Initiates creating a network recovery archive using the `make_tape_recovery` command. See Chapter 11, System Recovery, for more details.
- **Create Tape Recovery Archive** — Initiates creating a recovery archive using the `make_tape_recovery` command. See Chapter 11, System Recovery, for more details.
- **Move to History** — Saves critical files for the client, adds them to the history file and removes the client icon. The client must be "complete" (fully installed) for the configuration to be moved to the history file.
- **Remove Client** — Deletes the icon for the selected client configuration. Client data except for the recovery archive is removed.
- **View Hardware** — Lists hardware associated with the selected client.

- **View/Print Manifest** — Allows you to see or print the manifest and/or Software Certificate. The manifest is also available in saved form on the client and server systems after the installation as the manifest files. On the client, the manifest is in:`/var/opt/ignite/local/`

  On the server, it is in: `/var/opt/ignite/clients/0x`*LLA*`/`

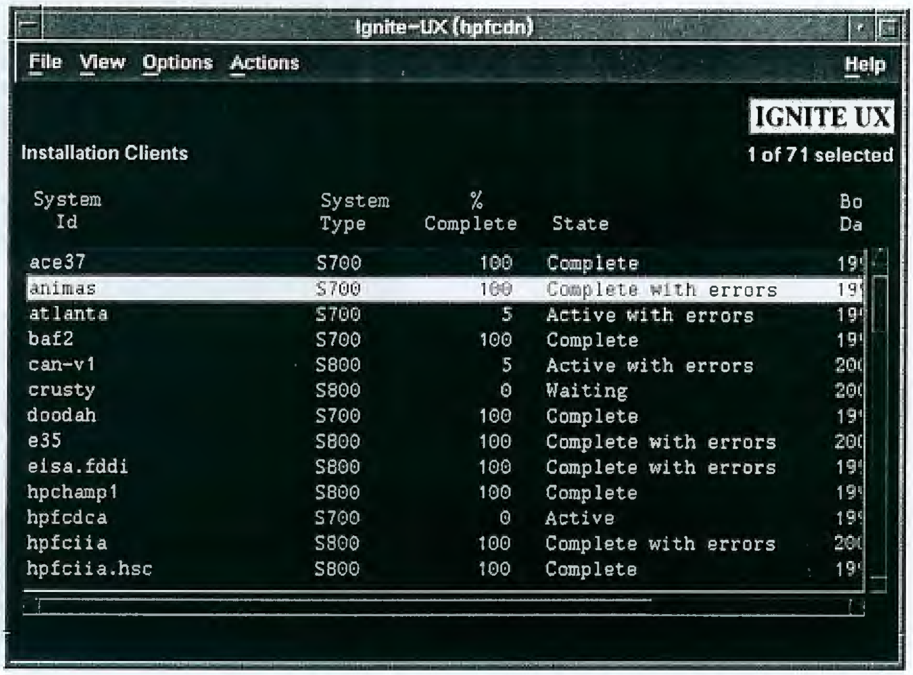
  For an example, see "Viewing and Printing a Manifest" on page 104.
- **Change Icon Name** — Displays a form for renaming the icon for the selected client.

View menu

Use the **View** menu selections to customize the Ignite-UX screen for your needs:

- **Columns**— Re-arrange icons by system attributes.
- **Filter** — View a selected subset of system icons per selected criteria.
- **Sort**— Sort the displayed icons per selected criteria.
- **By Properties** — List clients in a text format rather than with icons. To return to the default icon display, select: **View** –> **By Name and Icon**.

  Using the **By Properties** view along with sorting by **% Complete** can make it easier to quickly scan for clients that have finished installing. Select **Descending Direction** to have all completed systems listed at the top of the display. Here's a portion of a **By Properties** view:



Installation Clients

1 of 71 selected

System Id	System Type	% Complete	State	Bo Da
ace37	S700	100	Complete	19
animas	S700	100	Complete with errors	19
atlanta	S700	5	Active with errors	19
baf2	S700	100	Complete	19
can-v1	S800	5	Active with errors	20
crusty	S800	0	Waiting	20
doodah	S700	100	Complete	19
e35	S800	100	Complete with errors	20
eisa.fddi	S800	100	Complete with errors	19
hpchamp1	S800	100	Complete	19
hpfcdca	S700	0	Active	19
hpfciia	S800	100	Complete with errors	20
hpfciia.hsc	S800	100	Complete	19

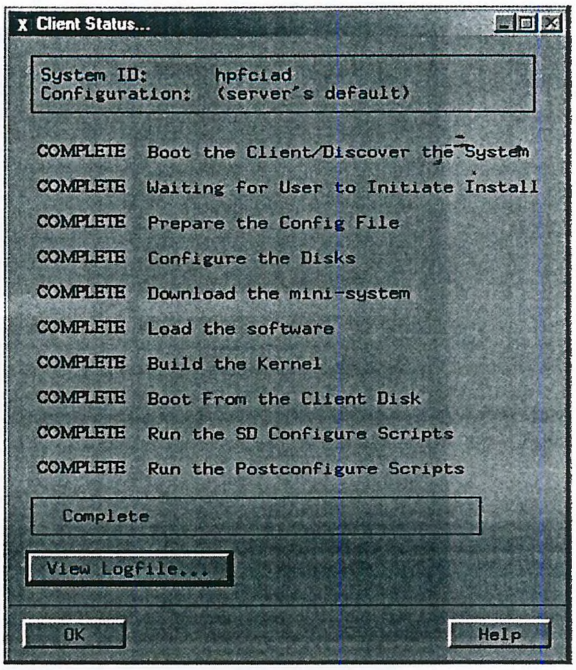
Review client status

After you see client systems displayed on the Ignite-UX screen, you can review the status of any client by:

Step 1. Click once on a client icon to select it for further actions.

Step 2. Double-click the client icon to get the **Client Status** screen, or select Client Status from the Actions menu, or *right-click* a client icon to get a menu similar to the pull-down **Actions** menu.

Any of these actions result in the status of the client being polled and displayed as in the following example:



```
System ID:       hpfciad
Configuration:   (server's default)

COMPLETE   Boot the Client/Discover the System
COMPLETE   Waiting for User to Initiate Install
COMPLETE   Prepare the Config File
COMPLETE   Configure the Disks
COMPLETE   Download the mini-system
COMPLETE   Load the software
COMPLETE   Build the Kernel
COMPLETE   Boot From the Client Disk
COMPLETE   Run the SD Configure Scripts
COMPLETE   Run the Postconfigure Scripts

Complete
```

J: Configuring Server and Session Options

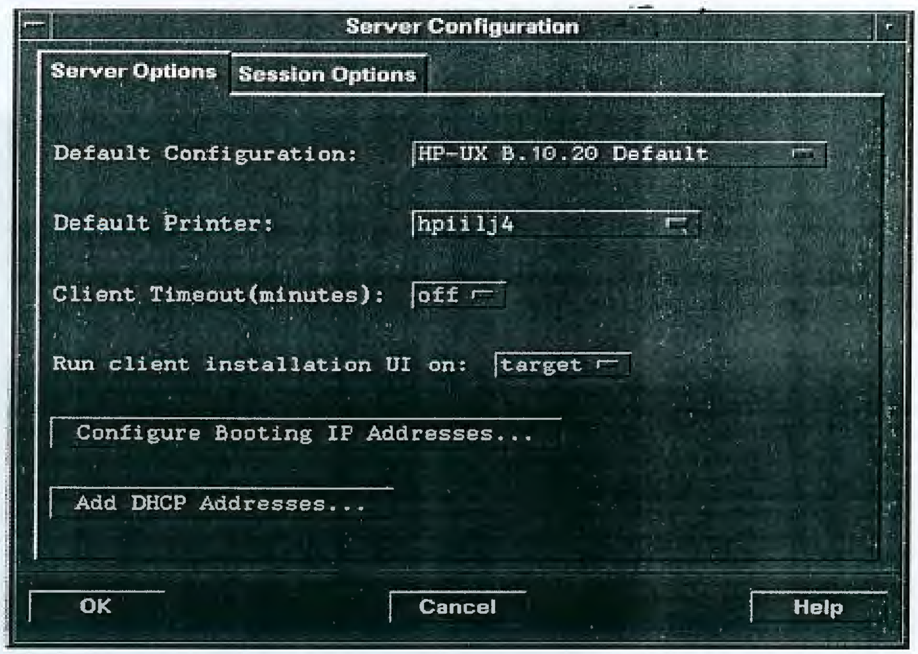
The Ignite-UX server and session options must be configured as described in this section.

Use fields in the **Options** -> **Server Configuration** -> **Server Options** and **Session Options** tabs to:

- Set up your network installation **Precision Architecture Reduced Instruction Set Computing** (PA-RISC or PA)-based or IPF-based server. Network installation details when using Ignite-UX versions B.4.1 and B.4.2 are found in “Release Specific Server Configuration” on page 46.
- Configure the IP addresses to be used for initially booting the install clients (target systems).
- Configure the DHCP address range to be used for directing the client installation process.

Configuring server options

Step 1. Select **Options** –> **Server Configuration**



```
Default Configuration:      HP-UX B.10.20 Default
Default Printer:            hpiilj4
Client Timeout(minutes):    off
Run client installation UI on:  target
```

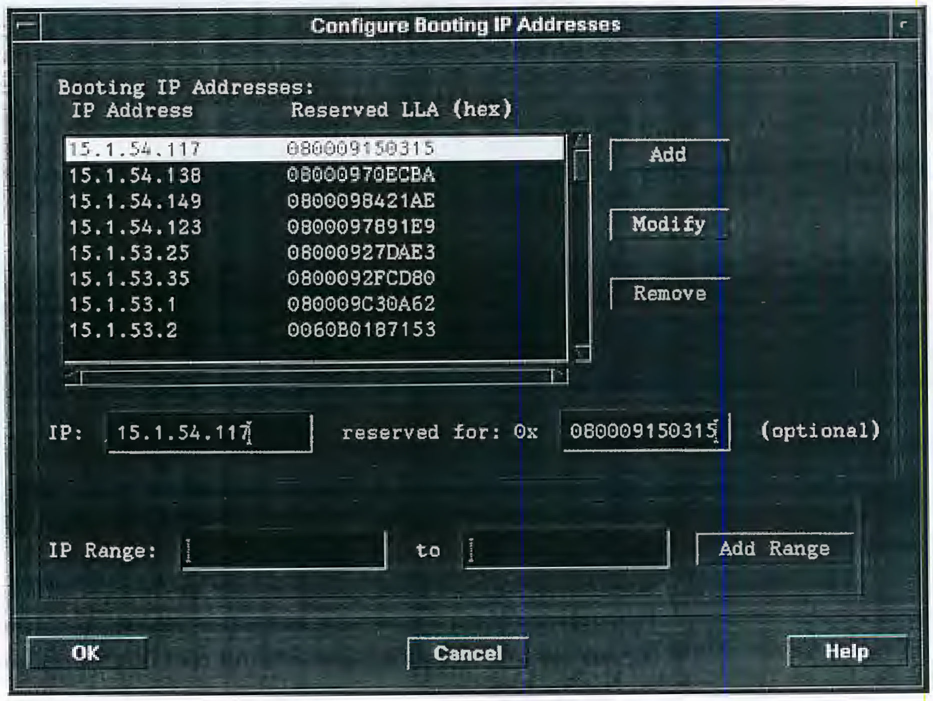
Step 2. Select the **Default Configuration** box and highlight the OS or OE you want. The selected configuration from this list will be installed on to the client's target system. The default setting can be overridden on a per-client basis by Ignite-UX.

Step 3. Click on the **Default Printer** pull-down menu to display the available (configured) printers. Select the one you want to use. If needed, use the **System Administration Manager** (SAM) **Default Printer** area to configure a new printer onto the system. This will be the printer for printing the manifest or installation history. The printer IP address will be checked by Ignite-UX before a job is sent.

Step 4. Select the appropriate **Client Timeout** value, **on** or **off**. This will set a limit on the time since the client install log has been written into. Some points in the installation may require 15 to 30 minutes. A warning note will be displayed if this time is exceeded.

Setting Client Timeout to **off** disables this notification.

Step 5. Use the **Run client installation UI on** menu to designate where you want to view the client UI for this installation. If you have a server configured, you have the choice of running the client installation interface from either the **target** (as a TUI) or **server** (as the Ignite-UX screen). If the client installation is to be non-interactive (no user intervention), select **none**.



Booting IP Addresses:

IP Address	Reserved LLA (hex)
15.1.54.117	080009150315
15.1.54.138	08000970ECBA
15.1.54.149	0800098421AE
15.1.54.123	0800097891E9
15.1.53.25	08000927DAE3
15.1.53.35	0800092FCD80
15.1.53.1	080009C30A62
15.1.53.2	0060B0187153

IP: 15.1.54.117 reserved for: 0x 080009150315 (optional)

IP Range: to

The default location for the GUI to be displayed is the Ignite-UX server.

Step 6. If you are using Ignite-UX version B.4.0 or earlier, you can configure which Ignite-UX servers are used to boot client servers in two ways using the GUI: by identifying IP or DHCP addresses. Select one of the following methods:

a. Click **Configure Booting IP Addresses**
Enter the appropriate IP addresses for the initial boot of the target systems. The number of such addresses determines the number of simultaneous boots you can do.

TIP Be sure that IP addresses entered here are not assigned elsewhere, or you could (re)boot the wrong system.

These IP addresses are used to initially boot ~~target~~ systems. They are used until the system is assigned one of the DHCP boot addresses. One address is required for each simultaneous boot. Typically one to three are needed, depending on your usage.
This data can also be configured by using the `/opt/ignite/lbin/setup_server` command. Or, you can directly edit the `instl_boottab` file; this is necessary for modifying the list order for existing IP addresses.
See the *instl_bootd* (1M) manpage for further details.

Or

b. Click **Add DHCP Addresses** Ensure that the listed IP addresses are not assigned elsewhere. These IP addresses are used during the OS download and application loading. The addresses are in use for most of the Ignite-UX download to a target machine. One address is required for each simultaneous download. You should set more, if the addresses are assigned permanently.

Click the **Temporary** box if you would like to manage a small group of temporary IP addresses, just for use in doing installations, and then reassign the clients new addresses when they are deployed.

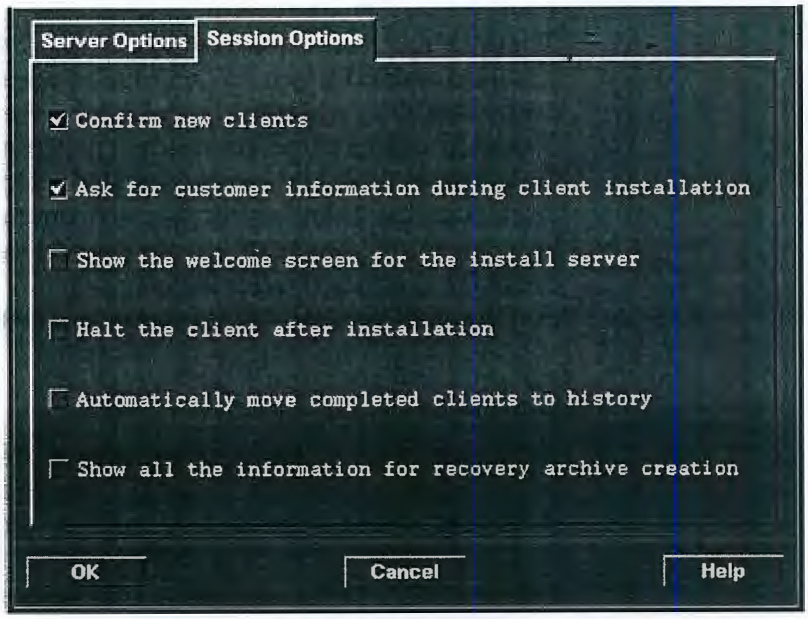
The provision of DHCP capability is for the purpose of installation only and you may want to limit configurations so that they do not interfere with prior DHCP server functions.

See Appendix C, Configuring for a DHCP Server, for details on configuring for DHCP. See the *setup_server* (1M) and *instl_adm* (4) manpages for more information on setting up DHCP functions, addresses and class IDs.

Configuring session options

To configure client response behavior, select:

Options –> Server Configuration –> Session Options



☑ Confirm new clients

☑ Ask for customer information during client installation

□ Show the welcome screen for the install server

□ Halt the client after installation

□ Automatically move completed clients to history

□ Show all the information for recovery archive creation

- **Confirm new clients** — Controls the appearance of a dialog window each time a new client is booted from the Ignite-UX server.
- **Ask for customer information during client installation** — Controls the appearance of an input window for Customer Name, System Serial Number, and Order Number. You may want to refrain from using this option as this information is geared to HP and HP distributor-partner manufacturing.
- **Show the welcome screen for the install server** — If selected, Ignite-UX automatically displays the Welcome screen. This is a useful default if many new operators run Ignite-UX.
- **Halt the client after installation** — Controls whether the client system is halted (rather than the default, reboot) after installation.
- **Automatically move completed clients to history** — Select this button to automatically add completed clients to the end of the history log, `/var/opt/ignite/clients/history/history.log`. It will also move their config and manifest files to the history directory on the

Ignite-UX server for future reference. The client icon will be removed from the client/server screen. The client must be `complete` (fully installed) for this to take place.

- **Show all the information for recovery archive creation.**

Your Ignite-UX server is now ready to ignite HP-UX on client systems in your network.

Proceed to Chapter 4, Installing HP-UX with Ignite-UX on Clients Locally, or to Chapter 5, Installing HP-UX with Ignite-UX on Clients from a Server, depending on where you want to execute the Ignite-UX process.

Release Specific Server Configuration

With the release of Ignite-UX B.4.1, unique server configurations have become necessary. The server specific configurations described in this section are considered cumulative with each release unless specifically stated otherwise.

Follow the specific server configuration that is appropriate for the Ignite-UX version you are installing:

Ignite-UX B.4.2 PA/IPF Server Setup

The Ignite-UX B.4.2 and later releases provide enhanced support for server response to anonymous IPF clients with changes to the `instl_bootd` server. This enhancement is available for both PA and IPF server architectures.

The changes to `instl_bootd` requires that the `bootpd` daemon is not running on the given Ignite-UX server, rather the `instl_bootd` daemon is used by Ignite-UX to respond to all boot requests from clients. The `instl_bootd` daemon normally runs on a set of unique network ports, 1067/1068, that are used only for booting IPF clients. However, in this implementation the `instl_bootd` will run on the standard `bootpd` ports, 67/68.

Using `instl_bootpd` to support anonymous IPF clients

Follow these steps to configure your server to run `instl_bootd` as a replacement for `bootpd`:

Step 1. Set up your Ignite-UX server as described in “Installing an Ignite-UX Server” on page 27.

Step 2. Once your server has been setup, ensure that `bootpd` is disabled on ports 67/68 by commenting out the following line in `/ect/inetd.conf` as shown in this example:

```
#boots dgram udp wait root /usr/lbin/bootpd bootpd
```

Step 3. Restart the `inetd` daemon:

```
/usr/sbin/inetd -c
```

Step 4. Enable the `instl_bootd` daemon on ports 67/68 by adding the following line to `/ect/inetd.conf`:

```
boots dgram udp wait root /opt/ignite/lbin/instl_bootd
instl_bootd
```

Step 5. You must restart `inetd` again to invoke the change made in the previous step:

```
/usr/sbin/inetd -c
```

See the *instl_bootd* (1M) and *inetd* (1M) manpages for more details. Your Ignite-UX server is now configured to respond to anonymous clients.

Ignite-UX B.4.1 IPF Server Setup

Ignite-UX release B.4.1 and later support the installation of IPF systems running HP-UX 11i Version 1.6.

Configuring DHCP support for anonymous IPF clients

Network installation of an IPF system with Ignite-UX B.4.1 requires that you perform the following unique network installation steps.

Step 1. At a minimum, the Ignite-IA-11-22 bundle should be loaded on your system. If it is not, load this bundle with `swinstall`.

Step 2. Add your client's entries to `/etc/bootptab` on the server. The following example is provided in `/etc/bootptab` :

```
ignite-defaults:\
        ht=ethernet:\
        hn:\
        bf=/opt/ignite/boot/nbp.efi:\
        bs=48
System-IPF:\
        tc=ignite-defaults:\
        ha=00d009000000:\
        ip=190.40.101.22:\
        sm=255.255.248.0:\
        gw=190.1.48.1:\
        ds=190.1.48.11
```

All entries in the `ignite-defaults` section can be used without modification.

Duplicate (cut and paste) the `System-IPF` entries and change this section in the following ways:

1. Change `System-IPF` to reflect the client system's hostname.
2. Change the `ha` and `ip` fields for that client.
3. Change the `sm`, `gw`, and `ds` fields to reflect your network.

You can modify the system name, hardware address, IP address and other information for the client.

The following describes fields you may need to change per system and which fields are unique to your network:

- The **ha** field requires setting to the hardware address (`Mac` or *LLA* address of the client system). This address can be found from the firmware's user interface when adding a boot option. See , "IPF Client Network Booting Option" on page 70 of Chapter 4. If the system is up and running, the `lanscan` command can also be used to find this value.
- The **ip** field is the IP address that has been reserved for the client you are about to install and must be an IP address that is valid for your network.
- The **sm** field is the network subnet mask and is probably the same for all systems on your network.
- The **gw** field is the network gateway. It is optional for booting purposes, but useful to provide the system defaults.
- The **ds** field is the domain name server (DNS) and is also optional for booting purposes, but useful to provide as a default.

Step 3. Enable `bootp` services in the `/etc/inetd.conf` file by uncommenting the `bootps` entry.

Step 4. Restart the Internet daemon by entering:

```
/usr/sbin/inetd -c
```

See the *bootpd* (1M) and *inetd* (1M) manpages for more details. Your Ignite-UX server is now configured to respond to anonymous clients.

3 Using Configuration Files

This chapter introduces Ignite-UX configuration files and shows example config-file applications. See Chapter 9, "Automating Installations," on page 135 for more examples of config files.

config Files

Ignite-UX's central data store is called a **config file**. A config file can be thought of as a recipe for how to construct a target system. The config file is expressed in a language designed for this purpose. The language is fully defined in the *instl_adm* (4) manpage. The syntax is human-readable; config files may be created directly by you or via the Ignite-UX screen. The config file language is much like programming languages in that it supports the use of variables and conditional expressions.

Most of the important elements which make up an installed system can be described in the config file:

- Disk and file system layout.
- Software to be installed.
- Target system's identity and network-configuration kernel modifications (additional drivers or tunable parameter settings).
- User-defined scripts which will run at various points in the installation process to further customize the target system.

Types of config Files

For maintenance convenience, the configuration information is split into several types of config files:

- **Default disk and file system layout** — Because the capabilities of each operating system release differ somewhat, HP supplies a different set of defaults for each release. These are located in: `/opt/ignite/data/Rel_`*`release`*`/config`

  where: *`release`* is the result of the `uname -r` command. For example, this file contains the default disk layout for HP-UX 10.20: `/opt/ignite/data/Rel_B.10.20/config`

- **Software description of a single SD depot** — Config files which describe software available from SD depots can be automatically generated via Ignite-UX's `make_config` tool. This tool produces one config file per SD depot. Software description config files are located in: `/var/opt/ignite/data/Rel_`*`release`*`/*`

- **Software description of an archive** — Config files can be hand built to allow access to archives (templates are provided with Ignite-UX in `/opt/ignite/data/examples/` to give you a good starting point). Archives may be in either tar or cpio format. Archive software description config files are also located in: `/var/opt/ignite/data/Rel_`*`release`*`/*`
- **Local configuration overrides that apply globally** — It is often convenient to specify defaults which will be applied to every system installed from a particular server. For example, you might want to specify the same NIS domain for all systems. Place overrides in: `/var/opt/ignite/config.local`
- **Boot control parameters and networking information** — It is possible to specify defaults for attributes like the IP address of the Ignite-UX server and whether to run a UI to install a new target. These can be specified in the first 8KB of the install file system, `/opt/ignite/boot/INSTALLFS` . Use the `instl_adm` command to add, change, or delete this information.
- **Client-specific configuration files** — Each client to be installed has a unique configuration file located at: `/var/opt/ignite/clients/0x`*`LLA`*`/config`

  LLA is the link-level address of the client. This file is typically created when using the Ignite-UX user interface to specify the target system configuration.

  This file usually refers to other config files mentioned above. It also contains specific directives to override what may have been defined in the other files. For example, you may wish to customize the disk layout beyond what the defaults allow in: `/opt/ignite/data/Rel_`*`release`*`/config`

  The customizations appear in: `/var/opt/ignite/clients/0x`*`LLA`*`/config`
- **Named configurations created by saving a configuration via Ignite-UX screen**— You can create your own default configurations via the Ignite-UX screen and save them for future use. For example, you might have a large number of users with similar systems who all run CAD tools. You could build a configuration which matches what they need and save it in a configuration called "CAD System". When you need to install a new system of this type, you can select **CAD**

System from the UI and you're done (or you could customize it further using CAD System as the template). Saved configurations are located in: /var/opt/ignite/saved_cfgs/*

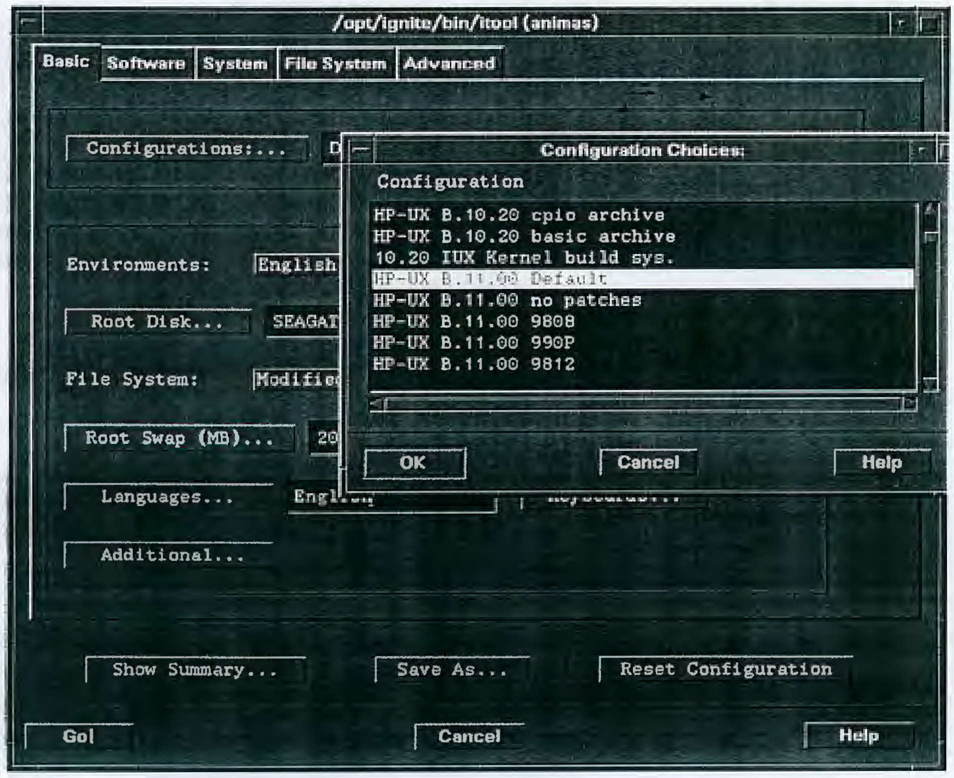
You can build your own config files to specify a particular building block you are interested in, and then combine them in arbitrary ways. Place these building block config files in:
/var/opt/ignite/data/Rel_*release*/*

The next section describes how multiple config files can be combined to define a single configuration.

Combining config Files via INDEX Entries

The grouping of config files into useful configurations is accomplished in /var/opt/ignite/INDEX . This file contains a list of valid configurations, each of which is made up of one or more config files. You can view these configurations from the Ignite-UX GUI when installing a new client at the top of the **Basic** tab by selecting:

Actions –> Install Client -> New Install



Environments: English

Root Disk... SEAGAT

File System: Modified

Root Swap (MB)... 20

Languages... English

Configuration

```
HP-UX B.10.20 cpio archive
HP-UX B.10.20 basic archive
10.20 IUX Kernel build sys.
HP-UX B.11.00 Default
HP-UX B.11.00 no patches
HP-UX B.11.00 9808
HP-UX B.11.00 990P
HP-UX B.11.00 9812
```

For example, the INDEX file might contain:

```
cfg "HP-UX B.10.20 Default"  {
     description "This selection supplies the default system
       configuration that HP supplies for the B.10.20 release.”
     "/opt/ignite/data/Rel_B.10.20/config"
     "/var/opt/ignite/data/Rel_B.10.20/core_700_cfg"
     "/var/opt/ignite/data/Rel_B.10.20/core_800_cfg"
     "/var/opt/ignite/data/Rel_B.10.20/apps_700_cfg"
     "/var/opt/ignite/data/Rel_B.10.20/apps_800_cfg"
     "/var/opt/ignite/data/Rel_B.10.20/patches_700_cfg"
     "/var/opt/ignite/data/Rel_B.10.20/patches_800_cfg"
     "/var/opt/ignite/config.local"
}
cfg "CAD System-10.10" {
     description "This selection is the typical CAD system

     installation for HP-UX B.10.10”
     “/opt/ignite/data/Rel_B.10.10/config”
     “/var/opt/ignite/data/Rel_B.10.10/core_700_archive_cfg”
     “/var/opt/ignite/data/Rel_B.10.10/apps_700_cfg”
     “/var/opt/ignite/data/Rel_B.10.10/patches_700_cfg”
     “/var/opt/ignite/config.local”
} = TRUE
```

With this INDEX file, the Ignite-UX would present two configurations: **HP-UX B.10.20 Default** and **CAD System-10.10**. The **CAD System-10.10** configuration is the default (it is marked TRUE). Once you choose one of these base configurations, you can do further customizations with the UI or accept the config defaults and do the install immediately.

If you selected **CAD System-10.10**, you would get the combination of the five config files listed for that clause. The order of the config files is significant; attributes specified in a later config file can override the same attributes specified in an earlier config file. There are also two config files which are implicitly used every time. Any information stored in the first 8KB of /opt/ignite/boot/INSTALLFS is implicitly appended to each configuration. The client-specific configuration file /var/opt/ignite/clients/0x*LLA*/config is implicitly added as the last config file for each configuration.

A default cfg clause for each release is shipped as part of Ignite-UX. Additional cfg clauses are added when you:

- Save a named configuration from the GUI with the **Save As** button.
- Create a configuration by modifying the INDEX file directly.
- Use the manage_index file to help automate INDEX file modifications.

Example Config Files

This section shows a few example config files to give you an idea of their look and capabilities. See the *instl_adm* (4) manpage for a complete description of Ignite-UX config files.

Defining disks

This example shows how a disk might be defined. Here, the disk is located at hardware address 2/0/1.6.0 and does not use LVM or VxVM. The disk contains the / file system and a swap area. The swap area takes up 64 MB and the file system takes up whatever space is left over:

```
partitioned_disk {
    physical_volume disk[2/0/1.6.0]

    fs_partition {
        mount_point ="/
        usage=HFS
        size=remaining
        file_length=long
    }
    swap_partition {
        usage=SWAP
        size=64Mb
    }
}
```

Combining disks to form a single volume group

In this example, two disks are put together to form a single volume group. Two file systems are defined; both are striped across both disks. The first file system, /apps1, is sized by calculating the amount of space required by the software which is to be loaded, and then adding a 30% free-space cushion. The second file system, /apps2 , gets the remaining space on the disks.

NOTE

The following example shows LVM as the volume manager. However, it is also applicable to VxVM if usage=LVM is changed to usage=VxVM.

```
volume_group “appsvol” {
    usage=LVM
    physical_volume disk[2/0/1.5.0] {
    }
    physical_volume disk[2/0/1.4.0] {
    }
    logical_volume “apps1”

         size=30% free
         usage=VxFS
         mount_point=/apps1
         minfree=5
         stripes=2
    }
    logical_volume “apps2” {
        mount_point= “/apps2”
        usage=VxFS
        size=remaining
        minfree=5
        stripes=2
    }
}
```

Defining networking

This example defines a few of the network parameters which will be assigned to the system after it has been installed:

```
final system_name = "acorn1"
final ip_addr["lan0"] = "15.99.45.123"
final netmask["lan0"] = "255.255.248.0"
final nis_domain = "nis1"
final route_gateway[0] = "15.99.45.1"
```

Defining an install depot

This example defines a single SD depot from which software can be installed. Two different pieces of software are defined for the SD depot. Each can be selected independently for installation. The impact lines tell Ignite-UX how much space this software requires in a given directory. This information is used to size the file systems correctly. The sw_category construct allows you to group the software so that the user interface can present it in chunks which make sense to you. Since this example references an SD depot, it would have been created by make_config:

```
sw_source "ee_apps_depot" {   description = "Electrical Engineering
Application"    source_format = SD
   source_type = "NET"
   sd_server = "15.23.45.6"
   sd_depot_dir = "/var/opt/ignite/depots/Rel_B.10.20/ee_apps"
}
sw_category "Applications" {
   description = "User Applications"
}
sw_sel "EE CAD Package" {
   sw_source = "ee_apps_depot"
   sw_category = "Applications"
   sd_software_list = "EECad,r=1.2,a=HP-UX_B.10.20_700"
   impacts = "/var" 90524Kb
   impacts = "/sbin" 1248Kb
}
sw_sel "EE Routing Package" {
   sw_source = "ee_apps_depot"
   sw_category = "Applications"
   sd_software_list = "EERoute,r=2.4,a=HP-UX_B.10.20_700"
   impacts = "/usr" 12568Kb
   impacts = "/var" 26788Kb
}
```

Customizations Based on the Target System

The config file syntax provides a large number of system attribute keywords which describe the target system. Some examples are:

- The size of the disk at the specified *hw_path*:

```
disk[hw_path].size
```

- The amount of memory present on the target system:

  ```
  memory
  ```

- The string returned from **uname -m**:

  ```
  hardware_model
  ```

- The link-level address of the target system:

  ```
  lla
  ```

System attribute keywords can be used in expressions in config files so that a particular clause is only included in specific target situations. The basic format of these clauses is:

```
   (x) {y}
```

which translates roughly to "if the expression *x* is true, then do *y*."

For example, this clause sets the size of some kernel tunable parameters if the target system has more than 256 MB of memory:

```
(memory > 256Mb) {
    mod_kernel += "nproc (20+12*MAXUSERS)"
    mod_kernel += "maxuprc 1000"
}
```

As another example, use this if you want to run a script to do some particular graphics customizations, but you only want to do so when the target system has the appropriate hardware:

```
(graphics[0].planes > 0) {
    post_config_script +=
        "/var/opt/ignite/scripts/multi_plane_graphics"
}
```

You can also specify multiple conditions. This example installs a particular piece of (previously defined) application software if the target system is a workstation (Series 700) having at least two disks. A message lets the user know why it is happening:

```
( (hardware_model ~ "9000/7.*") & (num_disks >= 2) ) {
    note += "Installed apps1 because this is a big series 700."
    init sw_sel "apps1" = TRUE
}
```

It is also possible to add an else clause. This example uses a generic variable capability and mathematical expressions to set the primary swap size based on the amount of memory in the target system:

```
(memory > 512Mb) {
    init _hp_pri_swap = 512Mb
}
else {
    init _hp_pri_swap = memory * 2
}
```

Customizations Based on User Selection

It is sometimes advantageous to be able to select particular customizations independent of the target system's hardware setup. For example, you might have some systems which you intend to use as NFS file servers. You would like the ability to select NFS server capability from the UI when you are configuring the target system.

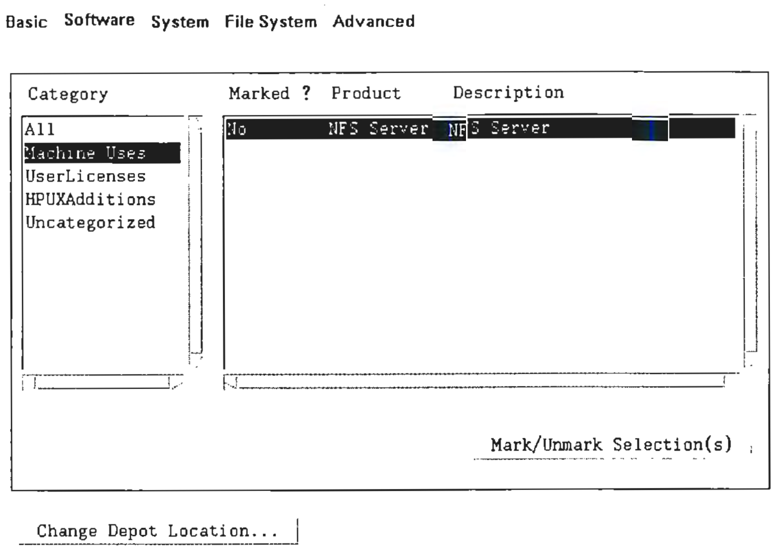
You have found that NFS file servers are more efficient if some of their kernel parameters are modified. NFS file servers also require some changes to the /etc/rc.config.d/nfsconf file via ch_rc.

One solution is to define a custom software selection with a sw_sel clause, which Ignite-UX shows on the **Actions** –> **New Install** –> **Software** tab when you are configuring a new installation. For example:

```
sw_source "special configs" {
    source_format = cmd
}

sw_sel "NFS Server" {
    sw_category = "Machine Uses"
    sw_source = "special configs"
    mod_kernel += "dbc_min_pct 35"
    mod_kernel += "dbc_max_pct 65"
    post_config_cmd += "
        /usr/sbin/ch_rc -a -p NFS_SERVER=1
        /usr/sbin/ch_rc -a -p NFS_CLIENT=1
        /usr/sbin/ch_rc -a -p NUM_NFSD=8"
}
```

The next figure shows the **Software** tab when the NFS server config file is used. As shown, the selected category is `Machine Uses` as defined in the config file. Choosing a different category would display a different set of software. If you were to select `NFS Server` from this screen, the kernel modifications specified in the config file would be applied during the installation. Likewise, the `ch_rc` commands specified in the config file will be run as part of the installation.



```
Category              Marked ?  Product       Description
All                   No        NFS Server    NFS Server
Machine Uses
UserLicenses
HPUXAdditions
Uncategorized
```

Using install tabs to configure client installations is explained in Chapter 5, “Installing HP-UX with Ignite-UX on Clients from a Server.”.

Debugging config Files

Designing a config file to meet your needs can be a very tedious task. It usually requires a lot of trial and error. Beginning with Ignite-UX version A/B 2.2.4 (May 2000), the `instl_dbg` command is available to help you with config file design. With the `instl_dbg` command you can:

- Parse a client's configuration files for syntax errors.
- Place all relevant configuration information into one file for review.
- Display and set variables, software selections, and use models.
- Detect any other errors that may occur during a client installation due to faulty configuration files, such as missing software depots/archives.

After you have developed a new config file, run `instl_dbg` from the Ignite-UX server to parse the specified client's config file as well as any of the server's configuration files referenced by the client's config file. `instl_dbg` first scans for any syntax errors. After syntax is checked, `instl_dbg` substitutes variables, use models, and software selections (`sw_sel`) with real values, and writes a single, unified config file if the `-f` option is specified. You can then compare this file with your original to determine required changes, or use this file as is to install the client. More options are available for more thorough checking or to provide more detail.

Example uses

To debug a client system1 config file and print the debugged config file to stdout and save the debugged config file to `system1_cfg.out`:

```
instl_dbg -D /var/opt/ignite/clients/system1 -d -f
system1_cfg.out
```

Debug the config file for the client named system1, show the effects upon the disk layout when the value of `_hp_disk_layout` and `_hp_pri_swap` are changed, and print the "very, very verbose" (`-vvv`) output to the screen as well as the verbose output to `system1_cfg.out`:

```
instl_dbg -D /var/opt/ignite/clients/system1 -d \
-V _hp_disk_layout="Whole disk (not LVM) with HFS" \
-V _hp_pri_swap=500MB -vvv -f system1_cfg.out
```

Additional examples can be found in the *instl_dbg* (1M) manpage.

4 Installing HP-UX with Ignite-UX on Clients Locally

You can install the client locally by **pulling** the HP-UX operating system from an Ignite-UX server in **terminal user interface** (TUI) mode, as explained in this chapter.

For multiple target installations, you will generally be executing the installation from an Ignite-UX server. Ignite-UX allows you to install one or more client systems manually from the Ignite-UX screen as explained in Chapter 5, from a remote system by using bootsys which is also in Chapter 5, or automatically as explained in Chapter 10. These are called **pushing** installations.

Both installation methods, pushing or pulling, require that a configuration (config) file be created, as explained in Chapter 3. The configuration can include any supported HP-UX 10.*x*, 11.0, or 11i OS, plus any required patches and applications.

This chapter discusses the steps for installing HP-UX on client systems locally. Topics are:

- Preparing Clients for Installation.
- Non-Interactive Installation Using bootsys.
- Booting Client Systems from the Network.

Preparing Clients for Installation

Boot each Series 700 or Series 800 client system that supports network boot either by entering the appropriate command explained in the following pages or by using the Ignite-UX screen. If a client with a known IP address is already running HP-UX, you can use the `bootsys` command (see page 65) from the Ignite-UX server to install a specific configuration without further interaction.

TIP To interrupt the boot process on any HP computer system, press **Esc** on the given system.

The next section provides a brief review of the manual boot process. Boot ROM commands for manual booting are explained in the installation guide supplied with the HP-UX OS/OE media:

- *Installing and Updating HP-UX 10.x, Chapter 3.*
- *HP-UX 11.0 Installation and Update Guide*
- *HP-UX 11i Installation and Update Guide*

If the client cannot find the server to boot from, check these items:

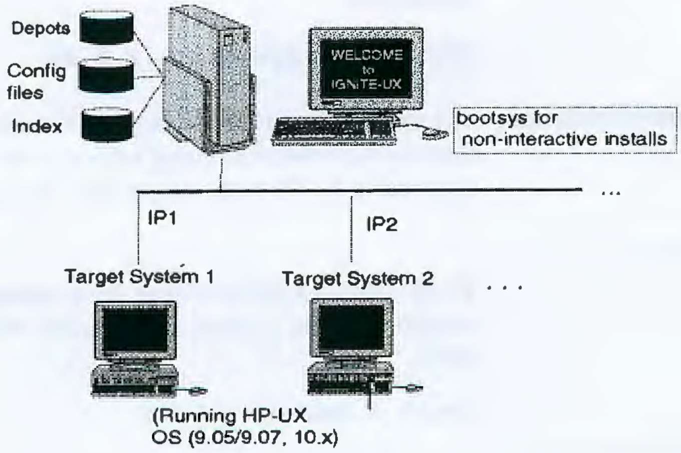
- Client is on the same subnet as the server.
- Any `instl_bootd` errors in: `/var/adm/syslog/syslog.log`
- The `/var/adm/inetd.sec` file to make sure that IP address `0.0.0.0` is not being disallowed.
- If `/etc/services` comes from NIS, make sure that the NIS server has `instl_boot*` entries.

The icons for all clients booted from the Ignite-UX server should now appear on the Ignite-UX client/server screen. If the Ignite-UX server has not been set up completely, or if the client could not obtain enough networking parameters via DHCP, then the client may require interaction on the Ignite-UX client/server screen.

Now that you can view clients on the Ignite-UX client/server screen, you can proceed to Chapter 5.

Non-Interactive Installation Using bootsys

You can use bootsys to start an interactive system installation on one or more clients without logging onto the client system, as illustrated in the following diagram.



It can be invoked either from a command shell, or from the Ignite-UX screen by selecting:

Actions –> Boot Client

Each client must:

- Be currently booted under HP-UX 10.20 or later.
- Be accessible on the network.
- Have enough disk space in the /stand directory to hold these files:

  /opt/ignite/boot/INSTALL

  /opt/ignite/boot/INSTALLFS

bootsys copies the Ignite-UX kernel and RAM file system to each client and then sets the system AUTO file in the LIF area of the root disk to automatically boot from this kernel at the next system reboot.

Examples

This sample command will boot the client system from the boot1 server and wait for install instructions from the Ignite-UX server:

```
bootsys -w boot1
```

If you have already run an install session from the server, issuing `bootsys` without the `-w` option results in automatic installation without further intervention.

To automatically install `system1` using a different IP address than what is currently assigned and without waiting for server interaction, use this command:

```
bootsys -a system1:1.2.3.45
```

More information...

See the *bootsys* (1M) manpage for more information and examples. Common problems using `bootsys` with Ignite-UX are covered in Appendix A, “Troubleshooting,” on page 233.

TIP

To prevent a critical client from being inadvertently booted via bootsys, create the file, `/.bootsys_block`. For example, you can create the file with:

```
touch /.bootsys_block
```

Booting Client Systems from the Network

NOTE

Network boot applies to HP Workstations and HP servers except D, K, and R-class servers that do not support the remote network booting feature. For more details on supported systems, see “Ignite-UX Hardware Requirements” on page 25. See Appendix A “Booting older workstations” on page 239 for more information.

This section provides an overview of booting HP computer systems if you have HP computer systems that may not be running HP-UX.

If you need further help with the boot process, enter:

```
BOOT ADMIN> help boot
```

If the client system is already running an OS, use this procedure or the bootsys command as described in the previous section.

Step 1. Determine your network server address for the install. If necessary, see your system administrator for this information.

Step 2. Turn the power ON for the target system.

Step 3. When you see a message about stopping the boot search, quickly press and hold **Esc** down to stop the boot-selection process.

Booting Current Workstations and Servers

After the power is turned on, you will see a GUI screen (workstations) that displays instructions to press **Esc** to stop the boot process. (On servers, the TUI is used.)

Step 1. Press **Esc** to view the BOOT ADMIN menu:

```
Command                                    Description
-------                                    -----------
Auto [boot|search] [on|off]                Display or set auto flag
Boot [pri|alt|scsi.addr] [isl]             Boot from primary,alternate or
SCSI
Boot lan[.lan_addr] [install] [isl]        Boot from LAN
Chassis [on|off]                           Enable chassis codes
Diagnostic [on|off]                        Enable/disable diagnostic boot
```

```
mode
Fastboot [on|off]                        Display or set fast boot flag
Help                                     Display the command menu
Information                              Display system information
LanAddress                               Display LAN station addresses
Monitor [type]                           Select monitor type
Path [pri|alt] [lan.id|SCSI.addr]        Change boot path
Pim [hpmc|toc|lpmc]                      Display PIM info
Search [ipl] [scsi|lan [install]]        Display potential boot device
Secure [on|off]                          Display or set security mode
------------------------------------------------------------------
BOOT_ADMIN>
```

Step 2. If your network only has one Ignite-UX server available, enter:

```
BOOT ADMIN> boot lan install
```

Step 3. Otherwise, to make sure you boot from the correct server, either make the system search for servers and pick one or explicitly tell the system where to boot, as follows:

1. To search for servers type the following (workstations only):

   ```
   BOOT ADMIN> search lan install
   ```

2. The list of servers will be displayed with IP addresses. You may need to run the `nslookup` command on another running system to determine which address corresponds to your Ignite-UX server, if this information isn't already available.

3. Once you know the IP address of your server (as provided by the search or the `nslookup` command), boot the system by entering:

   ```
   BOOT ADMIN> boot lan.nn.n.nn.n install
   ```

   where: *nn.n.nn.n* is your server's IP address.

   The system then begins to load the install kernel from the network server. This should take 3 to 5 minutes.

Booting Older Series 700 Workstations

On older Series 700 systems, you will eventually see this menu:

```
b)    Boot from specified device
s)    Search for bootable devices
a)    Enter Boot Administration mode
x)    Exit and continue boot sequence
?)    HelpSelect from menu:
```

Do one of the following:

- If your network has only one install server and your system is not configured as a diskless client, then type:

  `boot lan`

  The boot may fail the first time because of an intentional delayed response by the install server. If it fails, try it again. If it fails more than three times, check for problems on the install server (see Appendix A, Troubleshooting,) *OR...*

- If your network has multiple install servers, make sure you boot from the network server address specified by your system administrator.

Search for servers

Step 1. Enter: `BOOT ADMIN>` **`search lan`**

Step 2. If your Ignite-UX server does not appear during the search, exit by entering: **`x`**

1. If necessary, enter the search command again:

   `BOOT ADMIN>` **`search lan`**

TIP

It typically takes two or three searches before the Ignite-UX server will be found, due to a built-in delayed response from the server system.

2. Identify your LAN server from the listing.

3. If three attempts result in no response from the desired server, see Appendix A, "Troubleshooting," on page 233.

Step 3. If you know the Ethernet™ address of your server and can specify where to boot without going through the search process, enter:

`BOOT ADMIN>` **`boot lan.080009-`***`nnnnnn`*

where: `080009-`*`nnnnnn`* is the Ethernet address of the install server. (Some newer systems may not use the `080009` prefix.) This number can be found by running the `lanscan` command on the server.

Step 4. If your server is listed during the search, you can boot the system by entering p and the index number of the server. For example:

```
BOOT ADMIN> p1
```

This will cause the boot to begin. Or, exit this screen by entering:

```
BOOT ADMIN> x

BOOT ADMIN> boot p1
```

IPF Client Network Booting Option

Step 1. From the EFI Boot Manager menu, you will see a prompt to select a boot option. Select **Boot option maintenance menu**.

```
EFI Boot Manager ver 1.10 [14.54]  Firmware ver 0.0 [4209]

Please select a boot option

    EFI Shell [Built-in]
    Boot option maintenance menu
    Security/Password Menu (*** Prototype ***)

Use up and down-arrows to change option(s).
Use Enter to select an option
```

Step 2. The Main Menu appears and prompts you to choose an operation. Select **Add a Boot Option**.

```
EFI Boot Maintenance Manager ver 1.10 [14.54]

Main Menu. Select an Operation

        Boot from a File
        Add a Boot Option
        Delete Boot Option(s)
        Change Boot Order

        Manage BootNext setting
        Set Auto Boot TimeOut

        Select Active Console Output Devices
        Select Active Console Input Devices
        Select Active Standard Error Devices

        Cold Reset
        Exit
```

Step 3. The following menu displays. Select an appropriate network card for network boot. For example, look for entries with a MAC followed by the Mac/*LLA* address of the LAN card.

```
EFI Boot Maintenance Manager ver 1.10 [14.54]

Add a Boot Option.  Select a Volume

    Removable Media Boot
[Acpi(HWP0002,0)/Pci(2|0)/Ata(Primary,Maste
    Load File [EFI Shell [Built-in]]
    Load File [Acpi(HWP0002,0)/Pci(3|0)/Mac(00306E1E4ED4)]
    Load File [Acpi(HWP0002,100)/Pci(2|0)/Mac(00306E1E3ED6)]
    Exit
```

Step 4. Enter an appropriate boot option name at the message prompt. For this example, new boot options are named LAN1 and LAN2.

Step 5. Exit to the main menu. The new boot option will now appear in the EFI Boot Manager main menu.

```
EFI Boot Manager ver 1.10 [14.54]  Firmware ver 0.0 [4209]

Please select a boot option

    SCSI2-HPUX
    EFI Shell [Built-in]
    LAN2
    LAN1
    Boot option maintenance menu
    Security/Password Menu (*** Prototype ***)

Use up and down-arrows to change option(s).
Use Enter to select an option
```

Step 6. Select the new boot option you created. The following is an example of a successful boot using the new boot option.

```
Loading.: LAN1
Running LoadFile()

CLIENT IP: 15.1.52.128  MASK: 255.255.248.  DHCP IP: 15.1.53.37
GATEWAY IP: 15.1.48.1
Running LoadFile()

5 Installing HP-UX with Ignite-UX on Clients from a Server

This chapter discusses the steps for installing HP-UX on client systems from an Ignite-UX server. Topics are:

- Methods of Installing Client Systems.
- Installing from the Ignite-UX Server.
- Configuring the Installation.
- Advanced Tab.
- Executing the Installation: Go!.
- Viewing and Printing a Manifest.

Methods of Installing Client Systems

Ignite-UX allows you to install client systems manually from the Ignite-UX screen as explained here, or automatically as explained in Chapter 10. These are called pushing installations. You can also install clients from a remote system by using `bootsys`, as explained at the end of this chapter, or install the client locally by pulling an OS from an Ignite-UX server as explained in Chapter 4.

Each installation method requires that a configuration (config) file be created, as explained in Chapter 3. The configuration can include any supported HP-UX 10.*x*, 11.0, or 11i OS, plus any required patches and applications.

This chapter describes installing from the Ignite-UX server, either using the Ignite-UX GUI or remotely using the `bootsys` command.

Supported Peripherals

All disk drives supported on HP computer systems are supported for installation. Fibre channel, tape devices, and LAN cards are also supported.

Disk arrays can be installed with HP-UX, but the installation tasks do not support configuring an array. See your array documentation for configuration information.

The HP-UX client-side installation tools support VT100 and Wyse 60 terminals, compatible emulations, and all HP terminals.

Network Requirements

If you are loading your server depots or client software from a remote system, your target system will also need a network card. If the target system has multiple LAN cards, select the card that is configured onto the correct network by navigating to the **System → Additional Interfaces** menu. Only one LAN card can be used during the installation, configured on the Ignite-UX screen or handled automatically by `bootsys`.

Your server system will need to be configured. In addition you will need:

- If you plan to perform a network boot for a target client then the server must be on the same subnet as the target system that will be installed. Other options include using a boot-helper system on each subnet from which to boot clients. See Appendix B, "Using a Boot-Helper System," on page 261 to set up a boot-helper system or using the `bootsys` or `make_tape_recovery` commands.
- If you have more than one LAN connection, you must select the one to be used for the install process.

TIP You can only boot over the network from the system's built-in Ethernet interface. FDDI is also supported, but for non-booting only.

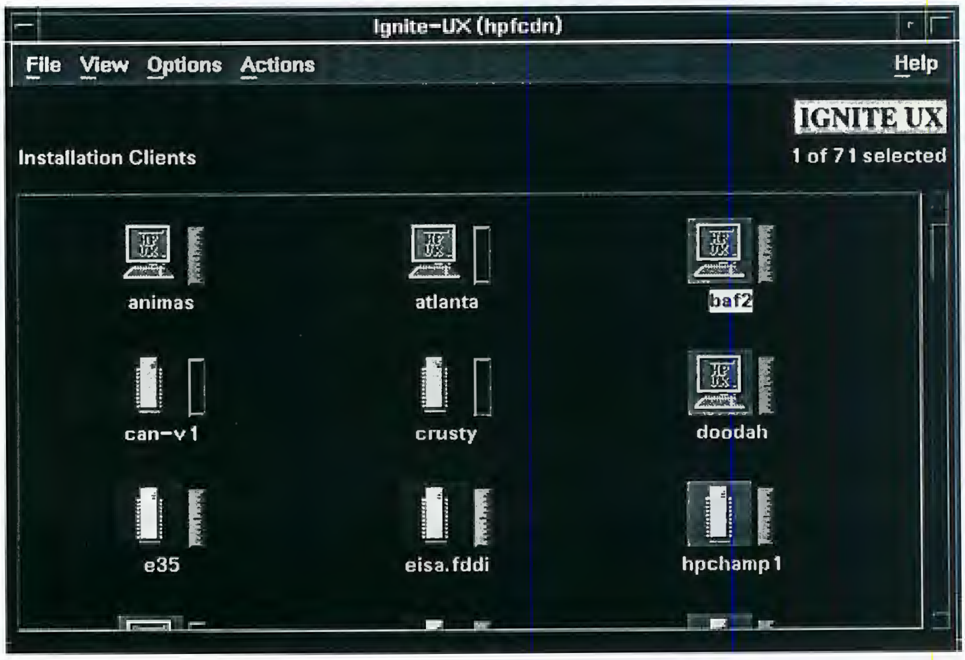
Installing from the Ignite-UX Server

Starting Ignite-UX If you have not already done so, run Ignite-UX on the server as root:

```
/opt/ignite/bin/ignite
```

Running Ignite-UX on the server is explained in the following procedures. Running Ignite-UX remotely from a client or other system provides a TUI with equivalent keyboard navigation.

Ignite-UX screen

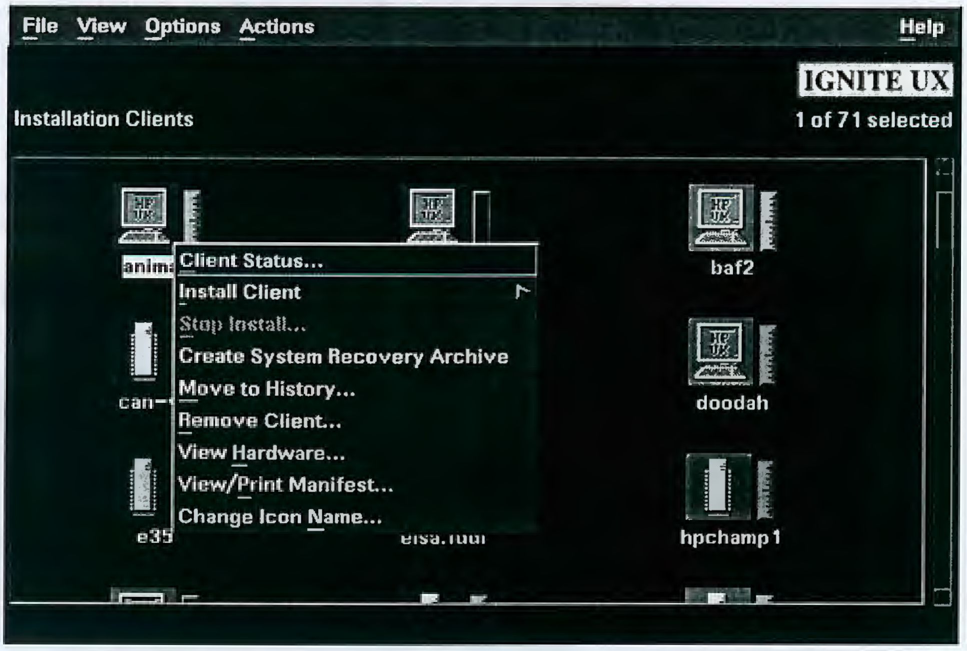


Before any new clients are represented as icons on the Ignite-UX screen, they must first be booted from the Ignite-UX server. If the client is already running an OS, this can be accomplished remotely via the server using: **Actions –> Boot Client**

If the client is not running, see “Booting Client Systems from the Network” on page 67.

After the client icons display, you may:

- Click once on the client icon to select it for further actions.
- Double-click the client icon to get a Client Status screen.
- Right-click the selected client icon to get an Actions menu, which is very similar to the pull-down **Actions** menu:



For more about the available Ignite-UX selections, see Chapter 4, "Installing HP-UX with Ignite-UX on Clients Locally," on page 63 or click **Help**.

Configuring the Installation

To begin the installation, first select a client icon. Then, from the **Actions** menu, select either:

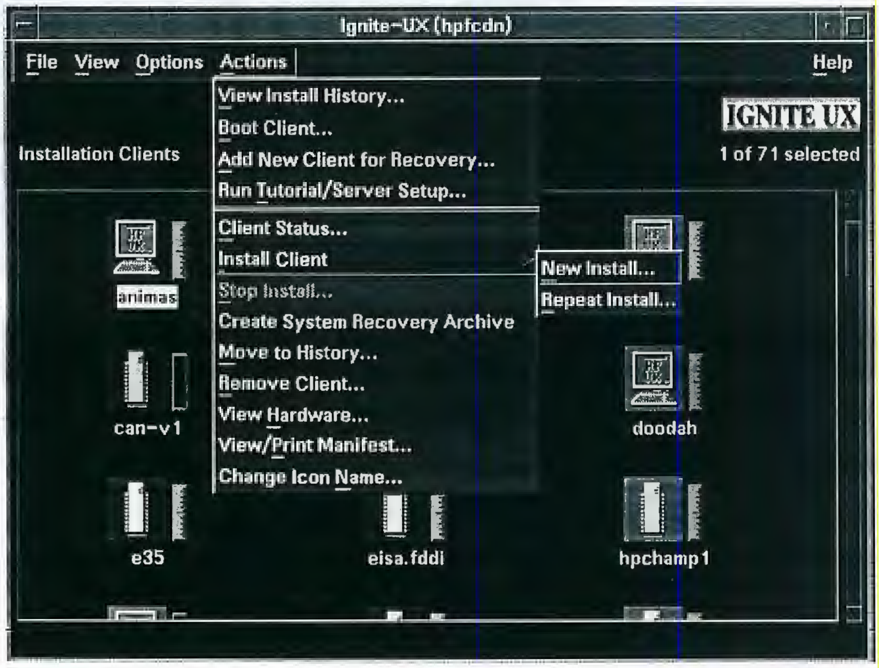
- **Install Client** –> **New install** to install a new client, OR
- **Install Client** –> **Repeat install** to use another clients configuration.

If you have previously installed a client, you will be asked if you want to use the same configuration data again.

If the following message displays:

```
Settings from a previous installation session were found at
startup.  Do you wish to retain these settings for the
current session?
```

Respond **Yes** to re-use some or all of the configuration used in the previous session. Respond **No** to use an entirely new configuration.



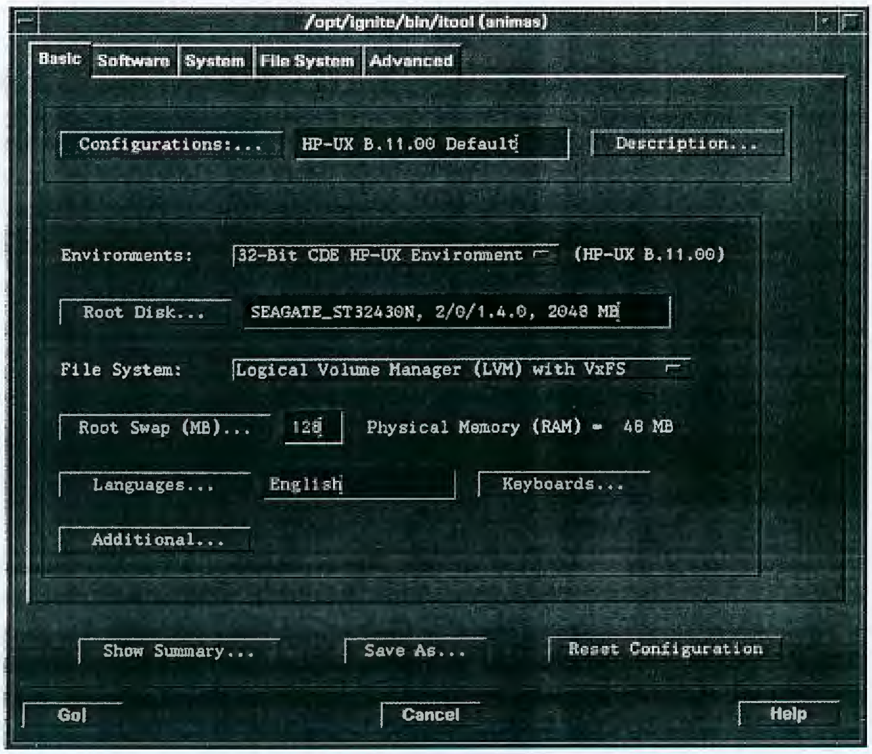
config file parameters

All configuration parameters from an installation are identified and saved as a config file in: `/var/opt/ignite/clients/0x`*`LLA`*`/`

You can use config files in a non-interactive installation using the bootsys command. You can choose a preset configuration in the **Repeat Install** selection list to repeat a previously installed configuration and execute it within Ignite-UX, without further intervention.

Basic Tab

After you choose to install a system, you see the **Basic** screen:



```
Configurations:...   HP-UX B.11.00 Default
Environments:        32-Bit CDE HP-UX Environment   (HP-UX B.11.00)
Root Disk...         SEAGATE_ST32430N, 2/0/1.4.0, 2048 MB
File System:         Logical Volume Manager (LVM) with VxFS
Root Swap (MB)...    128     Physical Memory (RAM) = 48 MB
Languages...         English          Keyboards...
Additional...
```

This screen shows all the basic information for setting up the file system and for loading the OS environment and selecting an HP-UX 11i OE. It also allows you to configure languages, locale, and keyboard requirements. A **Save As...** button also allows saving configurations for later use.

Configurations

Click this selector to display a list of available OS configurations. Then select the one you want to use for this installation. The **Description** button shows more information about each configuration.

Your configuration files are stored in a server location referenced by the `/var/opt/ignite/INDEX` file. The `INDEX` file defines the list of configurations.

OS and HP-UX 11i OE Environments

Select the OS or HP-UX 11i OE environment from the choices available in the list. For HP-UX 11.0/11i, this may include 64-bit or 32-bit OS version. The choices and defaults depend on the releases available on the server, and may include, for example, Common Desktop Environment (CDE) as the default.

File System

Select one of the following:

- **Whole Disk (not LVM)** — This may be the appropriate choice for single-disk systems with disks less than 2GB.
- **Logical Volume Manager (LVM) with HFS** (High-Performance File System) — This selection will format single or multi-disk systems to combine the disk space into a single, large disk pool, and then allocate volumes as needed. The root volume in this case and the swap must be on the same physical volume, and will be configured in this manner by Ignite-UX. The File System tab will provides additional opportunities to configure the LVM volumes. In the File System tab, you can edit the sizes of LVM partitions, or use the values that Ignite-UX computes for you.
- **Logical Volume Manager (LVM) with VxFS** (Veritas File System) — This will format single or multi-disk systems to combine the disk space into a single, large disk pool, and then allocate volumes as needed. VxFS is the same as the Journaled File System (JFS) and allows file system size to be changed after installation. With the optional HP OnlineJFS product you can resize, defragment, or make a "snapshot" of a mounted file system.

- **VERITAS Volume Manager (VxVM) with VxFS** — This will format single or multi-disk systems to combine the disk space into a single, large disk pool, under VxVM, and then allocate volumes as needed. The root, boot, and primary swap volumes must be on the same physical disk and will be configured in this manner by Ignite-UX. The File System tab provides you additional opportunities to configure the VxVM volumes. VxFS is the same as the Journaled File System (JFS) and allows file system size to be changed after installation. With the optional HP OnlineJFS product you can resize, defragment, or make a "snapshot" of a mounted file system.

NOTE VxVM 3.5 is currently only available for HP-UX 11i Version 1.0. VxVM 3.1 is available for HP-UX 11i Versions 1.5 and 1.6.

See "File System Tab" on page 92 for detailed information on File System configuration.

Root disk To change root disks, select this button, select another disk from the list of available disks, and click **OK** in that screen.

For example, a root disk is usually located at SCSI bus location 6.

Root swap The amount of root swap space depends on the applications being loaded. You can choose to use the default which Ignite-UX computes, based on available memory on the target system. Or you can select **Root Swap** and select from the choices that appear in the list. You can also edit the field directly and type in the amount of swap space you wish. The swap will be rounded to a multiple of 4MB or the LVM extent size.

Computing swap space is explained in these HP-UX guides:

- HP-UX 10.*x* — *System Administrator Tasks*.
- HP-UX 11.0 and 11i — *Managing Systems and Workgroups*.

Languages

The languages available in your HP-UX system will be shown when you select this field. Select the item(s) you want, if it is other than the default. The dialogue screen allows you to select more than one language. Highlight the additional items by double-clicking on each. You can also drag the pointer down the screen to highlight a range of items; then press the mark/unmark button.

You can make any of the selections the system default language. This will become the system default language after it is installed.

Locale

Each language will have a corresponding locale (language variant). A locale describes the system management of a language for doing the following:

- Messaging
- Representing numbers
- Displaying monetary values
- Telling time
- Generating characters
- Sorting text

HP-UX can have more than one installed language. The "default language" is the language environment represented on the target system at boot, unless you select another installed language using the HP-VUE or CDE login screen, reset the LANG environment variable, or use geocustoms (HP-UX 10.30 and after) to change it.

Default language choices

Click **Default Language...** to see the **Default Language Choices**. They are listed in two columns: **Language** and **Locale**. Each language may have more than one way of representing itself on the system. If this is the case, there will be multiple locale entries for the same language.

Languages may be activated is several ways:

- **ASK_AT_FIRST_BOOT** allows you to leave the language setting open (unset) until the client system is first booted. At that time, the user will be prompted. The language setting will be performed as part of the initial system configuration. (This applies only to HP-UX 10.30 and later).
- **SET_NULL_LOCALE** creates a NULL language environment, with the locale variables set to NULL by default. A null locale allows programs to execute without using localized message catalogs. This can increase system performance. All HP-UX messages appear in English if the locale is set to **NULL**.

Keyboards... Select the type of keyboard to be used, from the adjacent field. Otherwise, you can use the default selection.

Additional... Click **Additional...** to select among certain pre-configured use-models and variables from your current configuration files. The buttons available are determined from the variables in your config file. When using LVM, you will see selections for easily setting up multiple disks, striping, and file system creation. For details, see the *instl_adm* (4) manpage.

Functions Available on All Tabs

Save as... In server mode, when you have finished your configuration for all tabs, you can save the configuration as a specific file. The saved configurations will then appear under the **Configurations** menu for use in future installations. This function is not available when running the Ignite-UX interface on the install client.

Show summary... Click **Show Summary...** to display the current HP-UX, the basic disk layout, hardware inventory, and other software that will be installed.

Reset configuration Click **Reset Configuration** to change the configuration settings for the currently-selected configuration back to the default settings. You can do this from any tab.

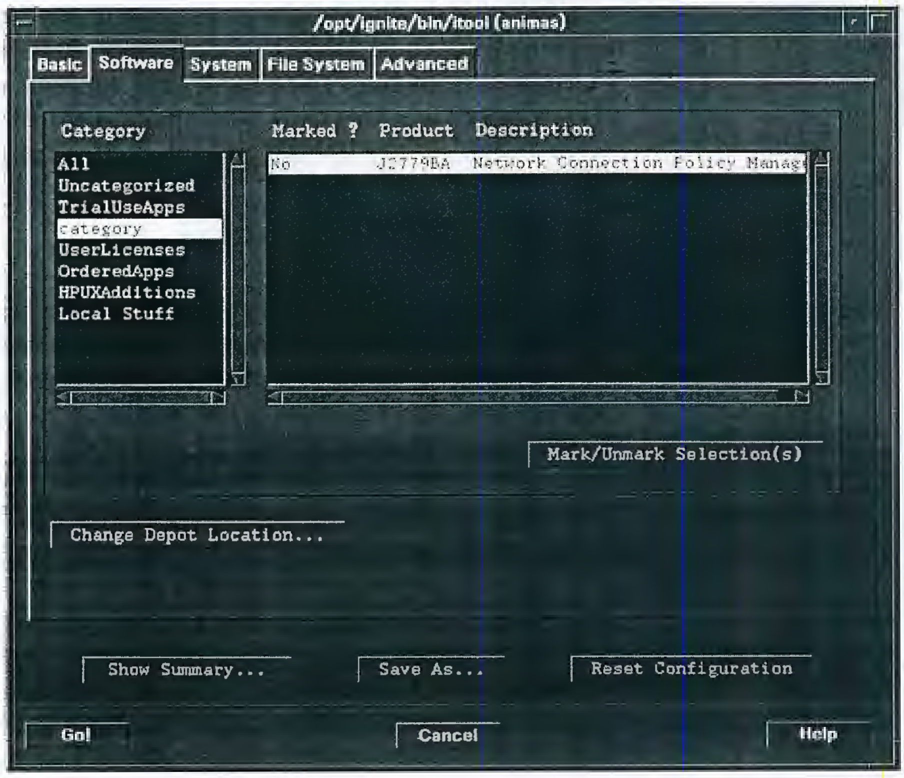
Go! Click **Go!** to initiate an installation. Since **Go!** is always available, click it from any of the tabs. If you don't need to do any customization, click **Go!** now to begin the installation. Then see “Executing the Installation: Go!”, later in this chapter.

After clicking **Go!**, you will still have the opportunity to cancel out of the install sequence.

Cancel Click **Cancel** to exit installing this system.

Help Help information is available on all screens, and you can get context-sensitive help for specific areas by pressing the **F1** function key.

Software Tab



```
Category
All
Uncategorized
TrialUseApps
category
UserLicenses
OrderedApps
HPUXAdditions
Local Stuff
```

```
Marked ?  Product   Description
No        J2779BA   Network Connection Policy Manag
```

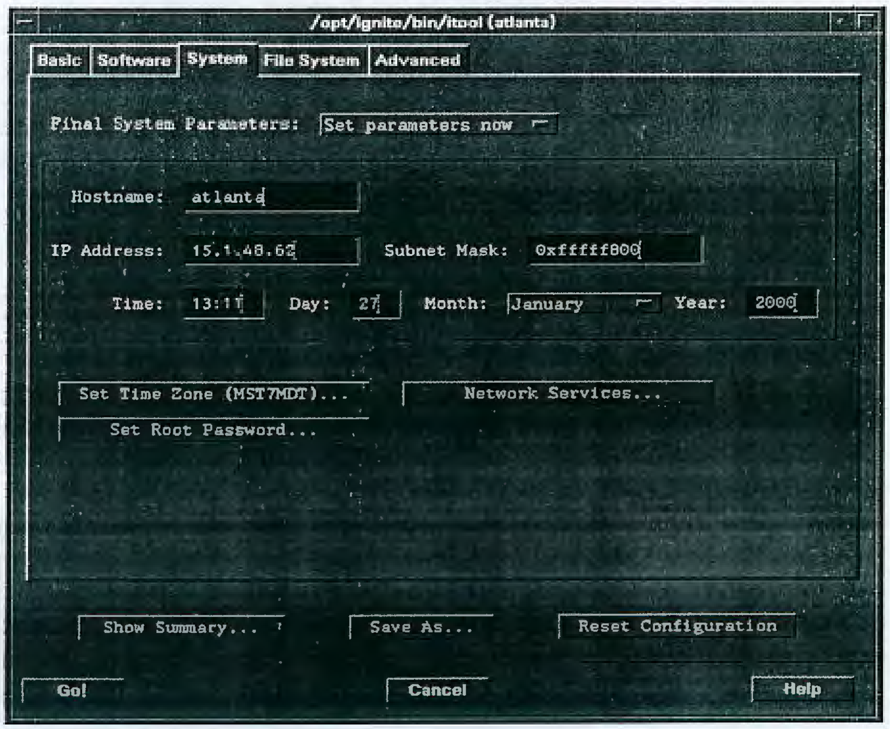
This tab allows you to choose licensing level and additional applications that you configured when you set up your server. To access a specific depot, you can also change depot locations. This display does not dynamically update from a newly-selected depot. When choosing a new depot, it must be identical in content to the current one. If not, use `make_config` on the server to configure the new depot.

- **Category** — Select a topical category to display products available.
- **Product List** — Double-click on a product in the list to select (highlight) it and to toggle its "marked" status (**Yes** or **No**). Alternately, use **Mark/Unmark Selection(s)** to toggle the "marked" status for a selected item.

If patches are kept in a separate depot, by default they are loaded after Core software. If there is more than one non-Core software to be loaded, you may need to specifying the load order for the patch(es) in a config file.

System Tab

You will see a choice selection allowing you to set parameters now, or at first boot of the target system. If you choose to set these parameters now, you see this screen:



Final System Parameters: Set parameters now

Hostname: atlanta

IP Address: 15.1.48.62 Subnet Mask: 0xfffff800

Time: 13:11 Day: 27 Month: January Year: 2000

Hostname

Your system must have a unique system name (a "hostname"), which can be a simple name.

A system name must fulfill the following conditions:

- It must contain no more than eight characters
- It must contain only letters, numbers, underscore (_), or hyphen (-).
- It must start with a letter. Upper case letters are not recommended.

9

- The first component of a host name should contain no more than eight characters, for compatibility with the uname command.

IP address

Use this field to enter the IP address of the form:

n.n.n.n

where: each *n* can be `0` through `255`.

For example:

```
15.1.48.140
```

To determine an existing IP address, use:

`nslookup` ***`hostname`***

Subnet mask

This field sets the subnet mask. The subnet mask will typically be provided by your network administrator, and is of the IP address form or a corresponding hex number. For example:

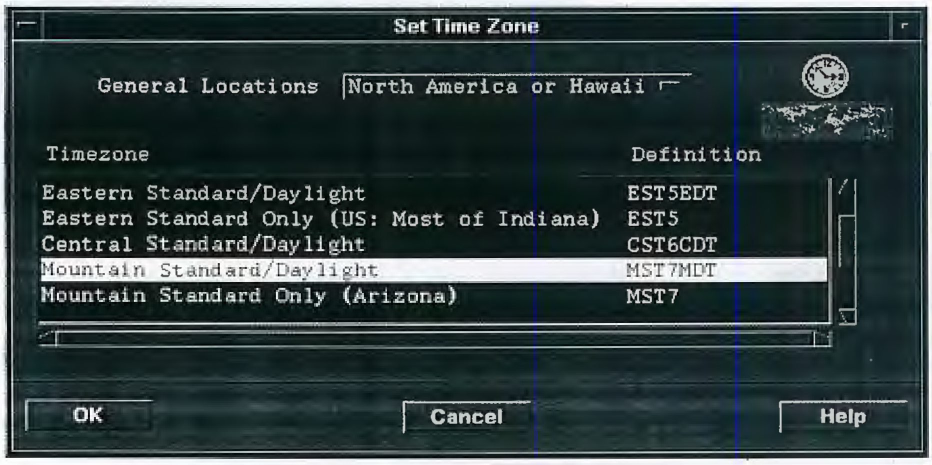
```
255.255.248.0
```

Time and date information

If necessary, enter information for the **`Time`**, **`Day`**, **`Month`**, and **`Year`** fields: For time, use the 24-hour format: *hh*:*mm*

Select the correct month by clicking on the button and selecting from the list. Edit other fields by using the **Backspace** and **Delete** keys.

Set Time Zone screen



Set Time Zone

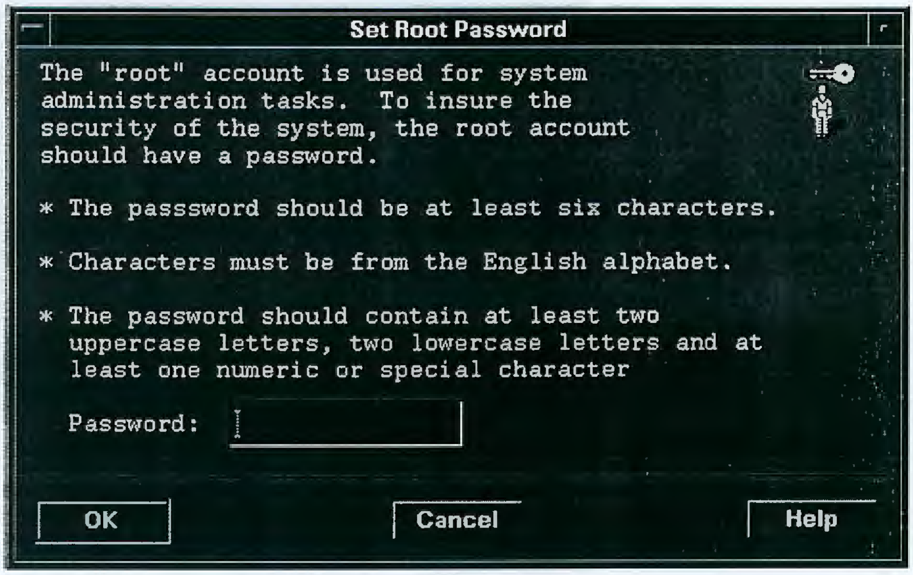
General Locations: North America or Hawaii

Timezone	Definition
Eastern Standard/Daylight	EST5EDT
Eastern Standard Only (US: Most of Indiana)	EST5
Central Standard/Daylight	CST6CDT
Mountain Standard/Daylight	MST7MDT
Mountain Standard Only (Arizona)	MST7

Select this button to bring up a display of time zone selections. You will see two selector lists: the first consists of general locations, and the second has corresponding time zones.

Select an item and click **OK** to make a choice.

Set Root Password screen



Set Root Password

```
The "root" account is used for system
administration tasks.  To insure the
security of the system, the root account
should have a password.

* The password should be at least six characters.

* Characters must be from the English alphabet.

* The password should contain at least two
  uppercase letters, two lowercase letters and at
  least one numeric or special character

  Password:
```

The root account is used for system administration tasks. To insure the security of the system, the root account should have a password.

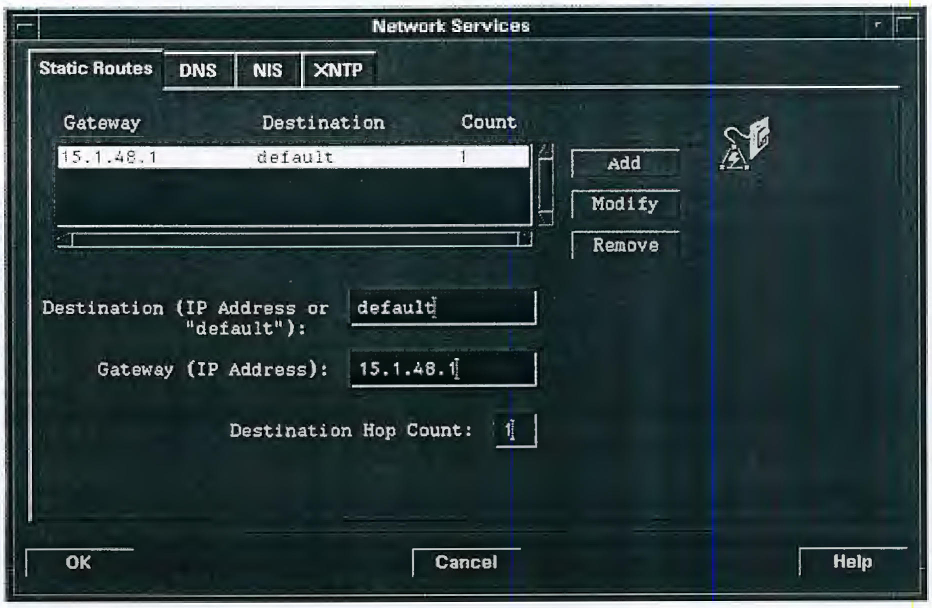
You should observe the following requirements when setting a password:

- The password must be at least six characters long.
- Characters must be from the English alphabet.
- The password should contain at least two uppercase letters, two lowercase letters and at least one numeric or special character.

Network services Click **Network Services** to access tabs used to enter information on:

- **Static Routes**
- **DNS**
- **NIS**
- **XNTP**

Static routes screen



Gateway	Destination	Count
15.1.48.1	default	1

Destination (IP Address or "default"): default

Gateway (IP Address): 15.1.48.1

Destination Hop Count: 1

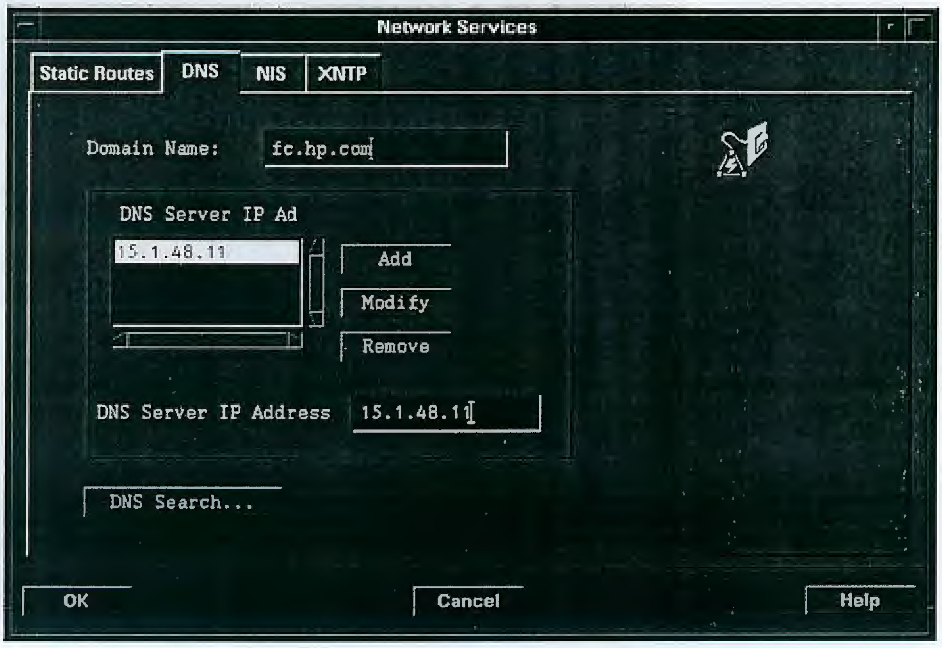
If your network is divided into subnets, you will probably need to specify a gateway system to reach other subnets:

- **Destination** — The field has the word **default** or the IP address of the destination network.
- **Gateway** — The IP address of the device connecting your network to the remote network, or your own IP, if wildcard routing is used.
- **Destination Hop Count** — If your gateway IP is not your system's own IP, this is usually set to `1`. If your gateway IP is the same as your system's, then the Hop Count is `0`.

Once the appropriate fields have been completed on this screen, click the **Add** button.

For more information, see the *routing* (7) manpage.

DNS screen



Domain Name: fc.hp.com

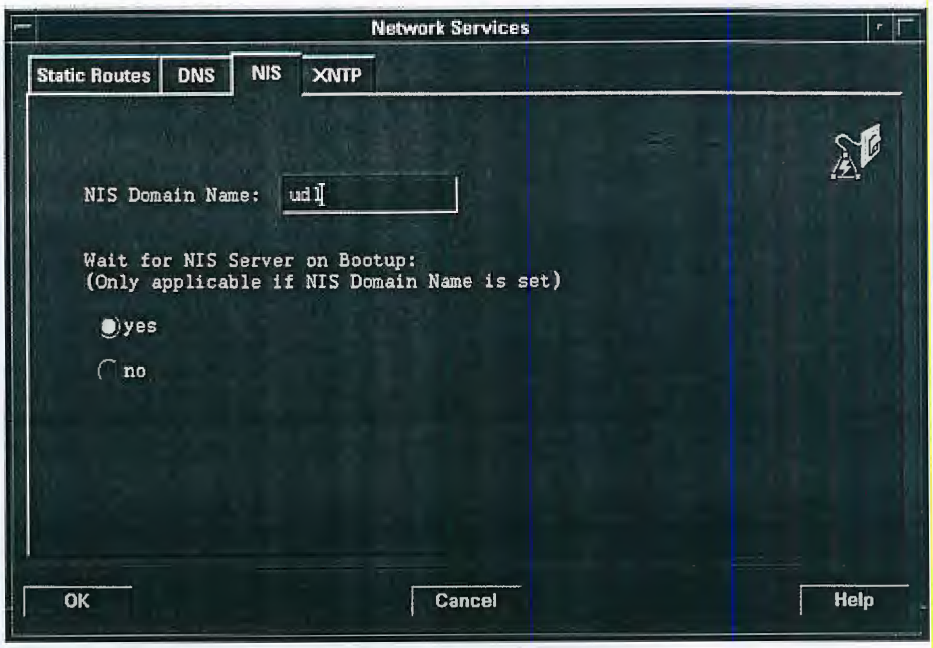
15.1.48.11

DNS Server IP Address 15.1.48.11

On this screen, you can configure the **Domain Name** (an extension to the host name, such as `fc.hp.com`) and the IP address of the Domain Name Server. The listing of current servers is displayed, if they are predefined in the Ignite-UX server. Use the `nslookup` command on a running system to find this information.

After entering a DNS server, click **Add**. Use **Modify** if you are changing an existing entry.

NIS screen



NIS Domain Name: udl

Wait for NIS Server on Bootup:
(Only applicable if NIS Domain Name is set)

● yes

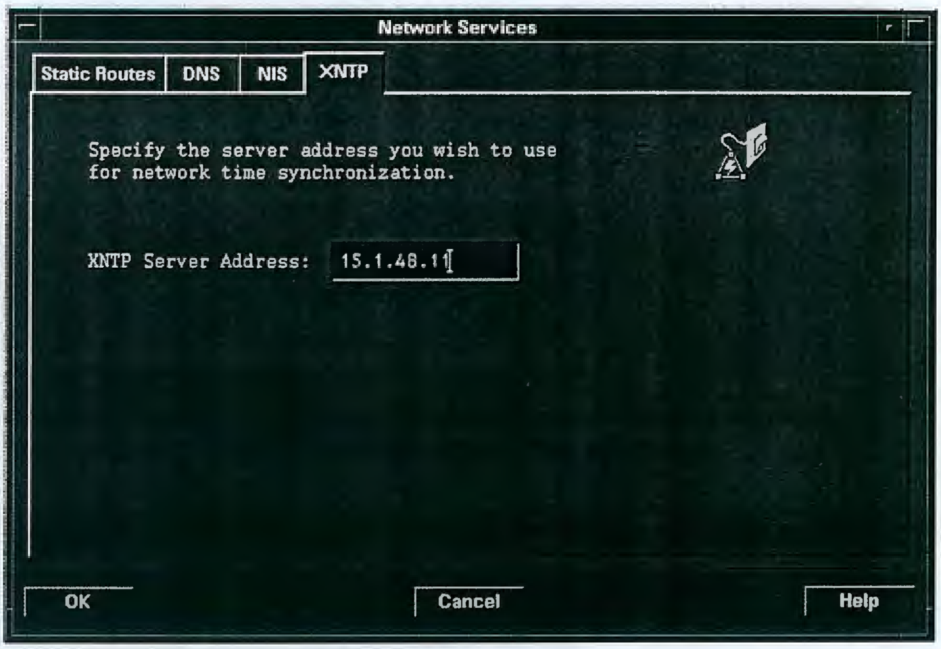
○ no

Typically, the (non-server) hosts in a network are NIS clients. Whenever a process on an NIS client requests configuration information, it calls NIS instead of looking in its local configuration files. The set of maps shared by the servers and clients is called the **NIS domain**.

For more information on NIS, see the *domainname* (1M) manpage or the guide *Installing and Administering NIS Services*.

Wait for NIS server on bootup Select **yes** or **no**, depending on your configuration for NIS.

XNTP screen



```
Specify the server address you wish to use
for network time synchronization.

XNTP Server Address: 15.1.48.11
```

The xntpd daemon maintains system time, in agreement with Internet standard time servers. It does all computations in fixed point arithmetic and clock adjustment code is carried out with high precision.

For more information, see the *xntpd* (1M) manpage.

Additional (network) interfaces

Use this button to bring up a screen for entering information identifying additional LAN interface cards in the target system.

This screen enables you to enter or change IP and Subnet information, as needed, and designate the Primary Interface.

NOTE If the target system has more than one interface, the Primary LAN card will be associated with the host name of the system in `/etc/hosts`.

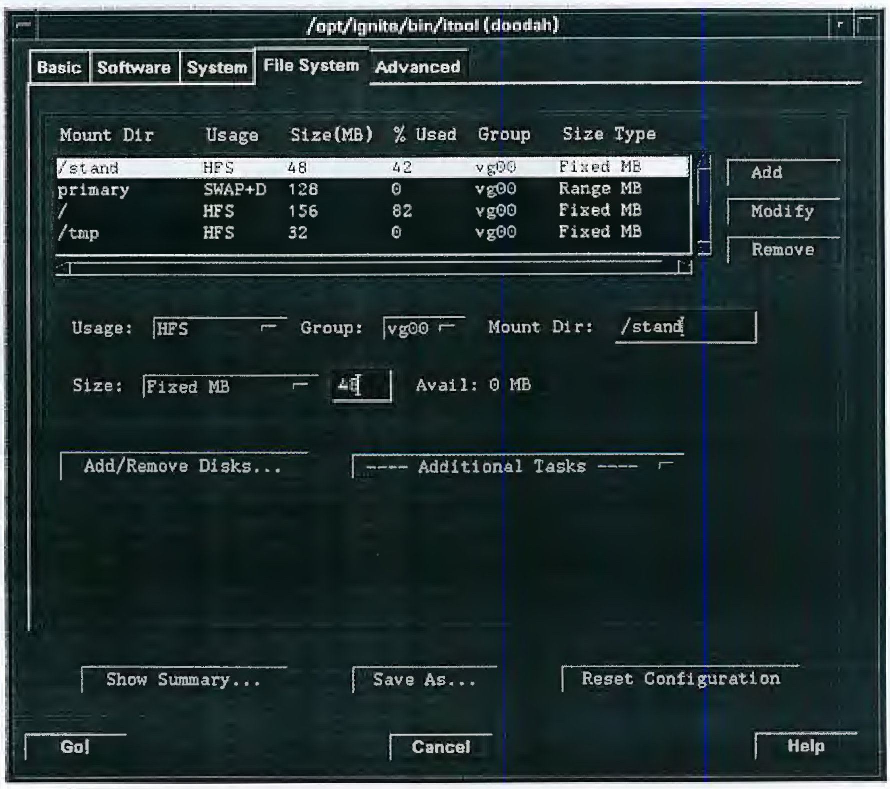
1. Select an **Interface** card from the selection list.
2. Enter or modify the **IP Address**, as needed.
3. Enter or modify the **Subnet Mask**, as needed.

6462 Paula

4. Activate **Primary Interface**, depending on the status you want for this interface.

5. Click **Modify** when you have finished with changes for each interface.

File System Tab



```
Mount Dir    Usage     Size(MB)  % Used  Group   Size Type
/stand       HFS       48        42      vg00    Fixed MB
primary      SWAP+D    128       0       vg00    Range MB
/            HFS       156       82      vg00    Fixed MB
/tmp         HFS       32        0       vg00    Fixed MB

Usage: HFS        Group: vg00    Mount Dir: /stand

Size: Fixed MB    48    Avail: 0 MB
```

This tab enables you to do a variety of file-system and disk-configuration tasks and will differ in appearance, depending on whether you previously selected LVM, VxVM or whole disk, on the **Basic** tab. This illustration is what you would see if you had picked LVM on the **Basic** tab.

Adding and changing file system configuration

To add or change any configurations on the display of file systems:

1. Enter the information in an appropriate field below the display.

2. Select one of the buttons to the right: **Add**, **Modify** or **Remove**.

3. To see more information on the file system display, use the horizontal scroll bar or resize the screen.
4. The **Avail:** indication shows how much space is unallocated in the volume group of the highlighted volume.

For LVM:

- One of the volumes must be root (/).
- A swap volume (primary) is required.
- Directory names must have valid HP-UX names (`/usr`, `/database`, etc.).

For VxVM:

- One of the volumes must be root (/).
- One of the volumes must be boot (`/stand`) with HFS usage.
- A swap volume (primary) is required.
- Directory names must have valid HP-UX names (`/usr`, `/database`, etc.).

The buttons which activate changes are **Add, Modify** and **Remove**.

Generally, changes are not put into effect until you select one of these. If you make a change and then leave the tab without using one of these buttons, your changes may not be applied.

Usage

Select the **Usage** field to see list of file system usage types. If you want to change file system type or usage for the selected item, select an item in this list. The usages are as follows:

- **HFS** — Select this item to create a High-Performance File System.
- **SWAP** — Select this item to create swap.
- **SWAP-Dump** — Select this item to create an area for both swap and system dump.
- **VxFS** — Select this item to create a JFS. This is an extent-based, journaled file system featuring high-reliability, fast recovery time and on-line administration.
- **Unused** — This means the logical volume will be created, but not used.

Group

Click on the **Group** field to open a selection list. You can choose a volume group name from the list.

IMPORTANT

Renaming or changing the disk file-system structure causes the old file system on that disk to be lost (a warning message will remind you of this).

- If you want to add a new/unused disk and give it a different volume group name or create a new volume group, select the **Add/Remove Disks...** field and follow the procedure.
- If you want to reconfigure the volume group in general, including renaming it, click **Additional Tasks** –> **Group Parameters**, where you can fill in a custom group name, and change other disk parameters.
- Click **OK** when you are finished with the sub-screens for any of these tasks. You will be returned to the **File System** tab.

Mount dir

For the root disk, use the standard HP-UX mount directory designations (`"/"`, `"/usr"`, `"/stand"`, `"/var"`, `"/opt"`, etc.) You can also specify your own mount points such as "`/special`" or "`/apps`".

Size

For setting up each selected file system (as shown in the Mount Dir display), the following choices are available:

1. First select an item in the directory display for the file system you want to change. The current selection will show in the **Mount Dir** field.
2. The sizing method (such as "Fixed Size") currently used for that particular file system will appear in the **Size** field. To change the Sizing Method:
   a. Make sure the file system you want to change is selected in the directory display list.
   b. Select the sizing method field to open the list of sizing methods.
   c. Select one of the items (such as **Size Fixed MB**). It will then remain displayed in that field.
   d. Click **Modify** to execute the change on the selected file system.

The types of sizing are:

Fixed The selected (highlighted) file system is set to this size.

All Remaining The selected file system automatically takes over all remaining file system space on the disk or volume group.

Free Size Use this selection when you know how much free space you wish the volume to have after the system is installed. The size of the volume will be the specified amount plus the amount the selected software requires.

Free Percent This category is similar to free size, but expressed in percent. It is used if you know how full you wish the volume to be, in percentage of the volume size. If you indicate "20%", then the volume would be 80% full after the installation of the selected software.

Size Range Select this category in the list to set a maximum size for the file system (the minimum is determined by the software impact on the volume).

NOTE /usr must have sufficient space to accommodate an OS update. The absolute minimum is 324 MB for a 64-bit system. See the installation guide supplied with your HP-UX media.

Add/remove disks This opens a display which allows you to do the following:

- Add a new disk and configure its file system type and volume group designation, if any.
- Remove a disk from current usage on the target system by designating it as **Unused**.
- Determine your current disk usage.

6458
Paula

To change a disk usage status:

- Select a disk in the displayed list.
- Click **Usage** to set a new usage. If you select `LVM` or `VxVM` the **Disk Group**: button appears.
- Click **Disk Group:** to see the volume group choices or type in a new volume group name in the entry field.
- Click **Modify** to execute any changes.

Additional Tasks

This button enables you to configure advanced information in the following categories, as needed. Click on the field to see the following menu items:

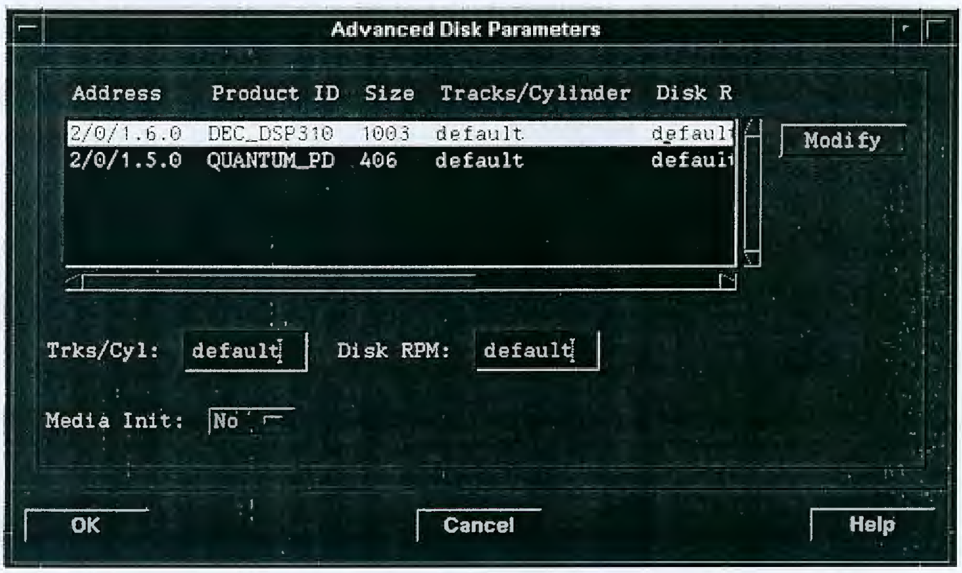
- **Disk Parameters**
- **File System Parameters**
- **Volume Parameters**
- **Group Parameters**

Clicking on one of these will open a screen which will enable you to change advanced parameters. The button will retain the label of the area you are currently working in.

NOTE

Screen choices differ depending on the file system choices you made on the **Basic** tab.

Advanced Disk Parameters screen



```
Address     Product ID  Size  Tracks/Cylinder  Disk R
2/0/1.6.0  DEC_DSP310  1003  default          defaul
2/0/1.5.0  QUANTUM_PD  406   default          defaul
```

Trks/Cyl: default

Disk RPM: default

Media Init: No

Step 1. Highlight a disk in the selection list to select it.

Step 2. Configure the **Trks/Cyl** and **Disk RPM** by direct editing, as needed.

Step 3. Indicate whether Media Init is required by clicking on the selection box and selecting a choice.

Step 4. Click **Modify** to configure changes.

Step 5. Click **OK** to leave **Advanced Disk Parameters** and return to the **File System** tab.

Tracks per cylinder

Step 1. Select a disk by clicking on its entry.

Step 2. Edit the **Trks/Cyl** field as needed and click **Modify** to execute any changes.

Step 3. Click **OK** to leave this screen and return to the **File System** tab.

Disk RPM

Step 1. Select a disk by clicking on its entry.

Step 2. Edit the **Disk RPM** field as needed and click **Modify** to execute any changes.

Step 3. Click **OK** to leave this screen and return to the **File System** tab.

NOTE Running `MediInit` is not recommended unless hardware damage is suspected.

Media init

Step 1. Select a disk by clicking on its entry in the list displayed.

Step 2. Click **MediaInit** to open the selection list.

Step 3. Click **Yes** or **No**. If this is set to **Yes**, you will also see the **Interleave** field.

Step 4. Click **Modify** to execute any changes.

Step 5. Click **OK** to leave this screen and return to the **File System** tab.

More information...

- *mkfs_vxfs* (1M)
- *mkfs_hfs* (1M)
- *mediainit* (1)

Intrlv

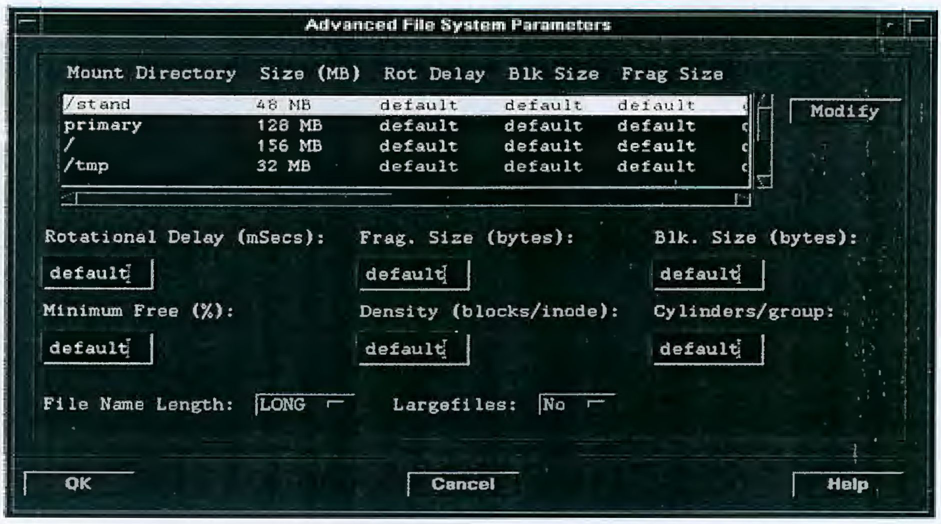
This field is available if **Media Init** is set to **Yes**.

The interleave factor, "interleave", refers to the relationship between sequential logical records and sequential physical records on the disk. It defines the number of physical records that lie between the beginning points of two consecutively numbered logical records. The choice of interleave factor can have a substantial impact on disk performance.

For more information, consult the guide for your disk hardware.

Also see the *mediainit* (1) manpage.

Advanced File System Parameters screen



Advanced File System Parameters

Mount Directory	Size (MB)	Rot Delay	Blk Size	Frag Size
/stand	48 MB	default	default	default
primary	128 MB	default	default	default
/	156 MB	default	default	default
/tmp	32 MB	default	default	default

Rotational Delay (mSecs): default

Frag. Size (bytes): default

Blk. Size (bytes): default

Minimum Free (%): default

Density (blocks/inode): default

Cylinders/group: default

File Name Length: LONG

Largefiles: No

These parameters apply only to HFS file systems:

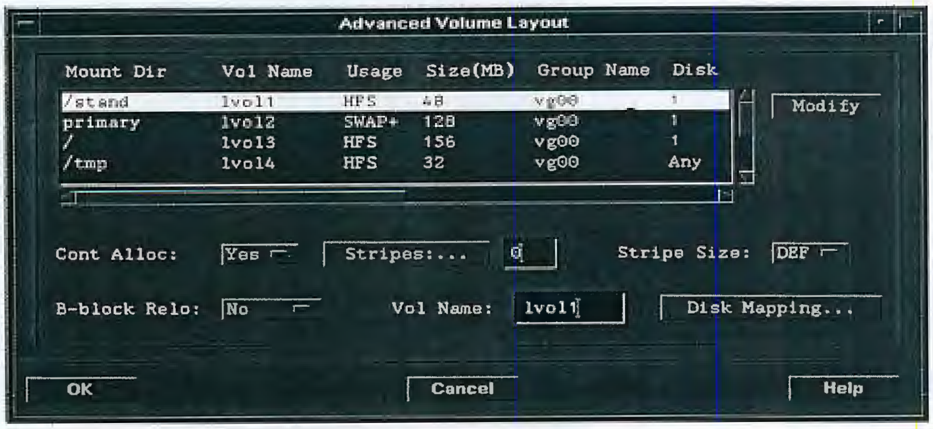
- **Rotational Delay**
- **Fragment Size**
- **Block Size**
- **Minimum Free**
- **Disk Density**
- **Cylinders/Group**

You can use the default values computed by Ignite-UX, or change them, as needed. Selecting **default** means it will use the default defined by the `mkfs` command. When you have finished with this area, click **OK** to return to the **File System** tab.

To get more details, see the *mkfs_hfs* (1M) and *mkfs* (1M) manpages.

6454
Paula

Advanced Volume Layout screen (Volume Parameters)



```
Mount Dir     Vol Name    Usage    Size(MB)   Group Name   Disk
/stand        lvol1       HFS      48         vg00         1
primary       lvol2       SWAP+    128        vg00         1
/             lvol3       HFS      156        vg00         1
/tmp          lvol4       HFS      32         vg00         Any
```

Cont Alloc: Yes   Stripes:... 0   Stripe Size: DEF

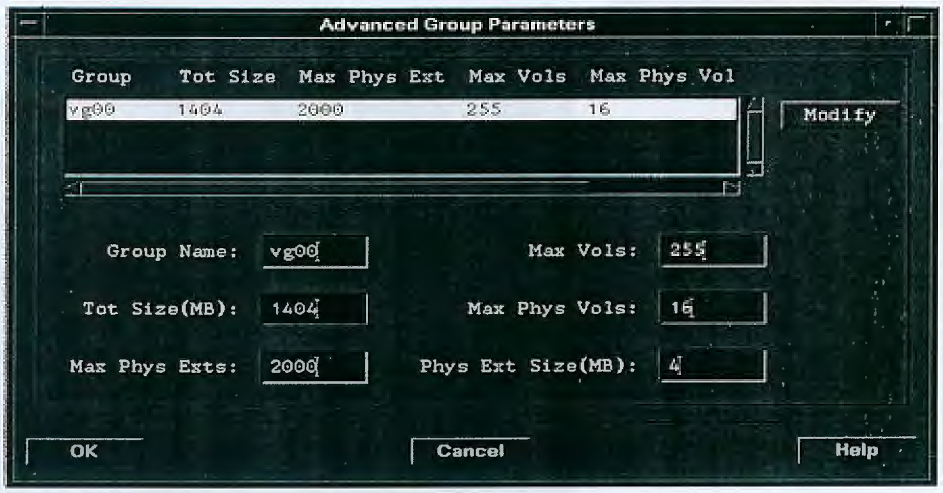
B-block Relo: No   Vol Name: lvol1

Example is shown using LVM.

Use this screen to perform detailed configuration of volumes, as needed, in the following areas. For more detailed information, see the *lvcreate* (1M) manpage for LVM or the *vxassist* (1M) manpage for VxVM.

- **Cont Alloc** — This sets the contiguous allocation policy. A contiguous logical volume has these characteristics:
  - — Physical extents are allocated in ascending order.
  - — No gap is allowed between physical extents within a mirror copy.
  - — Physical extents of any mirror copy all reside on a single physical volume.
  - — The root volume (/), the boot volume (/stand), dump volumes and primary swap must always be created with **Cont Alloc** set to **Yes.**
- **B-block Relo** (Bad-Block Relocation)
- **Stripes** — If two or more disks are in the volume group, then you may enable data striping over multiple disks for performance purposes.
- **Stripe Size** — Configure this if you have at least two disks in a volume group. The default stripe size is 64Kb.
- **Vol Name** — Enter the name you want for the selected volume.
- **Disk Mapping** — Displays a screen which allows you to restrict the disk drives on which the volume data will reside. Normally, the data will be allocated over these disks sequentially.

Advanced Group Parameters screen



Group	Tot Size	Max Phys Ext	Max Vols	Max Phys Vol
vg00	1404	2000	255	16

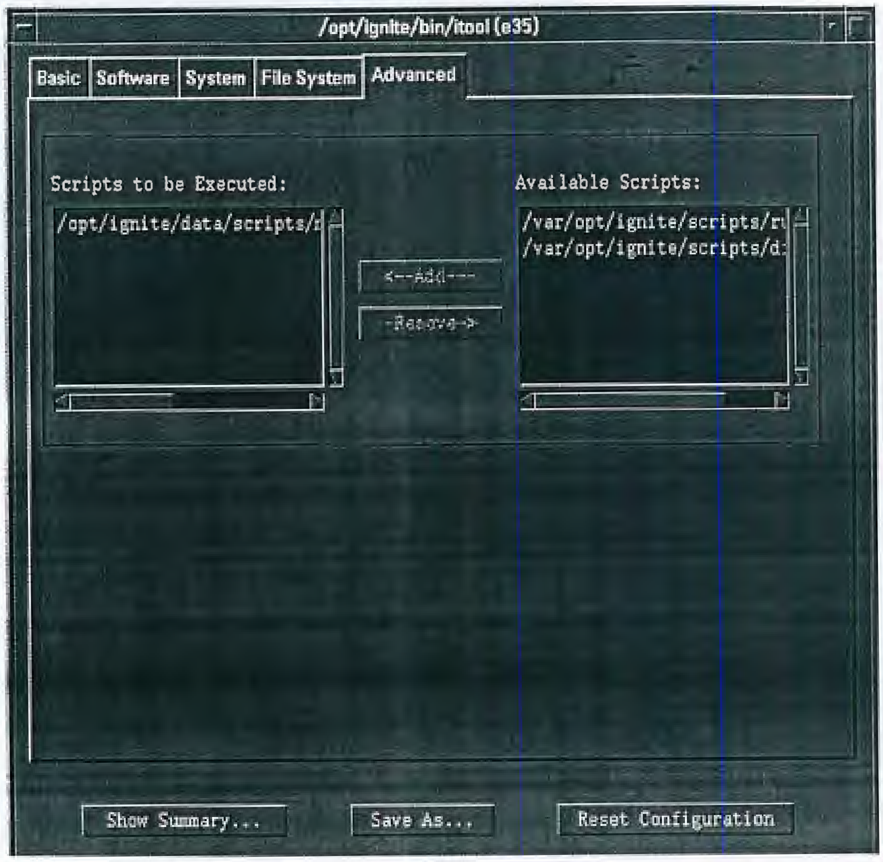
Group Name: vg00
Tot Size(MB): 1404
Max Phys Exts: 2000
Max Vols: 255
Max Phys Vols: 16
Phys Ext Size(MB): 4

Example is shown using LVM.

Use this screen perform detailed configuration of volumes, as needed, in the following areas. For more detailed information, see the *vgcreate* (1M) manpage for LVM or the *vgdg* (1M) manpage for VxVM.

- **Group Name** — Use to rename existing volume groups.
- **Max Vols** — Maximum number of logical volumes.
- **Total Size** — Total size of all volumes.
- **Max Phys Vols** — Maximum number of volumes.
- **Max Phys Exts** — Maximum physical extents.
- **Physical Ext Size** — Physical extent size in MBs.

Advanced Tab



```
/opt/ignite/data/scripts/r
```

```
/var/opt/ignite/scripts/r
/var/opt/ignite/scripts/d
```

Use this screen to activate any HP or custom scripts which you might want to run as part of your installation. Note that the scripts listed are those with a "scripts" keyword in the `/var/opt/ignite/INDEX` file.

Adding a script To add an item, select the item from **Available Scripts** and click: **Add**

Removing a script To remove an item, select the item in **Scripts to be Executed** and click: **Remove**. The item is deactivated, but remains in the **Available Scripts** list.

Executing the Installation: Go!

Select **Go!** in any Ignite-UX tab to initiate the installation. You do not need to examine all tabs, if you simply want to do a generic installation.

A confirmation screen lists disks that will be written on during the installation process and a log of any warnings or errors.

- If you do not wish to proceed with the installation at this time, click: **Cancel**
- The pre-install analysis display screen is scrollable. Be sure to inspect this information and check to see that the disk(s) described in the display list is the one you intend to install on.
- Any errors which are listed must be corrected before you proceed.

As the installation proceeds, you will see a log including the warnings and errors which may need to be addressed before proceeding.

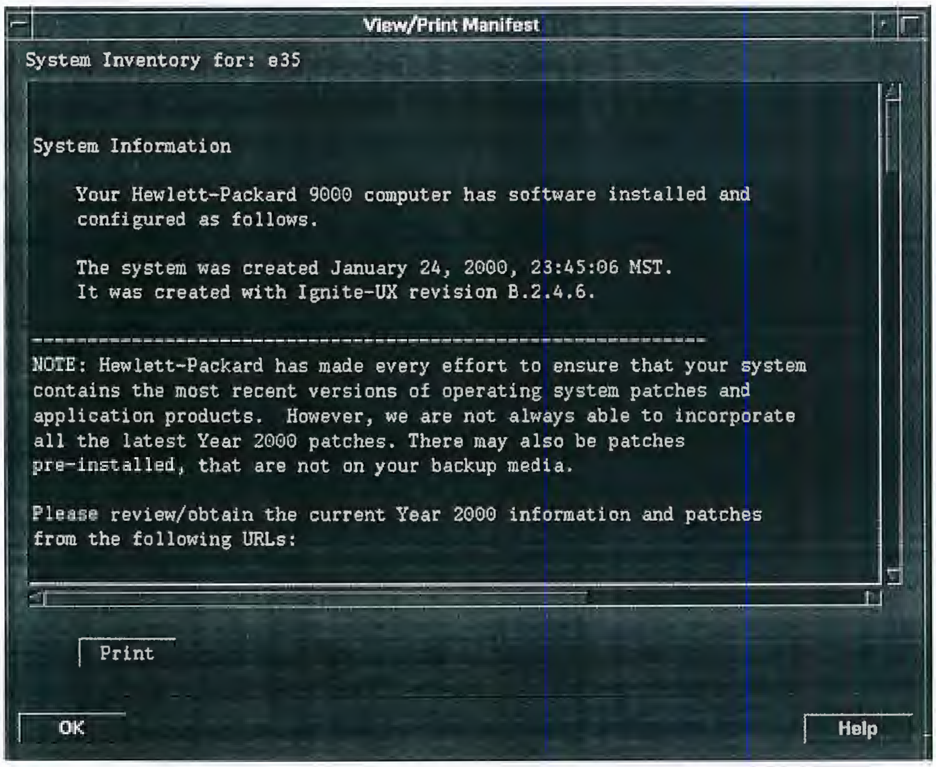
When the installation is complete, you can print a manifest. Then either save the client data in a history directory, remove the client and its data from the server, or just leave the data on the server.

6450
Paula

Viewing and Printing a Manifest

From the Ignite-UX screen

To view a system manifest from Ignite-UX, select a client icon and click: **Actions -> View/Print Manifest**. This is also available from the Client Actions menu (right-click on client icon). The system search may take a moment.



```
System Inventory for: e35

System Information

    Your Hewlett-Packard 9000 computer has software installed and
    configured as follows.

    The system was created January 24, 2000, 23:45:06 MST.
    It was created with Ignite-UX revision B.2.4.6.

------------------------------------------------------------
NOTE: Hewlett-Packard has made every effort to ensure that your system
contains the most recent versions of operating system patches and
application products.  However, we are not always able to incorporate
all the latest Year 2000 patches. There may also be patches
pre-installed, that are not on your backup media.

Please review/obtain the current Year 2000 information and patches
from the following URLs:
```

The manifest provides customer order information for the selected target system.

You can view or print the manifest when a target client is "Complete", as indicated by the Client Status screen. The online information is scrollable.

The manifest contains the following information:

- Customer information, if this has been entered on the individual client configuration screen.
- Hardware connected to the system.
- Storage Devices.
- Installed Software.
- Disk layout.
- File System layout.
- Swap Configuration.
- Kernel Configuration.
- System Information.

Using the print_manifest command

To print the system manifest from the server command line, enter:

```
/opt/ignite/bin/print_manifest
```

The ASCII file is printed to stdout using format instructions from the manifest template file (explained below).

Location of manifest files

Manifest files are saved on the server in:

```
/var/opt/ignite/clients/LLA/manifest/manifest.info
```

and on the target client system in:

```
/var/opt/ignite/local/manifest/manifest.info
```

If the client data is moved to history, that data includes both the client's manifest and config file. Both these files can be recalled at a later time.

Customizing manifest output

Add printer formatting — Include the -e option to add PCL control codes to the output, adding bold headings, etc. to the output.

Print an existing manifest file — Include the -s option to use previously stored data, rather than starting a new system search.

Specify a template file —Use the -t option to specify a template file to customize the manifest output to your needs. A sample template file is: /var/opt/ignite/local/manifest/template.def. The template uses pcl3 formatting commands (similar to printf), allowing you to structure the output as desired. To create your template, be sure to edit a copy of this file, not the original.

For example, if you want a condensed, machine-readable output, you can remove all blank lines and headings from your template. This will also speed-up the manifest generation. This command prints a condensed manifest using the existing manifest file and referencing a template you created named condensed.def:

```
print_manifest -s  -t
/var/opt/ignite/local/manifest/condensed.def
```

You can also access the raw manifest data via a script or program. This file is updated on the Ignite-UX server each time print_manifest is run without the -s option:
/var/opt/ignite/clients/LLA/manifest/manifest.info

6 Installing Patches with Ignite-UX

Ignite-UX uses existing SD depots to distribute software. To distribute patches with Ignite-UX, you need to first bundle them into SD depot format. Patches can be installed along with the Core software being patched.

This chapter shows how to create a patch depot containing HP-UX 11.0 patches, create a single patch bundle of the contents of the depot, and add this bundle to an existing Ignite-UX configuration.

For more details, see the “Managing Patches” chapter in the *Software Distributor Administration Guide* available on the HP-UX Instant Information CD and on the web:

`http://docs.hp.com`

Creating a Patch Depot

Follow these steps to create a patch depot on an HP-UX system.

Step 1. Obtain the set of patches you want to place and manage in an SD depot. For example:

```
PHCO_7891 PHCO_9348 PHKL_9361 PHSS_7726 PHSS_8966 PHSS_9400
PHCO_8353 PHKL_8376 PHKL_9569 PHSS_8667 PHSS_9201
```

HP patches delivered by the Response Center or the web are `shar` files consisting of a serial depot and a `ReadMe` file.

Step 2. Unshar the patches using:

```
for i in PH*
do
sh $i
done
```

Step 3. Combine the separate depots into one depot:

1. Create the directory to store the patches:

   ```
   mkdir /var/opt/ignite/Patches
   ```

2. Copy the individual patch depots into the target depot:

   ```
   for i in PH*.depot
   do
   swcopy -s ${PWD}/$i \* @ /var/opt/ignite/Patches
   done
   ```

Step 4. Verify the contents of the depot:

```
swlist -d @ /var/opt/ignite/Patches
```

Here's the output for the example list of patches above:

```
Initializing...
Contacting target "interop1"...
Target: interop1:/var/opt/ignite/Patches
No Bundle(s) on interop1:/var/opt/ignite/Patches
Product(s):
PHCO_7891 B.10.00.00.AA allows mount to turnon hfs-specific opts
PHCO_8353 B.10.00.00.AA cumulative awk(1) patch
PHCO_9348 B.10.00.00.AA cron(1M) and at(1) patch
PHKL_8376 B.10.00.00.AA Fix vmtrace bug.
PHKL_9361 B.10.00.00.AA Fix panic caused by MP race
PHKL_9569 B.10.00.00.AA NFS and VxFS (JFS) cumulative patch
PHSS_7726 B.10.00.00.AA CDE Dtterm August 96 patch
PHSS_8667 B.10.00.00.AA CDE Runtime Nov96 Patch
PHSS_8966 B.10.00.00.AA LIBCL cumulative patch
PHSS_9201 B.10.00.00.AA fix for aC++ dld.sl
PHSS_9400 B.10.00.00.AA ld(1) cumulative patch
```

The output shows that the depot has "No Bundles." HP-UX Patches are SD "products", but Ignite-UX can only manage SD "Bundles."

Step 5. Convert the individual patches into a single bundle and put the bundle in the Patches depot:

```
make_bundles -B -n Misc_Patches \
-t "HP-UX 11.00 Patches" /var/opt/ignite/Patches
```

Step 6. Rerun `swlist` on this depot to verify that the bundle has been created:

```
swlist -d @ /var/opt/ignite/Patches
```

Here's the output assuming the example patches:

```
Initializing...
Contacting target "interop1"...
Target: interop1:/var/opt/ignite/Patches
Bundle(s):
Misc_Patches HP-UX 11.00 Patches
```

By default, `swlist` shows only the higher level software bundles. This command shows the patch "products" contained in the bundle:

```
swlist -l product -d @ /var/opt/ignite/Patches
```

NOTE If you need to add additional patches to the depot in the future, simply unshar the patches as described above, swcopy them into the Patches depot, and rerun make_bundles. This will repackage the depot.

If you would like to remove a patch from the depot, simply use the swremove command. You can either run swremove and use its friendlier user-interface, or run swremove in command-line mode. This example removes the PHKL_8376 patch from the depot:

```
swremove -d Misc_Patches.PHKL_8376 @ \
/var/opt/ignite/Patches
```

Step 7. If you inadvertently create a bundle of a bundle (for example, if you add an HP product you want distributed with the patch depot), use swremove interactively to examine and delete the extra bundle.

Step 8. Create a config file for the newly-created Misc_Patches bundle. Follow the steps outlined in “Adding a SD Bundle to the Archive Environment” in Chapter 8. Use /var/opt/ignite/Patches for your source depot and specify a new configuration file:

```
make_config -s /var/opt/ignite/Patches -a 700 \
-c /var/opt/ignite/data/Rel_B.11.00/misc_patch_bundle_cfg
```

Step 9. Modify the /var/opt/ignite/INDEX file to include the new bundle in our “HP-UX B.11.0 archive” configuration:

```
cfg "HP-UX B.11.00 archive" {
description "The ARCHIVE B.11.00 release with patches."
"/opt/ignite/data/Rel_B.11.00/config"
"/var/opt/ignite/data/Rel_B.11.00/core_700_archive_cfg"
"/var/opt/ignite/data/Rel_B.11.00/patch_bundle_cfg"
"/var/opt/ignite/data/Rel_B.11.00/misc_patch_bundle_cfg"
"/var/opt/ignite/config.local" }
```

Step 10. To force the installation of the new `Misc_Patches` bundle with the golden-image archive, add this line to the `sw_sel` clause for the patch bundle in `/var/opt/ignite/data/Rel_B.11.00/misc_patch_bundle_cfg`:

```
load_with_any = “golden image”
```

(This file was created with `make_config` in Step 8.)

IMPORTANT Most software distributed by HP, such as applications on DART CDs, are already bundles and will not need (and should not be) bundled again!

6442
Paula

Avoiding Backup Patch Files

When loading HP-UX patches from SD depots, the files that are patched are normally saved, just in case you want to remove the patch at a later date. However, doing this takes up additional space in the /var directory, so you may want to turn this feature off.

The way you control this feature depends on whether you are loading HP-UX 10.*x* or 11.0/11i. It also differs if the patches are coming from the Core depot and being controlled by the hw_patches_cfg config file. See /opt/ignite/share/doc/ace_hwe_setup for more info on hw_patches_cfg.

For HP-UX 10.*x* releases

Control this feature by the existence of the file /var/adm/sw/patch/PATCH_NOSAVE. If you don't want to save the patched files, then you need to have a pre_load_cmd that touches this file. pre_load_cmd can be at the global level or in the sw_source for the patch depot. You can remove this file in a post_load_cmd if you want this feature re-enabled after the load is done. For example:

```
pre_load_cmd += "
   mkdir -p /var/adm/sw/patch
   touch /var/adm/sw/patch/PATCH_NOSAVE"
# Put PATCH_NOSAVE back to the way it was.
post_load_cmd += "
   rm -f /var/adm/sw/patch/PATCH_NOSAVE
"
```

For patches in the core depot that are loaded via the hw_patches_cfg config file, PATCH_NOSAVE is always created and put back the way it was after the core load is complete. See this file for details: /opt/ignite/data/Rel_B.10.20/hw_patches_cfg

For HP-UX 11.0/11i releases

Control this feature by this option in the swinstall command:
-xpatch_save_files=false|true

You can use the sd_command_line keyword, either at the global level or within individual sw_source clauses depending on if you want it specified for all loads or just certain ones.

For patches in the Core depot, this option is specified by the /opt/ignite/date/Rel.B.11.*/hw_patches_cfg file. It is controlled by the config file variable: _hp_patch_save_files and is listed on the Additional Configuration Controls screen.

To specify this option at the global level (for example in the /var/opt/ignite/config.local file), you can add the line:

```
sd_command_line += " -xpatch_save_files=false "
```

To default the variable controlling the Core patches to "NO", add the following to config.local (which must be listed after hw_patches_cfg in the INDEX file):

```
init _hp_patch_save_files = "NO"
```

Paula
OPL

Avoiding Problems with Superseded Patches

When you are loading HP-UX 10.20 systems from multiple depots that contain patches, it's easy to run into the situation where patches in one depot supersede patches that have already been loaded from another. The superseded patches will prevent themselves from loading by giving an error. Ignite-UX indicates this failure by changing the client icon in the client-server screen to red.

What to do

To work around this problem, use the Ignite-UX `/opt/ignite/bin/fix_patches` script on each depot that contains patches. This script modifies the patch's `checkinstall` script so that it will "EXCLUDE" itself from loading without giving an ERROR.

See `/opt/ignite/share/doc/ace_hwe_setup` for more details. Although there is no manpage for `fix_patches`, enter the following to see command-line syntax:

```
/opt/ignite/bin/fix_patches -?
```

7 Using Golden System Images

This chapter describes how to build and install your own Ignite-UX installation media. Topics include:

- Installing from System Images.
- Creating an OS Archive.
- Configuring Ignite-UX Server to Recognize the OS Archive.
- Enable the Target System.
- Install the OS Archive on the Target.
- Restoring OnlineDiag LIF Volumes.

Examples in this chapter create a **golden system image** or **OS archive**, which is a snapshot of a known, good installation for use to copy to other systems. The copied (source) system is called the golden system image. The OS archive is a compressed tar or cpio archive that will be installed on other client machines.

Ignite-UX does not require creating a golden image to install a new client OS. Installing a golden image, however, is much faster (typically under 30 minutes) than installing the OS via `swinstall`.

6438
Paula

Installing from System Images

In addition to supporting the standard OS installations from an SD depot, Ignite-UX supports installing from system images. This method recognizes that many, if not all, target nodes in a network may be identical (or almost identical) to each other. It is possible to take advantage of this fact by building an archive which contains all of the files you want installed on each of the targets and then using Ignite-UX to install them.

This approach can have several advantages:

- Because the compressed system image is unpacked directly to disk over the network, the installation process can be much faster than an equivalent process using SD. The time savings will depend on the size of the installation being done and the capacity of the network, but a typical system image can be extracted in about 20 minutes compared to about an hour for an SD install.
- Instead of troubleshooting a target, it is often more cost-effective to completely re-install with a known, good system image.
- When coupled with dataless nodes (all volatile data is on a separate file server), system replacement time or move time is drastically reduced.
- Once a system image has been created, it is simple to apply it to multiple target systems. Very little or no user interaction is required during these subsequent installs, reducing the chance of error.

Building this golden system image is done by setting up a single system the way that you want all of your systems to look, and then creating an archive of that system. Follow instructions in this chapter to set up the first system.

Creating an OS Archive

In general, the golden image is simply a system configured with all the software and customizations needed to distribute to a group of target systems. The golden image can be saved on tape or CD from the golden system and installed on individual systems. Or, the golden image can be stored on another system and installed remotely over the network.

Most large HP-UX sites already have the equivalent of a golden system, that is maintained by the IS certification or QA department. This system is configured with customer modifications on top of a base HP-UX system. Critical patches which all users need are installed onto the OS. Local, common software that all users use are also layered on the OS. The resulting system is tested to ensure proper operation in the customer's environment.

These systems represent a prototype or starting point for all users. The steps needed for install customizations are normally captured and are well known. They make good candidates for a golden image archive as explained here. If a golden system already exists, skip to "Configuring Ignite-UX Server to Recognize the OS Archive" on page 121.

Creating a golden system from scratch involves the following steps described in this section:

A. Install the HP-UX OS from media.

B. Load critical patches onto the OS.

C. Load optional HP and third-party software.

D. Customize the system.

Once you have a golden system with the base OS, use Ignite-UX to create an OS archive. It's up to the administrator, to define exactly what constitutes a golden system. You may choose to place patches, applications, kernel configurations, etc. on the golden system, or just include the Core OS. In our example, we only include the Core OS. For speed, you may want to place all of your common applications, patches and tools onto the golden system.

Ignite-UX is capable of installing systems from SD depots and/or archives. You may want to use this capability when setting up your golden system, since you will need to have a system installed before you can get an image.

6436
Paula

A: Install HP-UX OS

Although this can be performed without an Ignite-UX server by using `swinstall` from CD or tape, this example uses Ignite-UX and a network depot as the source of our software.

Step 1. On the Ignite-UX server, set up the Core software to be distributed:

```
make_depots -r B.11.00 -a 700 -s
hpfclc:/release/S700_11.00/B3782EA
/opt/ignite/bin/make_config -r B.11.00
```

`make_depots` copies HP-UX B.11.00 software at the SD depot pointed to by the `-s` option (this pathname depends on the setup of the SD depot you are accessing) onto the local Ignite-UX server. (You can also run `make_config` and point it to the remote depot directly.)

`make_config` then adds this software as a configuration available for Ignite-UX installations.

Step 2. Begin installing HP-UX onto the target golden system by booting the target from the Ignite-UX server:

- If the target is currently running HP-UX, enter:

```
bootsys -v -w -f -i "HP-UX B.11.00 Default" target_hostname
```

- If the target is not currently running HP-UX, enter this on the target console:

```
boot lan install
```

Step 3. Select the configuration you've just set up, "HP-UX B.11.00 Default", and continue with the next section.

B: Load Critical Patches onto the OS

At this point you should have a target system with the basic HP-UX 11.0 release. If you have patches which you wish to distribute to all users, install them now. This is normally done using the standard SD tools.

For example, to install patch PHSS_8375:

Step 1. Download and unshar PHSS_8375 to obtain two files: `PHSS_8375.depot` `PHSS_8375.text`

Step 2. Install the patch non-interactively:

```
swinstall -x autoreboot=true -x match_target=true \
-s /PHSS_8375.depot
```

These instructions can also be found in the `PHSS_8375.text` file.

C: Load Optional Software

Load any optional HP and third-party software you want to make available to *all* users. Keep in mind that we are creating a golden system, and anything put on this will be distributed to all systems installed using the golden image. You'll need to keep in mind licensing restrictions, as well.

HP software (such as compilers) are normally loaded using SD from media or a network SD depot. Third-party software installation varies depending on the vendor.

D: Customize the System

Perform any customizations that you want to distribute to all users. These might include customized CDE login screens, base `/etc/passwd` files, additional phone tools and manpages, or corporate-wide default DNS and NIS setup. It would *not* include system, work-group or site-specific changes such as gateways, user accounts, or machine-specific networking. These will be taken care of by Ignite-UX later.

Use the next steps to create the golden image from the golden system, and configure Ignite-UX to use it. The `make_sys_image` command is provided to assist in creating the OS archive. See the *make_sys_image* (1M) manpage for details.

Step 1. Copy `/opt/ignite/data/scripts/make_sys_image` to `/tmp` on the golden system. Make sure it is an executable file. `/var/tmp` is the default location where `make_sys_image` stores the archive image. You can also have it save the image to a remote server that allows remote access from this client. Whichever method you choose, you will need to have sufficient disk space to hold the image. The amount of disk space will be approximately 1/2 the amount of data contained on your golden system (assuming about 50% compression ratio provided by 1).

6434
Paula

IMPORTANT

Do not use the system while make_sys_image is running in the next step. Device files are removed, and the host and/or networking information on the system are reset. After the command is complete these files are put back.

Step 2. On the golden system, run:

```
/tmp/make_sys_image [options]
```

By default, this will create a gzip-compressed archive in `/var/tmp` with the name *`hostname`*`.gz` , and all specific host information, device files, log files, and network information will be removed. Optionally, if you do not have enough disk space, or you would like for the archive to be created on a remote server, you may use the following options:

```
/tmp/make_sys_image -d directory_to_place_archive \
-s destination_system_IP_address
```

For example:

```
/tmp/make_sys_image -d \
/var/opt/ignite/archives/Rel_B.11.00 -s 15.2.72.150
```

The make_sys_image command can also build an archive containing any combination of tar, cpio, gzip and compress formats. We recommend tar and gzip formats.

Step 3. On the Ignite-UX server, create an archives directory to store the golden image:

```
mkdir -p /var/opt/ignite/archives/Rel_B.11.00
```

The `-p` option creates intermediate directories. It's best to keep the naming conventions `Rel_B.11.00` (or the release you're using.) This directory will need to be NFS exported if you'll be using NFS to transfer the archive to the target.

Step 4. Move the OS archive. For example, if hpfcnjm2 is the hostname: */var/opt/ignite/archives/Rel_B.11.00/hpfcnjm2.gz*

Configuring Ignite-UX Server to Recognize the OS Archive

To create an Ignite-UX configuration file for the OS archive, use the example file: /opt/ignite/data/examples/core11.cfg

Step 1. Create a copy of the example config file:

```
cp /opt/ignite/data/examples/core11.cfg \
/var/opt/ignite/data/Rel_B.11.00/core_700_archive_cfg
```

The destination file name is arbitrary. You can store configuration files anywhere on the system you chose. Ignite-UX manages the names and locations via the INDEX file (see Step 3 below). This file must be accessible via tftp.

Step 2. Modify the core_700_archive_cfg section to set up the OS archive for NFS transfer. Key changes are:

a. In the sw_source clause, change the following:

```
nfs_source =
"15.2.72.150:/var/opt/ignite/archives/Rel_B.11.00"
```

(This points to directory where the archive lives and must be NFS exported.)

b. In the init sw_sel clause, change the following:

```
description = "Archive HP-UX 11.00 CDE"
```

(This will now appear in the Environments section of the Ignite-UX user-interface as a menu choice).

```
archive_path = "hpfcnjm2.gz"
```

(This points to the actual file in combination with the nfs_source line).

c. Add impacts lines in the init sw_sel clause by executing:

```
/opt/ignite/lbin/archive_impact -t -g archive_file
```

6432
Paula

and including the results in the file, replacing the example impacts lines. By default, this assumes that we created a tar archive that was gzipd.

Here is the complete sw_sel clause (some extra clauses in the example have been deleted for simplicity):

```
init sw_sel “golden image” {
description = “Archive HP-UX 11.00 CDE”
sw_source = “core archive”
sw_category = “HPUXEnvironments”
archive_type = gzip tar
# For NFS, the path to the archive is relative to the mount
# point specified in the sw_source:
archive_path = “hpfcnjm2.gz”
# ftp/remsh sources can use a full path:
# archive_path = “/pub/IUXarchives/B.11.00_700_CDE.gz”
impacts = “/” 23Kb
impacts = “/.dt” 35Kb
impacts = “/TT_DB” 18Kb
impacts = “/etc” 1375Kb
impacts = “/export” 1Kb
impacts = “/opt” 74079Kb
impacts = “/sbin” 13449Kb
impacts = “/stand” 1Kb
impacts = “/tmp” 1Kb
impacts = “/usr” 225459Kb
impacts = “/var” 5736Kb
} = TRUE
```

Step 3. Add the new configuration file to Ignite-UX:

Edit the /var/opt/ignite/INDEX file to install a new “configuration” to Ignite-UX. For this example, add a new “cfg” clause as follows:

```
cfg “HP-UX B.11.00 archive” {
description “some description of this archive...”
“/opt/ignite/data/Rel_B.11.00/config”
“/var/opt/ignite/data/Rel_B.11.00/core_700_archive_cfg”
“/var/opt/ignite/config.local” }
```

The line of most interest is the one containing the core_700_archive_cfg, which is the config file we added in Step 2.2. The “config” and “config.local” are standard configurations.

/var/opt/ignite/config.local should be last. The last config file has the highest priority and can override values in prior config files.

The file /opt/ignite/data/Rel_B.11.00/config supplies the disk and file-system layout defaults, plus other control information required by Ignite-UX. It must be first in every cfg clause.

Each cfg clause appears as an available configuration to Ignite-UX. Therefore, the string HP-UX B.11.00 archive will now appear as a valid configuration.

Step 4. Ensure NFS file system is exported correctly.

In the above sw_source clause, we specified the location of the OS archive to be a file on an NFS server. You need to ensure target systems have access to this directory.

Make sure the NFS configuration is correct. To view the current status and ensure the directory containing the archive is correctly exported, enter:

```
exportfs -v
```

Ignite-UX will automatically try to export /var/opt/ignite/clients for its use. In our example, /var/opt/ignite/archives/Rel_B.11.00 must also be exported because that is where we placed the OS archive.

Here's our /etc/exports file:

```
/var/opt/ignite/clients -anon=2
/var/opt/ignite/archives/Rel_B.11.00 -ro,anon=2
```

If these are not correct, use SAM to set them up correctly.

6430
Paula

Enable the Target System

Since the Ignite-UX server now knows about your new OS archive, you can use Ignite-UX to load the OS archive onto a target system. To do this, you need to get the target system to inform Ignite-UX that it is ready to install a new OS. There are two methods for doing this.

Method 1:

If the system is currently running HP-UX 10.x or higher — From the Ignite-UX server, use bootsys to reboot the target for which you wish to install the new OS. The target system can be booted in a mode in which it can be controlled by the Ignite-UX user interface.

```
/opt/ignite/bin/bootsys -w -v system_name
```

This will cause the target system to boot a copy of the Ignite-UX kernel and file system that bootsys copies to the target. An icon representing the system will appear in the Ignite-UX user interface on the server when the system has completed boot. (This may take several minutes.) An icon appears on the Ignite-UX UI when each client is booted.

If the server cannot resolve the system name, specify to bootsys the *system_name* and *IP_address*:

```
/opt/ignite/bin/bootsys -w -v system_name:IP_address
```

Method 2:

If the system does not have an OS — Manually reboot the system. Interrupt the boot process and select the Ignite-UX server as the lan boot source. This command will be slightly different depending on your target system. As an example, to install to a Model 712 workstation, enter the following from the boot admin mode:

```
boot lan.15.2.72.150 install
```

Older Series 700 workstations that use the RMP (rbootd) protocol instead of BOOTP require that you use the hardware LAN address of the server, and omit the install keyword:

```
boot lan.080009-123456
```

Replace the above IP/Ethernet addresses with the correct value for your Ignite-UX server. When prompted with a message about interacting with the IPL, respond **NO**

Install the OS Archive on the Target

In this section, we will use Ignite-UX to customize an OS install. Chapter 9 explains how this can be done with no user/administrator interaction.

Step 1. Run Ignite-UX by executing this as root:

```
/opt/ignite/bin/ignite
```

When the target has rebooted (using either `bootsys` or manual network boot), and is ready for installation, it will appear as an icon, labeled either as its original hostname (if rebooted using `bootsys`), or by the hostname supplied by DHCP, or at Ignite-UX screen.

Step 2. Select or click the icon of the system you wish to install.

Step 3. Select **Actions** –> **Install Client** –> **New Install**

You should now see the Ignite-UX screen with five tabs across the top. (If you see the System Hardware Inventory screen, simply select **OK** to bypass it).

Step 4. In the **Basic** tab (the top tab at startup), select:
Configurations: –> **HP-UX B.11.00 archive**

Ensure that the Root Disk, Root Swap and other fields are correct for your installation. *Any disks you select here will be over-written!* If you have a disk with existing user information you don't want to modify, add it manually after Ignite-UX has installed the OS.

Step 5. In the **Software** tab: Because there is only an archive at this point, the screen is blank. We'll add a patch and application depot later.

Step 6. In the **System** tab, select:
Final System Parameters –> **Set parameters now**
Fill in the blanks with the correct data.

Also fill in the appropriate data under **Set Time Zone, Network Services...** and, optionally, **Set Root Password**

Step 7. In the **File System** tab: Verify the correct disk usage. You can also add disks at this point or modify the disk and file system parameters. *A newfs will be performed on all selected disks!*

Step 8. In the **Advanced** tab: Nothing to specify here at this time. Later, we'll add post-process scripts to execute.

Step 9. When finished entering data, select **Go!** Review the data in the configuration dialog box and select **Go!** again.

Step 10. To display target installation status, double-click the target system icon on the Ignite-UX screen during execution.

Done!

In less than 30 minutes, the target system should have the new OS installed, a new kernel built, and the system rebooted and ready for use. Status of the target system will be shown on its icon, and in the status screen.

When using the Ignite screen

Ignite-UX determines the state of a target by reading the files in the `/var/opt/ignite/clients/`*`LLA`* directory. Seeing an icon on the Ignite-UX screen does not mean that the target actually exists, only that its config and control files exist in the Ignite-UX directories. We can use this behavior to our advantage to reinstall systems. This means that if you are reinstalling a system that Ignite-UX has already installed, you may need to either re-execute `bootsys` or boot the client from the Ignite-UX server.

Restoring OnlineDiag LIF Volumes

To restore OnlineDiag LIF volumes after installing from a golden image, set up a script in the INDEX file to be run as a post-configure script. For example, add this stanza to the /var/opt/ignite/INDEX file:

```
scripts {
   "/var/opt/ignite/scripts/diag.sh"
}
```

The diag.sh script is included as an example script in the /opt/ignite/data/examples directory. It runs this command which copies the OnlineDiag LIF volumes onto the root disk:

```
/usr/sbin/diag/lif/lifload -f /usr/sbin/diag/lif/updatediaglif
```

8 Customizing Your Installation

This chapter shows how to do local customizations using scripts:

- Using Post-installation Scripts.
- Installing Netscape® as a Post-config Step.

Other example uses of scripts to customize installations are in the *make_medialif* (1M) manpage.

Using Post-installation Scripts

Any number of tasks may be performed on the target system after the OS is installed by providing a script to be run on the target system. This section touches on some common examples, but scripts can easily be written to mount additional disk drives, add additional software, modify configurations based on system use, etc.

There are a number of points in the install process in which you can force scripts or commands to be run. Check the “Command and Script Execution Hooks” section on the *instl_adm* (4) manpage for specifics. One point to note is that `post_config_script` will run after all software has been loaded and the system has been booted with its final kernel, but *before* any of the normal `/etc/rc startup` scripts have been run.

Adding a Post-install Script

Example task

1. Create a script to perform the desired task. When Ignite-UX runs this script as a post-configuration, it will be run on the target system.
2. Add the script to your configuration file. Ignite-UX post-configuration scripts are defined using the `post_config_script` variable. For example, you can place this line into your `core_700_archive_cfg config` file:

   ```
   post_config_script += \
   "/var/opt/ignite/scripts/install_default_printer"
   ```

   The line above will define the `install_default_printer` script to be run as a post-installation process on the target system. The line should stand alone, placed *outside* of any clause (such as a `sw_sel` clause). By default, the script will always be run on the targets. You can change the behavior by navigating to **Install Client** –> **New install** –> **Advanced** tab.
3. If you want to make a script available under all configurations, add it to the `/var/opt/ignite/INDEX` file. Add the following to the end of this file:

   ```
   scripts {"/var/opt/ignite/scripts/install_default_printer"}
   ```

   It will then show up in the **Advanced** tab for all configurations.

NOTE Ignite-UX accesses scripts via tftp. Make sure the directory the script resides in is available to tftp by examining and/or changing the /etc/inetd.conf file.

Managing Network Printers

Example task One task an administrator generally needs to perform after a new OS installation is setting up printers. To automate this process, write a script which performs the HP-UX commands for adding a printer. Here is a script for adding a remote printer named “printbob”, and turning on the lp scheduler. The script turns SAM logging on for “commands-only”, performs the tasks desired, and extracts those commands from the SAM log file.

```
#!/sbin/sh
# Post process IUX script to add a local default printer
# Performing task "Add Remote Printer": Adding "printbob"
#
/usr/sbin/lpadmin -pprintbob -ormhpfcmgw.fc.hp.com -orptsslj \
-mrmodel -v/dev/null -orc -ocmrcmodel -osmrsmodel
/usr/sbin/lpadmin -dprintbob
/usr/sbin/accept printbob
/usr/bin/enable printbob
# Turn on lp scheduler
#
lpsched -v
```

Installing Netscape® as a Post-config Step

Here is an example of using Ignite-UX post-installation scripts to load software on new installs. Netscape is one of those tools which seems to have a new version every six months. Due to the frequency of the changes, this tool may not make sense to include on the "golden system".

This example shows one way of accomplishing the task using a `post_config_script`. Another way would be to create a software selection (`sw_sel`) that would reference the tar archive, and then a `post_config_script` (or `post_config_cmd`) associated with the `sw_sel` that would be run only if the selection was picked for loading. Using a `sw_sel` would have the advantage of making it appear in the UI as just another software selection, and would have the `sw_impact` statements to ensure sufficient file system space. For more examples, see the files in `/opt/ignite/data/examples`.

NOTE Be sure the Netscape Navigator product is appropriately licensed prior to installation.

Step 1. Get Netscape Navigator — Netscape Navigator is typically pulled from one of the Netscape ftp server sites. The pulled files are gzip compressed tar images with an encoded name similar to:

```
netscape-v30-export.hppa1.1-hp-hpux.tar.gz
```

Step 2. Special Considerations for Netscape — In order to run Navigator, each user needs the correct network preferences. Unfortunately, these preferences cannot be defaulted, and must exist in every users `$HOME/.netscape` directory. To get around this limitation, we have supplied a "run-netscape" script. Instead of running "netscape", the user can run a link to "run-netscape" which will install the default preferences at first invocation.

A sample "run-netscape" script is shown below. You will also need to create a default configuration file. Merely take an existing one and remove all user and host specific information.

Step 3. Write an install and customization script — Attached below is a script we used for installing Netscape in our environment. The script does the following:

1. Remote copies from a server to the local target netscape, a default-preferences file, and the special run-netscape script.

2. Unpacks Netscape.

3. Makes `/usr/local/bin/netscape` a link to "run-netscape" to ensure user defaults will be installed.

4. Performs the special netscape customization.

5. Cleans up.

We named and placed our script under:

`/var/opt/ignite/scripts/install_netscape`

Step 4. Add the install script to Ignite-UX customization — Add a line like this to one of your config files (not in a clause):

```
post_config_script="/var/opt/ignite/scripts/install_netscape"
```

For details of adding a post configuration script, see Chapter 9. This script will need to be accessible using tftp.

Example script Here's an example post-install script for Netscape:

```
# !/usr/bin/ksh
#
# Post Ignite-UX installation script used to install Netscape
version 3.0.
# This installation assumes HP-UX 11.00 because it
depends on gzip
# already loaded on the system.
#
PATH=${PATH}:/usr/sbin:/sbin:/usr/contrib/bin
IUX_SERVER=interop1.fc.hp.com
IUX_ARCHIVE_DIR=/var/opt/ignite/archives/Netscape
NETSCAPE_GZIP=netscape-v30-export.hppa1.1-hp-hpux.tar.gz
NETSCAPE_INSTALL_DIR=/opt/Netscape
NETSCAPE_RUN_DIR=/usr/local
echo "* Loading Netscape"
mkdir ${NETSCAPE_INSTALL_DIR} cd ${NETSCAPE_INSTALL_DIR}
rcp ${IUX_SERVER}:${IUX_ARCHIVE_DIR}/${NETSCAPE_GZIP}
${NETSCAPE_GZIP} rcp ${IUX_SERVER}:${IUX_ARCHIVE_DIR}/run-netscape
. rcp
```

```
${IUX_SERVER}:${IUX_ARCHIVE_DIR}/default-preferences .
gzip -dc ${NETSCAPE_GZIP} | tar -xvf -
echo "* Finished loading Netscape"# # Configure netscape
runtime # echo "* Configuring Netscape"
chmod 755 ${NETSCAPE_INSTALL_DIR}/run-netscape ln -s
${NETSCAPE_INSTALL_DIR}/run-netscape
${NETSCAPE_RUN_DIR}/bin/netscape
# # Install java_30 # mkdir ${NETSCAPE_RUN_DIR}/lib/netscape
ln -s ${NETSCAPE_INSTALL_DIR}/java_30 \
${NETSCAPE_RUN_DIR}/lib/netscape/java_30
# # Install plugins library # mkdir
${NETSCAPE_RUN_DIR}/lib/netscape/plugins ln -s
${NETSCAPE_INSTALL_DIR}/libnullplugin.so
${NETSCAPE_RUN_DIR}/lib/netscape/plugins/libnullplugin.so
mkdir ${NETSCAPE_RUN_DIR}/lib/netscape/mime.types mkdir
${NETSCAPE_RUN_DIR}/lib/netscape/mailcap
rm -f ${NETSCAPE_GZIP}
echo "* Finished configuring Netscape"
Example run time script for Netscape
#!/bin/sh
# # Put this script in /usr/local/bin/netscape
set -e
# Set this to the location of the real Netscape executable #
REAL_NETSCAPE=/opt/Netscape/netscape
# Set this to the location of the default preferences file. #
DEF_PREFS=/opt/Netscape/default-preferences
if [ ! -e $HOME/.netscape/preferences ]; then echo '(installing
default Netscape preferences...)' mkdir $HOME/.netscape
cp -p $DEF_PREFS $HOME/.netscape/preferences echo '(done)' fi
# The "-name" option is to avoid confusing the users' X resources.
# exec $REAL_NETSCAPE -name netscape $*
```

9 Automating Installations

This chapter shows how to use bootsys and configuration files to automate the Ignite-UX install process.

Setting up your Ignite-UX server so that the default configuration is correct for any given system will save you time and allow you to easily automate installations. This chapter discusses setting up the defaults the way you like them, as well as setting up a configuration for a specific target system.

Ignite-UX can install HP-UX on a target system with no additional configuration information (the default configuration as specified in the /var/opt/ignite/INDEX file will be used). You can, however, select from other configurations listed in the INDEX file on the bootsys command line.

Starting an Automatic Installation with bootsys

To start an automatic installation, enter:

```
bootsys -a -v [-i configuration]  [-f]  target_hostname
```

`-a` specifies an automatic install.

`-v` specifies verbose mode.

`-f` forces Ignite-UX to disregard prior configuration info for that target.

`-i` selects an alternate configuration. If not set, the default is used.

See the *bootsys* (1M) manpage for details on how to select a configuration and to force its use. The default is set in the Ignite-UX server options menu, or can be set manually with the `=TRUE` statement after a `cfg` clause in the `/var/opt/ignite/INDEX` file.

Ignite-UX will contact the target system and extract its hostname, IP address and default gateway. The default configuration is installed. Post install, Ignite-UX will reset the hostname, IP address and gateway to their original values. (remsh access to the target is required. If not available, `bootsys` will prompt the user for the root password on the target.)

This is the quickest way to install a system. The drawback is that you will receive the default config, which may have incomplete networking information unless you are using a previously "saved" configuration, or you specify the defaults in the `/var/opt/ignite/config.local` file as shown later.

Using a "Saved" Configuration

When using Ignite-UX during an install session, you may choose to save the result as a named configuration when finished specifying the configuration for particular target. This will save any changes that you made during the session for use in subsequent sessions. Then either specify the configuration as the default, and/or just use the name you give it to `bootsys` using the `-i` option.

Specifying Defaults in the config.local File

The /var/opt/ignite/config.local file is normally included in every cfg clause in the INDEX file. This provides a convenient location to store default parameters that are the same for all configurations. Typically this will be networking, default software selections, kernel modifications.

It may be easiest to cut and paste information written to the files /var/opt/ignite/clients/*/config by the user interface. However you can do more here than with the Ignite-UX screen. See the *instl_adm* (4) manpage for more details. Below is an example of what a config.local file could look like. The sw_sel's will depend on what you have defined in config files on the server.

```
dns_domain="fc.hp.com"
dns_nameserver[0] = "15.2.72.2"
nis_domain="udl"
wait_for_nis_server=FALSE
root_password="rlW2xSrugUvi2"
timezone="MST7MDT"
ntpdate_server="15.1.48.11"
init sw_sel "Misc_Patches"=TRUE
init sw_sel "B3919DA_AGP"=TRUE
mod_kernel += "maxuprc 100"
mod_kernel += "dbc_max_pct 80"
```

Always run this after making manual edits to verify that the syntax is correct:

```
instl_adm -T
```

See "Setting Install Parameters Dynamically" on page 143 to see how default information may be specified dynamically depending on the target system's configuration.

Setting defaults with instl_adm

Some network parameters need to be known by the target clients when they first boot. bootsys or DHCP/BOOTP can supply the hostname and IP address; however, the netmask and gateway need to be supplied in the RAM filesystem (INSTALLFS). This can done by using the instl_adm command, which has options to set netmask, gateway, Ignite-UX/tftp server, etc. Or you can dump the current settings to a file and edit it, then load the settings back. Just loading Ignite-UX sets some of the parameters.

For example, you may want to set the keyboard language so that it never prompts you for it when booting from Ignite-UX. The file you store using **instl_adm -f** may look like this:

```
# instl_adm defaults:
server="15.2.72.150"
route_gateway[0]="15.2.70.1"
route_destination[0]="default"
netmask[]="255.255.248.0"
# end instl_adm defaults.
kbdlang="PS2_DIN_US_English"
```

Using the per-target client config file

Until now, we have discussed specifying default parameters that all target systems may use. If you would like to specify a specific configuration for an individual target system, you may use the following procedure.

When Ignite-UX begins an install session, it scans the directory `/var/opt/ignite/clients` for a directory matching the *LLA* of the target system. As an example, if the *LLA* of the target is `0x08000992E346`, Ignite-UX looks for a file named `config` in: `/var/opt/ignite/clients/0x08000992E346/config`

Ignite-UX keeps the last configuration installed to the respective system in this file so it can perform a repeat install.

If found, the configuration data in this file is used to overwrite the default values. This file has the highest precedence over all other config files listed in the `INDEX` file.

CAUTION Ignite-UX will write over this file at the end of the install, so you may want to keep an original copy elsewhere.

The easiest way to create the config file is to use one already built by Ignite-UX. If you've previously installed a system (it's best to use one from a similar system to your target,) you can find a config file in the `/var/opt/ignite/clients/`*LLA* directories. Use this as the basis for your new file. Copy it to: `/var/opt/ignite/clients/`*LLA*`/config`

Edit its contents to correspond to your new system.

Example config Ffle

Here is an example config file:

```
cfg "HP-UX B.11.00 archive"=TRUE
_hp_cfg_detail_level="ipvs"
#
# Variable assignments
# init _hp_disk_layout="Whole disk (not LVM) with HFS"
init _hp_pri_swap=68304K
init _hp_root_disk="2/0/1.5.0"
init _hp_sec_swap=0K
init _hp_root_grp_disks=1
init _hp_root_grp_striped="NO"
init_hp_locale="SET_NULL_LOCALE"
init_hp_keyboard="PS2_DIN_US_English"
init _hp_default_final_lan_dev="lan0"
init _hp_boot_dev_path="2/0/1.6.0"
#
# Software Selections
# init sw_sel "golden image"=TRUE
init sw_sel "English"=TRUE
#
# System/Networking Parameters
# hp_custom_sys+={"Current System Parameters", "Original Defaults"}
init _hp_custom_sys="Current System Parameters"
_hp_custom_sys help_text "Final System/Networking Parameters"
(_hp_custom_sys=="Current System Parameters")
{
final system_name="hpfcnjm2"
final ip_addr["lan0"]="15.2.75.14"
final netmask["lan0"]="255.255.248.0"
final dns_domain="fc.hp.com"
final dns_nameserver[0]="15.2.72.254" TIMEZONE="MST7MDT"
is_net_info_temporary=TRUE
}
# end "Current System Parameters"
```

Typically, you would want to change the networking parameters to the correct values. For example:

```
final system_name="system11"
final ip_addr["lan0"]="15.2.75.193"
```

The values specified should be self explanatory, and should be edited to the desired new values. It is also possible to add kernel parameters to this file. See "Setting Install Parameters Dynamically" on page 143 later in this chapter.

You should also update the variable, _hp_cfg_detail_level when adding new types of parameters or they will get lost by the UI or by the file rewrite.

To perform an automatic install with a config file:

Step 1. Determine the *LLA* of the target system, either through the `boot_admin` commands (at bootup) or with the `lanscan` command.

Step 2. Create the following directory (assuming the *LLA* is `0x08000992E346`) and copy in your config file:

```
mkdir /var/opt/ignite/clients/0x08000992E346

cp config /var/opt/ignite/clients/0x08000992E346/config
```

Step 3. Since these files will be accessed using NFS, make sure they have the correct permissions:

```
chown bin:bin /var/opt/ignite/clients/0x08000992E346

chown bin:bin \
/var/opt/ignite/clients/0x08000992E346/config
```

Step 4. Run `bootsys`:

```
bootsys -a -v target_hostname
```

Ignite does not need to be running. Ignite-UX will install the default configuration (or the configuration specified with the `-i` option) and will include the specific changes provided in the config file.

The target system should boot into the Ignite-UX install process and complete the install automatically. Errors will be reported on the client screen and in the `install.log` file.

Monitor the install process via this file:

```
/var/opt/ignite/clients/0x08000992E346/install.log
```

Setting the Local Time Zone

The TZ environment variable governs what time zone the message in the `install.log` contain. The "time zone" config file keyword does not have any effect on the messages that occur during the install, but does determine the time zone setting on the target system (the two can be independently set).

To set the TZ environment variable, it is best to do so in the INSTALLFS file so that it is set as early in the process as possible. However, the first message will still be in EST since it is produced before the config file contents of INSTALLFS are read. The procedure for setting this to MST7DT is:

```
/opt/ignite/bin/instl_adm -d > /tmp/cur_cfg
echo 'env_vars += "TZ=MST7MDT"' >> /tmp/cur_cfg
/opt/ignite/bin/instl_adm -f /tmp/cur_cfg
```

Scheduling Installations

Client installations are easily automated via the cron daemon. For repeated installations, add crontab entries (see *cron* (1M) and *crontab* (1) manpages). For single installations, use the at command. For example, to perform an installation on a target system at 8:00 PM using the at command, as root enter:

```
at 8:00pm
bootsys -a -v target_system (press Ctrl-D)
```

Setting Install Parameters Dynamically

Ignite-UX can make intelligent decisions about install parameters when it runs, based on information it reads from the target system. Instead of forcing static values for example, swap size or kernel parameters, the best values for these can be determined based on the characteristics of the target system.

This can make configurations set up by the system administrator more general purpose and limit the need for multiple, custom configurations to handle minor system differences.

These decisions are specified in a C-like language and grammar unique to Ignite-UX. The variables and syntax are documented in the *instl_adm* (1M) manpage.

Example This example sets the primary swap size of the target system root disk dynamically at install time based on the size of the disk, and on the size of the target system RAM. The algorithm will set swap to 125MB if the disk is large (> 500MB) and if the amount of system RAM is greater than 64MB. If the disk is small, make the swap very small to maximize the amount of space available for HP-UX.

Step 1. Add these lines to the end of the file `/var/opt/ignite/config.local` to be the default for all configurations:

```
# default to very minimal swap of 25MB
# unless the disk is larger than 500 MB
# and we have more than 64MB ram
(disk[_hp_root_disk].size > 500MB & memory > 64MB)
{
   init _hp_pri_swap=125MB
}
else
{
   init _hp_pri_swap=125MB
}
```

You could also put this in a separate file, say, `/var/opt/ignite/data/Rel_B.11.00/custom_cfg`, and add the file name to the `INDEX`.

This could also be added to the `config` file created for automatic installs. Note that if the `_hp_pri_swap` parameter is set later in the order of files searched in the “cfg” definition, this setting will be overwritten. The order the files are evaluated is documented in the *instl_adm* (1M) manpage and in Chapter 3. Also be aware that the `config` file used for automatic installs is overwritten as part of the install process.

Step 2. To force the load of a patch bundle if the target system matches the regular expression `71*`, such as a `710` or `712`, add the following lines to the end of the file:

```
/var/opt/ignite/data/Rel_B.11.00/custom_cfg
# check for H/W model 71x
# and add the Misc_Patches bundle if true
(hardware_model ~ “9000/71*”) {init sw_sel “Misc_Patches” = true}
```

Step 3. Run a previously created post-install script and increase a tunable kernel parameter if we determine our target system is a Model 755. If not, it sets a default value for the kernel parameter:

```
post_config_script += “/var/opt/ignite/scripts/755special”
(HARDWARE_MODEL == “9000/755”) {
   mod_kernel += “maxuprc 300”
} else {mod_kernel += “maxuprc 100”}
```

Step 4. Select an entirely different default configuration based on the size of the system RAM and disk. For this to have effect, it must go into the `INSTALLFS` file by using `instl_adm` as described earlier:

```
# For a system with only one disk and small memory, select
# the “small system configuration”
(num_disks == 1 & memory < 64MB )
{cfg “small system configuration” = true}
```

Step 5. To check the syntax of all configuration files that are listed in the `/var/opt/ignite/INDEX` file, enter:

```
instl_adm -T
```

Step 6. To check the syntax of a file that is not yet in the `INDEX` file, enter:

```
instl_adm -T -f file
```

10 Creating Your Own Install Media

This chapter explains how to create custom installation media to use with Ignite-UX. It's assumed here that you have a basic knowledge of Ignite-UX operations, as explained in the previous chapters.

Why Use Custom Install Media?

You may want to build customized install media ~~if~~:

- You have a large number of systems that are basically identical, and:
  - — The systems do not have network boot capability, or...
  - — The networking will not allow easy or fast access to an Ignite-UX server, or...
  - — The systems are geographically widespread.
- You have HP servers that lack network boot, and so a boot medium is required to contact the Ignite-UX server.
- You want to deliver media to a technician or operator and have the entire install process automated without human intervention or interaction.
- You want a single media that contains all the desired parts of the operating system (HP-UX, applications, patches, diagnostics and local customizations).

Using customized install media also provides both system standardization and customization simultaneously. The standardization comes from using golden system images which contain a base operating system, applications, patches, third-party software and local customizations, already packaged into an archive. The entire system has been tested, verified and tuned before creating the image. This image can be the starting point for all installs to ensure standardization.

The customization comes from using config files to load additional software, change kernel parameters, and run scripts. Software bundles can be:

- Interactively chosen.
- Pre-selected, unconditionally or conditionally.
- Invisible.

There are also parameters that control the environment in which Ignite-UX operates. The most important parameters are `run_ui` and `control_from_server`. When `run_ui` is false, no interaction will occur and the load will proceed according to all the configuration information provided to Ignite-UX. When `control_from_server` is true, an attempt will be made to contact the Ignite-UX server as defined in the configuration information. These modifications are explained in the procedures in this chapter.

Using a custom install media allows you to chose how things work, what you will leave up to the end user, what will happen automatically, and so forth.

Building Example Install Media

The remainder of this chapter describes building custom install media that meets these requirements:

- It will be shipped worldwide so that systems can be installed with a golden image.
- Both a Series 700 workstation and a Series 800 server golden images will be built with the `make_sys_image` command.
- There is a set of applications that are to be chosen interactively by the end user.
- All software will come from the media, and there will be no contact with nor need for an Ignite-UX server during installation. However, you do need an Ignite-UX server to create the media and execute Ignite-UX commands.

Building an Install Tape

This section describes the golden image layout and building an example install tape. We recommend using only 90 metre DDS-1 tapes to make install tapes with Ignite-UX to ensure that the tape will work with any DDS drive. For details on other supported tape formats, see the release notes available from the Ignite-UX Web site.

The Golden Image

Golden system images in these examples were created on Series 700 and Series 800 systems running HP-UX 10.20 using:

```
/opt/ignite/data/scripts/make_sys_image
```

The archives are in tar format and are gzipped. The files are:

```
/var/tmp/archive_700.gz
/var/tmp/archive_800.gz
```

This command has been run on these archives to get disk-space usage information (impacts) so that configuration information can be supplied:

```
/opt/ignite/lbin/archive_impact
```

DDS tape layout

A DDS install tape is constructed logically like this:

Table 10-1 **DDS Install Tape Construction**

LIF	A1/E	D/A2	A3	A4	...

LIF — A bootable tape starts with a Logical Interchange Format (LIF) volume containing all the components required to boot off the tape. It also includes the Ignite-UX toolset and configuration information that controls how Ignite-UX will operate. It includes config file information about the SD depot on the tape (should there be one) and all archives on the media.

A1/E — The next portion is either the first OS Archive (A1) or is Empty (E) if the installation is solely from the software depot.

D/A2 — The next portion is either a serial depot (D) or another OS archive (A2). There can only be one depot on a tape, and it must be the third file on the tape due to a SD restriction.

A3, A4,... — Beyond this, there may be other archives, limited only by the capacity of the tape. If more archives are needed, they can be put on a second medium.

LIF volume content

The make_medialif command is used to create the LIF volume. A typical LIF volume looks like this:

```
volume ISL10 data size 175771 directory size
filename    type   start   size    implement   created
ISL         -12800 16      240     0           98/02/10 14:06:38
AUTO        -12289 256     1       0           98/02/10 14:06:38
INDEX       BIN    264     1       0           98/02/10 14:06:38
CONFIG      BIN    272     58      0           98/02/10 14:06:38
HPUX        -12928 336     800     0           98/02/10 14:06:38
INSTALL     -12290 1136    57503   0           98/02/10 14:06:45
INSTALLFS   -12290 58640   31774   0           98/02/10 14:06:48
INSTCMDS    BIN    90384   9873    0           98/02/10 14:06:51
SYSCMDS     BIN    100264  45901   0           98/02/10 14:07:02
SCRIPTS      BIN    146168   30        0          98/02/10 14:07:02
```

ISL — Initial System Loader. If it is run interactively, it issues a prompt and waits for user interaction. Otherwise it looks for the AUTO file. It is extracted by make_medialif from the default boot file: /opt/ignite/boot/boot_lif

AUTO — Autoexecute file defines the default (possibly automatic) boot behavior.

INDEX — Default INDEX file (it has the same function as /var/opt/ignite/INDEX does on an Ignite-UX server). The file CONFIG is referenced in this file.

CONFIG — Contains all software configuration information. You should begin with the default config file for that release (for example, for the Ignite-UX B.10.20, look in: /opt/ignite/data/Rel_B.10.20/config) Additional config files can be added via the -f option of the make_medialif command. Information in this file will allow complete access to all the archives and depots on the media.

HPUX — HP-UX bootstrap utility. It is also extracted from the default boot file.

INSTALL — 32-bit kernel booted by 32-bit install clients. With a 64-bit kernel, use the make_medialif -o 64 option to create a LIF volume called VINSTALL for V-class systems. For other 64-bit kernels, use the -o 64w option to create WINSTALL files. Use the make_medialif -a option to create all NSTALL and INSTALLFS files.

INSTALLFS — The RAM file system used by install clients. Configuration information stored in the first 8KB of this file is accessible using `instl_adm`. If this is a 64-bit LIF volume, the file is called `VINSTALLFS`. For 64-bit systems, the file is `WINSTALL`.

INSTCMDS — gzip archive of the commands needed for disk layout. These commands run on the install kernel and inside the `INSTALLFS`.

SYSCMDS — gzip archive of commands used to load the software onto the system. There are different archives for each release.

SCRIPTS — gzip archive of all `post_load` and `post_config` scripts that are required. By default when loading a core archive (`load_order` is zero, which means it gets loaded first), the two scripts in `/opt/ignite/data/scripts` called `os_arch_post_l` and `os_arch_post_c` are executed.

Scripts like these are discussed in depth in the *instl_adm* (1M) manpage.

For more information on what happens during system boot and what files do what, see "System Bootup Sequence" on page 162.

Important Config Files

You need to consider two important config file concepts when building archives and bundles to be loaded onto a target system:

- `sw_source` — specifies the access method to either an archive or a depot.
- `sw_sel` — specifies the path of an archive or a bundle in a depot.

For details on these objects, see the *instl_adm* (1M) manpage.

Be sure to pass all user-generated config files through this command to check for syntax errors:

```
instl_adm -T -f cfg_file
```

Accessing a DDS Tape Archive

The best place to start when creating a config file for an archive is to use the template file supplied by Ignite-UX in /opt/ignite/data/examples/. Other files are available for HP-UX 11.0/11i 32- and 64-bit systems. This file can be copied elsewhere, say, to /var/tmp/archive.cfg, and then edited to suit your situation.

Assume that our tape will be used more for installing Series 700 systems than Series 800 systems. Hence, we will put the Series 700 archive on the tape first. In the diagram above, it will be A1. Since there will be a serial depot on the tape, the Series 800 archive will be located at A3.

To modify the config file to access the Series 700 archive, the following attributes need to be changed in /var/tmp/archive.cfg in the sw_source core archive stanza:

Table 10-2

Attribute	Old Value	New Value
source_type	NET	MT
change_media	#change_media=FALSE	change_media=FALSE
nfs_source	nfs_source=*IP:depot*	#nfs_source=*IP:depot*

These changes will modify the source type from network (NET) access (which is either NFS, ftp or remsh) to magnetic tape (MT). Since the archive is going to reside on the same media, change_media is set to false by un-commenting that attribute. To avoid trying to NFS mount that directory, the nfs_source is commented out.

Since the template file already has conditional logic that provides for different Series 700 and Series 800 archives, we will use that to our advantage.

Inside the stanza enabled by HARDWARE_MODEL ~ 9000/7.* the following fields must be changed:

Table 10-3

Attribute	Old Value	New Value
archive_path	B.10.20_700_CDE.gz	1
impacts	/ 27KB	(as reported by archive_impact)

The change in archive_path indicates that there is one EOF mark to skip on the tape and the archive will begin right after that mark. The archive will be the second file on the tape after the LIF volume. The impacts lines must be replaced with whatever was reported by archive_impact for the Series 700 archive.

Inside the same stanza the sw_sel and description strings can be changed to something more descriptive and applicable to your situation. The text inside the double quotes can be changed to whatever you like. They will be visible on the Ignite-UX UI. archive_type must match what was done by make_sys_image. See *instl_adm* (4) for more about archive_type.

Since we have only one Series 700 archive the entire stanza called golden image2 can be deleted. It was included in case you had two different types of archives, for example one for VUE and one for CDE. If more than one archive per architecture is on the media, it is advisable to use an exrequisite attribute between them so only one archive can be selected at one time.

In the stanza for the Series 800 (it is an else clause later in the file) the same sort of changes must be made. However remember that the Series 800 archive is in a different location on the tape. So these attributes need to change:

Table 10-4

Attribute	Old Value	New Value
archive_path	B.10.20_700_CDE.gz	3
impacts	/ 27KB	(as reported by archive_impact)

The change in archive_path indicates that there are three EOF marks to skip on the tape (LIF volume, Series 700 archive, and the serial depot). The Series 800 archive is the fourth file on the tape. The impacts lines must be replaced with whatever was reported by archive_impact for the Series 800 archive.

It is important not to change anything else in the file, unless you are very sure of what you are doing. In particular, it is potentially dangerous to change the sw_category and other sw_source and sw_sel attributes not mentioned above.

Accessing the Serial Depot on a DDS Tape

Assume there is a depot (/var/tmp/depot) that contains all the applications you wish to install on top of the archive. It can be a mixture of Series 700-only applications, Series 800-only applications, and applications that can be loaded on both architectures. Use the make_config command to create config file information for this depot, and the config file is modified to reflect the ultimate destination of the depot.

Step 1. Create config files by entering these commands:

```
make_config -s /var/tmp/depot -a 700 -c
/var/tmp/depot_700_cfg
```

```
make_config -s /var/tmp/depot -a 800 -c
/var/tmp/depot_800_cfg
```

On a tape, the depot must be the third file so there is no need to specify a path to the depot.

Step 2. Change both config files by removing these attribute lines:

```
sd_server = IP_address
sd_depot_dir = /var/tmp/depot
```

Step 3. Change this attribute in both files:

Table 10-5

Attribute	Old Value	New Value
source_type	NET	MT

The deleted information is not needed when accessing a serial depot on a tape. The change to source_type indicates that the depot is located on a tape instead of over the network.

Step 4. Create the Serial Depot. The depot put on a DDS tape is known as a serial depot. It can exist as a regular file, but it cannot be accessed remotely.

To create a serial depot from /var/tmp/depot and store it in /var/tmp/serialdepot, enter:

```
swpackage -s /var/tmp/depot -x target_type=tape \
@ /var/tmp/serialdepot
```

Step 5. Assembling the DDS Tape. Now that all the components of the tape are done, create the LIF volume in /var/tmp/lifvol using the make_medialif command:

```
make_medialif -f /opt/ignite/data/Rel_B.10.20/config \
-f /var/tmp/archive.cfg -f /var/tmp/depot_700_cfg \
-f /var/tmp/depot_800_cfg -l /var/tmp/lifvol
```

This creates the LIF volume that includes all the configuration information, including defaults Ignite-UX provides and information on the archives and depot. For HP-UX 11.0 systems, also use the -a option to include all INSTALL and INSTSALLFS files.

Step 6. Modify INSTALLFS Config. Change configuration information in INSTALLFS. To set run_ui and control_from_server variables using instl_adm to TRUE and FALSE, respectively, based on our scenario:

```
instl_adm -d -F /var/tmp/lifvol > /var/tmp/cfg

vi /var/tmp/cfg        #Add/change the two variables

instl_adm -T -F /var/tmp/lifvol  #Check syntax

instl_adm -d -F /var/tmp/lifvol #Verify changes
```

Step 7. **Make a New Device File.** DDS-1 density is used so that the tape is more readily readable by all DDS tape devices, which are notorious for being finicky at times. To create a device with these characteristics, enter:

```
ioscan -fC tape #get the hardware path
mksf -v -H hardware_path -b DDS1 -n -a
```

You can also create this file using SAM:

1. Click: **Peripheral Devices –> Tape Drives**
2. Select (highlight) the tape drive you want to use: **Actions –> Create Device Files –> Create Custom Device File**
3. Change **DENSITY** to **DDS1**; turn off **Compressed Mode** and **Rewind on Close**
4. Click: **OK**

Step 8. **Create the Install Tape.** Create the tape using a DDS-1 density, no compression, no rewind device file (for example /dev/rmt/c0t3d0DDS1n):

```
mt -t /dev/rmt/c0t3d0DDS1n rew

dd if=/var/tmp/lifvol of=/dev/rmt/c0t3d0DDS1n obs=2k

dd if=/var/tmp/archive_700.gz \
of=/dev/rmt/c0t3d0DDS1n obs=10k

dd if=/var/tmp/serialdepot \
of=/dev/rmt/c0t3d0DDS1n obs=10k

dd if=/var/tmp/archive_800.gz \
of=/dev/rmt/c0t3d0DDS1n obs=10k

mt -t /dev/rmt/c0t3d0DDS1n rew
```

The tape is now ready for installations.

Building an Install CD-ROM

CD-ROM layout

There are similarities between putting a CD-ROM together and putting a tape together, as explained in the previous pages. One major difference, however, is in disk space usage. You have to create a logical volume (or provide a whole disk) large enough to hold the archives and the depots. This paper will assume that a logical volume is used. You need that much space again to copy the raw logical volume to a regular file. So you probably end up using around three times the disk space consumed by your archives and depots.

A bootable CD-ROM is not a serial device like a tape. It has a file system on it, and it also has a LIF volume that contains the same information as above except for the config files which describe the archives and depots. Access to these objects is somewhat different.

The file system on the CD-ROM can be either HFS or CDFS. You can create an HFS file system using standard HP-UX commands. Various third-party applications are available for a CDFS file system. Note that there is less capacity on a CD-ROM (650 MB) than on a 90 meter DDS-1 tape (2GB).

Step 1. Create the logical volume. Assume that the logical volume that will be used is /dev/vg00/image, and it is mounted at /var/tmp/image. Also assume that an HFS file system will be used. Using HFS and standard HP-UX commands, create the logical volume (assume everything fits in 500 MB):

```
lvcreate -L 500 -n image vg00

newfs -F hfs -f 2048 /dev/vg00/rimage

mkdir -p /var/tmp/image

mount /dev/vg00/image /var/tmp/image
```

For CDFS file systems there are similar commands. Check the software supplier documentation.

Step 2. Access a CD-ROM Archive. The file system in the logical volume will contain both the archives and the depots. Place the archives in the CD-ROM image by copying them into the file system just created:

```
cp /var/tmp/archive_700.gz /var/tmp/image

cp /var/tmp/archive_800.gz /var/tmp/image
```

Step 3. Creating config file information for the archives is similar to what was done for the DDS tape. Start with a new copy of `/opt/ignite/data/examples/core.cfg` in `/var/tmp/archive.cfg`

To modify the config file to access the Series 700 archive, the following attributes need to be changed in `/var/tmp/archive.cfg` in the `sw_source` core archive stanza:

Table 10-6

Attribute	Old Value	New Value
`source_type`	NET	DSK
`change_media`	#change_media=FALSE	change_media=FALSE
`nfs_source`	nfs_source=*IP:depot*	#nfs_source:*IP:depot*

These changes will modify the source type from a network (NET) access to CD-ROM (DSK). The other changes are as described before.

Step 4. Inside the stanza enabled by `HARDWARE_MODEL ~ 9000/7.*` the following fields must be changed:

Table 10-7

Attribute	Old Value	New Value
`archive_path`	`B.10.20_700_CDE.gz`	`archive_700.gz`
`impacts`	/ 27KB	(as reported by archive_impact)

The change in archive_path indicates that the archive will be found in the pseudo-root of the CD-ROM in a file called archive_700.gz . Ignite-UX will prepend the mount point it uses to access the archive. As before, the correct set of impacts lines need to be included.

Step 5. Again you can change the sw_sel and description strings to something more descriptive and applicable to your situation. The text inside the double quotes can be changed to whatever you like. Note that archive_type must match what was done by make_sys_image.

Step 6. Delete the entire stanza called golden image2 again.

Step 7. In the stanza for the Series 800 (it is an else clause later in the file) the same sort of changes must be made. These attributes need to change:

Table 10-8

Attribute	Old Value	New Value
archive_path	B.10.20_700_CDE.gz	archive_800.gz
impacts	/ 27KB	(as reported by archive_impact)

The change in archive_path indicates that the archive will be found in the pseudo-root of the CD-ROM in a file called archive_800.gz. Ignite-UX prepends the mount point it uses to access the archive. As before, the correct set of impacts lines need to be included. It cannot be emphasized enough not to change anything else in the file.

Step 8. **Create and Access the CD-ROM Depot.** Tape is restricted to a single depot. That restriction does not apply to a CD-ROM. However, we will use a single depot for simplicity sake. Create the depot using swcopy to a target in the logical volume:

```
swcopy -s /var/tmp/depot \* @ /var/tmp/image/depot
```

Step 9. Once again, use make_config to create the start of the config files for the depot:

```
make_config -s /var/tmp/depot -a 700 -c
/var/tmp/depot_700_cfg
```

```
make_config -s /var/tmp/depot -a 800 -c
/var/tmp/depot_800_cfg
```

Step 10. **Edit config Files.** Since the SD server is the system that is being installed, remove this attribute. Change both config files by removing this attribute line:

```
sd_server=IP_address
```

Step 11. **Change these attributes in both files:**

Table 10-9

Attribute	Old Value	New Value
source_type	NET	DSK
sd_depot_dir	var/tmp/depot	depot

The change to source_type indicates that the depot is located on a CD-ROM instead of over the network. The change in sd_depot_dir indicates that the depot will be found in the pseudo-root of the CD-ROM in a depot called depot. Ignite-UX prepends the mount point it uses to access the depot.

Step 12. **Assemble the CD-ROM.** The raw file system just created must be copied into a regular file so it can be written to the CD:

```
umount /var/tmp/image

dd if=/dev/vg00/rimage of=/var/tmp/fs_image bs=1024k
```

Step 13. **Create the LIF Volume.** Now that most of the components of the CD-ROM are complete, use make_medialif to create the LIF volume:

```
make_medialif -f /opt/ignite/data/Rel_B.10.20/config \
-f /var/tmp/archive.cfg -f /var/tmp/depot_700_cfg \
-f /var/tmp/depot_800_cfg -l /var/tmp/lifvol
```

This creates the LIF volume that includes all the configuration information. It includes the defaults Ignite-UX provides and provides the access to the archives and the depot.

Step 14. Modify INSTALLFS Config. Change configuration information in INSTALLFS. To set run_ui and control_from_server variables using instl_adm to TRUE and FALSE, respectively, based on our scenario:

```
instl_adm -d -F /var/tmp/lifvol > /var/tmp/cfg

vi /var/tmp/cfg    #Add/change the two variables

instl_adm -T -F /var/tmp/lifvol    #Check syntax

instl_adm -d -F /var/tmp/lifvol    #Verify changes
```

Step 15. These two objects (the raw file system and the LIF volume) must be combined using instl_combine. The result is a single file with the LIF volume wrapped around the file system, which can then be written to the CD:

```
/opt/ignite/lbin/instl_combine -F /var/tmp/lifvol \
-C /var/tmp/fs_image
```

Step 16. Complete the CD config. Using your CD-ROM writer software, copy /var/tmp/fs_image to the CD.

The CD-ROM is now ready for installations. You can test the image out before burning a CD by copying it to an unused raw disk and rebooting the system off that disk.

Media from make_tape_recovery

There are many similarities between a tape produced by make_tape_recovery and one constructed by the method described here. In fact, make_tape_recovery performs many of the same steps. But there are some important differences as well. The primary purpose of a recovery tape is to restore enough of a system to get it going following some catastrophe, so the rest of the system can be recovered from backups.

Additional Archives and Depots Media

If there is insufficient space on either a tape or a CD to hold all the archives and depots, it is possible to put them onto separate media. In this case, the config file describing these archives or depots would have change_media set to true. Ignite-UX would prompt the user for the new medium. If this is a CD, the instl_combine step is needed only for the first CD.

E 6392 Paula

System Bootup Sequence

This sequence of events occurs when an HP computer system boots up:

Step 1. The firmware determines from which device to boot via either user input or primary path.

Step 2. The firmware looks for a LIF header on that device, and if it finds it, it looks in the LIF header for where the ISL starts.

Step 3. The firmware loads the ISL into memory from the boot device and executes it. It passes a flag to it that indicates whether to run interactively or to autoboot.

Step 4. If the ISL is interactive then it gives the `ISL>` prompt and waits for user input before proceeding.

Step 5. If the ISL is not interactive, then it looks for the `AUTO` file on the boot device to determine what to run next.

Step 6. The `AUTO` file or user input usually supplies the `hpux` *args* command. This tells ISL to load the program `HPUX` from the LIF header on the boot device and to run it with the given arguments.

Step 7. The hpux program (also known as the secondary loader) figures out what HP-UX kernel to load, and what arguments to pass to it (like init state).

Step 8. `hpux` loads the kernel and starts running it.

Step 9. For the INSTALL kernel, the kernel looks at its name and realizes that it fits the pattern `*INSTALL` and then loads the matching `*INSTALLFS` file from the boot device.

In all these cases the firmware (Processor Dependent Code, or PDC) API services are used when accessing the boot device.

11 System Recovery

This chapter describes important system recovery tools available with Ignite-UX:

- Creating a Bootable Recovery Tape.
- Duplicating make_tape_recovery Tapes.
- Creating a Recovery Archive via the Network and Tape.
- Archive Creation Steps.
- Verifying Archive Results.
- Retaining “Known-good” Archives.
- Making config File Additions.
- Selecting File Systems During Recovery.
- Tape Recovery with make_net_recovery.
- Tape Recovery with No Tape Boot Support
- Notes on Cloning Systems.
- Expert Recovery Using the Core Media.
- System Recovery Questions and Answers.

NOTE

The `make_tape_recovery` tool replaces `make_recovery` for creating recovery tapes, beginning with Ignite-UX A/B 3.2, March 2001. With the `make_tape_recovery` command, you can make recovery archives on local and remote systems, as explained in this chapter. For more details, see the *make_tape_recovery* (1M) manpage.

Overview

HP-UX provides two recovery methods as part of the standard product: system recovery and expert recovery. The method you use depends on the situation.

System Recovery via Network and Tape

The system recovery tools available with Ignite-UX allow you to quickly recover from a failed disk (root disk or disk in the root volume group). The failure can be either a hardware failure or a catastrophic software failure.

System recovery requires some work *before* a problem occurs. On a regular basis, you need to run the appropriate tool on each of your systems: use the `make_net_recovery` command to create an archive on another system or the `make_tape_recovery` to create an archive on tape.

The `make_tape_recovery` and `make_net_recovery` commands both create a bootable recovery (install) archive which is customized for your machine. The archive contains your system's configuration information (disk layout, etc.) and files on your root disk or root volume group. You can exert some control over which files are saved as part of the archive.

Once you have a recovery archive on tape or another system, recovering a failed system is easy:

1. If a disk failed, replace it.
2. Boot from your recovery tape or system.
3. Wait for the recovery to complete.
4. Once the system comes back up, recover the latest copies of files from the last system backup.

Expert Recovery

Expert recovery, formerly called Support Media Recovery, allows you to recover a slightly damaged root disk or root volume group. With this method, you repair the boot/root disk and root volume group from the network or HP-UX Core media. Once the recovery system has been booted, you can:

- Put a known, good kernel in place.
- Fix the LIF volume on the disk.
- Copy essential files and commands into place.

Expert recovery does not require that you do any preparation before you use it. The media used is supplied by HP; it is not customized to your site. In addition to the media, you can also boot from your Ignite-UX server. However, this also means that any customization you have are not reflected in the files you recover via expert recovery. Depending on the failure cause, expert recovery gives you enough capabilities to get your system back up again. At that point, you need to use your normal restore tool to recover your system to the state it was in before the problem occurred. Expert recovery is not useful to recover from hardware failures.

System Recovery Tools

Comparing Features

The make_net_recovery and make_tape_recovery tools share many features in common with few differences that exist, mainly due to the different media that are used and ways of handling them. Both system recovery tools share the same basic archive creation options, data structures, archive file content, and installation dialogues.

To determine which system recovery tool is best suited for your needs, consider the following:

Use make_tape_recovery if:

- Managing a single or limited number of systems locally
- Cloning a "like system"
- Systems are not networked
- Suitable tape drive exists.

6388
Paula

- Tape media is needed for an off-site recovery system

Use `make_net_recovery` if :

- Managing central, networked systems
- Cloning a "like system"
- Avoid tape issues (media cost and handling, multi-tape archives, etc.)
- Suitable disk space for archive storage
- Performing unattended backups without tape handling

The following table summarizes and compares some of the features of the `make_tape_recovery` and `make_net_recovery` tools:

Table 11-1 **Comparing System Recovery Tool Features**

Feature	`make_tape_recovery`	`make_net_recovery`
Minimum hardware configuration	Stand-alone system; local tape drive	Two networked systems; sufficient disk space to hold archive
Archive Creation Interface	Client command line; Server GUI; Client TUI	Server GUI; Client command line; Client TUI
Archive	Self contained image; written to the client's tape drive	Requires an Ignite-UX server to install; written to NFS mounted file system

Archive Contents

The `make_net_recovery` and `make_tape_recovery` commands allow you to view and control archive contents:

- The list of essential files to be included in the archive is available as a simple text file: `/opt/ignite/recovery/mnr_essentials`. This file allows you to see what files and directories are included by default in the archive.
- You can specify what additional volume groups, directories, and files you want included, and what directories and files you want excluded. This is done using simple syntax in the client-specific content file, `/var/opt/ignite/clients/LLA/recovery/archive_content` or

using command line options. You are not restricted to one or two volume groups. You can create a complete multi-volume group file system archive if you want.

- You can use the user interface to find out which volume groups and/or disks will be untouched, which will be partially restored, and which will be restored in full if the archive is used, based on the specifications in the `mnr_essentials` file and the `archive_content` file.
- You can also use the user interface to edit the `archive_content` file and dynamically see the changes in the volume groups and disks that are affected.
- The policies for user-specified content are documented in "Archive Configuration Policies" on page 175.

`make_tape_recovery` creates a bootable tape that can be used to restore a system via the system's tape drive. `make_tape_recovery` is subject to the requirements and limitations inherent with tape media:

- A tape drive must be available on each system to be archived.
- If you want to save the previous good archives before creating new ones, you need to remove the old tapes and insert different tapes on each system.
- If an archive exceeds the capacity of a tape, you need to swap tapes for both creation and extraction.
- If you want to make sure that the newly created tapes are good, you need to check the log files on every system.
- Tape drives are more error-prone than a local network.

Dependency on Ignite-UX Server for Recovery

make_tape_recovery

The tape created by `make_tape_recovery` is completely self-contained and does not require an Ignite-UX server. The `make_tape_recovery` archive contains a specially prepared LIF volume. The config file in the LIF volume is the configuration file for the archive. The `INDEX` file in the LIF volume specifies the recovery configuration as the default for the system. The `INSTALLFS` in the LIF volume contains additional configuration information so no user interaction will take place. Additional files needed for booting and installing are copied from

6386
Paula

/opt/ignite/boot and /opt/ignite/data to the LIF volume, so that everything the system needs to recover is there. You could use your make_tape_recovery tape even if you removed your Ignite-UX server.

make_net_recovery The archives created by make_net_recovery are designed to work with an Ignite-UX server; you could not remove your server and still use your recovery archive.

Creating a Bootable Recovery Tape

IMPORTANT

copyutil is a diagnostic tool for HP-UX 10.*x* or later, and should not be used for system recovery. Instead, use one of the tools described in this chapter.

Ignite-UX's make_tape_recovery command can create a system recovery tape. This tape can be used to boot and recover a system which has become unbootable due to corruption of the root disk or volume group. A system can be booted and installed from the tape without user intervention for configuration, customization, software selection, hostname, or IP address.

NOTE

A bootable recovery tape can also be created from the Ignite-UX server. However, the client must have a local tape drive.

The make_tape_recovery tool creates a system recovery archive and stores the archive on a local tape. make_tape_recovery is capable of creating system recovery tapes for tape devices, with the ability to span multiple tapes. The archive created by make_tape_recovery is specific to the system it was created for and its identity includes hostname, ip_address, networking information, etc. In the event of a root disk failure, the recovery archive can be installed via tape to restore the system.

The contents of the system recovery archive will always include all files and directories which are considered essential to bringing up a functional system. This **essential** list is pre-defined by make_tape_recovery and is located in the following file: /opt/ignite/recovery/mnr_essentials. By running make_tape_recovery in interactive mode, the directories and files which make up the essential list can be displayed. In addition to the essential list, data can be included in the archive on a disk/volume group, file, or directory basis. Non- essential files and directories can also be excluded.

NOTE

It is preferable to use the Ignite-UX GUI menu command on the Ignite-UX server when running an interactive make_tape_recovery session. Running it from Ignite-UX causes any additional server configuration of NFS mounts to be performed. It also provides a better progress report and an easier to use interface.

Logging

On a server, progress and errors are logged to:

/var/opt/ignite/clients/<*LLA*>/recovery/<*datetime*>/recovery.log

On a local system, progress and errors are logged to:

/var/opt/ignite/recovery/<*datetime*>/recovery.log

Task: Recover a minimal OS

Preform these operations as root.

To create a minimal operating system recovery tape at /dev/rmt/0mn, containing only the OS elements required to boot the system, perform the following steps:

Step 1. Load a writable tape in the default tape drive for your system.

Step 2. Enter: **make_tape_recovery**

A tape will be created without further interaction.

System recovery from this tape would involve booting from the tape to recover the minimum Core OS. Then you would follow up with data recovery of all user files newer than those restored from the recovery tape.

Task: Create a system recovery archive of entire root disk volume

To create a system recovery tape at the default device /dev/rmt/0m, and that includes the entire root disk in the archive, perform the following steps:

Step 1. Load a writable tape in the default tape device for your system.

Step 2. Enter the appropriate command:

```
make_tape_recovery -x inc_entire = vg00
```

A tape will be created without further interaction.

Task: Create a system recovery archive tape with the -A option

To create a system, you can create a system recovery tape as follows:

Step 1. Load a writable tape in the default tape device for your system.

Step 2. Enter: `make_tape_recovery -A`

A tape will be created without further interaction. You can boot this tape on your new system.

Task: Install a system recovery from an archive tape

To install a system recovery from an archive tape:

Step 1. Mount the system recovery tape on the tape drive.

Step 2. Boot the system.

Step 3. Interrupt the boot sequence to redirect it to the tape drive by pressing **Esc**.

Step 4. Cancel the non-interactive installation by pressing any key when given the opportunity.

Step 5. Allow the install process to complete.

For more information on creating recovery tapes, see the *make_tape_recovery* (1M) manpage.

Duplicating make_tape_recovery Tapes

A tape created with `make_tape_recovery` contains two tape "files": a 2KB LIF file and a 10 KB tar archive. If you have two tape drives on a system, you can easily duplicate the tapes using two `dd` commands with a no-rewind-on-close device file for the first command. For example:

```
dd if=/dev/rmt/0mn of=/dev/rmt/1mn bs=2k
dd if=/dev/rmt/0m of=/dev/rmt/1m bs=10k
```

If you only have one tape drive, and have enough disk space to hold the contents of both tape files, use something like this:

```
dd if=/dev/rmt/0mn of=/var/tmp/f1 bs=2k
dd if=/dev/rmt/0m of=/var/tmp/f2 bs=10k
```

(Insert blank tape now)

```
dd if=/var/tmp/f1 of=/dev/rmt/0mn bs=2k
dd if=/var/tmp/f2 of=/dev/rmt/0m bs=10k
```

Also see the *copy_boot_tape* (1M) manpage.

Creating a Recovery Archive via the Network and Tape

Ignite-UX A.2.0, B.2.0 and later versions allow you to create recovery archives via the network onto the Ignite-UX server system, or any other specified system. You can either use the Ignite-UX `/opt/ignite/bin/ignite` or run `/opt/ignite/bin/make_net_recovery` on a client system. Use Ignite-UX to recover specified systems on the net. Systems can be recovered across subnets from a boot tape using `make_boot_tape`, local boot server or the `bootsys` tool from an Ignite-UX server.

The `make_net_recovery` tool creates a system recovery archive and stores the archive on the network. The archive created by `make_net_recovery` is specific to the system it was created for and its identity includes hostname, ip_address, networking information, etc. In the event of a root disk failure, the recovery archive can be installed via Ignite-UX to restore the system.

The contents of the system recovery archive will always include all files and directories which are considered essential to bringing up a functional system. This essential list is pre-defined by `make_net_recovery`. By running `make_net_recovery` in interactive mode, the directories and files which make up the essential list can be displayed. In addition to the essential list, data can be included in the archive on a disk/volume group, file, or directory basis. Non- essential files and directories can also be excluded.

Networking features

Two NFS mount points are established on the client by `make_net_recovery`. The `/var/opt/ignite/clients` directory on the Ignite-UX server is mounted to the client system to store configuration files which describe the client configuration and location of the recovery archive. The second mount point is made to the *`archive_server:archive_dir`* (see the `-a` option) and is used to store the recovery archive of the client system. After successful or unsuccessful completion of the system recovery archive, the NFS mount points are un-mounted.

The NFS mount for the archive directory may be exported on a per-client bases. A separate archive directory is used for each client. This allows you to NFS export each directory only to the individual client owning the archive, which provides security.

If the client system does not have the most recent versions of Ignite-UX tools, the Ignite-UX GUI uses `swinstall` to install the "recovery package" which includes all necessary files to perform the recovery.

Create a Recovery Archive from the Ignite-UX Server

To create a system recovery archive from an Ignite-UX server:

Step 1. On your host system, allow the Ignite-UX server access to your to display by adding the Ignite-UX server hostname to your xhost list:

```
xhost + Ignite-UX_server_hostname
```

Step 2. Set the DISPLAY variable to your local host system, if necessary. For example:

```
export DISPLAY=Elvis:0
```

Step 3. On the Ignite-UX server, as root run:

```
/opt/ignite/bin/ignite
```

Step 4. Select: **Actions –> Add New Client for Recovery** You will need to respond to a dialogue to identify the system.

Step 5. Click the client icon when its appears on the Ignite-UX screen.

Step 6. Select: **Actions –> Create Network Recovery Archive.** You may be prompted for the root password for the targetsystem.

The network recovery tools needed on the client will automatically be installed.

After some information screens, you will see an Include/Exclude selection screen. To view the essential files, click the **Show** button. Essential files cannot be excluded, but you can customize the archive by specifying additional volumes, directories, or files. In case an item is duplicated as both Include and Exclude, the Exclude category dominates.

Archive Configuration Policies

When specifying archive content for both make_net_recovery and make_tape_recovery, either via the Ignite-UX GUI or the command line, the following rules apply:

- No essential file or directory can be excluded.
- Files and directories inside an included directory will be included recursively.
- If a symbolic link to a file or directory is included, only the link will be included in the archive, not the actual file or directory, unless it, too, is included. A warning will be given when the item itself is a symbolic link.
- If a directory is included which contains symbolic links to other files or directories, the symbolic links will be included but not the referenced files or directories, unless they, too, are included. No warnings are given regarding these links.
- If a directory contains local mount points, the files and directories under the local mount points will not be included, by default. This policy can be waived by specifying the option inc_cross (include directory and cross-mount points), in the selection interface or command line.
- In case of conflicting entries in the selections, Exclusions take precedence over Inclusions.

IMPORTANT If there are mount points below /etc, make_net | tape_recovery will not restore these files until the recovery generates errors. The recovery does not fail, but the mount points under /etc are missing.

More Examples

The follow examples apply for system recovery using either `make_net_recovery` or `make_tape_recovery`:

Create recovery from the client

This command creates a system recovery archive from the client, using settings from the last invocation of Ignite-UX, and using the options file on the Ignite-UX server (`myserver`) in the default location, */var/opt/ignite/clients/0xLLA/recovery/*:

```
make_net_recovery -s myserver
```

Create recovery from the client that includes volume group files

To create a system recovery archive from the client that includes files from all file systems in the `vg00` volume group, enter:

```
make_net_recovery -s myserver -x inc_entire=vg00
```

Create recovery archive file to replace mnr_essentials

To create a system recovery archive with all the files/directories on the disk(s)/volume group(s) containing the files specified by the default essentials file list `/opt/ignite/recovery/mnr_essentials` or the user defined version of this file, that replaces this file, `/var/opt/ignite/recovery/mnr_essentials`, enter:

```
make_net_recovery -s myserver -A
```

Preview system recovery

To preview the creation of the system recovery archive enter:

```
make_net_recovery -p
```

Large File Support

Specific support for large files is needed if archives greater than 2GB are to be created. This requires ensuring that both the file system and the NFS mount on the archive server will support large files.

The `fsadm` command can be used to determine whether large files are currently supported on a specific file system. The *fsadm* (1M) manpage has an example of how to change the file system to support large files. If you use `fsadm` to convert a file system, re-run **`exportfs -a`**, if it is already exported, in order for clients to be affected by the change.

To support NFS mount and network data transfer of large files, you will need to have NFS PV3 installed on both the client and server. If the client or server is running HP-UX 10.20, the Networking ACE patch (containing the NFS PV3 software) should be installed and updated with a patch cited in the Ignite-UX Release Notes. HP-UX 11.0 and later versions come with PV3 by default.

The Ignite-UX Release Notes (`/opt/ignite/share/doc/release_note`) identifies which patches are required for NFS support of archives greater than 2GB for HP-UX 10.20, 11.0 and later.

Recovering via the Network for PA Clients

To recover a failed disk or volume group using the system recovery archive:

Step 1. Boot the failed system using one of these ways (see "Booting Client Systems from the Network" on page 67):

- Using Ignite-UX after booting with: **`boot lan install`**
- Booting from an Ignite-UX server, using `bootsys` if the client OS is running.
- Booting the failed client locally by using a boot tape previously created with `make_boot_tape`.

Step 2. Do not interact with ISL.

Step 3. From the main menu, select **Install HP-UX**
At the client:

1. Respond to Network configuration dialogue screen.
2. Respond to the UI display options (run at Server or at Client).
3. If working from the Ignite-UX server, select the client icon for the system to be recovered.

Step 4. Select **Install/New Install**

Step 5. Select the recovery configuration to use.

Recovering via the Network for IA Clients

To recover a failed disk or volume group using the system recovery archive:

Step 1. From the EFI Boot Manager menu, you will see a prompt to select a boot option. Select **`Boot option maintenance menu`**.

```
EFI Boot Manager ver 1.10 [14.54]  Firmware ver 0.0 [4209]

Please select a boot option

    EFI Shell [Built-in]
    Boot option maintenance menu
    Security/Password Menu (*** Prototype ***)

Use up and down-arrows to change option(s).
Use Enter to select an option
```

Step 2. The Main Menu appears and prompts you to choose an operation. Select **`Add a Boot Option`**.

```
EFI Boot Maintenance Manager ver 1.10 [14.54]

Main Menu. Select an Operation

        Boot from a File
        Add a Boot Option
        Delete Boot Option(s)
        Change Boot Order

        Manage BootNext setting
        Set Auto Boot TimeOut

        Select Active Console Output Devices
        Select Active Console Input Devices
        Select Active Standard Error Devices

        Cold Reset
        Exit
```

Step 3. The following menu displays. Select an appropriate network card for network boot. For example, look for entries with a MAC followed by the Mac/*LLA* address of the LAN card.

```
EFI Boot Maintenance Manager ver 1.10 [14.54]

Add a Boot Option.  Select a Volume

    Removable Media Boot
[Acpi(HWP0002,0)/Pci(2|0)/Ata(Primary,Maste
    Load File [EFI Shell [Built-in]]
    Load File [Acpi(HWP0002,0)/Pci(3|0)/Mac(00306E1E4ED4)]
    Load File [Acpi(HWP0002,100)/Pci(2|0)/Mac(00306E1E3ED6)]
    Exit
```

Step 4. Enter an appropriate boot option name at the message prompt. For this example, new boot options are named LAN1 and LAN2.

Step 5. Exit to the main menu. The new boot option will now appear in the EFI Boot Manager main menu.

```
EFI Boot Manager ver 1.10 [14.54]  Firmware ver 0.0 [4209]

Please select a boot option

    SCSI2-HPUX
    EFI Shell [Built-in]
    LAN2
    LAN1
    Boot option maintenance menu
    Security/Password Menu (*** Prototype ***)

Use up and down-arrows to change option(s).
Use Enter to select an option
```

Step 6. Select the new boot option you created. The following is an example of a successful boot using the new boot option.

```
Loading.: LAN1
Running LoadFile()

CLIENT IP: 15.1.52.128  MASK: 255.255.248.  DHCP IP: 15.1.53.37
GATEWAY IP: 15.1.48.1
Running LoadFile()

Starting: LAN1

@(#) HP-UX IA64 Network Bootstrap Program Revision 1.0
Downloading HPUX bootloader
```

6374
Paula

```
Starting HPUX bootloader
Downloading file fpswa.efi  (371200 bytes)

Booting from Lan
Downloading file AUTO   (528 bytes)
Press Any Key to interrupt Autoboot
AUTO ==> boot IINSTALL
Seconds left till autoboot -   0
AUTOBOOTING...
```

Step 7. From the main menu, select **Install HP-UX**
At the client:

1. Respond to Network configuration dialogue screen.
2. Respond to the UI display options (run at Server or at Client).
3. If working from the Ignite-UX server, select the client icon for the system to be recovered.

Step 8. Select **Install/New Install**

Step 9. Select the recovery configuration to use.

Create a Bootable Archive Tape via the Network

This section explains how to create a self-contained recovery tape for a recovery configuration already stored on an Ignite-UX server via network system recovery. See the *make_net_recovery* (4) manpage for more details. It is important that the archive fit onto a single tape.

These instructions assume that:

- The hostname of the machine the archive was created for is sys1.
- The archive was created at “2001-03-12,09:00”.
- The archive will fit onto a single tape.

Step 1. Build the LIF file. The LIF file will contain the Ignite-UX tools and environment, the config files produced for the recovery archive, and the scripts used during recovery.

1. Use `make_medialif` to build the LIF file:

```
cd
/var/opt/ignite/clients/sys1/recovery/2001-03-12,09:00

make_medialif -f system_cfg -fcontrol_cfg -f archive_cfg\
-C "2001-03-12,09:00 sys1 recovery image" \
-l /var/tmp/my_lif -a -r os_rev
```

2. Modify the LIF file for use on the tape:

```
instl_adm -d -F /var/tmp/my_lif > /var/tmp/cfg
```

3. Add these lines to the end of the `/var/tmp/cfg` file:

```
control_from_server=FALSE

run_ui=TRUE
```

OR, if you just want the recovery to proceed without any interaction, make:

```
run_ui = FALSE
```

and specify to allow warnings as shown here:

```
env_vars += "INST_ALLOW_WARNINGS=10"
```

4. Enter:

```
instl_adm -F /var/tmp/my_lif -f /var/tmp/cfg
```

Step 2. Create the Tape. To write the LIF and archive to a tape:

1. Determine which tape device file you can use to write the tape. The device file must match the tape drive type you will use when actually recovering the system. Also, the tape device file must be the no-rewind type. For the rest of this example, assume that `/dev/rmt/c1t0d0DDS1n` is a no-rewind DDS-1/no compression device file.

2. Rewind the tape, write out the LIF and archive, and rewind again:

```
mt -t /dev/rmt/c1t0d0DDS1n rew

dd if=/var/tmp/my_lif of=/dev/rmt/c1t0d0DDS1n obs=2k

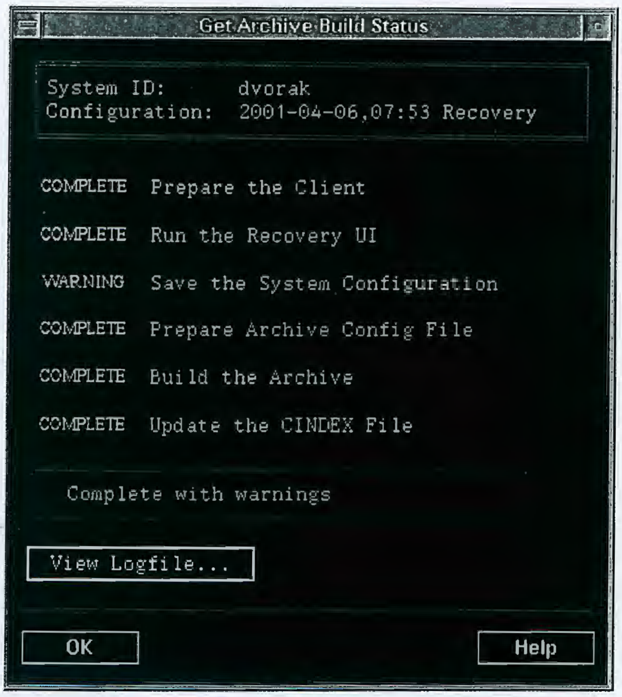
dd if=/var/opt/ignite/recovery/archives/sys1/2001-03-12,
09:00 \ of=/dev/rmt/c1t0d0DDS1n obs=10k

mt -t /dev/rmt/c1t0d0DDS1n rew
```

In this example, the archive is retrieved from the standard location on the Ignite-UX server for this host. If you have chosen to put the archive elsewhere, refer to that location instead.

Archive Creation Steps

Ignite shows the steps as an archive is being created with `make_net_recovery`:



```
System ID:      dvorak
Configuration:  2001-04-06,07:53 Recovery

COMPLETE   Prepare the Client
COMPLETE   Run the Recovery UI
WARNING    Save the System Configuration
COMPLETE   Prepare Archive Config File
COMPLETE   Build the Archive
COMPLETE   Update the CINDEX File

  Complete with warnings
```

Step 1. Prepare the client. `make_net_recovery's` primary tasks are to check that the recovery tools installed on the client are compatible with the versions on the Ignite-UX server, and to create the necessary directories and files. If the client was not previously installed using the Ignite-UX server, `make_net_recovery` creates a new directory for the client in `/var/opt/ignite/clients` on the server.

`make_net_recovery` also generates a timestamp for naming the archive, the configuration, and the configuration directory. The directory containing the configuration files for the archive will be something like:

`/var/opt/ignite/clients/`*`LLA`*`/recovery/2001-03-09,00:27`

The corresponding archive will be:

```
/var/opt/ignite/recovery/archives/client/2001-03-09,00:27
```

The timestamp is important for coordinating configuration files and archives, and for ongoing archive management.

Here's an overview of files located in the client's directory for network recovery (for a local tape the path would be /var/opt/ignite/recovery):

```
/var/opt/ignite/clients/<LLA>
        install.log
        CINDEX
        Client_status
        recovery/
                archive_content
                defaults
                latest
                2001-02-09,00:27/
                        archive_content
                        system_cfg
                        archive_cfg
                        config_cfg
                        recovery.log
                        flist
                        manifest
                2001-03-09,00:27/
                        archive_content
                        system_cfg
                        archive_cfg
                        config_cfg
                        recovery.log
                        flist
                        manifest
```

Step 2. Run the recovery Interface. If `-i` is specified on the command line, the Recovery user interface is run next. The interface enables users to set or change the following default values for the archive:

- Long description of the archive. This description may be used to add identifying information that can help to distinguish archives when the timestamp is not sufficient. This information is shown by clicking **Description** on the **Basic** tab during installation configuration.

- Maximum number of archives to keep. When the number of archives in the destination directory reaches this maximum, `make_net_recovery` removes the oldest archive. It uses the timestamp in the name of the archive to determine which one to remove.

- Destination host for the archive.

- Destination directory for the archive.

The user interface also gives users the opportunity to review and edit the `archive_content` file as mentioned above. When the user exits the recovery user interface, the default values that the user entered are written to:

`/var/opt/ignite/clients/`*`LLA`*`/recovery/defaults`

The archive content is written to:

`/var/opt/ignite/clients/`*`LLA`*`/recovery/archive_content`

Step 3. Save the system configuration. For all volume groups, even ones that are not included in the archive, `make_net_recovery` now backs up volume group configuration information and stores in the `system_cfg` file. It also obtains map files for volume groups that are not part of the archive using `vgexport`. The volume group configuration files and the map files generated at this stage are stored in `/etc/lvmconf`. This directory is included by the list of essential files, so the lvm files are included in the archive.

After the volume group information is saved, `make_net_recovery` creates the `control_cfg` file. This file includes the `post_config_cmds` to import all volume groups that were not included in the archive and to activate all volume groups that were imported. It also includes control flags, such as `recovery_mode=true`, to guide the behavior of Ignite-UX during recovery.

Step 4. Prepare the config file. Once the archive is created, `make_net_recovery` calls `make_arch_config` to create the `archive_cfg` file to reference it. `make_arch_config` uses `archive_impact` to calculate the file system impacts for the archive, and includes these in the `sw_sel` stanza it writes.

Step 5. Build the archive. make_net_recovery calls make_sys_image to create the archive. make_sys_image passes a pre-built flist to calculate the total disk space currently used by all the files to be included in the archive. It uses this information with a compression ratio to estimate the final size of the archive. If the destination directory has sufficient free disk space for the archive, make_sys_image creates the archive using pax.

Step 6. Update the CINDEX file. make_net_recovery uses manage_index to update the /var/opt/ignite/clients/*LLA*/CINDEX file for the client. This file contains a list of all the recovery cfgs available for the client. An entry for the most recently created archive looks something like this:

```
cfg "1999-03-10,00:27 Recovery" {
   description "This cfg is a pure mnr_essentials recovery
   archive."
   "recovery/1999-03-10,00:27/system_cfg"
   "recovery/1999-03-10,00:27/control_cfg"
   "recovery/1999-03-10,00:27/archive_cfg"
}=TRUE
```

Verifying Archive Contents

What files will be archived?

To list the files and directories that will be included in a make_net_recovery archive, enter:

```
/opt/ignite/lbin/list_expander -l -f input_file
```

You can examine the list of files that will be re-created during an installation from a make_net_recovery configuration, by viewing the /var/opt/ignite/clients/cca/recovery/fhist file. For example:

```
pg /var/opt/ignite/clients/cca/recovery/fhist
```

If make_tape_recovery was used, the list of recovery files resides in /var/opt/ignite/recovery/latest/fhist and can be viewed in the same manner as the above example.

What disks or volume groups will be recovered?

To list disks or volume groups that will be re-created during an installation from a make_net_recovery configuration, enter this from the client:

```
/opt/ignite/lbin/list_expander -d -f input_file
```

where: *input_file* is a file specifying what is to be archived. See the *make_net_recovery* (4) manpage for details on the format of the *input_file*. make_net_recovery can take input from an input file, no input, or input from the command line with the -x option. list_expander can take input from an input file, or no input, but does not have an x option like make_net_recovery does, so to see the result of using x options, put them in a file and pass list_expander the file name.

If you used the Ignite-UX to specify what is to be included in the archive, then the input file can be found on the server in:

/var/opt/ignite/clients/*client*/recovery/archive_content

You can copy this file from the server to the client, then run list_expander against that file itself.

Omitting -f *input_file* causes list_expander to use only the essential files as input. This will show what disks or volume groups will get re-created for the minimal archive. Here's an example output:

```
In?     dsk/vg   name         minor#  Associated disks
0       d         /dev/dsk/c0t3d0
1       v        /dev/vg00      0x00     /dev/dsk/c0t6d0
                                          /dev/dsk/c0t4d0
0       v         /dev/vg01      0x01     /dev/dsk/c0t1d0
0       v        /dev/vg02      0x02    /dev/dsk/c0t2d0
```

The dsk/vg column shows that the system has one whole disk (d) and three volume groups (v). The next column gives the names of the disks and volume groups. The In? column shows, for each disk or volume group, if it will be:

2 = included in full (INC_ENTIRE dsk/vg specified),

1 = included in part (some files included, some not), or

0 = not included at all (no files from this dsk/vg are included).

0 means the disk or volume group will *not* be touched. 1 or 2 means that the disk or volume group *will* be re-created, and files from the archive will be restored during a recovery operation.

Paula

Verifying Archive Results

During a system recovery, Ignite-UX strives to restore the system back to the way it was. However, Ignite-UX is a general-purpose installation tool, and can modify many system configuration files.

When you run `make_net_recovery`, a lot of system configuration information is gathered and saved in config files that are used later when the system is recovered. During the system recovery the user is allowed to make changes to this information, in which case Ignite-UX will make the appropriate changes to the system configuration. If a user does not make any changes, then it simply re-applies the same information and you should see no change to the system in the end.

Most of the system configuration files that Ignite-UX will modify are listed in the script: `/opt/ignite/data/scripts/os_arch_post_l`. The `os_arch_post_l` script checks for the system recovery case by checking the `$RECOVERY_MODE` variable. When this variable is TRUE, the os_arch_post_l script causes some configuration files to be protected from modification by using the "save_file" function. os_arch_post_l uses the "merge_file" function on files that Ignite-UX knows how to intelligently merge information into.

The files operated on by "merge_file", as well as those that have a commented out "save_file" line are those that are likely to be modified by Ignite-UX. Comments in the file explain any exceptions.

Because the list of files modified by Ignite-UX may change from release-to-release, it is best to look at the os_arch_post_l file on your system to see which files are saved as-is and which are merged with information from the Ignite-UX config files.

Retaining "Known-good" Archives

You may want to prevent known-good archives from being deleted from your system. `make_net_recovery` provides the -n option to specify the number of archives to save. To preserve disk space, the oldest archive(s) are removed as new archives are created. The number of archives that get removed is based on the number of archives specified to be saved.

One way to ensure that known-good archives are saved would be to specify the number of archives to save to be greater then the maximum number of archives you plan to store on the system at any given time. This would cost disk space.

An alternative and better approach to saving known-good archives is to rename the archive and edit the configuration file to include the new archive name. Follow these steps:

Step 1. Login to the system where the archive is to be stored (this could be different than the Ignite-UX server).

Step 2. Rename the archive. (The path to the archive may be different than the example below). The name of the archive to save can be anything unique, but it should be outside the naming convention: *yyyy-mm-dd,hr:min*

```
cd /var/opt/ignite/recovery/archives/system_name
mv old_archive_name saved_archive_name
```

For example:

```
mv 2001-05-11,15:14 Recovery_Archive.0511.save
```

Step 3. If the archive server is different from the Ignite-UX server, login to the Ignite-UX server system.

6364 Paula

Step 4. Edit this file to reference new archive name:

```
/var/opt/ignite/clients/client/recovery/  \
old_archive_name/archive_cfg
```

Change the `archive_path` variable inside the `(source_type == "NET")` conditional to the name of the saved archive. For example:

```
(source_type == "NET") {
  archive_path = "Recovery_Archive.0511.save"
}else {
  archive_path = "1"
}
```

Step 5. Optionally, edit the `cfg` tag entry in the file:

/var/opt/ignite/clients/`client`*/CINDEX*

so that configuration will be unique and descriptive when it is viewed via the Ignite-UX screen. For example:

Change from:

```
cfg "2001-05-13,06:51 Recovery Archive" {
description "Weekly System Recovery Archive"
...

}
```

To:

```
cfg "Saved Recovery Archive" {
description "Weekly System Recovery Archive"
...

}
```

Making config File Additions

To make configuration file additions to all recovery configurations for a given client, create a new Ignite-UX configuration file called:

```
/var/opt/ignite/clients/0x{LLA}/recovery/config.local
```

For local tapes the file is located in:

```
/var/opt/ignite/recovery/config.local
```

This `config.local` file will automatically be included into your recovery configuration for this client each time you run `make_net_recovery`. (`make_net_recovery` is run for you when you use Ignite-UX for network recovery).

If you already have recovery configurations for this client and would like them to include the `config.local` file, edit the `/var/opt/ignite/clients/0xLLA/CINDEX` file to include a reference to "recovery/config.local" in all of the configuration clauses.

E 6362 Paula

Selecting File Systems During Recovery

It is possible to change the way your disks are configured when you recover from an image saved by `make_net_recovery`.If you want to use a standard HP filesystem layout, you can specify the disk configuration using Ignite-UX:

Install Client –> New Install –> File System

If you do not want to use a standard HP filesystem layout, you can modify the `/var/opt/ignite/clients/0x`*`LLA`*`/CINDEX` file for the client you are recovering. The `CINDEX` file contains one or more configuration clauses that refer to the recovery images you have previously created with `make_net_recovery`. Add a new configuration file entry to the clause that you intend to recover from. If you want to add HP's standard file system choices, add the file:

`/opt/ignite/data/Rel_`*`release`*`/config`

Where: *release* is the operating system release on the client you intend to recover. For example:

`/opt/ignite/data/Rel_B.10.20/config`

would be added for a client with the HP-UX 10.20 operating system. This new configuration file entry should be the first entry in the clause you are modifying.

When you bring up the user interface during recovery, select the File System type you wish to use on the **Basic** tab.

Tape Recovery with make_net_recovery

There are two ways you can recover from a tape with `make_net_recovery`. The method you choose depends on your needs.

Use make_medialif This method is useful when you want to create a totally self-contained recovery tape. The tape will be bootable and will contain everything needed to recover your system, including the archive of your system. During recovery, no access to an Ignite-UX server is needed. Using `make_medialif` is described beginning on page 180 and also on the Ignite-UX server in the file: `/opt/ignite/share/doc/makenetrec.txt`

Use make_boot_tape This method is useful when you do not have the ability to boot the target machine via the network, but are still able to access the Ignite-UX server via the network for your archive and configuration data. This could happen if your machine does not support network boot or if the target machine is not on the same subnet as the Ignite-UX server. In these cases, use `make_boot_tape` to create a bootable tape with just enough information to boot and connect with the Ignite-UX server. The configuration files and archive are then retrieved from the Ignite-UX server. See the *make_boot_tape* (1M) manpage for details.

6360 Paula

Tape Recovery with No Tape Boot Support

You can use the Ignite-UX tape recovery tool to archive your system even if there is no tape boot support on the system. This support is provided in the Ignite-UX B.4.1 release and later only.

IMPORTANT Be sure to locate the December 2002 version or later of Ignite-UX (B.4.1 or later) media (CD or DVD) that can be used to boot your system to the interface screens to guide you through tape recovery using a tape drive.

Step 1. Insert the December 2002 version or later of Ignite-UX (B.4.1 or later) media into the appropriate drive, then boot from it.

The following interface screen appears:

```
                User Interface and Media Options

   This screen lets you pick from options that will determine if an
   Ignite-UX server is used, and your user interface preference.

Source Location Options:
   [ * ]  Media only installation
   [   ]  Media with Network enabled (allows use of SD depots)
   [   ]  Ignite-UX server based installation

 User Interface Options:
   [ * ]  Guided Installation   (recommended for basic installs)
   [   ]  Advanced Installation (recommended for disk and file
system management)
   [   ]  No user interface - setup basic networking, use defaults
and go
   [   ]  Remote graphical interface running on the Ignite-UX server

   Hint: If you need to make LVM size changes, or want to set the
         final networking parameters during the install, you will
         need to use the Advanced mode (or remote graphical
interface).

   [   OK   ]            [ Cancel ]              [  Help  ]
```

Step 2. Click the **OK** button to continue and you are advanced to the next screen:

```
                    Media Installation

  This screen provides an option to switch the install source
from the default CD/DVD to a recovery tape.  This is helpful
for those systems and for tape devices which do not support
booting from a tape.

   [   ] CD/DVD Installation
   [ * ] Boot from CD/DVD, Recover from Tape

   [ OK ]      [ cancel ]    [ Help ]
```

Step 3. Select the **Boot from CD/DVD, Recover from Tape** and click **OK** to advance to the Tape Drive Selection screen:

```
                      Tape Drive Selection

  There are one or more tape drives detected on the system.
Insert your recovery tape into one of the drives and then
select that drive from the list below.

    Use the <tab> and/or arrow keys to move to the desired
TAPE device
    to enable, then press <Return/Enter>.

        HW Path              Device File
Description

-------------------------------------------------------------

      [ 0/18/1/0/0.0.3.0    /dev/rmt/c0t0d0          HP C5683A ]
      [ 0/18/1/0/0.1.0.0    /dev/rmt/c1t1d1          HP A5580A ]
```

Step 4. Select the tape drive that contains the archive tape then press **Enter** to start the installation of the recovery tape archive from the chosen tape drive.

Notes on Cloning Systems

Ignite-UX offers two main options for replicating (cloning) systems. The traditional Ignite-UX method makes use of make_sys_image to create an archive of the source system, followed by manually modifying config files to meet your needs. A much simpler (but less flexible approach) uses make_net_recovery or make_tape_recovery. The pros and cons of each are described here.

In each case, the source system that is used must contain software that is compatible with all target systems. This means that the version of HP-UX, patches, drivers, etc., must be sufficient for all systems involved. This often requires loading a superset of software and drivers onto the source system that will be used on all potential targets.

Using make_sys_image

Using the traditional method of creating an archive with make_sys_image and then modifying Ignite-UX configuration files to reference the archive is very flexible, but somewhat time consuming. The end result gives you:

- Ability to install systems from network, tape, or CD-ROM from either an Ignite-UX server, or local clients.
- Ability to customize the process and tune it to accommodate many different situations.
- A "clean" system — log files and most remnants specific to the source system are removed.
- A rebuilt kernel containing just the drivers needed by the target system's hardware.
- Ability to load additional software or patches on top of the system archive from an SD depot. This reduces the need to recreate the archive, and allows you to add support for new hardware that requires new patches, or drivers without making a new archive.

Using make_net_recovery and make_tape_recovery

The make_tape_recovery and make_net_recovery tools are designed to reproduce a system exactly the way it was at the time the snapshot was taken. These tools try to accommodate for cloning in various ways:

- You can change hostname/networking information.
- You can make changes to disks and file systems during the recovery.

- Detect hardware model changes and rebuild the kernel.

However, their attempt to reproduce a system exactly may be undesirable:

- The disk layout is saved "as-is" from the original system and does not have flexible logic to accommodate disks of varying sizes or locations.
- Hardware instance numbers for devices that exist at the same paths between systems have the instance numbers preserved from the original system. This can cause non-contiguous assignments in instance numbers. Which is usually only a cosmetic problem.
- Many files that are specific to the system the recovery image was taken from, are preserved. This includes many log files, etc.
- When the kernel is rebuilt (in the "cloning" situation), drivers may be added as needed by the hardware, but unused drivers will not be removed.

The next section shows how to clone a system using make_net_recovery. System cloning using make_tape_recovery begins on page 169.

Cloning a System Using make_net_recovery

The recovery configurations and archives created by make_net_recovery are stored in a separate directory on the Ignite-UX server for each client. Using the configuration and archive created by make_net_recovery on one system to install a different system involves manually copying some configuration files, and allowing NFS access to the source system's archive. Follow these steps:

Step 1. Use make_net_recovery or Ignite-UX to create a system recovery archive of the source system.

Step 2. Login to the Ignite-UX server.

Step 3. If the target system to be installed does not currently have a directory in /var/opt/ignite/clients but is up and running, then use Ignite-UX to create that directory using **Actions –> Add New Client for Recovery**. If the system is not running, you will either need to boot the client from the Ignite-UX server (or from a tape made with make_boot_tape in order for this directory to be created.

Step 4. Copy the `CINDEX` and recovery directory from the source client to the target client directory. If the target client has previously used `make_net_recovery` then it will already have a `CINDEX` file. If the `CINDEX` file for the target system exists already, you may want to save a copy, and/or hand edit the file to add the desired entries from the source client. The commands below copy the required files. You may specify `src_client` and `target_client` using either the LAN addresses (such as 0x0060B04AAB30), or by using the client's hostname (which is a symlink to the LAN address):

```
cd /var/opt/ignite/clients/src_client
find CINDEX recovery | cpio -pdvma ../target_client
```

Step 5. Give the *target_client* NFS access to the archive of the source system. To do this, login to the server that holds the archive (normally the Ignite-UX server).

Typically each client has its own directory for storing the archives, and the directory is exported only to the individual client. In this case, you will need to edit the `/etc/exports` file to allow access to both the source and target clients:

1. Enter: **`vi /etc/exports`**

2. Append **`:target-client`** to the end of the source-client's line.

3. Enter: **`exportfs -av`**

Step 6. Boot the target-client from the Ignite-UX server (using any method you wish). Then when you install the system, you can select from the recovery configurations of the source system.

Step 7. Change the system networking parameters for the target system during the installation.

Expert Recovery Using the Core Media

If your system should become so compromised or corrupt that it will not boot at the login prompt, or the system boots, but critical files are corrupted, adversely affecting overall system performance, it may be useful to restore system elements with core recovery media.

Before you attempt to recover an HP-UX system, you should have the following information about your system disk available.

Much of this information, including file system types, can be obtained by accessing your on-line system manifest, either via Ignite-UX, or by reading the hardcopy that came with your system

- Revision of the HP-UX system which you are attempting to recover.

CAUTION Only attempt to recover HP-UX systems that match the version number of the recovery tools you are using, currently HP-UX 11.0. For example, you can use HP-UX 10.20 Core media to attempt to recover an HP-UX 10.20 file system.

- The hardware path of the root filesystem on the disk (that is, what file system you will be checking/repairing using `fsck`).
- The address of the bootlif path of that disk.
- What the autofile in the bootlif should contain.
- Whether you have an LVM, VXVM, or whole-disk system.

The more you know about the system disk and its partitioning scheme, *before you encounter major damage or corruption*, the easier it will be for you to recover.

The procedures which follow assume that both `fsck` and `mount` can be run successfully on the system disk; otherwise, the following procedures are not applicable.

6334 folha

Automated Recovery Procedures

There are four possible expert recovery situations, each of which has its associated recovery procedure:

- If, after a system problem, you can't get the system to the `ISL>` prompt from the system disk, you will want to rebuild the bootlif on the system disk, and install all critical files required to boot on the root filesystem.
- If you can get the system to the `ISL>` prompt, but cannot boot `vmunix`, the system disk is corrupted; you will want to install *only* the critical files required to boot on the root filesystem.
- If you can't get to the `ISL>` prompt, but you know that the root file system is good, you will want to rebuild the bootlif on the system disk.
- If you believe your kernel is corrupted, you will want to replace only the kernel on the root filesystem.

The following subsections describe these procedures in detail.

Rebuilding the bootlif and Installing Critical Files

Following is an example of the detailed procedure for rebuilding the bootlif of the system disk, and for installing all the critical files necessary to boot from the root filesystem:

Step 1. Have the Core OS CD for the appropriate HP-UX ready.

Step 2. Reset the System Processor Unit (SPU) using the reset button, or keyswitch, as appropriate.

The console displays boot path information. If Autoboot is enabled, the system console eventually displays messages similar to this:

```
Autoboot from primary path enabled
To override, press any key within 10 seconds.
```

Step 3. With older systems, press any key within 10 seconds. The system console displays:

```
Boot from primary boot path (Y or N)?>
```

Enter **n** at the prompt. The next prompt is:

```
Boot from alternate boot path (Y or N)?>
```

Step 4. If the alternate boot path specifies the address of the CD device where the Core CD is mounted, enter: **y**

If the alternate boot path does not specify the address of the CD device where the HP-UX Core media is mounted, enter **n** at the prompt. The next prompt is:

```
Enter boot Path or ?>
```

Step 5. Enter the address of the CD device where the HP-UX Core media is mounted. The next prompt is:

```
Interact with IPL (Y or N)>
```

Step 6. Enter **n** at the prompt.

After several minutes and several screens of status information, the this is displayed:

```
Welcome to the HP-UX installation/recovery process!
Use the <tab> and/or arrow keys to navigate through the
following menus,and use the <return> key to select an item. If
the menu items are not clear, select the "Help" item for more
information.

                    [    Install HP-UX        ]
                    [  Run a Recovery Shell   ]
                    [   Advanced Options      ]
                                 [ Help ]
```

Step 7. Select: **Run a Recovery Shell**. The next prompt is:

```
Would you like to start up networking at this time? [n]
```

Step 8. Unless you need networking to ftp to other systems, enter: **n**

```
* Loading in a shell...
* Loading in the recovery system commands...
             HP-UX SYSTEM RECOVERY CORE MEDIA
             WARNING:  YOU ARE SUPERUSER !!
NOTE: Commands residing in the RAM-based file system are unsupport
ed 'mini'commands. These commands are only intended for recovery p
urposes.

Loading commands needed for recovery!

Press <return> to continue.
```

Step 9. Press **Return** or **Enter**. The next prompt is:

```
Loading commands needed for recovery!
```

This menu is displayed:

```
HP-UX CORE MEDIA RECOVERY
   MAIN MENU
 s.  Search for a file
 b.  Reboot
 l.  Load a file
 r.  Recover an unbootable HP-UX system
 x.  Exit to shell

This menu is for listing and loading the tools contained
on the core media.  Once a tool is loaded, it may be run
from the shell. Some tools require other files
to be present in order to successfully execute.
Select one of the above:
```

Step 10. To load a file or files, enter `l` at the prompt.

```
Filesystem kbytes used avail %cap iused ifree iused Mounted on
/                 2011    1459 552  73%   137    343 29%   ?
/duped_root       2011    1418 593  71%    49    431 10%   ?
Enter the filename(s) to load:
```

Step 11. Enter the name(s) of the damaged/corrupted file(s) you wish to load. For example:

`sh vi date grep`

The following example lists two files (ex and egrep) which must be loaded before the files `vi` and `grep` can be loaded. It also lists a file (`date`) which is not in the load list.

```
NOTE :
  Since ./usr/bin/vi is linked to ./usr/bin/ex
  './usr/bin/ex' must precede './usr/bin/vi' in the load list.
The file 'date' is NOT in the LOADCMS archive.
<Press return to continue>
NOTE :
Since ./usr/bin/grep is linked to ./usr/bin/egrep
'./usr/bin/egrep' must precede './usr/bin/grep' in the loadlist.
********  THE REQUESTED FILE(S): ***********
./sbin/sh ./usr/bin/vi ./usr/bin/grep
Is the above load list correct? [n]
```

Step 12. This load list is incorrect, because `./usr/bin/ex` does not precede `./usr/bin/vi` in the list of requested files. So you would enter: **n**

```
Nothing will be loaded!
<Press return to return to Main Menu>
```

Step 13. Press **Enter** and the Main Menu appears. To search for a file you wish to load, select: **s**

```
Either enter the filename(s) to be searched for,
or 'all' for a total listing.
```

Step 14. Enter:

```
vi awk /sbin/sh date
```

You will receive this response:

```
./usr/bin/vi linked to ./usr/bin/ex
./sbin/awk
./usr/bin/awk
./sbin/sh
**** The file  'date' was not found in the LOADCMDS archive. ****
<Press return to continue>
```

Step 15. Press **Enter** to return to the Main Menu.

Step 16. To begin the actual system recovery and invoke the Recovery Menu, select: **r**

```
 HP-UX Recovery MENU
 Select one of the following:
a. Mount the root disk and exit to shell only.
b. Recover the bootlif/os partitions.
c. Replace the kernel on the root file system.
d. Both options b and c

v. Read information about VxVM/LVM recovery

m. Return to 'HP-UX Recovery Media Main Menu'.
x. Exit to the shell.
```

Step 17. To install both the bootlif and critical files, select: **a**

```
DEVICE FILE VERIFICATION MENU
This menu is used to specify the path of the root file sysem.
When the information is correct, select 'a'.

INFORMATION to verify:
       Device file used for '/'(ROOT) is c1t6d0
       The path to disk is 56/52.6.0
 Select one of the following:
  a.  The above information is correct.
  b.  WRONG!! The device file used for '/'(ROOT) is incorrect.
  m.  Return to the 'HP-UX Recovery MENU.'
  x.  Exit to the shell.
```

Step 18. Assuming the root device file is incorrect, select: **b**

```
Enter the device file associated with the '/'(ROOT)

file system. (example: c1t6d0):
```

On a system with hard-sectored disks, the prompt and response might look like this:

```
Enter the device file associated with the '/'(ROOT) file system
(example: c0t1d0s1lvm ) :  c0t0d0s13
/dev/rdsk/c0t0d0s13 not a special file
<Press return to continue>
Enter the address associated with the '/'(ROOT) file system
(example: 4.0.1) :  4.0.0
NOTE: if your '/'(ROOT) is not part of a sectioned disk layout
    enter a 'W' for whole disk layout
       or
    enter a 'l' for an LVM disk layout
  instead of a section number.
Enter the section associated with the '/'(ROOT) file system
(example: 13 ):  13
 making rdsk/c0t0d0s13 c 214 0x00000d
 making dsk/c0t0d0s13 b 26 0x00000d
```

Step 19. If you entered **c1t1d0** as the root device filename, you would see:

```
DEVICE FILE VERIFICATION MENU
This menu is used to specify the path of the root file
system When the information is correct, select 'a'.
INFORMATION to verify:
       Device file used for '/'(ROOT) is c1t1d0
       The path to disk is 56/52.1.0
 Select one of the following:
    a.  The above information is correct.
    b.  WRONG!! The device file used for '/'(ROOT) is incorrect.
    m.  Return to the 'HP-UX Recovery MENU.'
    x.  Exit to the shell.
```

Step 20. Since c1t1d0 is the correct root device filename, select: **a**

```
BOOTLIF PATH VERIFICATION MENU
This menu must be used to determine the path to the bootlif(ISL, H
PUX and the AUTO file).
When the information is correct, select 'a'.
INFORMATION to verify:
      Path to the bootlif is 56/52.1.0
Select one of the following:
      a.  The above information is correct.
      b.  WRONG!! The path to bootlif is incorrect.
      m.  Return to the 'HP-UX Recovery MENU.'
      x.  Exit to the shell.
     Selection:
```

Step 21. Assuming that the bootlif path is correct, enter: **a**

```
FILE SYSTEM CHECK MENU

The file system check'/sbin/fs/hfs/fsck -y /dev/rdsk/c1t10'
will now be run.
Select one of the following:
      a.  Run fsck -y .
      b.  Prompt for the fsck run string on c1t1d0.
      m.  Return to the 'HP-UX Recovery MENU.'
     Selection:
```

Step 22. Select **a** to run **`fsck -y`** to check your file system for corruption.

```
** /dev/rdsk/c1t1d0
** Last Mounted on /ROOT
** Phase 1 - Check Blocks and Sizes
** Phase 2 - Check Pathnames
** Phase 3 - Check Connectivity
** Phase 4 - Check Reference Counts
** Phase 5 - Check Cyl groups
6256 files, 0 icont, 149423 used,1563824 free(928 frags,195362 blo
cks)
Mounting c1t1d0 to the HP-UX Recovery Media /ROOT directory...
<Press return to continue>
```

Step 23. Assuming your file system is not corrupted, and you wish to continue with the system recovery, press **Return** to mount your root file system under the / directory. You'll see messages like this:

```
   ***** Downloading files to the target disk *****
x ./sbin/lvchange, 528384 bytes, 1032 tape blocks
./sbin/lvcreate linked to ./sbin/lvchange
./sbin/lvdisplay linked to ./sbin/lvchange

Filesystem kbytes used avail %cap iused ifree iused Mounted on
/ROOT    1713247  149426 1392496  10%  6261 275339  2%   ?

Should the existing kernel be
'left', 'overwritten', or 'moved'?[overwritten]
```

Step 24. To overwrite the existing kernel with your new file system, enter **`overwritten`** or **over** at the prompt.

```
 downloading INSTALL to /stand/vmunix
    **** Creating device files on the target disk ****
    ******* Renaming the following files: *******
     '/.profile' has been renamed '/.profileBK'
      *********** Installing bootlif  ***********
mkboot -b /dev/rmt/1m  -i ISL -i HPUX /dev/rdsk/c1t1d0
mkboot -a  hpux (56/52.1.0;0)/stand/vmunix /dev/rdsk/c1t1d0
```

Step 25. Complete the recovery process by selecting: **a**

```
NOTE:    System rebooting ...
-
PDC - Processor Dependent Code - Version   1.3

SErvice menu            Displays service commands
MFG menu                Displays manufacturing commands

DIsplay                 Redisplay the current menu
HElp [&<menu>|&<command>] Display help for menu or command
RESET                   Restart the system
-
Main Menu: Enter command or menu item.
```

Step 26. Enter **bo pri** at the prompt to boot from the primary boot path. The next prompt is:

```
Interact with IPL (Y or N)?>
```

Step 27. Enter **n** for unattended boot. Several screens of status information are displayed, followed by this warning:

```
THIS SYSTEM HAS BEEN BOOTED USING A TEMPORARY KERNEL!
DO NOT ATTEMPT TO INVOKE MULTI-USER RUN-LEVEL USING THIS KERNEL!
Type the following command from the shell prompt for more
information about completing the recovery process:

cat /RECOVERY.DOC
```

Step 28. To obtain more information on the recovery process, enter:

```
cat /RECOVERY.DOC
```

```
1) Restore valid copies of the following files (either from backup
 or
   from the filename.BK files created during the recovery process)
.
   /etc/fstab,        /etc/inittab,  /stand/ioconfig,
   /etc/ioconfig,      /etc/passwd,  /sbin/pre_init_rc,
   /.profile,   and /etc/profile
  NOTE:  The backup archive may be extracted using '/sbin/frecover
' or'/sbin/pax' (for backups made with 'tar' or 'cpio').
If using '/sbin/pax', linking it to 'tar' or 'cpio' will
force'pax' to emulate the respective command line interface.
2) Replace /stand/vmunix from backup, since the present kernelis p
robably missing desired drivers.
3) If you have an lvm root, refer to the /LVM.RECOVER text file.
```

Step 29. If you have an LVM system, and want more information on recovery procedures, enter:

```
cat /LVM.RECOVER
```

Follow the displayed instructions shown below.

NOTE If a card has been added to, or removed from, your system since the original installation was completed, there is a chance that the device file for the root disk has changed. Consequently, before you run the LVM script *./lvmrec.scrpt* (Step 2 in the displayed instructions below), you should first recover */stand/ioconfig* from backup, and reboot.

```
INSTRUCTIONS to complete your LVM recovery:
The system must now be up now in "maintenance mode".
NOTE: In order for the following steps to lead to a successful
      lvm recovery the LVM label information must be valid.
      If the bootlif was updated from the RAM-based recovery syste
m,
      then "mkboot -l" has already been run to repair this label.
step 1. If the autofile was altered to force the system to boot in
 maintenance mode, use "mkboot -a" to remove the "-lm" option.
 Example:
    to change  "hpux -lm (52.6.0;0)/stand/vmunix"
    to   "hpux   (52.6.0;0)/stand/vmunix"
    use
   mkboot -a  "hpux (52.6.0;0)/stand/vmunix"  /dev/rdsk/<device fi
le>
```

(Use `lssf /dev/rdsk/*` to match the device file with the boot address.)

```
step 2. Run '/lvmrec.scrpt' to repair the following LVM
 configuration information:
        a. LVM records (lvmrec)
        b. BDRA (Boot Data Reserve Area)
        c. LABEL information
 Requirement:  The following files must reside on disk before
        the script can complete:
        a. /etc/lvmtab
        b. /etc/fstab
        c. /etc/lvmconf/<rootvg>.conf
        d. all device files specified in /etc/fstab
 To run '/lvmrec.scrpt' provide the device filename used to
 access the bootlif as an argument to the script.
 Example:
  /lvmrec.scrpt c0t6d0
  In this example 'c0t6d0' is the device file used to
  access the bootlif.
step 3. Once '/lvmrec.scrpt' completes, issue the command "reboot"
 and bringthe system fully up.
 The recovery of the root LVM is complete.  If the'/lvmrec.scrpt'
issued the following warning:
  "************* I M P O R T A N T *****************          "Root
 logical volume has been repaired, but......."
  "you need to reboot the system and repair the Swap"
  "logical volume using the following LVM command:  "
  "   lvlnboot -A n -s /dev/<root lv>/<swap lvol>   "
  "because Recovery has no way to find out what is  "
  "the Swap logical volume information at this point"
  "*************************************************"

The Swap and Dump logical volumes will need to be re-configured
The BDRA contains the "root", "swap" and "dump" logical volumeinfo
rmation. '/lvmrec.scrpt' only fixes the root logical volume
information in the BDRA.The "swap" and "dump" areas can be updated
via the "lvlnboot" command.

 Example:
    lvlnboot -s /dev/<vg00>/lvol2
    lvlnboot -d /dev/<vg00>/lvol3
 In this example 'lvol2' and 'lvol3' are the "swap" and "dump"
  logical volumes respectively.

step 4. Perform any further data recovery deemed necessary.
```

```
*** NOTE ***
If the same volume group contains more than one corrupted bootdisk
, Repeat the above steps for each disk that needs to be repaired.
```

This completes the process for rebuilding the bootlif and installing critical files.

Installing Critical Root Files Only

Following is an example of the detailed procedure for installing all the critical files necessary to boot on the target root file system:

Boot the Core media, following the steps in Chapter 2. You will see some status messages, and then a menu:

```
Welcome to the HP-UX installation process!
Use the <tab> and/or arrow keys to navigate through the following
menus,and use the <return> key to select an item.  If the menu ite
ms are not clear, select the "Help" item for more information.

                     [    Install HP-UX       ]
                     [  Run a Recovery Shell  ]
                     [   Advanced Options     ]
                                   [ Help ]
```

Step 1. Select **Run a Recovery Shell**, the screen clears, and the following question appears:

```
Would you like to start up networking at this time? [n]
```

Step 2. If you have no need to access the net, enter: **n**

```
* Loading in a shell...
* Loading in the recovery system commands...

                         HP-UX SYSTEM RECOVERY CORE MEDIA
                         WARNING:  YOU ARE SUPERUSER !!
NOTE: Commands residing in the RAM-based file system are unsupport
ed 'mini' commands. These commands are only intended for
recovery purposes.
Loading commands needed for recovery!
WARNING: If ANYTHING is changed on a root (/) that is mirrored,
'maintenance mode' (HPUX -1m) boot MUST be done in order to force
the mirrored disk to be updated!

Press <return> to continue.
```

Step 3. Press: **Return**

```
Loading commands needed for recovery!

Then the following menu will be displayed:
```

6342 Paula

```
HP-UX CORE MEDIA RECOVERY
   MAIN MENU
 s.  Search for a file
 b.  Reboot
 l.  Load a file
 r.  Recover an unbootable HP-UX system
 x.  Exit to shell
 c.  Instructions on chrooting to a lvm /(root).
This menu is for listing and loading the tools contained
on the core media.  Once a tool is loaded, it may be run
from the shell. Some tools require other files to be preset
in order to successfully execute.
Select one of the above:
```

Step 4. To begin the actual system recovery, select **r** to see the HP-UX Recovery Menu:

```
 HP-UX Recovery MENU
 Select one of the following:
a. Mount the root disk and exit to shell only.
b. Recover the bootlif/os partitions.
c. Replace the kernel on the root file system.
d. Both options b and c

v. Read information about VxVM/LVM recovery

m. Return to 'HP-UX Recovery Media Main Menu'.
x. Exit to the shell.
```

Step 5. To install critical files only, select: **b**

```
DEVICE FILE VERIFICATION MENU
   This menu is used to specify the path of the root file system.
   When the information is correct, select 'a'.
 INFORMATION to verify:
       Device file used for '/'(ROOT) is c1t6d0
       The path to disk is 56/52.6.0
 Select one of the following:
       a.  The above information is correct.
       b.  WRONG!! The device file used for '/'(ROOT) is incorrect
       m.  Return to the 'HP-UX Recovery MENU.'
       x.  Exit to the shell.
```

Step 6. Assuming the root device file is incorrect, select **b**; you will be prompted to enter the correct device filename:

```
 Enter the device file associated with the '/'(ROOT) file system
 (example: c1t6d0):
```

On a system with hard-sectored disks, the prompt and response might look like this:

```
Enter the device file associated with the '/'(ROOT) file system
(example: c0t1d0s1lvm ) :  c0t0d0s13
/dev/rdsk/c0t0d0s13 not a special file
<Press return to continue>
Enter the address associated with the '/'(ROOT) file system
(example: 4.0.1) :  4.0.0
   NOTE: if your '/'(ROOT) is not part of a sectioned disk layout
    enter a 'W' for whole disk layout
       or
    enter a 'l' for an LVM disk layout
  instead of a section number.
 Enter the section associated with the '/'(ROOT) file system
 (example: 13 ):  13
 making rdsk/c0t0d0s13 c 214 0x00000d
 making dsk/c0t0d0s13 b 26 0x00000d
```

Step 7. If you were to enter, for example, **c1t1d0** as the root device filename, you would see this:

```
DEVICE FILE VERIFICATION MENU
   This menu is used to specify the path of the root file system.
   When the information is correct, select 'a'.
 INFORMATION to verify:
       Device file used for '/'(ROOT) is c1t1d0
       The path to disk is 56/52.1.0
 Select one of the following:
       a.  The above information is correct.
       b.  WRONG!! The device file used for '/'(ROOT) is incorrect
       m.  Return to the 'HP-UX Recovery MENU.'
       x.  Exit to the shell.
```

Step 8. Since c1t1d0 is the correct root device filename, select: **a**

```
FILE SYSTEM CHECK MENU
   The file system check '/sbin/fs/hfs/fsck -y /dev/rdsk/c1t1d0'
   will now be run.
 Select one of the following:
      a.  Run fsck -y .
      b.  Prompt for the fsck run string on c1t1d0.
       m.  Return to the 'HP-UX Recovery MENU.'
```

6340
Paula

Step 9. Select **a** to run **`fsck -y`** to check your file system for corruption.

```
** /dev/rdsk/c1t1d0
** Last Mounted on /ROOT
** Phase 1 - Check Blocks and Sizes
** Phase 2 - Check Pathnames
** Phase 3 - Check Connectivity
** Phase 4 - Check Reference Counts
** Phase 5 - Check Cyl groups
6256 files, 0 icont, 149423 used, 1563824 free (928 frags, 195362
blocks)
Mounting c1t1d0 to the CORE media /ROOT directory...
<Press return to continue>
```

Step 10. Assuming your file system is not corrupted, and you wish to continue with the system recovery, press **Return** to mount your root file system under the Core media / directory.

```
   ***** Downloading files to the target disk *****
x ./sbin/lvchange, 528384 bytes, 1032 tape blocks
./sbin/lvcreate linked to ./sbin/lvchange
./sbin/lvdisplay linked to ./sbin/lvchange
./sbin/lvextend linked to ./sbin/lvchange

Should the existing kernel be
'left', 'overwritten', or 'moved'?[overwritten]
```

Step 11. To overwrite the existing kernel with your new file system, enter **`overwritten`** or **`over`** at the prompt.

```
 downloading INSTALL to /stand/vmunix
    **** Creating device files on the target disk ****
    ******* Renaming the following files: *******
     '/.profile' has been renamed '/.profileBK'
    RECOVERY COMPLETION
    MENU
     Use this menu after the recovery process has installed all re
quested
     files on your system.
 Select one of the following:
      a.  REBOOT the target system and continue with recovery.
       b.  Return to the CORE Media Main Menu.
```

Step 12. Complete the recovery process by selecting: **a**

```
NOTE:    System rebooting...
   PDC - Processor Dependent Code - Version   1.3
   (c) Copyright 1990-1993, Hewlett-Packard Company,
        All rights reserved
    16 MB of memory configured and tested.
    Primary boot path:      56/52.5    (dec)
    Alternate boot path:    56/52.3    (dec)
Manufacturing permissions ON
- Main Menu -
        Command                        Description
        -                      -
        BOot  [PRI|ALT|<path>]       Boot from specified path
        PAth  [PRI|ALT]  [<path>]      Display or modify a path
        SEArch [DIsplay|IPL]  [<path>] Search for boot devices

        COnfiguration menu          Displays or sets boot values
        INformation menu            Displays hardware information
        SERvice menu                Displays service commands
        MFG menu                    Displays manufacturing commands
        DIsplay                     Redisplay the current menu
        HElp [<menu>|<command>]     Display help for menu or command
        RESET                           Restart the system
- Main Menu: Enter command or menu >
```

Step 13. Enter **bo pri** at the prompt to boot from the primary boot path.

```
Interact with IPL (Y or N)?>
```

Step 14. Enter **n** for unattended boot; several screens of status information will be displayed, followed by this warning:

```
THIS SYSTEM HAS BEEN BOOTED USING A TEMPORARY KERNEL!
DO NOT ATTEMPT TO INVOKE MULTI-USER RUN-LEVEL USING THIS KERNEL!
Type the following command from the shell prompt for more informat
ion
about completing the recovery process:
cat /RECOVERY.DOC
```

Step 15. To obtain more information on the recovery process, enter:

cat /RECOVERY.DOC

```
1) Restore valid copies of the following files (either from backup
 or
   from the <filename>BK files created during the recovery process
).
   /etc/fstab,       /etc/inittab,  /stand/ioconfig,
   /etc/ioconfig,     /etc/passwd,  /sbin/pre_init_rc,
   /.profile,    and /etc/profile
  NOTE:  The backup archive may be extracted using '/sbin/frecover
' or
   '/sbin/pax' (for backups made with 'tar' or 'cpio').
 If using '/sbin/pax', linking it to 'tar' or 'cpio' will force 'p
ax'
```

6338 Paula

```
    to emulate the respective command line interface.
2) Replace /stand/vmunix from backup, since the present kernel is
probably missing desired drivers.
3) If you have an lvm root, refer to /LVM.RECOVER .
```

Step 16. If you have an LVM system, and want more information on recovery procedures, enter:

`cat /LVM.RECOVER`

The file contains the following information:

```
If a card has been added to, or removed from, your system
since the original installation was completed,
there is a chance that the device file for the root disk has chang
ed.
Consequently, before you run the LVM script ./lvmrec.scrpt
(Step 2, below), you should first recover /stand/ioconfig
from backup and reboot.
INSTRUCTIONS to complete your LVM recovery:
The system must now be up now in "maintenance mode".
NOTE: In order for the following steps to lead to a
successful lvm recovery the LVM label information must be valid.
If the bootlif was updated from the RAM-based recovery system,
then "mkboot -l" has already been run to repair this label.

step 1. If the autofile was altered to force the system to boot in
 maintenance mode, use "mkboot -a" to remove the "-lm" option.
 Example:
    to change  "hpux -lm (52.6.0;0)/stand/vmunix"
    to   "hpux   (52.6.0;0)/stand/vmunix"
    use
   mkboot -a "hpux (52.6.0;0)/stand/vmunix"/dev/rdsk/<device file>
```

NOTE To match device file with boot address, use: **`lssf /dev/rdsk/*`**

```
step 2. Run '/lvmrec.scrpt' to repair the following LVM
 configuration information:
        a. LVM records (lvmrec)
        b. BDRA (Boot Data Reserve Area)
        c. LABEL information

 Requirement:  The following files must reside on disk before
        the script can complete:
        a. /etc/lvmtab
        b. /etc/fstab
        c. /etc/lvmconf/<rootvg>.conf
        d. all device files specified in /etc/fstab
 To run '/lvmrec.scrpt' provide the device filename used to
 access the bootlif as an argument to the script.
 Example:
  /lvmrec.scrpt c0t6d0
  In this example 'c0t6d0' is the device file used to
  access the bootlif.
step 3. Once '/lvmrec.scrpt' completes, issue the command "reboot"
 and bring the system fully up.
 The recovery of the root LVM is complete.  If the '/lvmrec.scrpt'
 issued the following warning:
              "************ I M P O R T A N T ******************"
              "                                                 "
              "Root logical volume has been repaired, but......."
              "you need to reboot the system and repair the Swap"
              "logical volume using the following LVM command:  "
              "   lvlnboot -A n -s /dev/<root lv>/<swap lvol>   "
              "because Recovery has no way to find out what is  "
              "the Swap logical volume information at this point"
              "                                                 "
"*******************************************************"

 The Swap and Dump logical volumes will need to be re-configured.

 The BDRA contains the "root", "swap" and "dump" logical volume
 information.  '/lvmrec.scrpt' only fixes the root logical volume
 information in the BDRA.  The "swap" and "dump" areas can be upda
ted
 via the "lvlnboot" command.

 Example:
    lvlnboot -s /dev/<vg00>/lvol2
    lvlnboot -d /dev/<vg00>/lvol3

  In this example 'lvol2' and 'lvol3' are the "swap" and "dump"
  logical volumes respectively.

step 4. Perform any further data recovery deemed necessary.

*** NOTE ***
  If the same volume group contains more than one corrupted boot d
isk,
  repeat the above steps for each disk that needs to be repaired.
```

This completes the process for installing critical files only.

6336 Paula

Rebuilding the "bootlif" Only

Boot the Core media, following the steps in Chapter 2. You will see some status messages, and then a menu:

```
Welcome to the HP-UX installation process!

    Use the <tab> and/or arrow keys to navigate through the follow
ing menus,
    and use the <return> key to select an item.  If the menu items
 are not
    clear, select the "Help" item for more information.

                          [    Install HP-UX       ]
                          [  Run a Recovery Shell  ]
                          [   Advanced Options     ]
                                  [ Help ]
```

Step 1. Select: **Run a Recovery Shell** . The screen clears, and this is displayed:

```
Would you like to start up networking at this time? [n]
```

Step 2. Enter: **n**

```
* Loading in a shell...
* Loading in the recovery system commands...

                  HP-UX SYSTEM RECOVERY CORE MEDIA
                    WARNING:  YOU ARE SUPERUSER !!

NOTE: Commands residing in the RAM-based file system are unsupport
ed 'mini'commands.

These commands are only intended for recovery purposes.

Loading commands needed for recovery!

      WARNING: f ANYTHING is changed on a root(/) that is mirrored
               a 'maintenance mode'(HPUX -lm) boot MUST be done in
                order to force the mirrored disk to be updated!!

     Press <return> to continue.
```

Step 3. Press: **Return**

```
Loading commands needed for recovery!
```

After boot steps, this message appears:

```
 HP-UX CORE MEDIA RECOVERY
   MAIN MENU
 s.  Search for a file
 b.  Reboot
 l.  Load a file
 r.  Recover an unbootable HP-UX system
 x.  Exit to shell
 c.  Instructions on chrooting to a lvm /(root).
Select one of the above:
```

Step 4. To begin the actual system recovery, select: **r**

```
       HP-UX Recovery MENU
 Select one of the following:
a. Mount the root disk and exit to shell only.
b. Recover the bootlif/os partitions.
c. Both options b and c

v. Read information about VxVM/LVM recovery

m. Return to 'HP-UX Recovery Media Main Menu'.
x. Exit to the shell.
```

Step 5. Select **c** to rebuild the bootlif.

```
    BOOTLIF PATH VERIFICATION
       MENU

     This menu must be used to determine the path to the bootlif

 (ISL, HPUX and the AUTO file).
     When the information is correct, select 'a'.

 INFORMATION to verify:
      Path to the bootlif is 56/52.1.0

 Select one of the following:
      a.  The above information is correct.
      b.  WRONG!! The path to bootlif is incorrect.

      m.  Return to the 'HP-UX Recovery MENU.'
      x.  Exit to the shell.

     Selection:
```

6334 Paula

Step 6.

```
BOOT STRING VERIFICATION MENU

        This menu must be used to verify the system's boot string.
        When the information is correct, select 'a'.

    INFORMATION to verify:
         The system's boot string should be:
          'hpux -lm (56/52.5.0)/stand/vmunix'

    Select one of the following:

        a.  The above information is correct.
         b.  WRONG!! Prompt the user for the system's boot string.

         m.  Return to the 'HP-UX Recovery MENU.'
         x.  Exit to the shell.

    NOTE: For an LVM '/'(ROOT) the '-lm' option MUST be specified
   (example: 'hpux -lm (2.3.4)/stand/vmunix' )

    Selection:
```

Assuming that the bootlif path is correct, enter: **a**

Step 7. Assuming the boot string is incorrect, enter **b** at the prompt. You will see a message similar to the following:

```
AUTO FILE should be (replacing 'hpux (56/52.5.0)/stand/vmunix'):
```

Step 8. Enter the correct information (for example, **hpux**); you will then see the BOOT STRING VERIFICATION MENU displayed again:

```
BOOT STRING VERIFICATION MENU

        This menu must be used to verify the system s boot string.
        When the information is correct, select 'a'.

    INFORMATION to verify:
         The system's boot string should be:
          'hpux'

    Select one of the following:
         a.  The above information is correct.
         b.  WRONG!! Prompt the user for the system's boot string.

         m.  Return to the 'HP-UX Recovery MENU.'
         x.  Exit to the shell.

    NOTE: For an LVM '/'(ROOT) the '-lm' option MUST be specified
```

```
        (example: 'hpux -lm (2.3.4)/stand/vmunix' )

  Selection:
```

NOTE

Use the `-lm` option to enter LVM administration mode only when recovering an LVM system.

Use the `-V` option to enter VxVM administration mode only when recovering a VxVM system.

Step 9. Assuming the information is now correct, enter: **a**

- For an LVM system, you will see something like the following:

```
      *********** Installing bootlif  ***********
mkboot -b /dev/rmt/1m  -i ISL -i HPUX /dev/rdsk/c1t1d0
mkboot -a  hpux (56/52.5.0;0)/stand/vmunix /dev/rdsk/c1t1d0
```

```
    RECOVERY COMPLETION MENU
     Use this menu after the recovery process has installed all
requested files on your system.
    Select one of the following:
      a.  REBOOT the target system and continue with recovery.
      b.  Return to the CORWE Media Main Menu.
     Selection:
```

Step 10. Complete the recovery process by selecting a, rebooting your system.

This completes the process for rebuilding the bootlif only.

6332 Paula

Replacing the Kernel Only

Boot the Core media, following the steps in Chapter 2. This menu appears after some status messages:

```
                Welcome to the HP-UX installation process!

    Use the <tab> and/or arrow keys to navigate through the follow
ing menus,and use the <return> key to select an item.  If the menu
 items are not clear, select the "Help" item for more information.

                          [    Install HP-UX       ]
                          [  Run a Recovery Shell  ]
                          [   Advanced Options     ]
                                  [ Help ]
```

Step 1. Click: **Run a Recovery Shell**

```
Would you like to start up networking at this time? [n]
```

Step 2. Enter: **n**

```
* Loading in a shell...
* Loading in the recovery system commands...

HP-UX SYSTEM RECOVERY CORE MEDIA
WWARNING:  YOU ARE SUPERUSER !!

NOTE: Commands residing in the RAM-based file system are
unsupported 'mini' commands. These commands are only intended for
recovery purposes.

Loading commands needed for recovery!

      WARNING:If ANYTHING is changed on a root(/) that is mirrored
               a 'maintenance mode'(HPUX -lm) boot MUST be done in
                order to force the mirrored disk to be updated!!

     Press <return> to continue.
```

Step 3. Press **Return** and the following status message is displayed:

```
Loading commands needed for recovery!
```

Step 4. You will see the following menu:

```
HP-UX CORE MEDIA RECOVERY
   MAIN MENU
 s.  Search for a file
 b.  Reboot
 l.  Load a file
 r.  Recover an unbootable HP-UX system
 x.  Exit to shell
 c.  Instructions on chrooting to a lvm /(root).
This menu is for listing and loading the tools contained
on the CORE media.  Once a tool is loaded, it may be run
from the shell. Some tools require other files to be present
in order to successfully execute.
Select one of the above:
```

Step 5. To begin the actual system recovery, select: **r**

```
 HP-UX Recovery MENU
 Select one of the following:
a. Mount the root disk and exit to shell only.
b. Recover the bootlif/os partitions.
c. Replace the kernel on the root file system.
d. Both options b and c

v. Read information about VxVM/LVM recovery

m. Return to 'HP-UX Recovery Media Main Menu'.
x. Exit to the shell.
```

Step 6. Select **d** to replace only the kernel on the root file system.

```
DEVICE FILE VERIFICATION MENU
   This menu is used to specify the path of the root file system.
   When the information is correct, select 'a'.
 INFORMATION to verify:
       Device file used for '/'(ROOT) is c1t6d0
       The path to disk is 56/52.6.0
 Select one of the following:
      a.  The above information is correct.
      b.  WRONG!! The device file used for '/'(ROOT) is incorrect.
      m.  Return to the 'HP-UX Recovery MENU.'
      x.  Exit to the shell.
```

Step 7. Assuming the root device file is incorrect, select: **b**

```
 Enter the device file associated with the '/'(ROOT) file system
 (example: c1t6d0):
```

On a system with hard-sectored disks, the prompt and response might look like this:

6330 Paula

```
Enter the device file associated with the '/'(ROOT) file system
(For example: c0t1d0s1lvm ) :  device_file
/dev/rdsk/device_file not a special file
<Press return to continue>
Enter the address associated with the '/'(ROOT) file system
(For example: 4.0.1) :  address
  NOTE: if your '/'(ROOT) is not part of a sectioned disk layout
   enter a 'W' for whole disk layout
      or
   enter a 'l' for an LVM disk layout
 instead of a section number.
Enter the section associated with the '/'(ROOT) file system
(For example: 13 ):  13
making rdsk/c0t0d0s13 c 214 0x00000d
making dsk/c0t0d0s13 b 26 0x00000d
```

Step 8. If you were to enter **c1t1d0** as the root device filename.:

```
DEVICE FILE VERIFICATION MENU
  This menu is used to specify the path of the root file system.
  When the information is correct, select 'a'.
INFORMATION to verify:
      Device file used for '/'(ROOT) is c1t1d0
      The path to disk is 56/52.1.0
Select one of the following:
    a.  The above information is correct.
     b.  WRONG!! The device file used for '/'(ROOT) is incorrect.
     m.  Return to the 'HP-UX Recovery MENU.'
     x.  Exit to the shell.
```

Step 9. Since c1t1d0 is the correct root device filename, select: **a**

```
    FILE SYSTEM CHECK MENU
  The file system check '/sbin/fs/hfs/fsck -y /dev/rdsk/c1t1d0'
  will now be run.
Select one of the following:
     a.  Run fsck -y .
     b.  Prompt for the fsck run string on c1t1d0.
     m.  Return to the 'HP-UX Recovery MENU.'
    Selection:
```

M

Step 10. Select **a** to run **fsck -y** to check your file system for corruption; you will see a display similar to the following:

```
** /dev/rdsk/c1t1d0
** Last Mounted on /ROOT
** Phase 1 - Check Blocks and Sizes
** Phase 2 - Check Pathnames
** Phase 3 - Check Connectivity
** Phase 4 - Check Reference Counts
** Phase 5 - Check Cyl groups
6256 files, 0 icont, 149423 used, 1563824 free (928 frags, 195362
blocks)
Mounting c1t1d0 to the CORE media /ROOT directory...
Filesystem      kbytes     used     avail %cap iused  ifree iused Mou
nted on
/ROOT                434773  352461   38834  90% 15241   54647 22%
  ?
Should the existing kernel be
'left', 'overwritten', or 'moved'?[moved]over
```

Step 11. To move the existing kernel with your new file system, enter **move** at the prompt.

Step 12. Complete the recovery process by selecting **a**, REBOOT the target system.

This completes the process for replacing the kernel only.

System Recovery Questions and Answers

Question: **Can I use a network recovery archive if my system is not network bootable or is not on the same subnet as the Ignite-UX server?**

Yes! One of the new tools developed with the network recovery toolset is `make_boot_tape`, a command that creates a minimal tape that can be used by any client. The tape contains just enough information to boot a client and then connect to the Ignite-UX server where the tape was created. If that is the server where the client's recovery configuration files are stored, the client can then be recovered.

If you initiate recovery archive creation from the Ignite-UX server, the server will warn you if a boot tape is needed for a client. If you ignore this warning, misplace your boot tape, or find that your tape is for the wrong Ignite-UX server, you can always create a new boot tape on the server that you want to use. There is no client-specific information on the tape.

Notice that a tape created by `make_boot_tape` is useful not only for recovery situations, but also for ordinary installations. If you do not want to set up a boot helper for systems not on the same subnet as the Ignite-UX server, you can now simply use `make_boot_tape`.

Question: **What happens if I make changes to a recovery configuration before clicking Go! ?**

In the past, Ignite-UX could not be used to override values in recovery configuration files. Any change made to a recovery configuration from one of the interface screens would result in recovery_mode being turned off, that is, set to false.

This was because Ignite carefully set aside the archive versions of files like */etc/fstab, /etc/mnttab*, and */etc/hosts* when it was running in recovery mode, and restored them after system configuration was complete. If Ignite-UX allowed the user to make changes to file systems, networking, etc. and continue in recovery mode, the files restored from the archive would be out of sync with the reconfigured system.

Beginning with the Ignite-UX A/B 2.0 releases, you can edit values in any of the interface screens without turning off recovery mode. This is possible because critical system files are no longer automatically overlaid by ones from the archive.

Recall that the */etc/fstab* file that Ignite-UX created while configuring the disks was saved to a backup copy prior to extracting the archive. After Ignite-UX boots from the client disk, this fstab is merged with the fstab file extracted from the recovery archive. This merging allows Ignite-UX to preserve information from the old fstab, like entries for file systems not included in the archive, NFS mounts, etc., while accurately representing the configuration changes requested.

Special care needs to be taken when making changes affecting disks not included in the archive. Imagine that you include `vg00` and `vg01` in your recovery archive but not `vg02`. You intend to leave vg02 untouched and simply let Ignite-UX import it for you.

You have also been planning on adding a new disk to the root volume group, and you decide that this is as good a time as any to do it. You choose your recovery configuration from the list and then go to the **Add/Remove Disks** dialogue, where you choose a disk to add. By mistake you choose a disk already in `vg02` instead of your new disk. When your system comes back up, `vg00` and `vg01` are fine, but `vg02` is corrupted.

To avoid scenarios like this, Ignite-UX now "hides" disks intended to be imported again. If you want to see these disks, click the **Additional...** button on the **Basic** tab and change the setting there to show the disks.

Question: **What happens if the pre-install checks fail after I make changes to a recovery configuration?**

In the past if the results of the pre-install checks included one or more ERRORS, Ignite-UX would have to turn off `recovery_mode` to allow users to interact with the user interface and resolve the errors. Unfortunately after the errors were resolved, it was not possible to turn `recovery_mode` back on for the reasons described above.

This created some frustrating situations for users. Imagine that the root disk on a system before it crashes is a 1GB disk with a whole disk layout (not LVM). The only replacement disk available is a 4GB disk. The system administrator therefore uses the 4GB disk, selects the recovery configuration or the system, and gets the following error message from the pre-install checks:

```
ERROR: The selected root disk is too large to use whole-disk
(non-LVM) partitioning. You must either switch to a smaller
root disk, or switch to using LVM to partition the root disk.
```

An experienced Ignite-UX user could do a little handcrafting to configuration files to work around the problem, but a novice user would be stuck.

With the new changes to Ignite-UX, it is no longer necessary to turn `recovery_mode` off when the pre-install checks fail. Now you can simply resolve the problem using the interface and continue running in recovery mode.

Question: **How can I change my setup so that a network recovery archive is available not only on the system for which it was created, but also on other systems with very similar hardware?**

Because networking information can now be changed using the interface and will not be overwritten by files extracted from the archive, it is natural to think about sharing recovery archives for systems with identical or nearly identical hardware. But unlike "global" configurations that appear in the configuration list of all clients, network recovery configurations only appear in the configuration list of the client for which they were created.

The source for shared cfgs is the */var/opt/ignite/INDEX* file that is shipped with Ignite-UX, and the source for client-specific cfgs is the CINDEX file that is created by `make_net_recovery` in the */var/opt/ignite/clients/LLA* directory. One simple way to share a recovery configuration among two systems with similar hardware is to copy the `CINDEX` file and the recovery directory of the client with the archive, to the directory of the client without the archive. The fact that the entries in `CINDEX` use relative paths means that you do not have to change the `CINDEX` file when you copy it. (You may need to export the directory containing the archive to the sharing client.)

Question: **I do not want to interact with the user interface after I reboot the client. How can I have my latest network recovery archive chosen automatically?**

As long as the client is currently booted, use **bootsys -a** to start the install process on the client without the need to interact with the user interface.

Ignite-UX chooses a configuration to use based on these guidelines:

- If */var/opt/ignite/clients/LLA/config* exists, use the cfg specified there.
- If */var/opt/ignite/clients/LLA/config* does not exist, use the default cfg for the client.

The default cfg for the client is the last cfg entry set to true in the CINDEX file if it exists. Otherwise the default cfg is the last cfg set to true in the INDEX file. Because make_net_recovery sets the most recently created recovery cfg to true in CINDEX whenever it creates a new archive, it will be the default unless it is manually changed.

Start Task

To have Ignite-UX choose the latest network recovery archive automatically:

1. Rename or remove the config file currently in the client's directory.
2. Run this from the Ignite-UX server:

```
bootsys -a client
```

Question: **Why does ioscan core dump when running make_tape_recovery or make_net_recovery?**

It is possible for ioscan to core dump due to the value set for the COLUMNS environment variable in versions prior to HP-UX 11i. When the -n option is used ioscan uses the COLUMNS variable to determine how wide the screen is when formatting the names of device files. If a core dump occurs, you will see messages similar to these:

```
sh: 13061 Floating exception(coredump)
WARNING: pclose of ioscan returned: 34816
```

6324

Should this happen, unset COLUMNS then rerun make_tape_recovery or make_net_recovery. If you are using an xterm, hpterm, or dtterm to run make_tape_recovery or make_net_recovery, do not resize the terminal window to a smaller size instead minimize it if is in the way.

Question:

Can I run make_net_recovery from a PA server to create an archive for an IPF client or vice versa?

Yes, this is possible though additional steps must be taken. Although the B.4.0 or later versions of Ignite-UX can be installed on both IPF and PA systems, make_net_recovery command cannot automatically swpackage the network recovery tools into /var/opt/ignite/depots/recovery_cmds depot for a client with mismatched hardware architecture.

For example, a server is an IPF system with the B.4.0 version of Ignite-UX installed and is being used for PA clients. When make_net_recovery is run from the GUI to create a recovery archive of a particular PA client, an error similar to this appears:

```
Error Message: Swinstall(1M) failed to install recovery tools from
: "funhouse: /var/opt/ignite/depots/recovery_cmds"
```

To work around this issue, you have to execute the following steps manually:

1. Run /opt/ignite/lbin/pkg_rec_depot command to generate the IUX-Recovery bundle in /var/opt/ignite/depots/recovery_cmds on the IPF server:

   ```
   /opt/ignite/lbin/pkg_rec_depot
   ```

2. Run swcopy the entire Ignite-UX product with the right architecture for the client.

   ```
   swcopy -x layout_version=0.8 -s /[depot path] B5725AA @ \
   /var/opt/ignite/depots/recovery_cmds
   ```

3. Ensure that the correct bundles are now in

   /var/opt/ignite/depots/recovery_cmds, by entering:

   ```
   swlist -l bundle -s /var/opt/ignite/depots/recovery_cmds
   ```

   Messages similar to the following should appear:

   ```
   # Initializing...
   ```

```
# Contacting target "funhouse"...
#
# Target:  funhouse:/var/opt/ignite/depots/recovery_cmds
#

B5725AA                 B.4.0.203      HP-UX Installation
Utilities    (Ignite-UX)

IUX-Recovery            B.4.0.203      Ignite-UX network
recovery tool subset

Ignite-IA-11-22         B.4.0.203      HP-UX Installation
Utilities for

Installing 11.22 IA Systems

Ignite-UX-10-20         B.4.0.203      HP-UX Installation
Utilities for

Installing 10.20  Systems

Ignite-UX-11-00         B.4.0.203      HP-UX Installation
Utilities for

Installing 11.00  Systems

Ignite-UX-11-11         B.4.0.203      HP-UX Installation
Utilities for

Installing 11.11  Systems
```

4. Re-launch Ignite-UX, enter:

   `ignite`

Now, you can create archives for different hardware architectures from this IPF server. The same steps can be used on PA servers to accomplish the same thing.

A Troubleshooting

Likely problem areas described in this appendix are:

- Errors and Warnings.
- Ignite-UX Server Problems.
- Installing Systems with Ignite-UX.
- Installing from Media.
- Installing from Archives (golden images).
- Running swinstall.
- Adjusting File System Size.
- Troubleshooting Large Systems.
- Media Recovery.
- Network Recovery.

This appendix includes troubleshooting hints from the Ignite-UX FAQ. For the latest on Ignite-UX problems and workarounds, see the Ignite-UX FAQ:

`http://www.software.hp.com/products/IUX/faq.html`

To receive the most-recent FAQ via email, send an empty message (no subject or content required) to:

`iux_faq@igniteux.fc.hp.com`

6320 Paula

Errors and Warnings

As an HP-UX install progresses, you will see messages relating to the progress being entered into the log file. Usually these messages are related to normal behavior. `ERROR` and `WARNING` messages have the following significance:

`ERROR` This indicates a serious problem, usually requiring action from the user in order to proceed with an installation.

`WARNING` This indicates something out of the ordinary, but *not* fatal. The warning *may* require action.

If you see a message, or experience unusual behavior, you can use the following sections as prioritized lists of likely problems and their solutions. They are grouped by the following topics, with the problems you are most likely to encounter near the beginning of each section.

Ignite-UX Server Problems

GUI core dumps

Ignite-UX GUI core dumps.

If your system has patch PHSS_12824 (Motif), remove it or install PHSS_13743. Patch PHSS_12824 was found to be bad.

Mixed versions of Ignite-UX

Can't find `/d_cfg_mnt_sb61/monitor_bpr` ***after updating the server.***

This is caused by having a mix of Ignite-UX fileset revisions on your server. In most cases it happens when you update only one release bundle (like Ignite-UX 10.20) even though you install other releases from that server.

An easy way to check for this case is to look at the output from the command:

```
swlist Ignite-UX
```

All the filesets should have the same revision, if not then you need to install all consistent versions. If you have **boot-helper** systems (see Appendix B), they also need to have the Ignite-UX product updated to match the same revision as the server that they reference.

Cannot determine dump size limit

Ignite-UX servers "Cannot determine dump size limit."

If you have a saved client config created using a version of Ignite-UX prior to 1.51, and then update Ignite-UX to 1.51 or later, and if you initiate the install from the Ignite-UX server GUI, it will give an ERROR looking something like this:

```
ERROR: Unable to determine dump size limit for disk (8/4.8.0),
release (B.10.20). Internal Ignite-UX error.
```

The problem is that an old version of the clients' `hw.info` file is being examined by the new Ignite-UX. To fix things, merely boot up the client system using:

```
boot lan.IP install
```

or whatever syntax your system supports from the boot prompt. *IP* is the IP address of your Ignite-UX server. The client `hw.info` file will be updated, and everything should proceed normally.

Installing Systems with Ignite-UX

Installs stop after 30 INDEXes

Installs are broken after 30 INDEX entries.

A modification was made to the **Basic** tab in Ignite-UX 1.42 so that if the `INDEX` file has more than 30 configurations (18 in the terminal user interface), then a list with scrolling is used. For example:

```
[Configurations:...] HP-UX B.11.00 Default [Description...]
```

One of the side effects of this is that sometimes a chosen configuration from a large list doesn't get parsed correctly.

Either update to the current Ignite-UX version or make sure that the text name for each configuration (when there are more than 30) is 25 characters or less. Then the chosen configuration will be correctly parsed. For example, this config name:

```
cfg "HP-UX B.10.10 long configuration name" {
description "long configuration name."
"/opt/ignite/data/Rel_B.10.10/config"
"/var/opt/ignite/config.local"
}
```

has a configuration of 37 characters, `"HP-UX B.10.10 long configuration name"`

and will not be correctly parsed. Shortening this will solve the problem:

```
cfg "HP-UX B.10.10 l.c.n." {
```

Another work-around is to use 30 configurations at most.

samreg errors

Igniting from an archive returns numerous "samreg" errors.

The problem is that the SAM filesets haven't been configured when certain products are trying to register themselves with sam. The workaround is to place the following config stanza in `/var/opt/ignite/config.local` or directly in the config file with the "core" sw_source:

```
sw_source "core"
{
post_load_cmd += "

swconfig -xautoselect_dependencies=false
-xenforce_dependencies=false SystemAdmin.SAM "
}
```

Problem installing clients on multiple subnets

Problems installing clients on multiple subnets.

There are a couple of problems with having an Ignite-UX server that is multi-homed (connected to multiple subnets):

- The `instl_bootd` daemon allocates IP addresses from the `instl_boottab` file without knowing which IP addresses are valid for the subnet that the client is requesting to boot from. Due to this lack of information, it can allocate an IP address that is not valid for the client's subnet, and thus the client will not be able to boot from the server.

  The workarounds for this problem are:

  - For every possible client that you may want to boot, assign "reserved" IP addresses in `/etc/opt/ignite/instl_boottab` that are tied to the client's LLA address. This will ensure that `instl_bootd` will allocate an appropriate address (See the comments in the `instl_boottab` file on how to reserve addresses). Alternatively, you can set up entries in `/etc/bootptab`.
  - Configure a boot-helper system on each subnet that the client can boot from before contacting your central Ignite-UX server. See Appendix C.

- The "server" keyword that specifies the IP address for your Ignite-UX server can only correspond to one of the LAN interfaces. If each subnet is routed such that all clients can use the one IP address to contact their server, then the install will work.. However, it is more efficient for the client to use the server's IP address that is connected

6.3b ✓

directly to the client's own subnet. If a client is on a subnet that does not have a route to the IP address specified by "server", then it will not be able to contact the server after it boots.

Workarounds for this problem are:

- Manually correct the server's IP address on the networking screen that appears on the client console when you boot the client.
- Use a boot-helper on each subnet. When using a boot-helper, the server's IP address can be specified correctly on each helper system.

Too much file space needed

Ignite-UX needs more file system space than expected.

Ignite-UX adds in minfree (normally 10%) to the amount required by the software impact. You may have software bundles that have overlapping contents (filesets and/or files). `make_config` makes `sw_impact` statements for each bundle without doing anything special to guard against over-counting when the bundles overlap. For example the Ignite-UX-10-*xx* bundles all overlap quite a bit, so that when you load all of them via Ignite-UX, it estimates too much space. To find the space needed, add the `sw_impact` of all the `sw_sels` that you are loading.

Debugging SD during cold install

How do I monitor SD operation during cold installs from the Ignite-UX server?

The first level debug of SD produces copious output. Because the logs are captured on the servers as well as the client this would run Ignite servers out of disk space rapidly if every install had this turned on.

It is fairly straight forward to do this on a per-session basis without modifying the config files. From the initial Ignite-UX menu, select: **Advanced Options -> Edit config file** This will run vi and you could add, for example:

```
env_vars += "SDU_DEBUG_RPC=1"

sd_command_line += " -x logdetail=true -x loglevel=2
```

Booting older workstations

An HP 9000 715/50 workstation won't network boot off of the Ignite-UX server.

Older Series 700 workstations require `rbootd` running on the server. If the server is FDDI, `rbootd` won't run. In that case boot from media then switch the source to the Ignite-UX server. Older ones use RMP not BOOTP and require rbootd to translate and hand off to `bootpd`.

RMP clients are the older Series 700 workstations: 705, 710, 715, 720, 725, 730, 735, 750, 755.

BOOTP clients are the Model 712 and future workstations, as well as K-Class, D-Class and newer Series 800 servers.

Booting errors

Error: `IPL error: bad LIF magic`

Possible problems are:

- Not having tftp access to `/opt/ignite` and `/var/opt/ignite`, the `/etc/inetd.conf` file on the server should have an entry such as:

  ```
  tftp dgram  udp wait   root /usr/lbin/tftpd    tftpd\
  /opt/ignite\
  /var/opt/ignite
  ```

  If not, fix `inetd.conf` and run **`inetd -c`**. Kill any `tftpd` processes that may be running. Loading Ignite-UX should set up inetd.conf. If not, check SAM.

- Using a bootptab entry for the client that is referencing a non-existent boot file (bf).
- A corrupted `/opt/ignite/boot/boot_lif` file.
- Perhaps some remnants of the old cold-install product (NetInstall) conflicting with Ignite-UX (old `instl_bootd` running)
- A defect in the `rbootd` daemon delivered in patch PHNE_10139. If you have this patch loaded and do not need it for DTC devices, try removing it or updating to patch PHNE_11017 (10.20) or PHNE_11016 (10.10).

Booting on IPF with /etc/bootptab error

Error: ***`PXE-E16: Valid PXE offer not received.`***

`Exit status code: Invalid Parameter`

When using `/etc/bootptab` to define Ignite-UX boot servers, a number of problems can be introduced resulting in this error. The following checklist can be used to isolate the problem:

1. Check `inetd`
   - Check `/etc/inetd.conf` to make certain `bootps` and `tftp` entries have been uncommented. Make certain the `tftp` line contains `/opt/ignite` and `/var/opt/ignite` paths on the `tftp` line.
   - Check to see if `inetd` was restarted or given an option to re-read the configuration files (`inetd -c`), after the files were edited? Is the `inetd` process running?
   - Check for entries in /`var/adm/inetd.sec` that may cause `inetd` to deny service to certain clients.
   - Check `/var/adm/syslog/syslog.log` to make certain `inetd` was restarted, and that no bad messages are found.
   - Check for messages from `bootpd` and `tftpd`.
2. `Check bootpd`
   - Check the `/etc/bootptab` entry. Make certain the MAC address matches the client MAC address. Use `dhcptools -v` to validate the format of the `/etc/bootptab` file.
   - Check for entries in `/etc/dhcpdeny` to insure that `bootpd` is not set to deny service for particular clients.
   - Check `/var/adm/syslog/syslog.log` for a message from `bootpd` that indicates it was started when a `bootpd` packet was received.

     If packets were not received, use a tool such as `tcpdump` to check for network packets. Verify that `bootp` packets are being seen by the system.
   - Check to see if there are other systems on the network that may also be replying to the booting client system.

- Check to see if the system booting is on a different subnet to the bootp server ensure that any router between the two allows the forwarding of bootp requests (Note that the configuration is router specific.).

3. Check tftpd

   - Check the tftp line in /etc/inetd.conf to make certain /opt/ignite and /var/opt/ignite directories are listed.
   - Check the tftpd connection manually by using the tftp command, for example:

```
a.  $ tftp [server-name]
b.  tftp> get /opt/ignite/boot/nbp.efi /tmp/nbp.efi
    Received [n] bytes in [s] seconds
c.  tftp> quit
```

Problems pointing to client over network

I put control_from_server=true and run_ui=false in the INSTALLFS, but I still get prompted for information on the client.

Possible problems are:

- If the screen is showing the client name in an editable field and a cancel button at the bottom of the screen, then all is well and there should be an icon waiting for you on the Ignite-UX screen. The text screen allows you to change the icon name, or switch to a client side install.
- If the screen is showing two or more lan interfaces to select from, then there wasn't enough information in the config files to tell it which LAN to use. Once you select a LAN and select **Install HP-UX**, you should be set.
- If the screen is prompting you for networking information, then either DHCP didn't respond or there isn't an entry in /etc/bootptab for the client. Enter the network information, select **Install HP-UX** and continue the install.

Mount errors when igniting 10.20 systems

Errors regarding mounting a file system occur when igniting 10.20 systems.

Patch PHCO_18317 supplies a new version of /sbin/mount but is not compatible with Ignite-UX. If this patch is loaded via either an archive or SD, then the next swinstall session will have fatal errors that appear like this

```
ERROR:   "c02380:/":  One or more filesystems that appear in the
filesystem table are not mounted and cannot be mounted.
ERROR:   Entry for filesystem "/dev/vg00/lvol1" in "/etc/fstab"
could
not be mounted.  If you do not want this file system mounted,
comment it out of the "/etc/fstab" file, or set the
"mount_all_filesystems" option to "false".
ERROR:   Cannot continue the Analysis Phase until the previous
errors
are corrected.
```

One workaround is to add the following to your configuration:

```
sd_command_line += " -xmount_all_filesystems=false "
```

However this has the unpleasant side effect that each swinstall session produces a warning message stating that file systems will not be mounted.

Patch PHCO_19694 replaces PHCO_18317. Note that recovery methods are unaffected because they are solely OS archives, and no SD activity takes place.

Applications hang after igniting

Some applications and shells hang over NFS after igniting.

The reason for the hang is most likely due to a problem with the NFS file locking daemons rpc.statd and rpc.lockd caused by the action of reinstalling the system. Many applications use file locking and can hang in this situation. Most common is user home directories that are NFS mounted, in which case sh and ksh will attempt to lock the .sh_history file and hang before giving the user a prompt.

When a system is running and has an active NFS mount with a server in which files have been previously locked, both the client and server cache information about each other. Part of the information that is cached is what RPC port number to use to contact the rpc.lockd daemon on the server and client.

This RPC port information is cached in memory of the running rpc.statd/rpc.lockd process on both the server and client sides. The rpc.statd process keeps a file in the directory /var/statmon/sm for each system that it knows it should contact in the event that the system reboots (or `rpc.statd`/`rpc.lockd` restarts). During a normal reboot or crash, `rpc.statd` will contact each system in `/var/statmon/sm` and inform them to flush their cache regarding this client.

When you re-install a system, the `/var/statmon/sm` directory is wiped out. In this case, if the reinstalled system tries to re-contact a server that has cached information, the server will try to communicate over a old RPC port. The communication will fail for `rpc.lockd` and any file locking done by an application over that NFS mount will hang.

There are a several ways to avoid and/or fix the problem if it happens:

- If you are using `bootsys` to install clients, use the `-s` option to allow the client to shutdown normally and thus inform servers that it is going down.
- If you experience a hang, you can reboot the client, or kill/restart `rpc.lockd` and `rpc.statd` on the client. At the point of the hang, the `/var/statmon/sm` directory will contain the name of the server, and thus rebooting or restarting the daemons will tell the server to flush it's cache. If more than one server is involved you may end up doing this multiple times until all servers are notified.
- As part of the installation, create a file for each server in `/var/statmon/sm` which contains the server's name. This will cause the first boot to generate a crash recovery notification message to each server, causing them to purge the stale port information. Below is an example `post_config_cmd` that could be placed in your `/var/opt/ignite/config.local` file. Replace `sys*` with your NFS server names.

```
post_config_cmd += "
   mkdir -p /var/statmon/sm
   for server in sys1 sys2 sys3
   do
      echo $server > /var/statmon/sm/$server
      chmod 0200 /var/statmon/sm/$server
   done
"
```

bootsys seems to work in reverse

With* `bootsys -w client`*, the client doesn't wait for the server. With* `bootsys client`*, the client waits for the server.

This was probably due to your running through the UI once on the server prior to running bootsys. The server drops the instruction for the client to start installing and the next time the client boots it picks that up and goes. Ignite-UX tells you that the install will happen the next time that `bootsys -w` is used, but does not really say it will happen automatically. And, the next time you did a bootsys, you had not used the UI without the client being booted from the server.

Booting diskless clients

bootsys does not work on diskless clients.

bootsys does not support rebooting HP-UX 9.x and 10.x diskless clients from the Ignite-UX server.

If you need to remotely reboot diskless clients from the Ignite-UX server, follow these steps:

1. If you need to duplicate the behavior of the `-w` or `-a` options to bootsys, you will need to modify the INSTALLFS file using instl_adm to set the keywords `run_ui` and/or `control_from_sever` appropriately. Or you can do this using Ignite-UX under the **Options -> Server Configuration** menu (Run client installation UI option).
2. Copy the `/opt/ignite/boot` directory and contents to the diskless server as `/opt/ignite/boot`:

   ```
   rcp -r /opt/ignite/boot  diskless-server:/opt/ignite/boot
   ```

3. Edit the client's entry in /etc/bootptab on the diskless server to set the `bf` (boot file) flag to be `/opt/ignite/boot/boot_lif`:

   ```
   bf=/opt/ignite/boot/boot_lif
   ```

   You may also need to set the bootptab entries for the gateway (gw), and subnet-mask (sm). The networking information in the bootptab file will satisfy the client's DHCP request for networking information when it boots. So it will need everything required to contact the Ignite-UX server.

4. Run `setup_tftp` on the diskless server to allow tftp access to `/opt/ignite`:

   ```
   /usr/sam/bin/setup_tftp /opt/ignite # on 9.X systems

   /usr/sbin/setup_tftp /opt/ignite # on 10.X systems
   ```

5. With this setup, the next time you reboot the client from the diskless server it will load the INSTALL kernel and INSTALLFS file system from the diskless server. The client will then contact the Ignite-UX server and the installation can proceed as usual.

Server not listed

`search lan install` doesn't list the server.

Check these items on the Ignite-UX server from which you are trying to boot:

- Messages from `instl_bootd` in `/var/adm/syslog/syslog.log`. If you need to add more IP addresses to `/etc/opt/ignite/instl_boottab` you will see messages in `syslog.log` such as the following:

  ```
  instl_bootd: Denying boot request for host: 080009F252B3 to
  avoid IP address collision. Try booting again in 214 seconds, or
  add more IP addresses to /etc/opt/ignite/instl_boottab.
  ```

- A message in syslog.log that indicates that you have no IP addresses in */etc/opt/ignite/instl_boottab* is:

  ```
  instl_bootd: No available IP address found in:
  /etc/opt/ignite/instl_boottab
  ```

- If the client is an older system that does not use the `BOOTP` protocol (like 720s, 710s, 735s, 750s) then also look in the log file `/var/adm/rbootd.log`, and check to make sure that the rbootd daemon is running. rbootd always runs, where as `instl_bootd` is started via `inetd` and only runs when needed.

  Also, for these older clients, there is an intentional delay built into the rbootd process when a client wants to do an install boot (as opposed to a diskless boot). This prevents the server from showing up during the first search. Retrying the search two or three times may be necessary.

bootsys fails with insufficient space

bootsys fails due to insufficient space in the `/stand` volume

bootsys needs to copy the two files: `/opt/ignite/boot/INSTALL` and `/opt/ignite/boot/INSTALLFS` from the server into the client's `/stand` directory. This error indicates that there is not enough space in /stand. To fix this, you may need to remove any backup kernels. Also check for kernels in the `/stand/build/` directory (like `vmunix_test`).

6-308

bootsys failure

bootsys -i configuration [sys1...] fails.

A defect in Ignite-UX A/B.2.2 releases prevents bootsys from successfully pushing a specific configuration out to a client. To fix this:

1. Enter: **vi /opt/ignite/bin/bootsys**
2. Move to line 848 in the file:

   ```
   if [[ "c_opt" != "$PUSH_MODE" ]]; then
   ```

3. Change c_opt to $c_opt and save the change. bootsys will now work correctly.

This defect will be fixed in the Ignite-UX A/B 2.3 release.

Installing from Media

DCE/RPC errors

DCE / RPC errors (RPC exceptions) occur during the configuration stage, plus a failure message is printed at the end of the installation.

There is an apparent problem with certain SD operations (for example, `swacl`) when only loopback networking is enabled. This would occur if the "media only" installation option is selected. The workaround is to install using the "media with networking enabled" option and set up (perhaps temporary) networking parameters: hostname, IP address, netmask, routing, etc. SD operations will complete normally.

Patch installation hangs

swinstall hangs during patch software analysis.

If you have created a CD-ROM that uses depots containing patches and the swinstall command that is loading the patches hangs, then you may be running into a defect in the `df` command.

To be sure, type `^C^C^C` until you get a prompt asking if you want to stop the install. Answer **yes**, then answer **yes** to push a debug shell. From the shell, run `ps -ef` and look for a hung `df` command.

The problem is caused by a defect in the df command. The defect is that it hangs whenever it sees a mount entry with a one-character device string (in this case the mount device is "/").

The workarounds for this problem are:

- If the core OS is loaded from an archive, make sure that the latest `df` command patch is part of that archive (PHCO_15344 or its successor)

6.308

- If the core OS and patches are both in the same depot, and you are using the hw_patches_cfg config file to cause loading of the patches, then add the following to your config file:

```
sw_source "core patches" {
   pre_load_cmd += "
      sed '/^. /d' /etc/mnttab > /tmp/mnt.fix &&
      cp /tmp/mnt.fix /etc/mnttab
      rm -f /tmp/mnt.fix
   "
}
```

- Install the latest version of Ignite-UX.

Installing from Archives (golden images)

Can't find specified archive

```
Errors: gunzip: stdin: unexpected end of file
        pax_iux: The archive is empty.
ERROR: Cannot load OS archive (HP-UX Core Operating System
Archives)
```

The NFS mount probably succeeded, but the file was not accessible from the target machine. Check these possibilities:

- File has a different name (check your config files).
- File has the wrong permissions such that it is not readable (check /etc/exports).

Missing .conf files

/etc/nsswitch.conf and /etc/resolv.conf files from the archive don't end up on the install target.

Ignite-UX changes some files during the configuration process, including resolv.conf and nsswitch.conf. Ignite-UX's os_arch_post_l and os_arch_post_c scripts place these files on the target system after the install.

These scripts are delivered in /opt/ignite/data/scripts/. You will probably only need to modify os_arch_post_l. Search on resolv.conf and nsswitch.conf for directions on what to change. After the script has been changed, modify your config file which describes the archive to point to the new script.

pax_iux errors

```
pax_iux: X: Cross-device link
pax_iux: X: File exists
```

Both of these errors may occur when loading a system from an archive that does not have the same file-system partitioning as the system from which the archive was created.

The Cross-device link error is caused when two files exist as hard links in the archive, and when the two files would end up in separate file-systems. For example, if you created an archive on a system that did not use LVM, in which case the root file system is all one file system. And, say you have two files: /usr/local/bin/f1 and /opt/myprod/bin/f2 are hard links. This error will occur if you make an archive of this system and try to apply it to a system that uses LVM and has /usr and /opt as separate file systems.

The File exists error may occur when the archive has a symlink, or regular file, that is named the same as a directory or mount point that exists when the archive is loaded. This may happen for example if the original system that the archive was made from has a symlink like */opt/myprod* -> */extra/space*. And then when you are loading a system from the archive you decide to create a mounted file system as /opt/myprod. The pax command will fail to create the symlink because a directory exists in it's place.

When the error happens you will be asked if you want to push a shell (on the target's console). Answer **yes**, and from the shell, enter **exit 2** to ignore the error and it will continue on. Once the system is up, you can more-easily determine what should be done with the paths it complained about.

To avoid the error, the system that the archive is created from should not contain hard links between directories that are likely to be created as separate file systems.

Running swinstall

Tape not readable

swinstall cannot read the tape. For example you may see:

```
Source connection failed for "ignitesvr:/dev/rmt/0m".
```

Possible causes and fixes are:

- Wrong device file — Use the **Actions** menu in SAM's **Peripheral Devices/Tape Devices** area to show the device files for the tape drive.
- Failure reading the contents of the tape:
  - No device file present for the tape — Use the **Actions** menu in SAM's **Peripheral Devices/Tape Devices** area to create the device files for the tape drive.
  - Bad/wrong tape — Verify label on tape. Check the contents. SD tapes are in tar format:

    ```
    tar tvf device_file | more
    ```

    For example, if the tape device is `/dev/rmt/0m`, enter:

    ```
    tar tvf /dev/rmt/0m | more
    ```

    You should see a tar format table of contents. If you do not see this, the tape is corrupt.
  - Dirty head in DDS tape drive — Use a DDS tape cleaning cartridge to clean the tape head.

Adjusting File System Size

The absolute minimum /usr file-system sizes needed to update to HP-UX 11.0 are:

- For 32-bit: 300 MB.
- For 64-bit: 324 MB.

If the required file-system size for the bundle you copy to a depot exceeds that file system limit set by your disk installation, you will get an error condition during the copy process. Use lvextend and extendfs in this situation to create a larger file system. You might have a problem updating your system(s) if the /usr or /var volume is too small.

If you try an update, swcopy determines how much disk space is required. If there isn't sufficient space, swcopy reports an error:

```
ERROR: The used disk space on filesystem "/var" is estimated
to increase by 57977 Kb.
This operation will exceed the minimum free space for this
volume.  You should free up at least 10854 Kb to avoid
installing beyond this threshold of available user disk space.
```

In this example, you would need to increase the file system size of /var by 10 MB, which actually needs to be rounded up to 12 MB.

Follow these steps to increase the size limit of /var:

Step 1. Determine if any space is available by entering:

```
/sbin/vgdisplay
```

You should see a display like this:

```
         - Volume groups -
VG Name                     /dev/vg00
VG Write Access             read/write
VG Status                   available
Max LV                      255
Cur LV                      8
Open LV                     8
Max PV                      16
Cur PV                      1
Act PV                      1
Max PE per PV               2000
VGDA                        2
PE Size (Mbytes)            4
```

```
Total PE                      249
Alloc PE                      170
Free PE                       79
Total PVG                          0
```

Free PE indicates the number of 4MB extents available, in this case this is 79 (equivalent to 316 MB).

Step 2. Shutdown the system: **`/sbin/shutdown`**

Change to single user state. This will allow `/var` to be unmounted.

Step 3. Enter: **`/sbin/mount`**

You will see a display similar to this:

```
/ on /dev/vg00/lvol1 defaults on Sat Mar 8 23:19:19 1997
/var on /dev/vg00/lvol7 defaults on Sat Mar 8 23:19:28 1997
```

Step 4. Determine which logical volume maps to */var*. In this example, it is `/dev/vg00/lvol7`.

Step 5. Enter: **`/sbin/umount /var`**

This is required for the next step, since extendfs can only work on unmounted volumes.

Step 6. Extend the size of the logical volume:

```
/sbin/lvextend -L new_size_in_MB /dev/vg00/lvol7
```

For example, this makes the volume 332 MB:

```
/sbin/lvextend -L 332 /dev/vg00/lvol7
```

Step 7. Extend the file system size to the logical volume size:

```
/sbin/extendfs /dev/vg00/rlvol7
```

Step 8. Enter: **`/sbin/mount /var`**

Step 9. Either go back to the regular init state,`init 3` *or*`init 4`, or reboot.

6.300

Troubleshooting Large Systems

During system analysis

On a large system such as a T500 with a very large number of disk drives (such as 50 or more), you may see messages such as these during the system analysis phase of cold install:

```
Out of inode- can't link or find disk
or
Write failed, file system is full.
or
File system full.
```

To reduce the likelihood of this problem occurring, before you do the installation you should *turn off any disks you don't plan to use for the installation process and start over.*

After the system is cold-installed, you may wish to add back all the file systems that existed under the previous installation, either manually or using SAM. However, for a large number of file systems (for example, over a hundred), some tables in the kernel may be too small to allow correct booting. This is because the newly-installed kernel contains default values for kernel table sizes, and does not allow for special configurations made to the kernel installed previously.

For example, the first boot after adding the file systems may result in error messages displayed to the console, such as the following:

```
inode: table is full
proc: table is full
file: table is full
```

Boot failures

The boot may fail in various ways. You may be have to do file system repair manually. If this is not possible, the kernel may need to be re-configured before booting. The following settings should allow the kernel to be booted, but may not be optimal for the system:

```
ninode = 2048 (default is 476)
nproc = 1024 (default is 276)
nfile = 2048 (default is 790)
```

Alternatively, you can re-configure the kernel by either raising `maxusers` to a large value, such as `200`, or selecting an appropriate bundle of SAM-tuned parameters from the SAM **Kernel Configuration Actions** menu. Be sure to determine the correct configuration for your system.

Media Recovery

tftp access

When running the recovery system option from a client booted in Ignite-UX, errors seem to point to files not being accessible via tftp.

Only /opt/ignite and /var/opt/ignite should be needed for tftp access.

make_sys_image broken

Level 2 make_sys_image is broken at version 1.51.

Yes, but there is a quick fix:

Change line 1303 of /opt/ignite/data/scripts edit make_sys_image from:

```
if [[ ${recovery_mode} != "TRUE" ]]; then
```

to:

```
if [[ ${recovery_mode} = "TRUE" ]]; then
```

Hot-swapping disks

Problems hot swapping disks during recovery.

Ignite-UX supports only hot swappable disks that are completely installed, and not removed when creating a recovery image. Proper software and hardware procedures must be used for hot swap disk removal or replacement before or after recovery, but not in the middle. The LVM command lvlnboot used by save_config does not work when a disk is removed and the system is in this odd state. If this command is not working, then make_recovery has no chance of succeeding.

Volume group error

Error: `The minor number of the volume group exceeds the value IUX can support.`

The make_net_recovery command check to ensure that it does not back up a system that Ignite-UX will be unable to recreate.

Ignite-UX version A.*x.x* can only create volume groups with group numbers in the range 0 to 10. This is due to the *maxvgs* kernel tunable being set to 10 in the INSTALL kernel. In order to continue to have Ignite-UX work on systems with 32 MB of memory, the kernel cannot have this parameter increased.

Ignite-UX B.*x.x* does not have this restriction due to reductions in the amount of memory LVM consumes.

`make_net_recovery` can operate on non-root volume groups so it is not uncommon to see the error with this tool.

Possible workarounds:

- If you got into this situation by manually recreating the LVM device files, then consider renumbering them to something less than 10.
- If using `make_net_recovery`, exclude that volume group from the archive.
- Use Ignite-UX B.*x.x* on HP-UX 11.0/11i systems.

`vgcreate` error

vgcreate error during recovery of a 9GB disk.

If you used Ignite-UX 1.48 or 1.49 to create a recovery tape of a system with a 9GB disk, you may experience a failure when you try to use this tape. The failure would result in the message similar to the following:

```
* Creating volume group "vg00".
vgcreate: Not enough physical extents per physical volume.
Need: 2170, Have: 2169.
ERROR:   Command "/sbin/vgcreate -A n -e 2169 -l 255 -p 16 -s 4
/dev/vg00 /dev/dsk/c1t15d0" failed.

The configuration process has incurred an error, would you like to
push a shell for debugging purposes? [y/n]
```

Either update to the latest Ignite-UX release and recreate the tape, or work around the problem when it happens. To work around the problem, answer **yes** to push a shell. From this shell, enter the command as shown in the error you get, but add 1 to the value shown for the `-e` option. When you successfully run `vgcreate`, enter **`exit 2`** from the shell to continue the install.

Online diagnostics not restored

Online Diagnostics LIF files are not restored during a recovery.

Ignite-UX destroys the old LIF area on the boot disk and lays down new LIF volumes every time the system is installed. At no point during the installation are the old LIF volumes copied and restored to the disk.

To restore the LIF volumes to the disk, reinstall the application, or look at the SD configure scripts for the application and rerun the commands which put the LIF volumes in place on the disk. For example, for the OnlineDiag bundle, the /var/adm/sw/products/LIF-LOAD/LIF-LOAD-MIN/postinstall script puts the OnlineDiag LIF volumes onto the root disk. It uses this command:

```
/usr/sbin/diag/lif/lifload -f /usr/sbin/diag/lif/updatediaglif
```

Bad IPL checksum error

"bad IPL checksum" error when booting B1000, C3000, and J5000.

The 1.8 revision of firmware on the B1000, C3000, and J5000 workstations has a defect that causes them to give a "bad IPL checksum" error when booting from a make_recovery tape (and possibly other bootable tapes as well).

If you have one of these systems, your options are to update the system firmware once a new version with a fix is made available, or to use Ignite-UX version A/B.2.0 or later which works around the problem.

Network Recovery

Failure when archiving large volumes

make_net_recovery fails when the archive is 2GB or more.

make_net_recovery uses NFS to write/read the system archive from the client to/from the server. To manage archives greater than 2GB requires that both the client and server use NFS protocol version 3 (PV3). NFS PV3 is available for HP-UX 10.20 when the Networking ACE set of patches are loaded, and is standard on HP-UX 11.0.

If you know you have NFS PV3 and are having problems, check:

- You must be running Ignite-UX version A.2.1(on HP-UX 10.*x*) or later, or B.2.0 (on HP-UX 11.*x*) or later.
- Some NFS patches in the past have caused problems with >2GB files. These problems have been fixed in patches:

  ```
  10.20: PHNE_17619 (S700), PHNE_17620 (S800)
  11.00: PHNE_17247
  ```

- If your NFS server is running HP-UX 10.20 with the newer NFS patches, then the /etc/rc.config.d/nfsconf file has a configurable parameter (MOUNTD_VER) which determines if the default mount should be PV2 or PV3. This must be set to 3.

  If your clients are running HP-UX 10.20 with the newer NFS patches, the /etc/rc.config.d/nfsconf file must have the parameter MOUNT_VER set to 3.

Volume groups erased

make_net_recovery version 2.0 erases volume groups that contain only unmounted and raw logical volumes.

make_net_recovery version 2.0 has a bug which causes volume groups that contain only unmounted and raw logical volumes to be re-created but not restored, causing loss of data. When recovering a system, the user can specify to not recreate these volume groups, so that data is not lost. However, the user will need to manually import these volume groups after recovery. This problem has been fixed with version 2.1.

Core dumps

make_net_recovery version 2.0 and 2.1 core dumps when archiving more than 8 volume groups.

This problem is fixed with Ignite-UX 2.2.

Problem with NFS mounts

`make_net_recovery` version 2.0 and 2.1 crosses and archives NFS mounts if an essential directory has a symbolic link to something that is NFS mounted, and the path to the NFS mounted directory contains a directory which is a symlink.

This problem is fixed with version 2.2.

LAN address changes

After replacing the client system, the LAN address is now different.

Ignite-UX uses a separate directory for each client under `/var/opt/ignite/clients`. Each subdirectory is named based on the client's LAN address (LANIC, LLA, MAC address, etc). If you replace the client hardware, or even the LAN card that the old LAN address was based on, it will no longer access the same directory on the server.

The simplest solution is to obtain the new LAN address, which you can do from the Boot-ROM console command LanAddress (actual command may vary from system to system). Once you have the new address, then manually rename the directory. You may just remove the hostname symlink (it will be recreated automatically). Note that the LAN address must be in all upper-case, and begin with `0x`.

If you already booted the client from the server which caused it to create a new directory, you can just remove that directory before renaming the old directory. Be careful not to remove the original directory or else you will loose the recovery information. For example:

```
cd /var/opt/ignite/clients

mv 0x00108300041F 0x00108300042A

rm old_hostname
```

Volume group error

`Error: The minor number of the volume group exceeds the value IUX can support.`

See "Volume group error" on page 255.

Hot-swapping disks

Problem with hot swappable disks during recovery.

See "Hot-swapping disks" on page 255.

B Using a Boot-Helper System

A system running HP-UX 10.*x*, 11.0, or 11i can use the Ignite-UX server across a gateway if the target system is booted via the `bootsys` command. If the system is booted manually, it will need a helper system to help it boot across a gateway, and enabling the target system to perform this to the local boot-helper system:

```
boot lan.IP_address install
```

This chapter describes how to configure the boot-helper system.

To boot HP-UX across a gateway, you need a system on the local subnet to provide the target with a minimum core kernel. The helper system can run either HP-UX 10.*x*, 11.0 or 11i. The setup is much simpler if the helper system is running HP-UX 10.*x*, 11.0 or 11i.

6292
2

Setting Up the Boot-Helper

Follow these steps to setup and use a system on a remote subnet to allow a client to do a network boot and then contact a remote Ignite-UX server:

Setting up an HP-UX 10.*x*, 11.0 or 11i helper

Step 1. Install the Ignite-UX minimum core functionality onto the helper system:

```
swinstall -s /dev/rmt/0m Ignite-UX.MinimumRuntime
```

Step 2. On the helper, run the following command to point the INSTALLFS at the correct Ignite-UX server:

```
/opt/ignite/bin/instl_adm -t Ignite-UX_server_IP
```

Verify that INSTALLFS is referencing the correct Ignite-UX server, and gateway for your subnet:

```
/opt/ignite/bin/instl_adm -d
```

Step 3. Specify a temporary IP address for the helper. On the helper, in the /etc/opt/ignite/instl_boottab file, add the IP addresses that clients can use to boot. The remote subnet needs to have temporary IP addresses to use during an initial bootup. These are located in the /etc/opt/ignite/instl_boottab file, and were provided during the initial Ignite-UX server installation. But, the remote gateway systems cannot use these, so the boot-helper system must supply its own. Therefore create an /etc/opt/ignite/instl_boottab file on the boot-helper system containing lines of the following format. (See /etc/opt/ignite/instl_boottab on the Ignite-UX server for more details). For example:

```
15.1.53.180
15.1.53.181
15.1.53.182
```

Install Using a Boot-helper

Boot up the target machine to the `boot admin` menu, and boot from the helper system. For example:

```
boot lan.helper_IP_address install
```

If there's only one install server available on the subnet, then just enter:

```
boot lan install
```

At that point, the install should proceed, controlled from the server by default.

C Configuring for a DHCP Server

HP-UX 10.20 and Ignite-UX supports retrieving network information via the Dynamic Host Configuration Protocol (DHCP). This appendix describes setting up DHCP:

- Overview of DHCP Services.
- Setting Up a DHCP Server.
  - — Details of the DHCP Services.
  - — Enabling DHCP on a System Not Initially Configured with DHCP.
  - — DHCP Usage Examples.
  - — Using bootptab as an Alternative to DHCP.

Ignite allows for setting up DHCP for use during system installation. This appendix is for the user who wishes to use DHCP for ongoing IP address management, as well as for system installation.

6.288
2

Overview of DHCP Services

DHCP provides these features:

- Allows for dynamically allocating IP addresses and hostnames.
- Automatically supplies most of the networking defaults that are requested during a system installation or first time boot.
- Provides for on-going IP address maintenance via a concept of an "IP address lease." Having a lease on an IP address means that if the system "goes away" for a specified period of time without renewing the lease, then that IP address can be given to a different system that request a new IP address lease.
- Assists in re-establishing valid network parameters when a system has been moved from one DHCP-managed network to another.

DHCP works best under these conditions and restrictions:

- When a range of currently unused IP addresses can be allocated for use during new system bring-up.
- When the IP address-to-hostname mapping can be made ahead of time (before the system to use it is installed). And this mapping can be configured in the name services database before installing a system.
- When the IP address and hostname that get assigned to a system are not important. A system will keep the same IP address and hostname for as long as it renews the lease. However, the original assignment is arbitrary.
- When the person installing the systems does not desire to choose a hostname for the system, but rather accepts the one already registered for the IP address supplied by DHCP. This will ensure that the system will be recognized immediately by its hostname.

- When existing systems that did not use DHCP before will continue not to use it. Or, if they did, they would be willing to accept an arbitrary hostname and IP address. This is the same as with a new system. There currently is no tool available for pre-loading the DHCP database with existing IP addresses and identifying the systems they belong to. A tool to do this may be available in a future release.

An alternative to using DHCP is to create `/etc/bootptab` entries for each specific client on the network. This allows for specific IP address mappings and greater control. For more detail, please see “Using bootptab as an Alternative to DHCP” on page 275.

Setting Up a DHCP Server

Once you have decided that using DHCP will provide a benefit, you will need to follow the steps below to set up a DHCP server. *Note that only one DHCP server per network subnet is required.* On the server system:

- Allocate a set of currently unused IP addresses (preferably a contiguous block of addresses). For example:

  ```
  15.1.48.50 -> 15.1.48.80
  ```

- Pre-assign and register hostnames to the IP address allocated above. Using the `-h` option to the dhcptools command may be useful. For example, this command creates a `/tmp/dhcphosts` file that can be incorporated into your `/etc/hosts` or DNS/NIS database:

  ```
  dhcptools -h fip=15.1.48.50 no=30 sm=255.255.255.0 hn=de
  vlab##
  ```

- Designate a system to act as the DHCP server for your network. This should be a system that is "always" available to it's clients.

Use SAM to configure the DHCP services on this server:

Step 1. As root, enter: **sam**

(you may need to set your `DISPLAY` variable to use the graphical version)

Step 2. Double-click **Networking and Communications**

Step 3. Double-click **Bootable Devices**

Step 4. Double-click **DHCP Device Groups Booting From this Server**

You should now see a screen that lists any DHCP groups already defined (there may not be any if DHCP is not already configured).

Step 5. To add the new group of IP addresses which you allocated in Step 1, click **Action –> Add DHCP Group**

Step 6. Now fill in the information on this screen. Some information may require additional research if you are not familiar with the terms or with your network.

- **Group Name —** This can be any name that isn't already defined as a DHCP group. For example: `group1`

- **Subnet Address** — This is the portion of an IP address that is not masked off by the subnet mask (see below). If you don't want to figure this out, then just enter one of the IP addresses in the range you picked along with the correct subnet mask and SAM will take care of the calculation. For example: `15.1.48.50`

- **Subnet Mask** — This depends on the "class" of your network, and basically determines how an IP address is separated into a network number and a host specific number. Press **F1** in this field for more information. For example: `255.255.255.0`

- **Subnet Address Pool** — Press this button to select the range of IP addresses that you allocated in Step 1. A new screen will display where you can enter the Start and End address. If there are addresses within the range that you picked that you do not want allocated via DHCP, you can use the Reserved Addresses button to specify those (or ranges of them).

- **Allow Any Device Class** — The SAM default allows any type of DHCP device to use the group of IP address you are configuring. This may be undesirable if you use a different method (or a different DHCP server or group) for managing systems such as PCs running Windows98™ or NT™.

  If you want this range of addresses to be used only by HP-UX systems, then unselect this button, and in the text field provided enter: **`HewlettPackard.HP-UX`**

  When using Ignite-UX to set up DHCP, it will set a class specific to the server, and will set the `dhcp_class_id` string to match. For more detail, see the *instl_adm* manpage.

- **Automatic Allocation to Bootp Clients** — Leave this option disabled. Enabling it will cause problems for bootp devices such as printers and terminals which rely only on their preconfigured server to respond to their boot request.

- **Accept New Clients** — Leave this option enabled.

- **Address Lease Time** — The lease time should be set sufficiently long so that if a client system is temporarily out of service (`off`) for a time, its lease will not expire too soon.

  Infinite leases will never expire and disable the IP-address reclamation features of DHCP. For example: 2 weeks.

6.284

- **Boot file name** — You can leave this field blank.
- **Additional Params** — There are many parameters that can be specified in this screen for such things as the default routers, time server, DNS server, and NIS domain. You can specify as much or as little as you like in this area.
- **Callback Routines** — None are necessary.

Step 7. Once the parameters are all filled in, then press **OK** on the Add DHCP Group screen. SAM will then make the modifications to the `/etc/dhcptab` file.

Step 8. Click **Action** –> **Enable Boot Server** (if it is not already enabled).

New systems that are installed with HP-UX 10.20 or newer version or booted with a pre-installed HP-UX 10.20 or newer version should now contact this server to get an IP address lease and other network information provided by the server.

Details of the DHCP Services

- When cold-installing HP-UX 10.20 or newer:

  The installation tools will broadcast out on the network for any available DHCP servers. The first server to respond will be chosen to provide the default network information that the user is presented with.

  In the network parameters screen during a cold install, you see the question: `"Is this networking information only temporary?"` Responding `yes` or `no` answer to this question implies the following:

  — `no` (the default) means that if the IP address and hostname were leased from an DHCP server, then that lease will be retained after the install is done, so that the first boot of the system will attempt to renew the same lease.

  — `yes` implies that the IP address and hostname lease should be returned to the server after the installation is complete. In this case, the first system boot will try to get a new lease. This is most useful when the system is being installed on a network that is different from its final destination.

This answer to the question can also be set in the configuration file with the `instl_adm` command using the keyword: `is_net_info_temporary`

When automating system installations, the DHCP services allows systems to get networking information without mapping the Ignite-UX configuration files. For more information, see *instl_adm* (1M) and *instl_adm* (4).

- When a system boots for the first time (either after a cold install or the first boot of a pre-loaded (Instant Ignition) system):

  With HP-UX 10.20, the `auto_parms` and `set_parms` tools (they let you configure the system identity and basic configuration parameters) will invoke the `dhcpclient`, which will broadcast out to find a DHCP server. The server, in turn, provides a default set of networking parameters.

  With HP-UX 11.0, you are asked if DHCP should be enabled and used (by set_parms). The default is to *not* use DHCP.

  In both cold install and a first boot of a pre-loaded system, if the user chooses not to use the IP address given by the DHCP server, the tool will inform the DHCP server that it can release the lease on it and give it to someone else.

- At each system boot:

  If a client system was initially set up using an IP address that was leased by a DHCP server, that client will check to ensure that the lease is still valid at each boot. In addition, the system will start a daemon process (`dhcpclient -m`) that will maintain and renew that lease while the system is running.

  If a system cannot contact the DHCP server from which it originally got the IP address lease, it will try to contact other DHCP servers in order to determine if it has been moved to a different network. If this is the case, the system will write a message to the `auto_parms` log file (*/etc/auto_parms.log*) indicating that it has detected a move to a new subnet and that it is attempting to request a new lease. If the new lease request is successful, new networking configuration values supplied by the DHCP server will automatically be applied.

Enabling DHCP on a System Not Initially Configured with DHCP

If a system has been set up without using DHCP, but you would like to start using it, the following steps may be taken.

NOTE The system's hostname and IP address may change based on what the DHCP server assigns to it the first time it boots.

There are two methods for enabling DHCP on a system that is not currently using it:

Enable DHCP using SAM

Step 1. As root, run: `sam`

Step 2. Double-click **Networking and Communications**

Step 3. Double-click **Network Interface Cards**

Step 4. Highlight the card on which you wish to enable DHCP.

Step 5. Click **Actions** –> **Configure**

Step 6. Click **Enable DHCP**

TIP If **Enable DHCP** appears grayed-out, use the alternate method below.

Step 7. Click **OK** and exit SAM.

Your system will now begin using DHCP after the next reboot. Please note that all of the current networking parameters will be overridden with new values supplied by the DHCP server. *If for some reason the system cannot contact a DHCP server during the next reboot, it will continue to use its current networking parameters.*

If you suspect that your system had problem contacting the DHCP server, examine `/etc/auto_parms.log` to determine if the lease request was successful.

Alternate method

You can also enable DHCP over a particular network interface using a text editor such as vi or emacs to edit the /etc/rc.config.d/netconf file. In the header of this file, you will find some brief instructions regarding a variable named DHCP_ENABLE. This variable is tied by an index number to an individual network interface. For example:

```
INTERFACE_NAME[0]=lan0
IP_ADDRESS[0]=15.1.50.76
SUBNET_MASK[0]=255.255.248.0
BROADCAST_ADDRESS[0]=""
DHCP_ENABLE[0]=1
```

Here, the variables are instructing the system to use the lan0 interface when attempting to contact a DHCP server. Similarly, if the lease request is successful, the above IP_ADDRESS variable would be updated to reflect the new value supplied by the DHCP server.

If the DHCP_ENABLE variable was set to 0 or if the variable did not exist, no DHCP operations would be attempted over the corresponding network interface.

As noted in the first method of enabling DHCP, if the variable DHCP_ENABLE does not exist for a particular interface, SAM will display a grayed out DHCP enable button.

In this case, you will need to add the variable definition to a specific interface variable block. As an example, you would need to add DHCP_ENABLE[2]=1 to the following interface variable block in order to enable DHCP on the lan1 interface:

```
INTERFACE_NAME[2]=lan1
IP_ADDRESS[2]=15.1.50.89
SUBNET_MASK[2]=255.255.248.0
BROADCAST_ADDRESS[2]=""
```

The contents of /etc/rc.config.d/netconf for this definition block should now look like the following:

```
INTERFACE_NAME[2]=lan1
IP_ADDRESS[2]=15.1.50.89
SUBNET_MASK[2]=255.255.248.0
BROADCAST_ADDRESS[2]=""
DHCP_ENABLE[2]=1
```

Correspondingly, you could disable DHCP over a particular interface by setting the variable to 0.

Again, as in the first method, the system will only begin using DHCP after the next reboot.

DHCP Usage Examples

To enable a DHCP server to respond only to specific clients during an installation, use `instl_adm` to configure specific *dhcp_class_id*s.

Your situation might fall into one of these categories:

- The network has a DHCP server that manages the whole network, and the clients doing installations will be using the addresses from this server permanently. In this case, do nothing since this line is entered in `INSTALLFS` file by default:

  ```
  is_network_info_temporary=false
  ```

- The network has a DHCP server, but the user would like to manage a small group of temporary IP addresses, just for use in doing installations, and the clients will get reassigned new addresses when deployed.

Step 1. Set up DHCP on Ignite-UX server.

Step 2. Use a unique *dhcp_class_id* in both the `dhcptab` and the 8KB config file. This *dhpc_class_id* could include the server's hostname. In this case, enter the following in `INSTALLFS` using `instl_adm`:

```
is_network_info_temporary=true
```

Step 3. Enter your class ID as the following in the dhcptab and `INSTALLFS`:

dhcp_class_id

If you have a non-HP server that does not recognize `dhcp_class_id`, specify the server using the `dhcp_server` keyword instead.

- The user would like to setup the Ignite-UX server as a "departmental" DHCP server, in which case the IP address leases are permanent, but they will be isolated to the department's DHCP server.

Step 1. Set up DHCP on the Ignite-UX server.

Step 2. Enter this line:

```
is_network_info_temporary=false
```

Step 3. *And* enter your class ID as the following in the dhcptab and INSTALLFS:

dhcp_class_id

(Or use the dhcp_server keyword as explained in the previous Step 3 above.)

Use a unique *dhcp_class_id* in both the dhcptab and the INSTALLFS file. This *dhcp_class_id* could have the server's hostname in it.

- You want to start using DHCP with this server managing the whole network. Refer to the preceding sections, /usr/sbin/sam, and the *sam*(1M) manpage for this procedure.

For more information, see the *setup_server* (1M) and *bootpd* (1M) manpages.

Using bootptab as an Alternative to DHCP

If you want to have more control over the allocation of IP addresses and their mappings to your clients, you can configure entries in /etc/bootptab for each client. Because BOOTP protocol is a subset of DHCP protocol, the client's request for a DHCP server will be satisfied with the BOOTP response.

If you also specify a boot-file (bf) of /opt/ignite/boot/boot_lif in the bootptab entries, then you do not need any additional entries in /etc/opt/ignite/inst_boottab. In this case, you would then boot the clients using boot lan instead of boot lan install. Only clients known in /etc/bootptab would be able to boot if you do not use instl_boottab.

A minimal example /etc/bootptab entry is shown below (use your own hostname, IP address, hardware address, and subnet mask). Other networking information may also be specified here or via instl_adm. Specify the Ignite-UX server's IP address with the instl_adm -t option.

```
sysname:\
  hn:\
  vm=rfc1048:\
  ht=ether:\
  ha=080009352575:\
  ip=15.1.51.82:\
  sm=255.255.248.0:\
  bf=/opt/ignite/boot/boot_lif
```

Background Information on DHCP Design

The DHCP protocol is implemented as extensions to the BOOTP protocol, and in fact the HP-UX DHCP server daemon and the BOOTP daemon are the same: `bootpd`. This daemon reads two configuration files: `/etc/bootptab` and `/etc/dhcptab`.

The mapping of systems to IP addresses and lease time information is kept in the DHCP database file `/etc/dhcpdb`. Some amount of management of this database is provided by the `dhcptools` command.

On the client side, a command called `/usr/lbin/dhcpclient` is used to contact the server to get an IP address lease. This command has the ability to broadcast out onto the network prior to the network interface being enabled.

The `dhcpclient` also serves as a daemon process that sleeps until the time that it needs to renew the IP address lease, at which time it will re-contact the server where it got the original lease in order to extend it.

The `dhcpclient` command is not intended to be run by users directly, and is called by other tools during system bootup and installation.

For More Information

See the *auto_parms* (1M)and *dhcpdb2conf* (1M) manpages for more information regarding the networking parameters which DHCP can supply.

More general information on DHCP can be found in the following locations:

- Manpages:

  bootpd (1M)
  dhcptools (1M)
  auto_parms (1M)
  dhcpdb2conf (1M)

- Web:

  `www.dhcp.org`

overview

MirrorDisk/UX License for Servers
Introduction

MirrorDisk/UX software prevents data loss due to disk failures by maintaining up to thre(data on separate disks. Applications can continue to access data even after a single dis addition, you can perform on-line backups to avoid user and application disruption.

To prevent the failure of a single I/O interface from causing a system failure, HP recomn mirrored disks be connected to separate interface cards.

Features and Benefits

- No single point of failure - separate controllers/power supplies
- Up to 3-way disk mirroring
- On-line backup while maintaining mirroring
- Application transparency
- Dynamic mirror configuration
- Selective mirror of data
- Fast data synchronization
- Menu-driven administration tools

Because high availability solutions require full-time access to data, HP has developed M to provide mirroring capability within the HP-UNIX® Operating System (HP-UX) environ

MirrorDisk/UX, the mirroring component of Logical Volume Manager (LVM) from the Op Foundation (OSF™), prevents data loss by maintaining up to three copies of data on se This enables data to remain intact after a single disk or interface card failure.

MirrorDisk/UX can mirror a disk partition, including the root and swap partitions. It suppc of raw disk access as well as file system access. MirrorDisk/UX can increase input/outp performance depending upon the mix of disk reads and writes.

Because MirrorDisk/UX works with the HP-UX kernel to manage the mirrored disks, it is to the applications, which require no modification.

MirrorDisk/UX allows customers to perform a backup by taking one disk of a mirrored pa while the other disk continues to service applications. As the backup is being performed occurring to the online disk are maintained in table memory. Upon completion of the bac procedure, a faxt update is done to synchronize the disks while application continuity is To prevent the possibility of data loss caused by a failure during a backup, three-way mi provides a fully redundant mirrored pair while the third copy is being backed up.

hp rack-optimized
rp5430 and rp5470
servers
entry-level UNIX® servers

hp servers
product brief

hp rack-optimized servers can help you be always on, always there, always connected

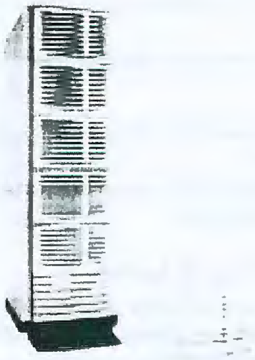
hp servers rp5430 and rp5470: smart, simple, stress-free

In today's economy, whether you're managing your own IT infrastructure or hosting someone else's, you have to operate with a faster time-to-solution, within budgetary constraints, and with the highest standards for customer service and operational efficiency.

To create and run an infrastructure for an always-on business, you need a computing platform that will support the way you—and your customers—do business. The HP Servers rp5430 and rp5470 give your business the fastest—and most reliable—means of succeeding in this new business environment.

The HP Servers rp5430 and rp5470 deliver the proven performance, scalability, and high-availability capabilities of UNIX—without high maintenance requirements and costs. And they give you plenty of room to grow. You can start at a low-price entry point and scale up to the leading 4-way UNIX performance—in the same rack-optimized form factor, without penalty. And with its industry-leading solution partners, HP has developed business solutions surrounding these servers that are tested, easy to deploy, and easy to manage.

With HP Servers rp5430 and rp5470, owning and operating a UNIX server is smart, simple, and stress-free.



hp servers rp5430 and rp5470

smart

HP Servers rp5430 and rp5470 offer leading entry-level server performance, dynamic scalability, and unmatched investment protection—all in a rack-optimized package—making them the smart choice for the most demanding applications.

leading performance—scalable functionality

- industry-leading OLTP performance
- massive bandwidth for I/O-intensive applications
- 7U-height and packed with CPUs, memory, and I/O, plus the ability to scale subsystems without compromise
- rack-optimized to make the best use of valuable data-center floorspace

unparalleled investment protection

- industry's only in-box upgrade from 2-way to 4-way UNIX computing
- built-in growth path to the HP Server rx5670, featuring Intel® Itanium® 2 processors

proven solutions for business-critical computing

simple

hp makes IT easy

With HP Servers rp5430 and rp5470, HP offers a unique combination of solutions designed to help you get started quickly and manage your IT environment effectively.

hp-ux: robust, proven enterprise operating environment for mission-critical applications

- industry-leading performance, scalability, availability, manageability, and security
- pre-packaged, integrated, and production-ready operating environments
- industry-leading Windows® and Linux interoperability
- centralized software updates that are timely, simple, and efficient
- powerful alliances with industry-leading software vendors and systems integrators to deliver robust solutions from e-commerce to enterprise resource planning (ERP) and beyond

leading-edge management capabilities with hp-ux virtual partitions and hp-ux workload manager

- system resource optimization enabling multiple workloads to run simultaneously on the same server, each with their own instance of HP-UX
- improved security and server availabilty through complete software and operating system isolation
- HP-UX Virtual Partitions integrate with HP-UX Workload Manager for the most efficient resource distribution across partitions, in a single server
- base offering complementary with HP-UX 11i for your HP Server rp5470

integrated management capabilities

- HP Servicecontrol Manager and integrated HP Secure Web Console capability for full remote management, including centralized configuration of multiple servers

the right server for today's applications

ERP (supply-chain management)
High availability, leading-edge manageability, and scalable performance support demanding end-to-end enterprise applications.

broadband
The combination of leading performance, I/O throughput, and capacity and high availability with end-to-end solutions delivers more powerful, reliable broadband services.

Internet infrastructure
Highly scalable, reliable, and manageable Web server, caching server, load balancing, e-commerce server, firewalls, or mail server.

e-commerce
Leading performance and I/O bandwidth, in-box scalability, rack-optimized form factor (five per standard 2-meter rack), high availability, and Internet management features.

technical computing
Leading performance and throughput, N+1 redundant components, extensive memory capabilities, and clustering solutions to meet the demands of computation, NFS file serving and product data management, and Web hosting.

flexible financing

- operating leases with a variety of attractive terms
- the Tech Refresh program for cost-effective upgrades to stay on the leading edge of new technology
- bundled Solution Finance program to consolidate and simplify financing arrangements

instant capacity on demand for your hp server rp5470

iCOD

- instant activation of incremental CPU power when you need it
- pay only for the processing power you use

temporary capacity for iCOD

- temporary activation of incremental CPU power for a limited period
- ideal for short-term, predictable processing demands

stress-free

make your business your focus

The HP Servers rp5430 and rp5470 handle the demands of users efficiently and reliably—so you can concentrate on running your business, not managing your IT resources.

high availability for continuous operations

- a rich set of in-box high-availability features
- affordable high-availability clustering solutions based on industry-leading HP MC/Serviceguard
- self-healing capabilities, a first for entry-level servers—proactively avoid faults to improve uptime
- a critical building block for your always-on e-business needs

total solution support

- options ranging from Web-based services to the industry's only 6-hour call-to-repair commitment
- "one-stop" solution support delivered with partners such as Cisco, Oracle®, SAP, i2, Inktomi, and many more

best UNIX server family—top to bottom

The low-cost entry point to the two-way HP Server rp5430 through the more scalable HP Server rp5470 are part of the powerful HP UNIX server line—servers that set the standards for business-critical computing and total cost of ownership. Simple in-chassis upgrades let you move up the line as your business grows. HP UNIX servers provide the hardware foundation for an Internet infrastructure that is always on. Combining leading technology with proactive and reactive services, HP offers complete, end-to-end solutions that include hardware, software, applications, services, support, consulting, and an extensive portfolio of experienced partners, so you can get to market quickly with a single source of expertise. The HP UNIX server family is robust from the top to bottom—from the high-end HP Superdome; through the HP Servers rp8400 and rp7410, the midrange performance and price/performance leaders; and to the scalable entry-level HP Servers rp5430 and rp5470. Rounding out the family are the hyper-dense HP rp2400 series servers for Internet applications and branch offices.

hp servers rp5430 and rp5470 features and benefits at-a-glance

features	benefits
smart	
1–4 (rp5470) or 1–2 (rp5430) 875MHz PA-8700+ CPUs with 2.25 MB on-chip cache per CPU or 750MHz PA-8700 CPUs with 2.25 MB on-chip cache per CPU	Superior performance over comparable systems, with plenty of headroom for growth
Up to 16 GB (rp5470) or up to 8 GB (rp5430) SDRAM memory with advanced ECC protection	Fast and reliable processing power for frequently accessed data
Up to 10 (rp5470) or 6 (rp5430) PCI I/O slots with 3.2 GB/s (rp5470) or 2.3 GB/s (rp5430) I/O bandwidth	Easily handles I/O-intensive applications and allows the system to scale I/O, CPUs, and memory without compromise
Core I/O, including 10/100Base-T LAN with auto speed-sensing, a second 10/100Base-T support LAN, Ultra2 LVD SCSI, and RS-232	Provides easy, ready-to-go networking capabilities
Up to 4 internal 36 GB, 73 GB, or 146 GB Ultra320 SCSI hot-plug high-uptime disks	Store critical data with massive internal capacity
1 internal DVD or DAT drive	Protects critical data
7U chassis with up to 5 servers per standard 2-meter rack; also available in standalone (pedestal) configuration	Optimizes use of floor space and delivers high-performance density in a racked configuration
Easy in-box upgrades from the rp5430 to the rp5470	Architectural scalability ensures these servers can grow with the business, maximizing flexibility and investment protection
Support of Intel Itanium Processor Family as well as PA-RISC processors	Provides investment protection through dual growth paths
simple	
Built-in unlimited user license for proven 64-bit HP-UX 11i and 11.0	Proven, enterprise UNIX operating system for mission-critical applications
HP Virtual Partitioning for the rp5470	Maximizes usage of computing resources
Integrated HP Secure Web Console and Servicecontrol Manager for full local, Web, and remote control of servers	Provide complete single-system and multisystem administration capabilities, including a range of security features, from any browser-based PC
Flexible financing programs	Make initial ownership and modular growth easy and affordable
Instant capacity on demand (iCOD); temporary capacity for iCOD	Immediate access to CPU power when you need it, either permanently or temporarily
HP global deployment and partner integration services	Offer guaranteed error-free solution deployment to reduce implementation time and cost
HP On-site Solution consolidated manufacturing, streamlined product assembly and testing, and state-of-the-art integration	Ensure superior quality and faster delivery
stress-free	
Error-correcting cache, parity checking on all buses, memory scrubbing and page de-allocation, dynamic processor resilience, and de-allocation of application processes Dual Ultra 2 SCSI buses and controllers for mirrored storage Hot-swap, redundant power supplies and fans; redundant, hot-plug PCI; Ultra2 SCSI hot-plug disks	Built-in high-availability features deliver superior levels of • error correction, • error containment, • data protection, and • serviceability to help maximize uptime for business-critical workgroups and applications
Integrated Event Monitoring Service (EMS) Built-in fault management system with separate support processor and bus Integrated with HP MC/Serviceguard, HP Toptools for Servers, and enterprise management software such as HP OpenView and CA Unicenter	Provides superior system uptime through constant, proactive fault avoidance, detection, and notification; monitors power, cooling system hardware, processors, memory, HP-UX resources, and external storage
Pre-tested and pre-integrated workgroup clustering solutions based on HP MC/Serviceguard	Deliver complete, ready-to-go solutions for clustered high availability that eliminate all single points of failure, at an affordable price
3-year on-site service warranty and HP services and support options ranging from Web-based support to mission-critical, 6-hour Call-to-Repair commitment; includes full solution support for hardware and software	Reduce risk through worldwide support for business-critical computing; provide "one-stop shopping" for support through partnerships with Cisco, Oracle, SAP, BroadVision, Inktomi, and others

stay ahead of the curve

configuration options	hp server rp5430	hp server rp5470
processor	875MHz PA-8700+ or 750MHz PA-8700	875MHz PA-8700+ or 750MHz PA-8700
SMP configuration	1 to 2 CPUs	1 to 4 CPUs
supported OS versions	HP-UX 11i PA-8700+ HP-UX 11.0, 11i PA-8700	HP-UX 11i PA-8700+ HP-UX 11.0, 11i PA-8700
minimum/maximum memory	512 MB/8 GB	512 MB/16 GB

maximum internal disk capacity	584 GB (4 disk bays)	584 GB (4 disk bays)
standard I/O features	Ultra2 SCSI, 100Base-T LAN, 3 RS-232 ports, 100Base-T support LAN, and Web-based console	
supported I/O connectivity	Ultra2 SCSI RAID, Ultra2 SCSI LVD (single- and dual-port), FWD SCSI (single- and dual-port), Fibre Channel, Gigabit Ethernet, 100Base-TX (single- and quad-port), 100Base-FX, ATM 155 Mb/s (MMF, UTP-5), ATM 622 Mb/s (MMF), FDDI dual-attach LAN, Token Ring 100 Mb/s; X.25/FR/SDLC (dual-port), multiplexer (8- and 16-port)	

environmental specifications	
electromagnetic interference	Complies with FCC Rules and Regulations, part 15, as a Class A digital device; Manufacturer's Declaration to EN 55022 Level A; VCCI Registered, Class I; Korea RLL
AC input power	100-240V 50/60Hz
maximum current requirements	13.8A at 110V
maximum power dissipation	1283 watts
physical dimensions	Depth: 774 mm (30.5 in) Width: 482 mm (19.0 in) Height: 368 mm (14.5 in)/7 EIA units Weight: 68 kg (150 lb)
operating temperature	+5° to 35°C (41° to 95°F)
nonoperating temperature	–40° to 65°C (–40° to 149°F)
maximum rate of temperature change	20°C/hour
operating relative humidity	15% to 80%, noncondensing, max. wet bulb @ 26°C
nonoperating relative humidity	5% to 90%, noncondensing
operating altitude	To 3.0 km (10,000 ft) above sea level
nonoperating altitude	To 4.5 km (15,000 ft) above sea level
compliance model number	RSVL - 0105-A

hp serviceguard extension for RAC

proven, flexible high-availability solution

the challenge

To maintain and manage a highly available mission-critical parallel database environment

the solution

HP Serviceguard Extension for RAC

business benefits

- data protection
- application availability
- ease of management
- flexible and easy deployment of applications
- expert consulting and support services

To best meet data center requirements for availability, flexibility, and scalability, HP offers a robust architecture that combines multiple computers into entities called "clusters." The systems—or nodes—of a cluster are connected in a loosely couplec manner, each maintaining its own separate processor(s), memory, and operating system. Special communications protocols and system processors bind these nodes togethei and allow them to cooperate to provide outstanding levels of availability and flexibility for supporting mission-critica applications.

Clusters maintain strict compliance to the principles of open systems. There are no propriety APIs that force vendor lock-in and require substantial development investment. Most applications will run in a cluster without any modification at all. And only standards-based hardware components such as SCSI or Fibre Channel storage devices and FDDI Ethernet LANs are used to create a cluster.

Clusters provide a cost-effective, flexible architecture for meeting the demanding requirements of the commercial UNIX® market.

Building on the superior capabilities of HP Serviceguard, HP Serviceguard Extension for RAC (formerly called Serviceguard OPS Edition) allows a group of HP 9000 servers to be configured as a highly available cluster that supports Oracle9*i* Real Application Cluster (RAC) on both HP-UX PA-RISC and Intel® Itanium™ Processor Family platforms. These two products are tightly integrated to provide the best aspects of HP enterprise clusters and Oracle® relational database servers: high availability, data integrity, flexibility, scalability, and reduced database administration costs.

scaling beyond one system

Oracle9*i* RAC-enhancing scalability

With the introduction of Oracle9*i* Real Application Cluster (RAC), the unique architecture of a Serviceguard Extension for RAC cluster enables the full aggregate processing power of up to 16 nodes to access the database, increasing overall throughput for certain kinds of applications. Examples of applications that can benefit from the performance gains and scalability of this cluster include query-intense applications such as decision support, applications that generate random reads and writes to very large databases, and applications that access separate partitions of the database.

enhancing performance

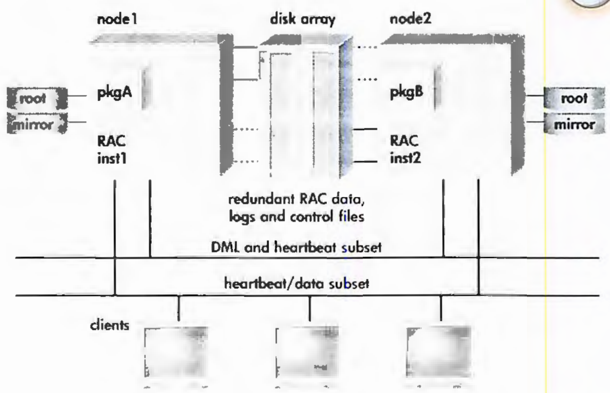
The new HP Hyper-messaging Protocol with Oracle9*i* RAC provides high-bandwidth, low-latency server-to-server communication that promises to deliver superior interconnect performance.

serviceguard extension for RAC

Serviceguard Extension for RAC provides all of the functionality needed to support the Oracle9*i* RAC environment on HP 9000 servers. The major components of Serviceguard Extension for RAC are listed here.

- **cluster manager:** establishes and monitors the cluster members and monitors various components within each node
- **cluster membership:** informs RAC about system failures to facilitate fast database recovery
- **package manager:** monitors and controls packages containing highly available applications
- **network manager:** detects and recovers from card and cable failures
- **shared logical volume manager** (ships with HP-UX): provides the basic functionality to share physical disks and buses between the nodes

Serviceguard Extension for RAC also provides further enhancements to the environment needed to support mission-critical applications. Special functionality is included to significantly enhance the availability of each node within the cluster and to provide extra protection for database integrity. Since high availability is a primary design goal, this cluster has been created with no single point of failure. The data disks are mirrored via a disk array, and multiple LANs are used.



key features and benefits

data protection

- multiple cluster arbitration mechanisms prevent failed nodes from jeopardizing the integrity of application data

availability

- local area network (LAN) monitoring ensures quick, transparent recovery to maximize database availability
- quick automatic detection and recovery time maximizes application availability and minimizes operator error
- the ability to survive multiple node failures provides a unique level of protection
- fast failback shortens startup time for applications in the primary active node
- rolling upgrades ensure application availability during hardware and software maintenance
- integration with HP Workload Manager ensures service-level objectives (SLOs) are maintained during planned and unplanned downtime
- tight integration with Oracle's specialized RAC HA Extension configuration offers quicker detection and failover
- the Enterprise Cluster Master toolkit provides quick and easy deployment of applications
- extended-distance clustering (up to 10 km) provides disaster-tolerant protection

flexibility

- multiple cluster configurations—active-active, active-standby, and rotating standby—offer flexibility

manageability

- an intuitive graphical user interface, Serviceguard Manager, reduces the total cost of managing multiple clusters from a single console
- support for virtual and hard partitioning addresses the increasing demand for systems consolidation

ROI

- integration with HP Pay per Use offers a cost-effective disaster-tolerant solution that is unique to HP

one call, one voice

hp and Oracle: joint facilities

To provide consulting and support expertise for customers working with enterprise clusters, HP and Oracle maintain joint facilities staffed with technical experts. These facilities are available for developing proofs-of-concept for new projects, executing benchmarks, and performing sizing activities for enterprise clusters.

support services

HP understands that ensuring a highly available mission-critical environment means more than just having the right technology—it is just as critical to have the right IT processes and support services in place. That's why HP has created a comprehensive portfolio of services, ranging from consulting, education and training, and disaster planning and recovery services to mission-critical support for HP hardware and software products—including Serviceguard Extension for RAC.

- **personalized systems support (PSS):** a comprehensive support solution. PSS combines proactive account services with industry-leading technical assistance to help you improve operational effectiveness and successfully manage and implement change within your IT environment.
- **business continuity support (BCS):** emphasizes downtime prevention through continuous improvement of your IT infrastructure, the best mission-critical processes, and constant vigilance. BCS starts with an extensive assessment to identify and analyze areas that put availability and service-level requirements at risk, and then it presents recommendations to minimize these risks.
- **critical systems support (CSS):** provides technical expertise through an integrated combination of proactive services and fast problem resolution to meet the demands of your computing environment. Also available through CSS is a portfolio of technical services designed to minimize system problems and downtime and to help you make more effective use of technology. Areas of interest include high-availability technologies, performance analysis, change planning, security review, and system administration.

value-added hp services

Because continued proactive management of your cluster is critical to ensuring high availability HP has introduced an additional technical service to help increase cluster availability and stability.

- **hp cluster consistency service (H8395AT)**—delivers a diagnostic tool for spotting potential disruptions to critical applications by identifying cluster configuration problems before they occur.

benefits of hp services

By taking advantage of HP services, you will realize major benefits:

- reduced implementation time with expertise, partnership, and hands-on assistance from your assigned high-availability–certified HP team
- decreased IT crisis risk and exposure through robust proactive services
- increased availability due to improved environment stability and rapid problem resolution through established and proven processes
- maximized end-user productivity thanks to optimized processes and system performance
- comprehensive planning support using proven HP methodology

hp server rp5400 series entry-level UNIX servers

August 2002

a technical white paper from Hewlett-Packard

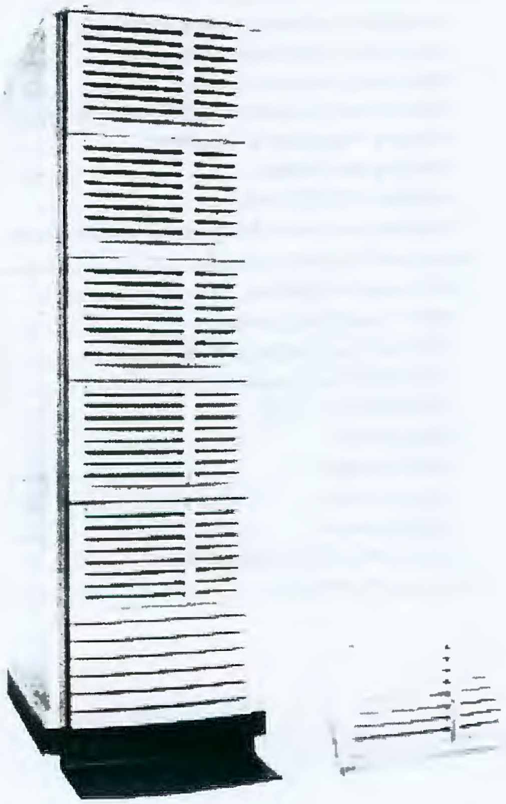

table of contents

introduction to the hp server rp5400 series

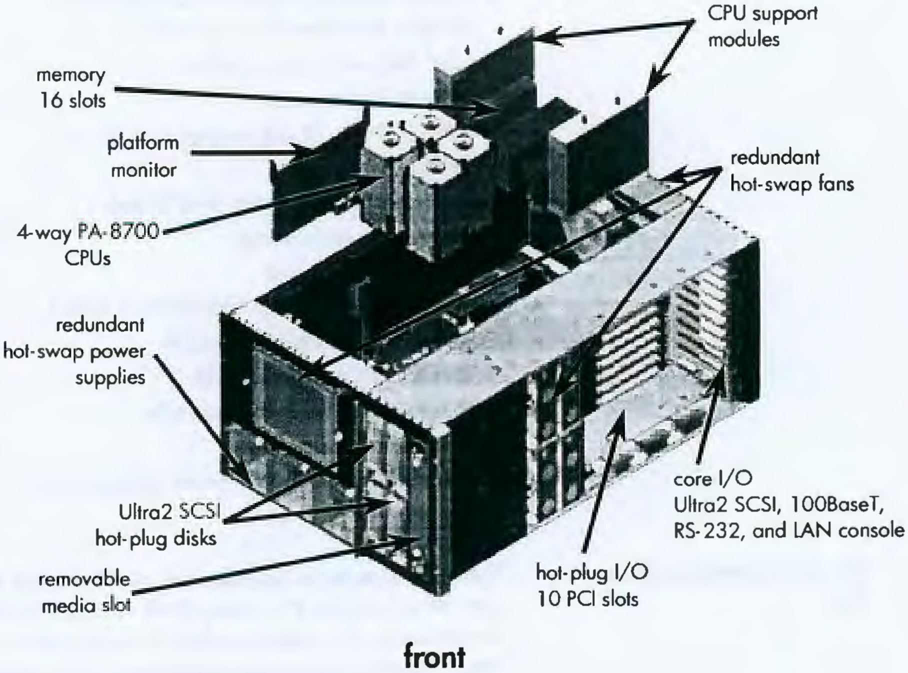
In today's economy, whether you're managing your own IT infrastructure or hosting someone else's, you have to operate with a faster time-to-solution, within budgetary constraints, and with the highest standards for customer service and operational efficiency.

The HP Server rp5400 series gives you the fastest and most reliable means to succeed in this new business environment. The rp5400 series consists of two products that deliver the proven performance, scalability, and high-availability capabilities of UNIX®—without high maintenance requirements and costs. And they give you plenty of room to grow. You can start with a low-price entry point and scale up to the leading 4-way UNIX performance—in the same form factor.

The rp5400 series is made up of two different servers, each with a unique ability to match your computing needs. The rp5430 is a 2-way system with time-proven, cost-effective PA-RISC technology. It offers the latest PA-8700+ processors and the same high-performance core electronics found in more expandable HP servers. The rp5470 is the high-performance flagship of the lineup. It supports up to 4-way PA-8700+ processing power and industry-leading bandwidth.

Both members of the rp5400 series use the same rack-optimized 7U package. This allows seamless scalability with simple in-box upgrades between servers in the series. Additionally, the rp5400 series was designed for board-swap upgrades to the Itanium 2-based HP Server rx5670. Together, the rp5400 series offers the industry's best 1- to 4-way lineup with unparalleled investment protection.

figure 1.1 a front view of the rp5400 series



CPU support modules
memory 16 slots
platform monitor
redundant hot-swap fans
4-way PA-8700 CPUs
redundant hot-swap power supplies
core I/O Ultra2 SCSI, 100BaseT, RS-232, and LAN console
Ultra2 SCSI hot-plug disks
hot-plug I/O 10 PCI slots
removable media slot
front

Figure 1.1 reveals the location of major components, as well as the mechanical and architectural features of the rp5400 series. The server is partitioned into two main electrical assemblies—the system board and the I/O backplane—and into three main volumes—processor and memory, I/O and disk, and power.

Looking at the front face, three hot-swap power supply bays are located in the lower left corner. To the right, a peripheral bay provides space for four hot-plug disks and one removable media device (either DVD-ROM or DDS-3). Directly above the power supply bays is the first of eight hot-swap cooling fans.

The right side of the system houses the I/O card bay. There are ten PCI I/O slots available. Two pairs of fans located here provide cooling for the I/O bay as well as the peripheral bay.

The opening at the top provides access to the system board, which supports the four CPUs, sixteen dual inline memory module (DIMM) slots, two processor support modules, and the platform monitor board. The core I/O is located at the rear of the system.

rp5430 features at-a-glance

- 1 to 2 PA-8700+ or PA-8700 CPUs
- 875MHz and 750MHz CPUs
- high-performance "stretch" core electronics complex (leveraged from rp7400)
- Intel® Itanium® 2 upgradable
- up to 8GB of memory
- 6 PCI I/O slots (5 are hot-plug 66MHz × 64-bit)
- 6 independent PCI buses for I/O slots
- N+1 power and cooling
- 4 hot-plug disk drives
- removable media bay: DVD-ROM or DDS-3
- 4.3GB/s system bus bandwidth
- 2.1GB/s I/O bus bandwidth
- 4.3GB/s memory bus bandwidth
- 64-bit HP-UX 11.0 & 11i
- high-density 7-EIA-unit, 19-inch rackmount or pedestal package

rp5470 features at-a-glance

- 1 to 4 PA-8700+ or PA-8700 CPUs
- 875MHz and 750MHz CPUs
- high-performance "stretch" core electronics complex (leveraged from rp7400)
- Intel Itanium 2 upgradable
- up to 16GB of memory
- 10 PCI I/O slots (8 hot-plug, 2 non-hot-plug; all are 66MHz × 64-bit)
- 9 independent PCI buses for I/O slots
- N+1 power and cooling
- 4 hot-plug disk drives
- removable media bay: DVD-ROM or DDS-3
- 4.3GB/s system bus bandwidth
- 3.2GB/s I/O bus bandwidth
- 4.3GB/s memory bus bandwidth
- 64-bit HP-UX 11.0 & 11i
- high-density 7-EIA-unit, 19-inch rackmount or pedestal package

the hp server product line

The rp5400 series is the entry-level cornerstone of the business-critical proven HP server product line. HP servers are #1 among UNIX servers for reliability, scalability, availability, and price/performance. This robust product line addresses the major computing challenges customers face today in online transaction processing (OLTP), electronic commerce (ECOM), Internet/intranet serving (Web), enterprise resource planning (ERP), supply chain management (SCM), and technical applications.

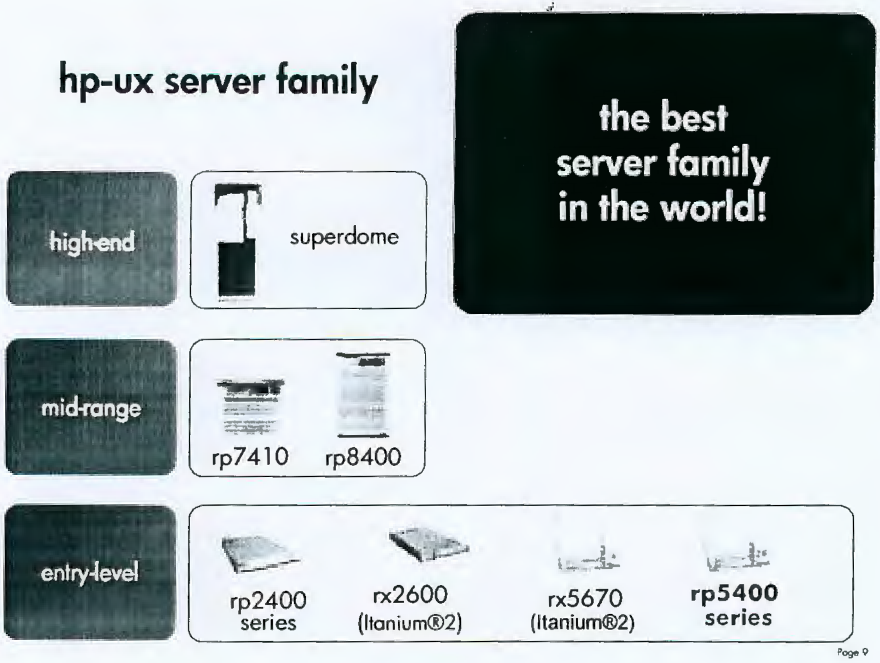
At the low end, affordable rp2400 and rp5400 series servers effortlessly handle Internet workloads and enterprise-size applications. Both platforms also add leadership price/performance and include bundled Internet software solutions.

In the midrange, the rp8400 and rp7410 deliver the high-performance, compact Internet-era UNIX server platform that today's IS executives are demanding. With up to 16 PA-8700+ processors, the HP server midrange lineup provides the robust performance and scalability needed for the most demanding workloads.

With exceptional OLTP performance, availability, scalability, and manageability, HP Superdome has become the pacesetter for high-end computing. Superdome, coupled with HP's always-on infrastructure strategy, provides UNIX application performance and Internet-critical high availability to help you meet the rigorous demands of e-services and systems consolidation, as well as large-scale, highly complex technical modeling and simulations.

All of HP's UNIX servers provide excellent investment protection with a smooth transition path to future PA-RISC and/or Itanium-based architectures. So whether your business requires cutting-edge e-services, systems consolidation, or a host of other solutions, our power-packed servers are business-critical proven and ready to meet the challenge—today and tomorrow.

figure 1.2 the industry's strongest UNIX lineup—top to bottom



binary compatibility

The rp5400 series supports the 64-bit HP-UX 11 operating system. With HP-UX 11, HP maintains its longstanding tradition of providing the industry's best record of investment protection. HP-UX provides forward binary compatibility, in which a fully bound application developed on an earlier version of HP-UX is ensured to run smoothly on HP-UX 11. Thus, current 32- and 64-bit applications can run without requiring recompilation.

Intel Itanium Processor Family ready

The rp5400 series was designed for several generations of PA-RISC and is upgradable to the Itanium 2-based HP Server rx5670. HP offers a board-swap upgrade to move any rp5400 series product or any legacy HP 9000 L-Class product to the Intel Itanium Processor Family.

The Intel Itanium Processor Family is based on Explicitly Parallel Instruction Computing (EPIC), a new architecture technology invented by HP Labs. The EPIC architecture breaks through the sequential nature of today's RISC and CISC processor architectures by allowing the software to communicate explicitly to the processor when operations can be done in parallel. EPIC serves as the enabler for future high-performance chips by providing explicit parallelism, massive resources, and inherent scalability not available with conventional RISC architectures. Increased performance is realized by reducing the number of branches and branch mispredicts and by reducing the effects of memory-to-processor latency.

Intel Itanium Processor Family transition

For the vast majority, the transition to the Intel Itanium Processor Family will be simple and seamless. For customers who require additional assistance, HP provides transition services around the world to help make this upgrade as smooth as possible. HP can provide assistance every step of the way, from assessment and design to verification and deployment. Consult the Intel Itanium processor section of HP's Web page for further information.

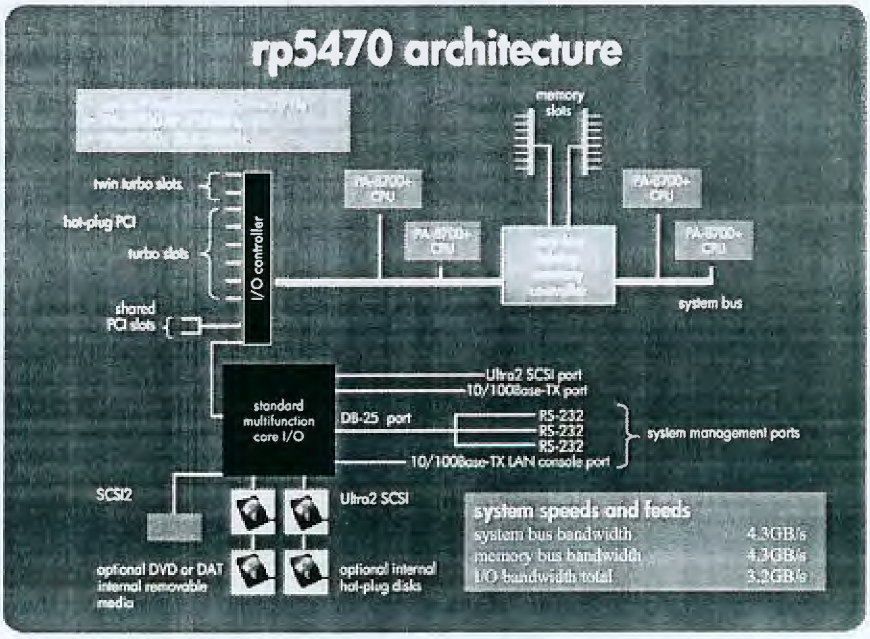
architecture

Figure 2.1 shows the relationship of the rp5470 main blocks with the buses that connect them. The rp5470 uses the "stretch" high-performance core electronics complex (CEC), which is also used in the midrange rp7400 server. This CEC, specifically designed for demanding Internet workloads, brings unprecedented levels of bandwidth and performance to the 4-way entry-level market.

Two front-side buses, both running at 133MHz, provide 4.3GB/s of bandwidth to four PA-8700+ or PA-8700 processors. The low-latency memory controller provides 4.3GB/s of memory bandwidth to two 8-slot memory extenders. The I/O controller provides twelve 250MB/s data channels, for an aggregate bandwidth of 3.2GB/s distributed among the 10 PCI slots and multi-function core I/O.

The rp5430 architecture is similar to the rp5470. However, only half of the processor, memory, and I/O slot capacity is utilized.

figure 2.1 rp5470 architecture



low-latency memory access

Both the rp5430 and rp5470 support one or two 8-memory-slot carrier boards, for a maximum of 16 memory slots. The memory for both systems is connected to the CEC through a low-latency/high-bandwidth bus. With approximately half the latency of HP's previous generation K-Class server, the rp5400 series can supply the CPU with requested data in a fraction of the time of competitive systems.

The rp5400 series uses state-of-the-art synchronous dynamic random access memory (SDRAM) technology, available in 256MB, 512MB, 1GB, and 2GB DIMM pairs, all with advanced error checking and correcting (ECC) protection to detect and correct single-bit errors. The rp5470 supports up to 16GB of total system memory. The rp5430 supports up to 8GB of memory. Although all sixteen memory slots are active in the rp5430, the system will not boot if more than 8GB of memory is loaded. Memory configurations should be planned appropriately.

The "stretch" core electronics complex used in the rp5430 and rp5470 supports memory chip spare. This high-availability technology detects and corrects multiple-bit errors on memory DIMMs. With chip spare, any single DRAM chip can fail and the system will continue to operate normally. Chip spare is not supported on the 256MB DIMM pair, nor is it supported on the older-generation rp5400 and rp5450 servers.

6.255

To decrease memory latency and improve performance, the memory address lines are buffered three times: once on the system board to drive each memory carrier, once on the memory carrier to drive banks of DIMMs, and again on each DIMM before driving the memory components.

speeds and feeds

Tables 2.1 and **2.2** show the theoretical maximum bandwidth for various system buses. Theoretical maximum bandwidth is defined as the bus width multiplied by the frequency and number of buses.

table 2.1 maximum bandwidth for rp5470 system buses

	# of buses (or controllers)	maximum bus bandwidth	aggregate bus bandwidth
twin-turbo PCI slots	2	500MB/s	1GB/s
turbo PCI slots	6	250MB/s	1.5GB/s
shared PCI slots	1	250MB/s	250MB/s
core I/O	1	250MB/s	250MB/s
I/O subsystem	1 (controller)	3.2GB/s	3.2GB/s
memory subsystem	2	2.15GB/s	4.3GB/s
CPU buses	2	2.15GB/s	4.3GB/s

table 2.2 maximum bandwidth for rp5430 system buses

	# of buses (or controllers)	maximum bus bandwidth	aggregate bus bandwidth
twin-turbo PCI slots	2	500MB/s	1GB/s
turbo PCI slots	3	250MB/s	750MB/s
core I/O	1	250MB/s	250MB/s
I/O subsystem	1 (controller)	2.1GB/s	2.1GB/s
memory subsystem	2	2.15GB/s	4.3GB/s
CPU buses	2	2.15GB/s	4.3GB/s

I/O subsystem design

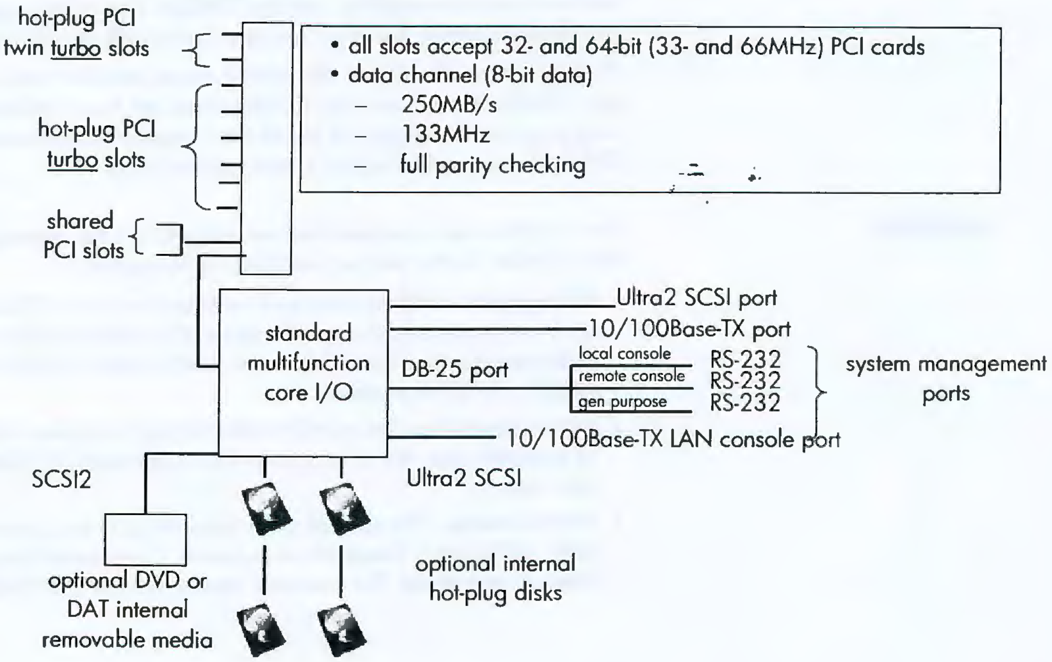
The rp5470 contains ten PCI I/O slots. The top eight slots have hot-plug capabilities under HP-UX 11i. The eight hot-plug slots all have independent I/O channels. This independent design prevents slow cards from affecting the performance of a fast card. Not only does independence provide great performance, but it also provides error containment. For example, if a card hangs slot 9, cards in slots 0–8 will still function properly. The first two hot-plug slots are twin-turbo slots, meaning they each have two dedicated 250MB/s channels or a total of 500MB/s per slot. These two slots should be reserved for the highest performing I/O cards, such as Fibre Channel, Gigabit Ethernet, or Hyperfabric controllers. The remaining six hot-plug slots are turbo slots, each with a single 250MB/s channel.

In addition to the eight hot-plug slots, the rp5470 has two shared PCI slots. These slots share a single 250MB/s channel.

All ten of the rp5470 I/O slots use HP-developed adaptive signaling technology to automatically match an I/O card's appropriate speed and data width. Therefore, all slots will accept 64- or 32-bit cards running at either 33MHz or 66MHz.

The rp5430 I/O subsystem is similar to the rp5470. In the rp5430, however, the shared PCI slots and three of the turbo slots are not active. Both twin turbo slots, four additional turbo slots, and the multifunction core I/O are available in the rp5430.

figure 2.2 **rp5470 I/O subsystem**



PCI is the optimized, industry-standard I/O bus. **Tables 2.3** and **2.4** summarize the PCI slots for each of the systems in the rp5400 series.

table 2.3 rp5470 PCI I/O

	# of slots	**hot plug**	**bandwidth per channel**	**bus width**	**signaling speed**	**slot keying**	**adaptive signaling**
twin turbo	2	yes	500MB/s	64 bits	66 & 33 MHz	5 volts	yes
turbo	6	yes	250MB/s	64 bits	66 & 33 MHz	5 volts	yes
shared	2	no	250MB/s	64 bits	33MHz	5 volts	yes

table 2.4 rp5430 PCI I/O

	# of slots	**hot plug**	**bandwidth per channel**	**bus width**	**signaling speed**	**slot keying**	**adaptive signaling**
twin turbo	2	yes	500MB/s	64 bits	66 & 33 MHz	5 volts	yes
turbo	4	3 of 4	250MB/s	64 bits	66 & 33 MHz	5 volts	yes

internal removable media

The rp5400 series contains a single removable media bay that can accommodate either a DVD-ROM or DDS-3. The media bay is supported by one of two SCSI controllers located within the core I/O.

A dedicated single-ended (SE) SCSI channel connects the media bay to the controller. The removable media bay does not support hot-plug capability. The DVD-ROM drive provides access of up to 650MB of data from one disk. The DVD-ROM drive provides enhanced features while preserving backward read compatibility with the CD-ROM. Data transfer rates of up to 6.75MB/s are achieved with the DVD format; 4.8MB/s can be achieved with the CD format.

The DDS-3 drive offered with the rp5400 series provides storage capacity of up to 12GB on a single tape. This drive can store up to 7.2GB of data per hour, and automatic read-after-write verification helps to ensure the integrity of stored data. Read-write backward compatibility with DDS-1 and DDS-2 allows continued use of existing archive tapes.

scalability

The rp5400 series is designed without tradeoffs in CPU, memory, internal storage, or I/O expandability to offer the best scalability in the market.

- **CPU upgrades**—With its entry-level configuration of one CPU and single-CPU increments available up to four processors, the rp5400 series offers great flexibility to cover a wide range of performance points. The rp5430 and rp5470 offer 875MHz PA-8700+ processors, as well as the 750MHz PA-8700 processor.
- **memory upgrades**—The rp5400 series memory subsystem is also designed for scalability. With 16 available slots, the servers range from a minimum of 256MB to a maximum of 16GB of main memory.
- **internal storage**—The rp5400 series supports up to four internal hot-plug disk drives, which can be either half-height or low-profile form factors. Current disk offerings include 18, 36, and 73GB Ultra160 disk drives. The maximum internal storage is 292GB, via four 73GB drives.

rp5400 series industrial design and packaging

The rp5400 series has been designed to fit into environments ranging from data centers to deskside. The industrial design is coordinated with other HP servers and peripherals for a consistent appearance.

racking density

The rp5400 series is designed to provide unprecedented performance density that easily adapts to different environments. At 7 EIA units (EIA unit= 1.75 inches), up to five rp5430 or rp5470 systems can be installed into a single 2-meter HP cabinet. With the high cost of computer room floor space, this small footprint dramatically lowers total cost of ownership.

The rp5400 series is supported in A490xA and A189xA cabinets. When using the high availability slider rail, bolt-on anti-tip feet are required. When using the slider in A189xA cabinets, ballasts are required (see the HP 9000 Enterprise Servers Configuration Guide for details).

The rp5400 series is also supported in a variety of third-party, non-HP racks and cabinets. Please refer to the HP 9000 Enterprise Servers Configuration Guide for the latest list of qualified third-party racks.

Note—dimensions for rack configuration: H= 12.25 inches (311 mm), D= 30.5 inches (775 mm), W= 19 inches (482 mm).

high availability slider rails

There are two rail options, static or slider, available for racking the rp5400 series into an HP cabinet. The high availability (HA) slider rails were designed to allow easy service access to the system, as well as to enable the hot-plug capability of the I/O slots and the hot-swap of four fans in the side cavity. With the HA slider rail, the rp5400 series can be completely serviced without removing it from the rack, thus allowing side-by-side racks of systems to be completely supported without sacrificing floor space for side access to the system. The slider rails also contribute to a 100% improvement in "mean time to repair" over D- and K-Class servers. The high availability slider rails are highly recommended.

Note—the slider mechanism occupies 1 EIA unit of rack space. When used with the rp5400 series, the combination will occupy 8 EIA units of rack space.

Static rails do not consume EIA space within the cabinet, therefore leaving more EIA space for peripherals. However, using static rails prohibits hot-plug of the I/O cards and hot-swap of the I/O bay fans.

cabinet spacing requirements

The rp5400 series requires a minimum of 24 inches (61 cm) of free space in both the front and rear of the cabinet for proper ventilation. During product installation and servicing, a total of 32 inches (82 cm) of free space is needed at the front of the cabinet.

The depth of HP A490xA cabinets is 39 inches (99 cm). Therefore, a minimum of 87 inches (221 cm) of total space is needed for each cabinet during normal operation. An additional 8 inches (21 cm) is needed during installation and servicing.

standalone/deskside configuration

The rp5400 series is also available in a standalone configuration when a cabinet is not desired. The standalone system is ideal for an office environment, under a desk, or on a shelf. The standalone configuration utilizes the same internal chassis and front plastic bezel as the racked version. However, a sheet metal cover, base, and casters are added for functionality and aesthetics. Casters can be removed when not desired.

Note—dimensions for standalone/deskside configuration: H= 14.5 inches (368 mm), D= 30.5 inches (775 mm), W= 19 inches (482 mm).

high availability

The rp5400 series has numerous high availability features that are unmatched in the entry-level server market—features such as redundant hot-swap fans and power, hot-plug I/O and disks, memory scrubbing and page deallocation, memory chip spare, independent PCI slots, failure avoidance and notification capability, and MC/Serviceguard support. These features improve the availability level of the total system and are introduced in this section.

redundant, hot-swap power supplies

HP power supplies have a long history of excellent reliability, and the redundant power supply option increases HP's commitment to even higher reliability and availability.

The rp5400 series power subsystem holds a maximum of three hot-swap power supplies. These supplies are located in the very front of the server. Each supply is capable of sustaining 930 watts of output. The rp5430 comes standard with one power supply; a second and even third supply can be added for N+1 or N+2 redundancy. The rp5470 comes standard with two power supplies; a third supply can be ordered for N+1 redundancy. Each power supply has its own power cord, which provides protection against losing the power from a single cord or breaker. To maximize availability, the power cords should be plugged into separate breakers whenever possible.

Because of the hot-swap capability, in the event of a power supply failure, the faulty supply can be removed and replaced without notifying the system. This, of course, is assuming that an N+1 condition exists.

Exchanging a power supply in a running system involves opening the hinged, front plastic bezel. The failed power supply is easily identified and removed. The power supply is exchanged with a good one and the door is then closed to finish the process. The system will log a management code to indicate that redundancy is re-enabled. It is that simple.

There is another advantage for those customers with rigorous preventative maintenance programs. While the server continues to operate, the power supplies can be removed one-at-a-time and dust buildup can be vacuumed using proper electrostatic discharge (ESD) procedures.

redundant power input protection

Figure 3.1 contains a diagram of the rp5400 series power subsystem. This section explains how customers can utilize these capabilities to achieve different levels of power input protection.

figure 3.1 power subsystem

3 power inputs (can be separate phases) for N+1 protection against AC power circuit failure
rear view
I/O

minimum supply
rp5430 = 1
rp5470 = 2
100 240V AC 50/60Hz
13.1 amp (@100V) total input current
shared across multiple power cords
1360 watt maximum power dissipotion
4380 BTUs maximum heat dissipation
support by 3 kVA and 5.5 kVA Powertrust UPS.

The server has three AC input line cords to reduce single points of failures. Each line cord supplies power to one of the three internal power supplies. The system is designed to operate on nominal 100–240 VAC and 50- or 60-Hz power without line-select switches. Each power supply can draw up to 930 watts. Because the servers will continue to operate with two of the three supplies functioning, many possibilities exist for the customer to configure the AC input depending on the level of protection desired. If the site has very stable AC power, all three line cords could be plugged into the same power grid. For additional protection, a single uninterruptible power supply (UPS) could be utilized to supply power to all three cords if primary AC power should fail.

- The next higher level of protection is to have three branch AC circuits, one for each AC input. This reduces the dependency on single-point breaker failures and common wiring. Additional protection for this configuration would utilize three smaller UPSs.
- The highest level of protection is three electrical utilities that each supply a branch circuit. This approach is expensive but does greatly reduce single points of failures. Large sites with many systems may find this configuration cost-effective. For the ultimate protection of large sites, install a large UPS on each branch circuit.

redundant, hot-swap cooling

The rp5400 series contains eight hot-swappable fans to cool system components. The eight cooling fans (1 front-access, 4 side-access, 3 rear-access) are arranged in an N+1 configuration so any fan can fail and not affect system uptime. In the event of a fan failure, the faulty fan can simply be removed and replaced while the server continues to run. The design pairs fans together. If one fan fails, the other speeds up to ensure adequate system cooling.

In addition, the server monitors ambient temperature and the power consumed within the box to determine the desired fan speed. By sensing the tachometer outputs from each fan, the actual speed is determined. Digital phase locked loop (DPLL) circuitry is used to individually adjust the speed of each fan to the desired common speed.

These smart algorithms reduce unnecessary fan noise, power consumption, and wear while producing a very clear indication of a working, cooling subsystem. In the unlikely event of a fan failure, it will drop out-of-lock with the DPLL. The server signals a fan failure via chassis codes to the console and will light an LED on the failed fan assembly.

There is another advantage for those customers with rigorous preventative maintenance programs. While the server continues to operate, the fans can be removed one-at-a-time and dust buildup can be vacuumed using proper ESD procedures.

main memory—advanced ECC and parity

Data stored in the main memory is protected by error checking and correcting (ECC) and address/control parity. The ECC design provides memory scrubbing and page deallocation functionality that will tolerate typical hard single-bit SDRAM failures without requiring DIMM replacement.

The data controllers generate ECC bits and store these ECC bits with the data in the DIMMs. The 256MB, 512MB, and 1GB DIMMs use x4 SDRAMs to store each bit of a word, including its ECC bits, in a different SDRAM within the DIMM pair. The 128MB DIMMs use x8 SDRAMs. When reading the data back, the data controllers are able to detect and correct single-bit data errors. Double-bit errors cannot be corrected. Double-bit data errors are highly unlikely because the data and ECC bits are stored one-bit-per-SDRAM, and multiple SDRAMs would have to be involved in the error. Hence, a single SDRAM could fail within each DIMM pair and the system would still function.

The system also detects address and control parity errors to prevent data corruption from reading or writing to the wrong location in main memory. The address controller and each address buffer generate address and control parity. Each address buffer detects address and control parity problems and reports it back to the address controller. There are three levels of address buffers as the address lines fan out. These address buffers are located on the system board and on each memory carrier on each DIMM.

memory chip spare technology

Chip spare is the ability of the system to continue to run in the face of any single or multi-bit chip error on a DRAM. DRAMs are basically N+1 per memory word. This functionality is essential in the design of reliable memory systems. Systems without this functionality are doomed to fail at an alarming rate when compared to HP servers.

Both the rp5430 and rp5470 support chip spare. The 256MB DIMM pair (product A5554A) does not support chip spare. To ensure maximum memory availability, the rp5430 and rp5470 should be configured with 512MB, 1GB, or 2GB memory modules only. The older generation rp5400 and rp5450 do not have chip spare capabilities.

hot-plug disk drives

The rp5400 series has four embedded SCSI disks accessible from the front of the server. These disks can be removed and inserted while the server continues to operate. This operation is called hot-plug, and it is different from hot-swap.

During both hot-plug and hot-swap operations, the power remains on and the system continues to function. However, hot-swap means that the assembly can be removed, added, or replaced without informing the system. Hot-plug requires the assembly to be deconfigured before removal and reconfigured before the system can utilize the newly inserted assembly. Because disks have unique information stored on them, hot-plug methods are used. Fans and power supplies are hot-swap assemblies.

Two dual-channel SCSI controllers manage the four internal hot-plug disks. For added availability, disk pairs are on separate channels as well as separate SCSI controllers. This means that with disk mirroring, a SCSI controller, SCSI channel, or root disk could fail and the server would continue to run properly.

The rp5400 series contains circuitry to properly control the disk's power and reset during the hot-plug operation. Either system administration manager (SAM) or the MESA suite of online diagnostic software can be utilized to effectively deconfigure and reconfigure the disk.

Another advantage for those customers with rigorous security programs is the ability to completely remove and isolate disks in a disaster- and theft-safe environment.

hot-plug PCI I/O slots

The ability to hot-plug PCI cards offers excellent flexibility for adding, reconfiguring, and maintaining I/O functions while the system continues operations. No reboot is required.

The I/O card bay is located at the right rear of the chassis. The I/O bay supports up to 10 PCI cards. Access to the I/O bay in rackmounted systems utilizing the high availability slider is achieved by sliding the server forward. Special features on the chassis, along with custom rack rails, allow the unit to move safely and smoothly during online service with all cables still attached. Once the system is slid into the service position, the I/O bay cover can be removed to gain side access to the PCI cards. In the standalone configuration, the outer shell is removed to gain access to the I/O bay.

The rp5470 has ten PCI I/O slots, and eight of those slots are hot-plug capable. Each hot-plug slot supports 64-bit × 66MHz PCI cards running at full speed and is connected to the I/O controller via independent, high-speed 250MB/s channels. This independent design prevents slow cards from affecting the performance of a fast card. Not only does independence provide great performance, but it also provides error containment. For example, if a card hangs in slot 10, cards in all other slots will still function properly. The highest-performing cards should always be placed in these independent slots.

The rp5430 has six PCI I/O slots. Ten physical slots are available, but only six of the slots are functioning electrically. Five of these six slots support hot-plug actions.

The PCI cards are spaced on a .9-inch pitch to allow for special hot-plug features and increased PCI reliability. Extra airflow holes between bulkheads more than double PCI airflow. Between the PCI slots, I/O card separators prevent electrical shorting and exposure to hazardous energy during hot-plug installation and removal. Locking features are designed into the main chassis to eliminate the need for individual PC board bulkhead screws, thus removing a potential electrical safety hazard.

Hot-plugging I/O cards have both hardware and software components. The hardware requirements are met by the electronics on the I/O backplanes and by mechanical design in the I/O cardcage. Bus idling, slot-to-slot electromechanical isolation, per-slot power and reset control, and visual indicators are all components of the total hot-plug hardware solution. With associated software, any card located in a hot-pluggable PCI slot can be removed, replaced, or added without power cycling, rebooting the system, or impacting the operation of other I/O transactions.

Please note that software support for hot-plug I/O is available in HP-UX 11i, but not in HP-UX 11.0.

dynamic processor deallocation and resilience

Every multi-CPU server with properly loaded HP-UX 11 has the capability for Dynamic Processor Deallocation and Resilience. Incorporated into HP-UX 11 is the capability to take a processor out of service while the system is running, without interruption to applications. This technology is referred to as Dynamic Processor Deallocation. Once a processor is deallocated, the HP-UX operating system will migrate all application processes that are currently scheduled on that processor to other active processors. Note that if the processor has been assigned to handle interrupts for any I/O drivers, it will continue to do so while it is deallocated.

The rp5400 series PA-RISC processors have the ability to detect and correct single-bit cache errors. The embedded event monitoring service (EMS) monitors the rate of correctable errors in each processor's on-board cache. These errors are manifested as low-priority machine checks (LPMCs). While occasional correctable errors are to be expected in the on-board cache, too many of these errors in a short period of time indicate an increased likelihood that a non-correctable cache error could occur. The EMS LPMC monitor will continuously monitor the rate at which LPMCs are occurring and dynamically deallocate a processor, using the Dynamic Processor Deallocation facility. This technology is referred to as Dynamic Processor Resilience.

manageability and support

The rp5400 series has many features to minimize the effort required to manage one system or an entire computer room. The server simplifies system management in several aspects: event notification, automatic error handling, power monitoring, and user interface to system management.

LED event notification

For an operator who is physically present, the simplest and easiest way to check system status is by quickly glancing at the status LEDs on the front of the system. The five LEDs each have a specific meaning:

- power—power is present and on, and power supplies are functioning properly
- remote—remote console is enabled
- run—system is up and running
- attention—occurrence of a non-catastrophic event, e.g., failure of an N+1 component
- fault—occurrence of a catastrophic system event

In addition to the five specific meanings of the LEDs, related system status is encoded based on whether the LED is solid or flashing. Examples include unexpected reboot system recovered, operating system not running, and operator intervention required.

event monitoring service

HP EMS is a system monitoring application designed to facilitate remote/centralized real-time monitoring and error detection for HP products in the enterprise environment. This framework provides centralized management of hardware devices such as the rp5400 series servers and system resources, and it provides immediate notification of hardware failures and system status. HP EMS can receive data on unusual activity, add information on the problem's source, and provide recommendations on problem resolution.

HP EMS consists of a set of system and network monitors within a monitoring environment. This monitoring framework has an easy-to-use interface and provides a mechanism for monitoring resources, registering monitoring requests, and sending notification when resources reach user-defined critical values.

How it works:

- A hardware event monitor detects abnormal behavior in one of the hardware resources (devices) it is monitoring.
- The hardware event monitor creates the appropriate event message, which includes suggested corrective action, and posses it to the EMS.
- EMS sends the event message to the system administrator using the notification method specified in the monitoring request (for example: e-mail, message to the console, entry in a system log).
- The system administrator (or HP service provider) receives the message, corrects the problem, and returns the hardware to its normal operating condition.
- If the peripheral status monitor (PSM) has been properly configured, events are also processed by the PSM. The PSM changes the device status to DOWN if the event is serious enough. The change in device status is possed to EMS, which in turn alerts MC/Serviceguard. The DOWN status will cause MC/Serviceguard to failover any package associated with the failed hardware resource.
- Any of the following consoles can be used with EMS to remotely monitor server farms: HP MC/Serviceguard, CA Unicenter, HP OpenView ITO, HP Secure Web Console, and HP Toptools.

The monitors can also poll hardware, disks, clusters, network interfaces, and system resources and send information to the framework. An "event" can be simply defined as something you want to know about—for example, a disk failure or file space dropping below a predefined level.

The primary EMS benefits include:

- enables efficient and effective system monitoring within a single, comprehensive framework
- delivers the ability to tailor the monitoring system to fit specific needs

- provides a wide variety of notification methods through multiple protocols (SNMP traps, TCP, UDP, OPC messaging)
- provides immediate alerts if a component fails, enabling proactive replacement
- integrates with HP MC/Serviceguard and Serviceguard OPS Edition to provide a complete high-availability solution

extended fault management system

The rp5400 series employs a dedicated processor to aid system management and diagnosis. The extended fault management system can diagnose a system failure even in the unlikely event that the system is unable to execute code. It allows system power to be remotely turned on or off, and it has battery backup that even allows diagnosis of power failures. The system interfaces with key components via an inter-integrated circuit (I^2C) bus to continually monitor the status of system fans, temperature, and power supplies; it signals the operator if any significant system events occur.

Major features of the extended fault management system include:

- system console redirection
- console mirroring
- configuration of system for automatic restart
- viewing history log of system events
- viewing history log of console activity
- setting inactivity timeout thresholds
- remote system control
- power control—remote power on and off
- viewing system status logs
- configuration of virtual front-panel display
- event notification to system console, e-mail, pager, and/or HP Response Centers
- auto system restart
- virtual front-panel display
- password security (same level as UNIX)

system platform monitor

Closely integrated with the extended fault management system is the system platform monitor. The system platform monitor controls and monitors system power and cooling. Aspects controlled and monitored by the system platform monitor are:

- power supply status and temperature
- system supply voltages—including remote system power on and off
- total system power consumption
- individual Processor Support Module status
- external ambient air temperature
- individual fan speed and status

Various temperatures are monitored to control the system fans, provide thermal warnings, and prevent permanent damage from overheating by graceful shutdown if the temperature is too high. (Note that the system fans are run only as fast as necessary to keep the system cool. The fans are kept in sync with each other, turning at exactly the same rate. This intelligent fan control allows the L-Class to generate as little noise as possible while maintaining an optimum operating environment to maximize reliability.)

The power monitor senses the presence of power supplies and the power consumption of system components to determine if the system is in an N or N+1 power configuration; it can determine:

- number of bulk power supplies
- number of CPUs
- amount of memory present
- number and power consumption of each installed PCI I/O card

System configuration and health is tracked by the system platform monitor and passed via a dedicated I^2C bus to the fault management processor. This information can be processed as follows: simply displayed on the system console, logged to an event file, or used to trigger an alert based on a specific threshold (system temperature, fan status, or power supply status, for example).

built-in Web console

The rp5400 series has integrated Web console functionality, which allows management of many systems from a single Internet browser. The Web console is embedded into the fault management processor and can be accessed through the core 10/100Base-TX management LAN. The external Secure Web Console box that shipped with older-generation HP servers is no longer needed. The Secure Web Console allows an Internet browser to be used as a system console, giving total system access to authorized system administrators anywhere, just as if they were at an ASCII console. A high level of password protection is used to control access to the Web console.

Major features of Secure Web Console include:

- system management over the Internet or intranet
- mirrored access—up to four operators can simultaneously share the same screen and keyboard
- security—built-in password encryption, data scrambling, and Java™ download protection
- universal browser-based support for Netscape v.3.0+ and Microsoft® Internet Explorer v.3.0+ Web browsers
- easy updates of Web console software over the network
- easy installation—just connect the L-Class console part to a LAN; there is no client software to install
- support for HTTP, FTP, TFTP, and other key Internet standards

LAN console

The server also provides a LAN console interface using industry-standard telnet connections. Like the Web console, the LAN console can be used remotely for managing many systems from a single control center. The telnet interface allows scripts to be used to vastly simplify multiple system management. Password protection provides a high level of security to control access to the LAN console, ensuring that only authorized personnel perform system management.

ASCII consoles

For users who wish to locally administer their systems, the rp5400 series provides an RS-232 part to use for ASCII terminal console connections. Any VT100-capable terminal or emulator can be used as a local system console.

remote access

As with previous HP server systems, an RS-232 interface for a remote console is useful for obtaining help from HP service experts. Customers need only add a modem to allow remote access via phone; security is ensured by having to explicitly enable remote console access, which is protected with a password, and via dial-back phone verification.

self-diagnosis

Many features have been designed into the server to maximize system uptime. There are several aspects to maximizing uptime: eliminating common single points of failure, allowing the system to continue running after some errors, and allowing quick identification and servicing of hardware faults if they do occur.

Besides using traditional diagnostic software, the server also continuously monitors system health with the platform monitor. Knowing a failure has occurred that reduces N+1 protection is important. It is important to minimize the risk of downtime by replacing a failed component as soon as possible to get back to the safety of an N+1 configuration. To enable this, the server provides several methods of event notification.

The rp5400 series has extensive firmware-based self-tests. These diagnostics are evoked on power-up or reset. The self-tests check for correct system operation prior to booting the operating system. The firmware diagnostics first check the processors, then processor caches and memory, and finally I/O devices. Testing complexity increases as more of the system is proven good and more pieces of the system can be relied upon to increase test coverage on the remaining parts. Self-test failures are reported to the system console and the support processor, along with failure specifics and recommended corrective action.

online and offline diagnostics

The rp5400 also offers traditional online and offline diagnostics to validate system health and provide extensive system fault coverage.

With online diagnostics, the system is tested while the operating system and applications continue to run. This allows basic testing of system components that are not currently being used, or it allows testing in situations where the testing does not prevent continued use of the operating system and applications.

Offline diagnostics provide increased coverage of system components for improved fault isolation and intensive system testing before returning to production.

CISCO SYSTEMS

CiscoWorks **VPN/Security Management** Solution Version 2.2

CiscoWorks VPN/Security Management Solution (VMS) is the flagship integrated security management solution from Cisco, and is an integral part of the SAFE Blueprint from Cisco for network security. CiscoWorks VMS protects the productivity and reduces operating costs for enterprises, by combining Web-based tools for configuring, monitoring, and troubleshooting enterprise VPNs, firewalls, and network and host-based intrusion detection systems (IDS). CiscoWorks VMS delivers the industry's first robust and scalable foundation and feature set that addresses the needs of small and large-scale VPN and security deployments.

Today's business challenges and resulting security deployments require more scalability than merely supporting a large number of devices. Many customers have limited staffing, yet are asked to manage a myriad of security devices. These customers must manage the security and network infrastructure; frequently update many remote devices; implement change control and auditing when multiple organizations are involved in defining and deploying policies; enhance security without adding more headcount; or roll out remote access VPNs to all employees and monitor the VPN service.

CiscoWorks VMS enables customers to deploy security infrastructures from a small to large environment, using the following multifaceted scalability features:

- Complete SAFE Blueprint Coverage

  To completely manage a SAFE environment, a network management solution must manage SAFE infrastructure components, support features based upon an appliance or Cisco IOS® Software, and support a range of management functions. CiscoWorks VMS is uniquely able to scale across SAFE Blueprint components, including firewalls, VPNs, and network- and host-based IDSs. CiscoWorks VMS also takes advantage of Cisco Secure Access Control Server (ACS) by using a common ACS logon. CiscoWorks VMS can manage a feature set through an appliance, for example, the Cisco PIX® Firewall, or through the Cisco IOS Software. Scalable management also involves more than configuring devices. CiscoWorks VMS provides the complete range of management with features to configure, monitor, and troubleshoot the network.

- Scalable Foundation

  CiscoWorks VMS implements a foundation with a consistent user experience, which makes it easier to scale management to many devices. CiscoWorks VMS provides users with a consistent GUI, workflow, ACS logon roles definition, platforms, database

Cisco Systems, Inc.

engine, installation, and more. An industry-leading feature of this foundation is the Auto Update feature, which allows numerous devices to be updated easily and quickly. Auto Update enables devices, even remote and dynamically addressed devices, to periodically "call home" to an update server and "pull" the most current security configurations or Cisco PIX operating system. Auto Update is required to effectively scale remote office firewall deployments across intermittent links or dynamic addresses. Prior policy updating methods relied on a "push" model. Although this model works for known devices, it does not work for remote devices with unknown addresses or devices that are not always active. Without Auto Update a more manual process is required to update each remote device. The Auto Update feature provides a dramatic scalability improvement for organizations that want to deploy devices with many remote and local locations. In addition to easier and faster policy updates, Auto Update also provides consistent policy deployments.

- Enterprise Operational Integration

  CiscoWorks VMS enables organizations to easily integrate management into their operations. One operational need is to replicate policies to multiple locations. The Smart Rules hierarchy addresses this need, by enabling administrators to define device groups and implement policy inheritance. For example, an administrator can define a device group for the New York sales office and deploy that same policy to all other sales offices quic and consistently. The Command and Control Workflow feature provides change control and auditing, and is particularly important for customers who have separate groups for network and security operations. The solution includes processes for generating, approving, and deploying configurations. This can help security operations to define and approve new policies. Network operations can later deploy the new policies during their regular maintenance window. An audit of the changes can be maintained.

- Centralized Role-Based Access Control (RBAC)

  Role-based access control enables organizations to scale access privileges. CiscoWorks VMS conveniently uses a common ACS logon for users, administrators, devices, and applications. CiscoWorks VMS enables different groups to have different access rights across different devices and applications.

- Integrated Infrastructure Management

  Scalability requires that multiple components be managed, not just firewalls, but also VPNs, network- and host-based IDSs, routers, and switches. CiscoWorks VMS not only manages the security infrastructure, but also manages the network infrastructure. Customers benefit from being able to manage these components from one solution. Integrated monitoring is also required to see the larger picture. CiscoWorks VMS provides integrated monitoring of Cisco PIX and Cisco IOS syslogs, and events from network and host-based IDSs, along with event correlation.

CiscoWorks VMS Functions

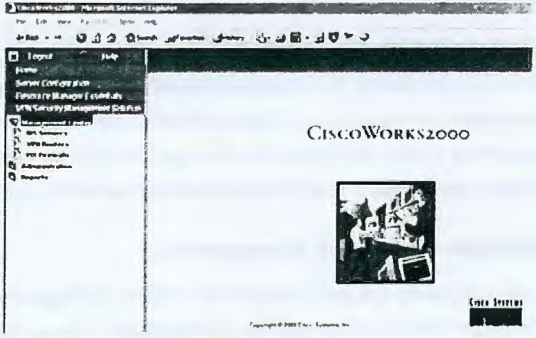
CiscoWorks VMS is launched from the CiscoWorks dashboard and is organized into several functional areas:

- Firewall management
- Auto Update Server
- IDS management, network and host-based
- VPN router management
- Security monitoring
- VPN monitoring
- Operational management

These functional areas supply multifaceted scalability by offering features such as a consistent user experience, auto update, command and control workflow, and role-based access control.

Figure 1 shows CiscoWorks VMS displayed as a "drawer" in the CiscoWorks dashboard.

Figure 1



Firewall Management

CiscoWorks VMS enables the large-scale deployment of Cisco PIX firewalls, by providing the following features:

- Smart Rules hierarchy and inheritance
- User-defined device and customer groups including nesting
- Global role-based access with administrative privileges per device and customer groups with other CiscoWorks products and Cisco Secure ACS
- Mandatory and default device settings inheritance
- Workflow deployment to device, directory, or Auto Update Server
- Look and feel of Cisco PIX Device Manager but with scalability to thousands of PIX firewalls
- Integration with other CiscoWorks network management software
- Complete SAFE Blueprint coverage for centralized management of Cisco PIX firewalls, including access control, VPN, IDS, and authentication, authorization, and accounting (AAA)

Smart Rules is an innovative feature that allows common information including access rules and settings to be inherited for all firewalls in a device or customer group. Smart Rules allows a user to define common rules once, which results in reduced configuration time, fewer administrative errors, and higher device scalability. Using Smart Rules, a user can configure a common rule such as allowing all HTTP traffic once and can apply this rule globally to all firewalls. Smart Rules can also be defined on a device or customer group basis. For specific information on the firewall management functionality of VMS, refer to: http://www.cisco.com/en/US/products/sw/cscowork/ps3992/index.html

Auto Update Server for Firewall Management

CiscoWorks VMS introduces the industry's first firewall Auto Update Server that allows users to implement a "pull" model for security and Cisco PIX operating system management. Auto Update Server permits remote firewall networks with unprecedented scalability. The Auto Update Server allows Cisco PIX firewalls to both periodically and automatically contact the update server for any security configuration, Cisco PIX Operating System, and PIX Device Manager (PDM) updates. The Auto Update Server supports the following features:

- Security management of remote Cisco PIX firewalls that use Dynamic Host Control Protocol (DHCP)
- Automated Cisco PIX OS distribution to groups of Cisco PIX firewalls
- Automated Cisco PDM updates to remote firewalls
- Configuration verification at periodic intervals
- Automated replacement of inaccurate or tampered configurations
- New firewalls configured at "boot time"

The Auto Update Server is an indispensable component of any large-scale remote Cisco PIX firewall deployment. Auto Update Server is an easy-to-use solution to automatically update all remote or local firewalls with new operating system releases. Cisco is the industry's first vendor to provide this pull model of security policy and operating system management. For specific information on the Auto Update Server component of VMS, refer to: http://www.cisco.com/en/US/products/sw/cscowork/ps3993/index.html

Network-Based IDS Management

Administrators can use CiscoWorks VMS to configure network and switch IDS sensors. Many sensors can be quickly configured using group profiles. Additionally, a more powerful signature management feature is included to increase the accuracy and specificity of detection. Some prominent features are:

- Easy-to-use Web-based interface
- Wizards that lead users through common management tasks
- Access to the Network Security Database (NSDB), which provides meaningful information about alarms for users without IDS security expertise
- Ability to define a hierarchy of sensors containing groups and subgroups, and the ability to configure multiple sensors concurrently using group profiles
- Support for several hundred sensor deployments from each console
- Use of a robust relational database to store a high volume of data

For specific information on the network-based IDS management functionality of VMS, refer to:

http://www.cisco.com/en/US/products/sw/cscowork/ps3990/index.html

Host-Based IDS Management

CiscoWorks VMS provides threat protection for server and desktop computing systems, also known as "endpoi VMS goes beyond conventional endpoint security solutions by identifying and preventing malicious behavior before it can occur, thereby removing potential known and unknown security risks that threaten enterprise networks and applications. Because CiscoWorks VMS analyzes behavior rather than relying on signature matching, its solution provides robust protection with reduced operational costs. Features of host-based IDS management include:

- Aggregates and extends multiple endpoint security functions by providing host intrusion prevention, distributed firewall, malicious mobile code protection, operating system integrity assurance, and audit log consolidation all within a single agent.
- Provides preventive protection against entire classes of attacks including port scans, buffer overflows, Trojan horses, malformed packets, and e-mail worms.
- Offers "zero update" prevention for known and unknown attacks

- Provides industry-leading protection for UNIX and Windows servers and Windows desktops allowing customers to patch systems on their own schedules.
- Open and extensible architecture offers the capability to define and enforce security according to corporate policy.
- Scalable to thousands of agents per manager to support large enterprise deployments.

For specific information on the host-based IDS management functionality of VMS, refer to: the Management Center for Cisco Security Agents Datasheet.

VPN Router Management

CiscoWorks VMS includes functions for the setup and maintenance of large deployments of VPN connections and provides users with a point-and-click interface for setting up and deploying connections. This application is intended for scalable configuration of site-to-site VPN connections in a hub-and-spoke topology for centralized, multidevice configuration and deployment of Internet Key Exchange (IKE) and IP Security (IPsec) tunneling policies on VPN routers.

Major features include:

- Wizard-based interface for the creation of IKE and VPN tunneling policies.
- Hierarchical inheritance and Smart Rules hierarchy to reflect the organizational and common setup of devices and simplified device management
- IKE-KA (IKE Keepalive) or generic routing encapsulation (GRE) with Open Shortest Path First (OSPF) and Enhanced Interior Gateway Routing Protocol (EIGRP) for failover routing scenarios.
- Centralized role-based access control model allows for centralized management of users and accounts.

For specific information on the VPN router management functionality of VMS, refer to: http://www.cisco.com/en/US/products/sw/cscowork/ps3994/index.html

Security Monitoring

CiscoWorks VMS provides integrated monitoring to reduce the number of security monitoring consoles, reduce the number of events to monitor, and provide a broader view of security status.

- Integrated monitoring is used to capture, store, view, correlate, and report on events from many of the devices in the SAFE Blueprint such as Cisco network IDSs, switch IDSs, host IDSs, firewalls, and routers.
- Event correlation is used to identify attacks that are not easily recognizable from a single event. A flexible notification scheme and automated responses to critical events also aid in quick action.
- The event viewer can read both real-time and historical events.
- Events are color-coded and administrators can quickly isolate problems. Administrators can also define thresholds and time periods when rules can be triggered to provide notification.
- On-demand and scheduled reports facilitate ongoing monitoring.

For specific information on the security monitoring component of VMS, refer to: http://www.cisco.com/en/US/products/sw/cscowork/ps3991/index.html

VPN Monitoring

CiscoWorks VMS offers a Web-based management tool that allows network administrators to collect, store, and view information on IPsec VPN connections for remote-access or site-to-site VPN terminations. Multiple devices can be viewed from an easy-to-use dashboard that is configured using a Web browser. This dashboard provides the following capabilities:

- Provides data on system resources related to real-time memory usage, percent CPU usage per device, and active tunnel and active sessions. This data simplifies the identification of devices with potential performance problems and devices with the highest usage.
- Enables viewing of current and long-term packet rates and packet dropped percentage which can aid in determining where excess capacity can be tapped or quickly identify bottlenecks and device throughput problems.
- Enables identification of the devices with the most persistent problems through the event log; key device and VPN statistics are evaluated against a set of global and device-specific thresholds, and exceptions are recorded in the event log.
- Provides graphing of important common metrics. Device performance comparisons provide a global view of short-term trends in VPN performance, enabling administrators to identify problem areas before they become critical failures.

For specific information on the VPN monitoring component of VMS, refer to: http://www.cisco.com/en/US/products/sw/cscowork/ps2326/index.html

Operational Management

CiscoWorks VMS provides the operational management for the network, allowing network managers to perform the following:

- Quickly build a complete network inventory
- Manage device credentials information
- Monitor and report on hardware, software, configuration, and inventory changes
- Manage and deploy configuration changes and software image updates to multiple devices
- Monitor and troubleshoot critical LAN and WAN resources
- Quickly identify devices that can be used for VPNs, if upgraded with the appropriate Cisco IOS Software
- Discover which VPN devices have hardware encryption modules
- Graphically compare configurations of VPN devices
- Isolate IPsec-related problems by running customized Syslog reports

For specific information on the operational management functionality of VMS, refer to: http://www.cisco.com/en/US/products/sw/cscowork/ps2073/index.html

Server Specifications (Minimum requirements)

Server Hardware

- PC-compatible computer with 1 GHz or faster Pentium processor
- Sun UltraSPARC 60 MP with 440 MHz or faster processor
- Sun UltraSPARCIII (Sun Blade 2000 Workstation or Sun Fire 280R Workgroup Server)

- CD-ROM drive
- 100BASE-T or faster connection
- 1 GB RAM
- 9 GB available disk drive space
- 2 GB virtual memory
- Color monitor with video card capable of 16-bit color

Server Operating System

CiscoWorks VMS requires the following operating systems:

- Windows 2000 Professional, Server, and Advanced Server (Service Pack 3)

Note: Support for Advanced Server requires that Terminal Services be turned off.

Sun Solaris 2.8 with patches:

109742 has been replaced by 108528-13

109322 has been replaced by 108827-15

109279 has been replaced by 108528-13

108991 has been replaced by 108827-15

Java Requirements

Sun Java plug-in 1.3.1-b24

Client Requirements

Hardware

- PC-compatible computer with 300 MHz or faster Pentium processor
- Solaris SPARCstation or Sun Ultra 10

Client Operating System

- Windows 2000 Server or Professional Edition with Service Pack 3, or Windows XP SP1 with Microsoft VM.
- Solaris 2.8

Client Browser

- Internet Explorer 6.0 Service Pack 1, on Windows operating systems
- Netscape Navigator 4.79, on Windows 2000 Server or Professional Edition with Service Pack 3, or Windows XP; Netscape Navigator 4.76 on Solaris 2.8

The CiscoWorks Management Center for Firewalls, and CiscoWorks Management Center for VPN Routers, are supported on Internet Explorer 6.0, but not on Netscape Navigator. In addition to supporting Internet Explorer The Management Center for IDS and the Monitoring Center for Security are also supported on Netscape Navigator.

Service and Support

CiscoWorks products are eligible for coverage under the Cisco Software Application Service (SAS) program. This service program offers customers contract-based 24-hour access to the Cisco Technical Assistance Center (TAC), full Cisco.com privileges, and software maintenance updates. A SAS contract ensures that customers have easy access to the information and services needed to stay current with newly supported device packages, patches, and minor updates. For further information about service and support offerings, contact your local sales office.

Ordering Information

CiscoWorks VMS is available for purchase through regular Cisco sales and distribution channels worldwide. CiscoWorks VMS includes all the necessary components needed for an independent installation on a Microsoft Windows or Sun Solaris workstation.

Data Sheet

Cisco IDS 4200 Series Sensors

Cisco integrated network security solutions enable organizations to protect productivity gains and reduce operating costs.

The Cisco IDS 4200 Series sensors are used in the Cisco Intrusion Protection System. These intrusion detection system sensors work in concert with the other components to efficiently protect your data and information infrastructure. With the increased complexity of security threats, achieving efficient network intrusion security solutions is critical to maintaining a high level of protection. Vigilant protection ensures business continuity and minimizes the effect of costly intrusions.

Additionally, Cisco's flexible deployment options allow businesses to minimize the total cost of ownership of their IDS deployments by delivering:

- unprecedented price/performance ratios
- the ability to simultaneously protect multiple network subnets through the support for multiple sniffing interfaces, thereby delivering up to five sensors in one
- a wide array of performance options
- investment protection by delivering modular, upgradable components
- support for multi-VLAN traffic
- embedded web-based management solutions packaged with the IDS sensors

Please refer to Table 1 for information on the characteristics of the Cisco IDS 4200 Series Sensors.

For details on the complete Cisco Intrusion Protection System, go to http://www.cisco.com/go/ids.

Deploying the Cisco IDS 4200 Series Sensors

The Cisco IDS 4200 Series includes four products: the Cisco IDS 4215, IDS 4235, IDS 4250 and IDS 4250-XL sensors. The Cisco IDS product line delivers a broad range of solutions that allow easy integration into many different environments, including enterprise and service provider environments. Each sensor addresses the bandwidth requirements at one of several speeds, from 80 Mbps to gigabits per second.

The Cisco IDS 4215 can monitor up to 80 Mbps of traffic and is suitable for T1/E1 and T3 environments. Additionally, multiple sniffing interfaces are supported on the IDS-4215 which allow the ability to simultaneously protect multiple subnets, thereby delivering five sensors in a single unit.

At 250 Mbps, the Cisco IDS 4235 can be deployed to provide protection in switched environments, on multiple T3 subnets, and with the support of 10/100/1000 interfaces it can also be deployed on partially utilized gigabit links.

The Cisco IDS 4250 supports a 500 Mbps speed and can be used to protect gigabit subnets and traffic traversing switches that are being used to aggregate traffic from numerous subnets. In addition, the Cisco IDS 4250 provides the flexibility to accommodate a simple hardware upgrade to scale to full line-rate gigabit performance.

At 1 Gbps, the Cisco IDS 4250-XL provides unprecedented performance by providing customized hardware acceleration to protect fully-saturated gigabit links as well as multiple partially-utilized gigabit subnets.

As shown in Figure 1, sensors can be placed on almost any network segment of the enterprise-wide network where security visibility is required.

Please refer to Table 2 for ordering information for the Cisco IDS 4200 Series Sensors.

Operating temperature	+5°C to +40°C (+41°F to +104°F)	10 to 35°C (50 to 95°F)	10 to 35°C (50 to 95°F)	10 to 35°C (50 to 95°F)
Nonoperating temperature	-25°C to +701/4°C (-13F to +1581/4°F)	–40 to 65°C (–40 to 149°F)	–40 to 65°C (–40 to 149°F)	–40 to 65°C (–40 to 149°F)
Operating relative humidity	5 to 95% (noncondensing)	8 to 80% (noncondensing)	8 to 80% (noncondensing)	8 to 80% (noncondensing)
Nonoperating relative humidity	5 to 95% (noncondensing)	5 to 95% (noncondensing)	5 to 95% (noncondensing)	5 to 95% (noncondensing)
Heat dissipation (most severe case with full power usage)	410 Btu/hr (full power usage (65W))	983 Btu/hr (maximum)	983 Btu/hr (maximum)	983 Btu/hr (maximum)

Note:

- This 80-Mbps performance for the Cisco IDS 4215 is based on the following conditions:
  - 800 new TCP connections per second
  - 800 HTTP transactions per second
  - Average packet size of 445 bytes,
  - Running Cisco IDS 4.0 Sensor Software
- This 250-Mbps performance for the Cisco IDS 4235 is based on the following conditions:
  - 3000 new TCP connections per second
  - 3000 HTTP transactions per second
  - Average packet size of 445 bytes

- Running Cisco IDS 4.0 Sensor Software
- This 500-Mbps performance for the Cisco IDS 4250 is based on the following conditions:
  - 5000 new TCP connections per second
  - 5000 HTTP transactions per second
  - Average packet size of 445 bytes
  - Running Cisco IDS 4.1 Sensor Software
- This 1000-Mbps performance for the Cisco IDS 4250-XL is based on the following conditions:
  - 5000 new TCP connections per second
  - 5000 HTTP transactions per second
  - Average packet size of 595 bytes
  - Running Cisco IDS 4.0 Sensor Software

Regulatory Compliance

- EMC—FCC (CFR 47 Part 15) Class A, CISPR 22 Class A, EN 55022 Class A, EN 55024, EN61000-3-2, EN61000-3-3, VCCI Class A, AS/NZS 3548 Class A, CE marking
- Safety UL 60950, CSA 22.2 No.60950, IEC 60950, EN 60950, AS/NZS 3260, CE marking.

Table 2 Ordering Information for the Cisco IDS 4200 Series Sensor

Product number	Product description
IDS-4215-K9	Cisco IDS 4215 Sensor (chassis, software, SSH, 2 onboard 10/100BASE-Tx interfaces with RJ-45 connector), 80-Mbps
IDS-4215-4FE-K9	Cisco IDS 4215 Sensor (chassis, software, SSH, 2 onboard 10/100BASE-Tx interfaces with RJ-45 connector plus 4FE interface card), 80-Mbps
IDS-4235-K9	Cisco IDS 4235 Sensor (chassis, software, SSH, 10/100/1000BASE-T with RJ-45 connector)
IDS-4250-TX-K9	Cisco IDS 4250 Sensor (chassis, software, SSH, 10/100/1000BASE-T with RJ-45 connector)
IDS-4250-SX-K9	Cisco IDS 4250 Sensor (chassis, software, SSH, 1000BASE-SX with SC connector)
IDS-4250-XL-K9	Cisco IDS 4250-XL Sensor (chassis, software, SSH, hardware accelerator, with dual 1000BASE-SX and MTRJ connectors)
IDS-XL-INT=	Cisco IDS Accelerator Card with dual 1000BASE-SX interfaces and MTRJ connectors
IDS-4250-SX-INT=	1000BASE-SX monitoring interface with SC connector
IDS-4FE-INT=	Spare 4FE (10/100 BaseTx) sniffing interfaces for 4215, 4235, & 4250
IDS-PWR=	Spare power supply for the Cisco IDS 4235 and 4250 sensors
IDS-SCSI=	Spare Small Computer Systems Interface (SCSI) hard disk drive for Cisco IDS 4250 Sensor
IDS-RAIL-2=	Two post rail kits for the Cisco IDS 4235 and 4250 sensor platforms
IDS-RAIL-4=	Four post rail kits for the Cisco IDS 4235 and 4250 sensor platforms

Cisco Intrusion **Detection** System

Q. What is a "network-based" IDS?

A. Two basic types of IDSs are on the market today: host-based and network-based systems. The fundamental difference between them is the source of the activity that they monitor and analyze to detect intrusions. Host-based IDSs monitor activity on a host or end system, while network-based IDSs monitor network traffic. Host-based IDSs are used to protect critical network servers or other individual systems containing sensitive information. Network-based IDSs are used to monitor activity on a specific network segment. Whereas a host-based IDS resides on a workstation and shares CPU with other user applications, a network-based solution is a dedicated platform. Network-based IDSs perform a rule-based or expert system analysis of traffic using parameters set up by the security manager, and the signatures, which flag suspicious or attack activity. The systems analyze network packet headers to make security decisions based on source, destination, and packet type. They also analyze packet data to make decisions based on the actual data being transmitted. These systems scale well for network protection because the number of actual workstations, servers, or user systems on the network is not critical, the amount of traffic is what matters. In addition, sensors placed around the globe can be configured to report back to a central site, enabling a small team of security experts to support a large enterprise. The Cisco® network-based Intrusion Detection System provides network administrators with enhanced security technology and capabilities to secure their networks.

Q. If I already have a firewall, do I really need an IDS?

A. Absolutely. Although an IDS will not replace your firewalls or other security devices for that matter, it serves a very complementary role and addresses certain risks that firewalls cannot. The primary function of the firewall is to control access to services and hosts based on your site security policy. If a service or connection to a specific host is permitted, firewalls typically permit all such traffic, and they do not inspect the content of the permitted traffic. An example is permitting public access to a Web server on a DMZ. All connection requests to the Hypertext Transfer Protocol (HTTP) port on that Web server will be permitted by the firewall, including malicious traffic directed at the HTTP server to exploit a buffer overflow vulnerability. Although most firewalls will not protect against data/content-driven attacks (for example, buffer overflow), IDSs will. Furthermore, firewalls typically will not protect you against attacks originating from inside your network or entering your environment from other ingress points not protected by firewalls (for example, remote access servers). IDSs can be strategically deployed to monitor activity from internal sources and other network ingress points without impacting your network. Deploying an IDS to complement your firewall(s) will significantly enhance your security posture.

Q. Is there a mechanism by which users may contact the IDS Product Team at Cisco?

A. Yes. Users may pose questions, requests, and comments to the following e-mail address:

ids-news@cisco.com

In addition, users have the ability to share experiences with other users and also pose questions to the Cisco IDS Engineering & Product Marketing teams at the IDS Networking Professionals Forum at:

http://forums.cisco.com/eforum/servlet/
NetProf?page=netprof&CommCmd=MB%3FcmdDdisplay_messages26mode3Dnew26location%3D.ee6e1fc

Q. Does anyone offer a managed IDS service using the Cisco IDS?

A. Yes, numerous managed service providers offer a managed IDS service using the Cisco IDS. These managed service providers include AT&T, Counterpane, IBM Emergency Response Services, NetSolve, Riptech, RedSiren, and Ubizen.

Sensors

Q. What are the new features of the Cisco IDS 4.0 Sensor software?

A. The Cisco IDS 4.0 Sensor software delivers a number of new features and enhancements to the network-based IDS portfolio. These features include:

- Re-architecture of communications protocol to enhance the efficiency of message transactions
- Common code base to allow feature parity between the appliance sensor and the switch sensor
- Delivery of a Layer 2 signature engine to mitigate issues such as man in the middle attacks and ARP spoofing in switched environments
- Introduction of an SMB engine to efficiently address attacks related to SMB
- Ability to capture the trigger packet that caused an alarm
- Enhanced shunning capabilities to allow shunning by port address
- Major enhancements to our existing protocol anomaly techniques
- Provision of Analysis Statistics Engine to deliver information of metrics such as bad checksums, bytes processed, data rates Mbps, TCP nodes per sec, and other analysis metrics
- Introduction of a full featured Cisco IOS-like CLI (command-line interface) for unprecedented sensor management over a secure SSH connection
- Capability of capture and display of the VLAN ID of the malicious traffic that was detected
- Enhancements to IP Fragmentation Reassembly
- Higher levels of granularity for the alarm information that is transmitted to the management console
- Support for ntp
- NAT support
- Logical signature groupings to allow global changes across the groupings
- Ability to implement exceptions to filter events to be displayed
- Tunability of IP session logging parameters

6.221
L

Q. What performance numbers (Mbps) are supported by the Cisco IDS Sensors?

A. The Cisco IDS 4215 supports 80 Mbps of performance and can be used to protect T1/E1/T3 environments.

At 250 Mbps, the Cisco IDS 4235 can be deployed to provide protection in switched environments, on multiple T3 subnets, and with the support of 10/100/1000 interfaces, it can also be deployed on partially utilized gigabit links.

The Cisco IDS 4250 supports superior performance at 500 Mbps and can be used to protect gigabit subnets and traffic traversing switches that are being used to aggregate traffic from numerous subnets.

Intrusion protection for fully saturated gigabit links is delivered by the Cisco IDS 4250-XL. Using customized hardware acceleration, the IDS-4250-XL can be used to protect gigabit subnets and multiple partially utilized gigabit links.

The Cisco Catalyst® 6500 Series Intrusion Detection System (IDSM-2) Services Module supports 600 Mbps. This module operates within the Catalyst 6500 Series and provides protection for traffic traversing the switch, which could be traffic from a single subnet or from numerous subnets that are being aggregated through the switch.

The Cisco IDS Network Module provides full-featured Intrusion Protection that is integrated into the Cisco 2600, 3600, and 3700 series routers. Each sensor addresses the bandwidth requirements of different routers up to 10 Mbps in the Cisco 2600XM, and up to 45 Mbps in the Cisco 3700 Series. By integrating IDS and branch office routing, Cisco reduces the complexity of securing WAN links and at the same time reduces operational costs. Additionally, by delivering full-featured intrusion protection to remote offices and branch offices, network administrators can now mitigate threats at these remote locations and effectively isolate them from the corporate network. The Network Module has the capability of inspecting GRE/IPsec encrypted packets that are traversing the router into which it integrates.

Q. How does the IDS sensor work?

A. Sensors monitor the network traffic by directly "tapping" the line (for example, via a shared-media hub) or by receiving copies of the traffic (for example, Switched Port Analyzer [SPAN] port on a switch) using a passive, promiscuous interface (the "monitoring interface"). The sensor analyzes the captured packets and compares them against a rule set of typical intrusion activity (that is, "signatures"). If the captured packets match a defined intrusion pattern in the rule set, the sensor sends an alarm to the management console and automatically responds (if configured to do so). The alarms are sent out a separate management interface so as not to impede continual packet capture by the monitoring interface.

Q. What kind of a performance impact does the sensor impose on the monitored network?

A. None. Sensors operate by "tapping" the network (for example, via a shared-media hub) or off copies of the packets (for example, via a switch SPAN port). The monitoring interfaces on the sensors are passive and do not source packets onto the network (the one exception is TCP reset packets for automatic response).

Q. How do you deploy sensors in a switched environment?

A. With most IDS products on the market today, sensors must be placed on the switch SPAN port to monitor network traffic. Although the SPAN port can provide access to network traffic, it does have certain limitations (for example, limited number of SPAN sessions). The Catalyst 6000 IDS Module was designed specifically to address switched environments by integrating the IDS functionality directly into the switch and taking traffic right off the switch backplane.

Q. What is the Cisco IDS Network Module for the Cisco 2600, 3600, and 3700 series routers?

A. The Cisco IDS Network Module is a network module that is installed in a Cisco 2600, 3600, or 3700 series chassis to provide full-featured intrusion protection services within the router. The Cisco 2600, 3600, and 3700 Series IDS Network Module provides the ability to inspect all traffic traversing the router, to identify unauthorized or malicious activity such as hacker attacks, worms, or denial-of-service attacks, and to terminate this traffic to suppress or contain threats.

Q. How does the Cisco IDS Network Module work?

A. The Cisco 2600, 3600, and 3700 Series IDS Network Module receives copies of packets directly from the router's backplane in a passive or promiscuous mode. The packets are passed through the internal monitoring interface for classification and processing. The Cisco 2600, 3600, and 3700 Series IDS Network Module analyzes the captured packets and compares them against a rule set of typical intrusion activity. If the captured packets match a defined intrusion pattern in the rule set, the IDS Network Module can take one of two actions. It can send a command to the router to either shut down the interface or it can send a TCP reset packet to the sender to stop the TCP session causing the attack.

Q. What is the rated performance of the Cisco 2600, 3600, and 3700 Series IDS Network Module?

A. The Cisco 2600, 3600, and 3700 Series IDS Network Module provides up to 10 Mbps for the 2600XM Series and up to 45 Mbps for the 3700 Series, depending on the platform in which the network module is inserted.

Q. Can the Cisco Network IDS Sensors monitor trunked traffic?

A. Both IDSM and the appliance sensors can monitior 802.1q traffic and, hence, are VLAN aware.

Q. What type of interfaces are supported on the appliance sensors?

A. Copper interfaces are supported on the IDS 4215 and IDS 4235. Both Copper and Fiber interfaces are supported on the IDS 4250 Sensor. The 4250-XL supports dual fiber interfaces with MTRJ connectors.

Q. Does Cisco IDS provide multi-interface support?

A. Yes. Dual sniffing interfaces are supported on the IDS 4250-XL. Up to 5 interfaces are supported on the IDS 4215, 4235, and 4250 Sensor appliances.

A configurable four Fast Ethernet interface card is provided for other models of the Cisco 4200 Series sensors to deliver a total of five sniffing interfaces for each sensor—one onboard sniffing interface plus four Fast Ethernet configurable interfaces.

The Cisco IDSM-2 can be used to monitor traffic from multiple interfaces. The network module for the Cisco access routers can monitor traffic from any of the router interfaces.

Q. Is the user notified when the sniffing interface of a sensor is disconnected?

A. Sensors are equipped with a monitoring interface for data packet capture and a command and control interface for transmitting alarms to the management console and receiving configuration information from the management console. When the sniffing interface is disconnected, an alarm is triggered. This setup provides the user with an alert mechanism when the interface is tampered with and, hence, assures persistent operation.

Q. Does the Cisco IDS Sensor provide an indication of when it is oversubscribed?

A. Yes. The sensor, IDSM, and network module issue an alarm when their respective performance ratings are exceeded.

Q. Where can I find more details on the IDS signature algorithms?

A. For more information on the signature algorithms, please refer to a white paper that may be downloaded at:

http://www.cisco.com/warp/public/cc/pd/sqsw/sqidsz/prodlit/idssa_wp.htm

Q. Does Cisco IDS protect against common IDS evasion techniques?

A. Cisco IDS also includes protection from a number of advanced, anti-IDS evasion techniques including:

- IP fragmentation reassembly
- TCP streams reassembly
- Unicode Web deobfuscation

Q. Can the sensor itself be attacked and compromised?

A. A properly configured and installed sensor cannot be compromised. The monitoring interface (connected to the production network) cannot be detected, and packets cannot be directed at it. The interface is in promiscuous mode, and has neither a protocol stack nor an IP address bound to it. It is not susceptible to "antisniff" detection techniques. The separate management interface does have an IP address, but Cisco recommends that a separate, isolated management subnet be used to provide connectivity from the management interface on the sensor to the IDS management console. In addition, only a very limited number of services are available from the management interface, and access controls can be configured to allow only designated management systems to connect to the sensor.

Q. What is Cisco Countermeasures Research Team (C-CRT)?

A. The core of the Cisco IDS solution—the advanced protection capabilities—is developed and maintained by C-CRT. This team of elite security professionals is dedicated to:

- Advancing countermeasures research
- Identifying and responding to new threats
- Distributing proactive signature files and signature micro-engines
- Maintaining our network security database (NSDB)
- Contributing research to the Cisco Security Encyclopedia (CSEC)
- Improving the state of threat mitigation science

The C-CRT is comprised of elite "white hat" personnel. C-CRT's esteemed credentials include:

- *Heritage and tenure*—most joined Cisco through the WheelGroup acquisition.
- *Government clearance*—greater than 65 percent have held Secret and Top Secret Department of Defense security clearances.
- *Military backgrounds*—experience logged from USAF Information Warfare Center, Department of Defense (DOD), Department of Energy (DOE), National Security Agency (NSA), Central Intelligence Agency (CIA), or other notable government organizations.
- *Security experience*—average member of the C-CRT has over six years of computer security experience, allowing Cisco to deliver the most mature, accurate, and industry-proven intrusion protection solutions.

Q. Can I create my own signatures?

A. Because the security objectives for each IDS deployment are unique, Cisco IDS adds granularity to the way in which sensors may be tuned to specifically suit the environment in which they are deployed. Using our innovative TAME (Threat Analysis Micro Engine) policy language, users can create new policies or modify existing policies to meet their unique security objectives. Since the TAME policies are decoupled from the sensing application, changes can be made without affecting sensor performance or reliability.

Q. Is it possible to record and replay the IP session of the source IP address that triggered an IDS alarm?

A. IP session logging provides extensive logging that is important for system troubleshooting as well as for reconstructing system events before and after attacks. Cisco IDS augments this capability by converting these logs to a standard TCP dump format that allows them to be viewed and replayed using public domain utilities, such as Ethereal and TCPReplay.

Q. Can the sensor detect attacks if the traffic is encrypted, for example IPsecurity (IPsec) or Secure Sockets Layer (SSL)?

A. The Cisco IDS Sensor analyzes both packet header information (context data) and packet data information (content data) to determine if suspicious activity is occurring. Encryption algorithms encrypt the data portion of the packet for confidentiality. Because it can process only what it can "see," the Sensor cannot detect attacks that require inspection of the payload or data fields within a packet. It will, however, still alarm and respond to attacks, which are detected from the unencrypted packet header information. All network-based IDSs suffer this problem. Therefore, in networks carrying encrypted traffic, Sensor placement is critical. To take advantage of their full intrusion-detection capability, the Cisco IDS Sensors should be installed where the traffic has already been decrypted. Otherwise, the Sensor can be placed on an encrypted segment and will detect all but the packet data or payload-based attacks.

Q. What techniques does Cisco use for mitigating threats?

A. Several techniques provide comprehensive protection against the latest cyber threats, including simple pattern matching, stateful pattern matching, protocol anomaly detection, heuristic-based detection, and anomaly detection.

Q. Does Cisco IDS deliver Peer to Peer signatures?

A. Yes. Cisco IDS delivers protection against file-sharing threats with support for advanced P2P attack mitigation techniques.

Q. How are the Cisco IDS signatures updated?

A. Cisco posts signature updates on Cisco Connection Online (CCO) approximately every 14 days. Cisco IDS provides a facility to automatically distribute new signature files and application upgrades to sensors without operator involvement. Utilizing a secure staging technique, new signature files are placed on a central server and passed to the sensor at scheduled intervals. After verifying the integrity of the package, the sensor automatically installs the update. This new capability significantly streamlines the process of regularly updating remote sensors, thereby lowering the recurring operational costs associated with this task. Additionally, users can subscribe to Cisco Active Update notification services to stay informed about breaking vulnerability news and posted countermeasures at:

http://www.cisco.com/warp/public/779/largeent/issues/security/idsnws/archive.html

Users may refer to the following site for a chronological listing of the Cisco IDS Active Update Notification Bulletins:

http://www.cisco.com/warp/public/779/largeent/issues/security/idsnws/archive.html

Q. How do the Cisco IDS Sensors and management consoles communicate with each other?

A. Communication between the Cisco IDS 4.0 Sensors and management consoles is provided by a secure (SSL) XML based messaging format. All alarm transmissions from the sensor to the management console are acknowledged.

If connectivity from the sensor to the management console is disrupted, the sensor will continue to monitor the network, and will queue alarms and retransmit until successful.

Q. How much additional network traffic does the Cisco IDS generate?

A. Because each alarm and acknowledgment is contained in a single UDP packet, there is negligible impact on network traffic.

Q. Is there a site that lists all the supported Cisco IDS signatures?

A. Yes. Users may access the latest Cisco IDS signatures at the Cisco Secure Encyclopedia site at:

http://www.cisco.com/pcgi-bin/front.x/csec/idsHome.pl

Q. Does Cisco support a centralized site that contains a compiled listing of the latest vulnerabilities?

A. Yes. Cisco's Security Encyclopedia is a one-of-a-kind clearinghouse of security and vulnerability information. Unlike other security databases that simply consolidate vulnerability information published on a number of public-source Web sites, the CSEC contains statistics on the vulnerabilities by industry or by sector. These statistics are compiled from over 400 actual Security Posture Assessments (SPA) performed by the Cisco Security Consulting team. CSEC is developed and maintained by the elite C-CRT. You may visit the CSEC site at:

http://www.cisco.com/go/csec

Q. Where can I download the latest IDS software?

A. Both current and archived IDS Sensor software can be downloaded at the Software Center on CCO (CCO login required):

http://www.cisco.com/public/sw-center/ciscosecure/ids/crypto/

Q. Where can I access documentation on the Cisco IDS Sensor Software?

A. Documentation for sensor software updates are available at:

http://www.cisco.com/univercd/cc/td/doc/product/iaabu/csids/index.htm

Threat Response Technology

Q. Is Threat Response an event correlator?

A. Threat Response is not an event correlator. Event correlation involves analyzing data from NIDS sensor, firewalls, routers, and other sources. Instead of correlating this type of data, Threat Response investigates the actual target of an attack. This is the same process an expert network security specialist would use, and is the best way to determine if a system has been compromised.

Q. Does Threat Response conduct network vulnerability scans?

A. No, Threat Response does not conduct enterprise wide scans of your environment, nor does Threat Response inventory your network. The designers of Threat Response have been network administrators for large mission-critical enterprises such as the U.S. Pentagon and know that downtime is unacceptable. Because of this, Threat Response conducts a low-impact investigation of targeted systems only when needed. Threat Response is able to work in dynamic network environments (including DHCP and wireless) without the need to run regular vulnerability scans that can disrupt your enterprise.

Q. Does Threat Response require deployment of software across the enterprise?

A. No, Threat Response does not require the deployment of software across the enterprise. Threat Response accesses these systems in the same way a security network administrator would—with read access privileges.

Q. How does Threat Response stay up to date with the latest attacks?

A. Cisco releases updates to keep the Threat Response IDS signature database up to date with the IDS vendors, as well as corresponding forensic signature updates to investigate IDS events. When an update is available, the administrator will be notified via the Threat Response GUI and can use the integrated auto-update feature to keep the product current.

Q. What does Threat Response do once real attacks are identified?

A. Threat Response will provide the user with detailed information on how the event was investigated, as well as any forensic data gathered showing details on the actual attack. This information can then be used by an administrator to quickly remediate an intrusion.

Q. What type of systems can Threat Response investigate?

A. Threat Response can conduct a full active investigation of systems running Windows-based operating systems. For systems running Linux, Solaris, and other forms of UNIX, Threat Response will perform passive checks as a first line of investigation. Based on this initial analysis, Threat Response can eliminate many alarms that are not targeted to those specific platform types.

Q. How do I get Threat Response technology?

A. Threat Response technology is currently available as a full featured, 90-day free trial software solution. The trial version ships with every Cisco IDS sensor. Once the trial has expired, customers have the choice of:

- switching to a reduced capabilities free version (only conducts basic level investigation of the targeted system)
- purchasing the full featured version, which will be offered as part of a VMS bundle

Management

Q. What management console options are available for the Cisco IDS?

A. See Table 1 and Table 2.

Table 1 Event Management

	IEV	IEV with CTR Technology	VMS SecMon	VMS SecMon with CTR Technology
Deployment method	Dedicated system required	Dedicated system required	Dedicated system required	Dedicated system required
GUI type	Java desktop application	Browser-based GUI	Browser-based GUI	Browser-based GUI
# sensors	5	5	Unlimited	Unlimited
Event types	IDS	IDS	IDS, Firewall, Router	IDS, Firewall, Router

Table 2 Device Management

	IDM	CLI	VMS Management Center
Deployment method	Integrated on sensor	Integrated on sensor	Dedicated system required
GUI type	Browser-based GUI	Browser-based GUI	Browser-based GUI
# sensors	Unlimited, by sensor	Unlimited, by sensor	Unlimited, by sensor groups
Event types	IDS	IDS	IDS, Firewall, Router

IEV = Cisco IDS Event Viewer, included free of charge with IDS sensor
VMS SecMon = CiscoWorks Monitoring Center for IDS, part of the CiscoWorks VMS bundle
IDM = IDS Device Manager, included free of charge with the IDS sensor
CLI = Command-line interface, included free of charge with the IDS sensor
VMS Mgmt Center = CiscoWorks Management Center for IDS, part of the CiscoWorks VMS bundle

For More Information

More information on Cisco's VMS solutions can be found at:

http://www.cisco.com/go/vms

In addition, augmentation to the alarm viewing, analysis, and reporting capabilities of the Cisco IDS Management solution are provided through third-party applications that are available from Cisco Security Associates partners.

For more details see:

http://www.cisco.com/warp/public/778/security/sap/management.html

Q. Are Cisco IDS communications encrypted?

A. IPsec functionality is included on the appliance Sensors to allow customers to encrypt traffic to management consoles with IPsec capabilities.

Q. If I lose connectivity to a remote sensor, can I tell from the management console?

A. The Cisco IDS management consoles monitor the health of a Sensor via a continuous heartbeat. If communications with the Sensor are lost for more than one minute (by default), a visual indicator is displayed on the management console, indicating a communications failure with the Sensor. If it is determined that a sensor has failed, it can be quickly replaced with another sensor and the configuration, stored on the management console, and can be quickly pushed to the new sensor.

Q. How many sensors can one Cisco IDS Management console manage?

A. Although the technical limit is very large (greater than 1000), Cisco typically recommends a ratio of 20 to 25 sensors per management console for practical reasons. With ratios greater than this, operators can be easily overwhelmed with the volume of information that they may be required to analyze, thereby diminishing the overall effectiveness of the IDS. For deployments larger than 25 sensors, multiple management consoles can be installed to scale the number of sensors.

Q. Can I have multiple Cisco IDS management consoles?

A. The Cisco IDS architecture supports the deployment of multiple management platforms. Sensors can send alarms to multiple management consoles simultaneously, and management consoles can forward alarms to other management consoles, allowing customers to build large, hierarchical management infrastructures.

Cisco IDS Accomplishments

Innovation – Leadership - Expertise

- 1996: First commercial network IDS
- 1998: Acquisition of WheelGroup
- 1999: Integration into Cisco IOS software
- 2000: Migration into Catalyst switch hardware
- 2001: Extensions of IDS appliance line and software
- 2002: Introduction of Gigabit sensing, embedded management, new Enterprise-class management and monitoring, intent to acquire Psionic
- 2003: Hardware-accelerated Gigabit sensing, converged code, false-positive reduction, in-line IDS, extended network integration

Efficient Intrusion Protection
Value Proposition

Efficient Intrusion Protection customers can deploy today:

- Accurate Threat Detection
- Intelligent Threat Investigation
- Ease of Management
- Flexible Deployments Options

Cisco's Unique Approach

Cisco.com

- Delivering dedicated and network integration devices – horizontal integration
- Increasing accuracy and reducing false-positives with combination of multi-mode threat detection and newly acquired threat response investigation
- Minimizing Total Cost of Ownership with hardware-integrated solutions and easy-to-use, scalable management and monitoring applications
- Leveraging seven years of leadership and innovation in IDS industry delivering accurate, reliable, and proven solutions. Team of security experts.

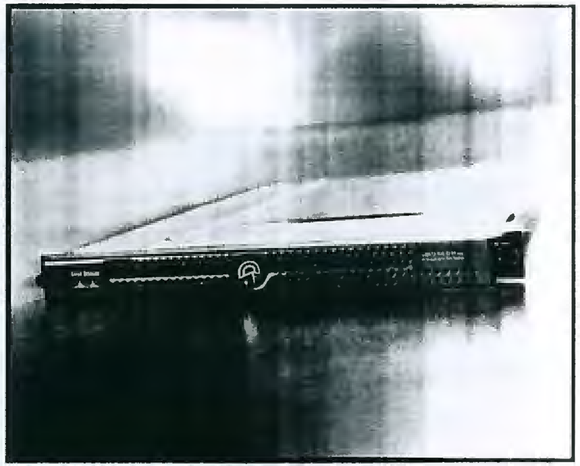
Gigabit Sensor Appliance - IDS-4250-XL

Performance-optimized, turn-key appliance

- 1000 Mbps performance
- NPU-based accelerator card
- Multiple sniffing interface support
- Integrated, web-based UI
- 1 RU form factor
- Optional redundant power

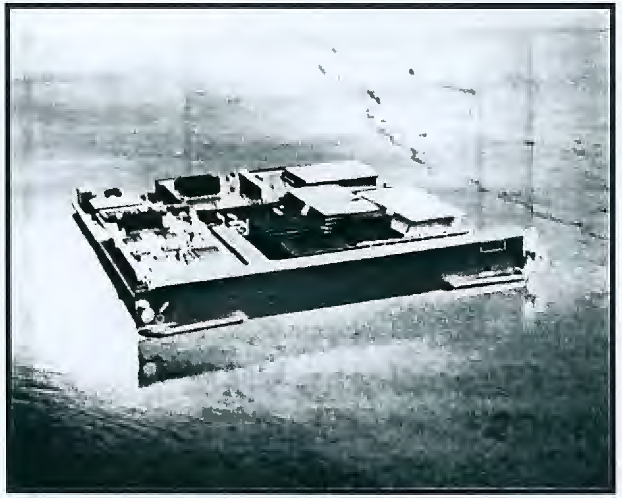


IDS 4250-XL
Performance: 1000 Mbps
Price: $40,000
Availability: Feb. '03

2nd Gen. Catalyst 6500 Module - IDSM-2

Network integrated security services module

- 600Mbps performance
- NPU-based accelerator card
- Integrated, web-based UI
- Occupies 1 slot in switch
- Fabric enabled
- *NTE Price: $29,995*
- *Availability: Mar 2003*



IDSM-2
Performance: 600 Mbps
NTE Price: $29,995
Availability: Feb. '03

CiscoWorks VMS
IDS Management Ctr
Security Monitor

Element Management
IDS Device Manager
IDS Event Viewer

Management Server

- Aggregate events from NIDS, HIDS, Firewall, and IOS syslog
- Central policy config

Sensors

- Network appliances
- Switch line cards
- Router software
- Firewall software
- Host/server sensors

Robust Sensing Protection

- Accurate Detection

  Leverage Multi-Mode Threat Detection

  Simple pattern matching, stateful pattern matching, protocol decoding, and heuristics analysis

  Unique Adaptive Scanning to validate events

- Reliable System

  Hardware-based, single vendor

- Active Response

  In-line: Drop packet or reset connection

  Passive: Reset connection or modify router/firewall

- Flexible Design

  T.A.M.E. signature language

  Customizable thresholds

  Broad delivery options – appliance, modules, line cards, agents

Scalable Configuration Management

- Enterprise Scale

  Manage 100s of devices

  Control IDS, FW, and VPN

- Flexible Device Grouping

  Group devices by function, by location, by configuration to perform mass configuration

  Deploy global settings quickly

- Roles-based Access Control

  Control administrative access to ensure authorization

- Secure Communications

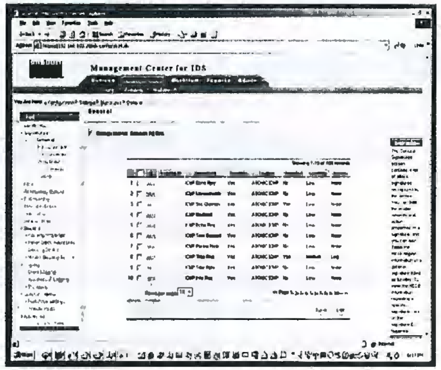
- Tiered Approval Model (optional)

  Separate configuration definition and deployment (maker-checker model)

- Granular Device Control

  Device embedded UI for detailed configuration control

Enterprise Management



Management Center for IDS

IDS Version 4.0

Cisco.com

- Convergence of IDS code bases

  Develop once, populate many

  Feature parity

  Consistent user experience

- Entry into “true” Gigabit IDS market

  Custom HW acceleration card (Intel IXP 1200)

  500 Mb appliances & IDSMs field upgradeable

- False-Positive Reduction

  Release new Cisco Threat Response product

  Extend our protocol analysis

- Remote Data Exchange Protocol (RDEP)

  XML-based configuration and event generation

  Pull vs. push method for event collection & analysis

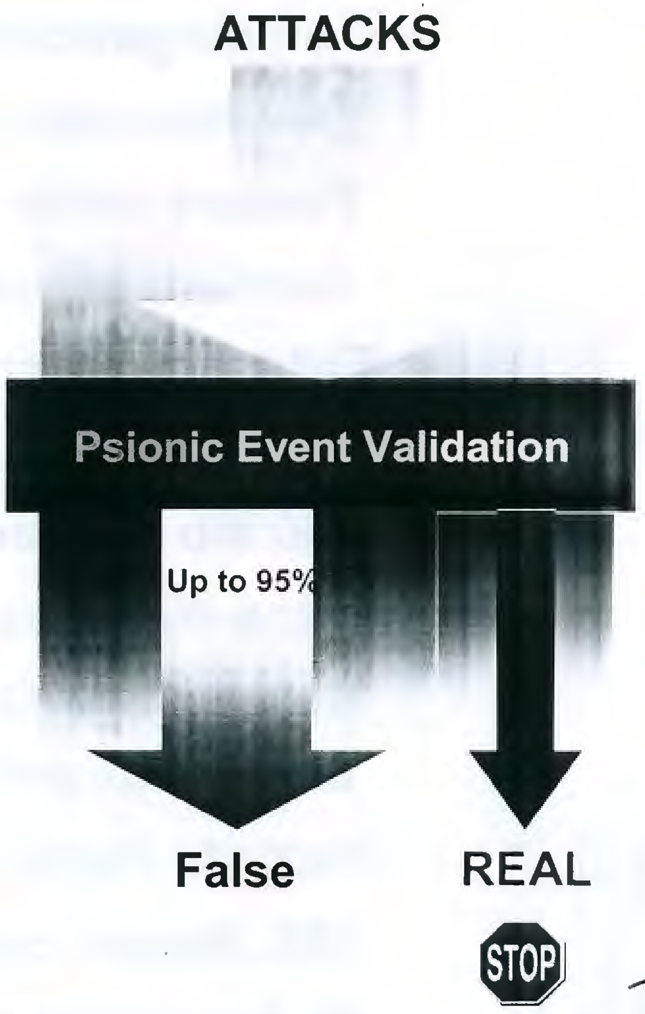
Advantages Cisco Threat Response

- Lowers cost of ownership by reducing false alarms up to 95%
- Uses patented adaptive scan techniques to
  - Validate IDS events
  - Escalate real attacks
  - Aid in remediation of costly intrusions
- Benefits

  Minimizes insignificant events against invulnerable systems

  Increases productivity of users enhancing accuracy

  Decreases time and manpower to deploy and manage IDS systems



6-198

More Than Just Products

- World-wide Training
  - Cisco IDS Course (NIDS & HIDS)
- Certification
  - Cisco Security Specialization
  - CCIE - Security
- Support
  - Award-winning, world-wide, 24x7 support
  - Four-hour replacement equipment available
  - Cisco Countermeasure Research Team (C-CRT)
- User Community
  - IDS Forum via Cisco Network Professional
  - IDS Newsletter & Active Update notification

Cisco Systems

Empowering the Internet Generation℠

Cisco will Acquire Psionic Software, Inc.

- Psionic develops security software (ClearResponse)

  Increases efficiency and reduces complexity and total cost of ownership associated with IDS systems by reducing false alarms up to 95%

- Cisco will integrate Psionic's technology with our broad IDS product family

  Provides high-performance security attack identification and suppression across a range of network environments

  Arms enterprise customers with a more comprehensive class of Intrusion Protection technology while minimizing typical IDS operational costs

CiscoWorks **VPN/Security Management** Solution Version 2.2

CiscoWorks VPN/Security Management Solution (VMS) is the flagship integrated security management solution from Cisco, and is an integral part of the SAFE Blueprint from Cisco for network security. CiscoWorks VMS protects the productivity and reduces operating costs for enterprises, by combining Web-based tools for configuring, monitoring, and troubleshooting enterprise VPNs, firewalls, and network and host-based intrusion detection systems (IDS). CiscoWorks VMS delivers the industry's first robust and scalable foundation and feature set that addresses the needs of small and large-scale VPN and security deployments.

Today's business challenges and resulting security deployments require more scalability than merely supporting a large number of devices. Many customers have limited staffing, yet are asked to manage a myriad of security devices. These customers must manage the security and network infrastructure; frequently update many remote devices; implement change control and auditing when multiple organizations are involved in defining and deploying policies; enhance security without adding more headcount; or roll out remote access VPNs to all employees and monitor the VPN service.

CiscoWorks VMS enables customers to deploy security infrastructures from a small to large environment, using the following multifaceted scalability features:

- Complete SAFE Blueprint Coverage

  To completely manage a SAFE environment, a network management solution must manage SAFE infrastructure components, support features based upon an appliance or Cisco IOS® Software, and support a range of management functions. CiscoWorks VMS is uniquely able to scale across SAFE Blueprint components, including firewalls, VPNs, and network- and host-based IDSs. CiscoWorks VMS also takes advantage of Cisco Secure Access Control Server (ACS) by using a common ACS logon. CiscoWorks VMS can manage a feature set through an appliance, for example, the Cisco PIX® Firewall, or through the Cisco IOS Software. Scalable management also involves more than configuring devices. CiscoWorks VMS provides the complete range of management with features to configure, monitor, and troubleshoot the network.

- Scalable Foundation

  CiscoWorks VMS implements a foundation with a consistent user experience, which makes it easier to scale management to many devices. CiscoWorks VMS provides users with a consistent GUI, workflow, ACS logon, roles definition, platforms, database

engine, installation, and more. An industry-leading feature of this foundation is the Auto Update feature, which allows numerous devices to be updated easily and quickly. Auto Update enables devices, even remote and dynamically addressed devices, to periodically "call home" to an update server and "pull" the most current security configurations or Cisco PIX operating system. Auto Update is required to effectively scale remote office firewall deployments across intermittent links or dynamic addresses. Prior policy updating methods relied on a "push" model. Although this model works for known devices, it does not work for remote devices with unknown addresses or devices that are not always active. Without Auto Update a more manual process is required to update each remote device. The Auto Update feature provides a dramatic scalability improvement for organizations that want to deploy devices with many remote and local locations. In addition to easier and faster policy updates, Auto Update also provides consistent policy deployments.

- Enterprise Operational Integration

  CiscoWorks VMS enables organizations to easily integrate management into their operations. One operational need is to replicate policies to multiple locations. The Smart Rules hierarchy addresses this need, by enabling administrators to define device groups and implement policy inheritance. For example, an administrator can define a device group for the New York sales office and deploy that same policy to all other sales offices quickly and consistently. The Command and Control Workflow feature provides change control and auditing, and is particularly important for customers who have separate groups for network and security operations. The solution includes processes for generating, approving, and deploying configurations. This can help security operations to define and approve new policies. Network operations can later deploy the new policies during their regular maintenance window. An audit of the changes can be maintained.

- Centralized Role-Based Access Control (RBAC)

  Role-based access control enables organizations to scale access privileges. CiscoWorks VMS conveniently uses a common ACS logon for users, administrators, devices, and applications. CiscoWorks VMS enables different groups to have different access rights across different devices and applications.

- Integrated Infrastructure Management

  Scalability requires that multiple components be managed, not just firewalls, but also VPNs, network- and host-based IDSs, routers, and switches. CiscoWorks VMS not only manages the security infrastructure, but also manages the network infrastructure. Customers benefit from being able to manage these components from one solution. Integrated monitoring is also required to see the larger picture. CiscoWorks VMS provides integrated monitoring of Cisco PIX and Cisco IOS syslogs, and events from network and host-based IDSs, along with event correlation.

CiscoWorks VMS Functions

CiscoWorks VMS is launched from the CiscoWorks dashboard and is organized into several functional areas:

- Firewall management
- Auto Update Server
- IDS management, network and host-based
- VPN router management
- Security monitoring
- VPN monitoring
- Operational management

These functional areas supply multifaceted scalability by offering features such as a consistent user experience, auto update, command and control workflow, and role-based access control.

Figure 1 shows CiscoWorks VMS displayed as a "drawer" in the CiscoWorks dashboard.

CiscoWorks2000
Cisco Systems

Firewall Management

CiscoWorks VMS enables the large-scale deployment of Cisco PIX firewalls, by providing the following features:

- Smart Rules hierarchy and inheritance
- User-defined device and customer groups including nesting
- Global role-based access with administrative privileges per device and customer groups with other CiscoWorks products and Cisco Secure ACS
- Mandatory and default device settings inheritance
- Workflow deployment to device, directory, or Auto Update Server
- Look and feel of Cisco PIX Device Manager but with scalability to thousands of PIX firewalls
- Integration with other CiscoWorks network management software
- Complete SAFE Blueprint coverage for centralized management of Cisco PIX firewalls, including access control, VPN, IDS, and authentication, authorization, and accounting (AAA)

Smart Rules is an innovative feature that allows common information including access rules and settings to be inherited for all firewalls in a device or customer group. Smart Rules allows a user to define common rules once, which results in reduced configuration time, fewer administrative errors, and higher device scalability. Using Smart Rules, a user can configure a common rule such as allowing all HTTP traffic once and can apply this rule globally to all firewalls. Smart Rules can also be defined on a device or customer group basis. For specific information on the firewall management functionality of VMS, refer to: http://www.cisco.com/en/US/products/sw/cscowork/ps3992/index.html

Auto Update Server for Firewall Management

CiscoWorks VMS introduces the industry's first firewall Auto Update Server that allows users to implement a "pull" model for security and Cisco PIX operating system management. Auto Update Server permits remote firewall networks with unprecedented scalability. The Auto Update Server allows Cisco PIX firewalls to both periodically and automatically contact the update server for any security configuration, Cisco PIX Operating System, and PIX Device Manager (PDM) updates. The Auto Update Server supports the following features:

- Security management of remote Cisco PIX firewalls that use Dynamic Host Control Protocol (DHCP)
- Automated Cisco PIX OS distribution to groups of Cisco PIX firewalls
- Automated Cisco PDM updates to remote firewalls
- Configuration verification at periodic intervals
- Automated replacement of inaccurate or tampered configurations
- New firewalls configured at "boot time"

The Auto Update Server is an indispensable component of any large-scale remote Cisco PIX firewall deployment. Auto Update Server is an easy-to-use solution to automatically update all remote or local firewalls with new operating system releases. Cisco is the industry's first vendor to provide this pull model of security policy and operating system management. For specific information on the Auto Update Server component of VMS, refer to: http://www.cisco.com/en/US/products/sw/cscowork/ps3993/index.html

Network-Based IDS Management

Administrators can use CiscoWorks VMS to configure network and switch IDS sensors. Many sensors can be quickly configured using group profiles. Additionally, a more powerful signature management feature is included to increase the accuracy and specificity of detection. Some prominent features are:

- Easy-to-use Web-based interface
- Wizards that lead users through common management tasks
- Access to the Network Security Database (NSDB), which provides meaningful information about alarms for users without IDS security expertise
- Ability to define a hierarchy of sensors containing groups and subgroups, and the ability to configure multiple sensors concurrently using group profiles
- Support for several hundred sensor deployments from each console
- Use of a robust relational database to store a high volume of data

For specific information on the network-based IDS management functionality of VMS, refer to:

http://www.cisco.com/en/US/products/sw/cscowork/ps3990/index.html

Host-Based IDS Management

CiscoWorks VMS provides threat protection for server and desktop computing systems, also known as "endpoints." VMS goes beyond conventional endpoint security solutions by identifying and preventing malicious behavior before it can occur, thereby removing potential known and unknown security risks that threaten enterprise networks and applications. Because CiscoWorks VMS analyzes behavior rather than relying on signature matching, its solution provides robust protection with reduced operational costs. Features of host-based IDS management include:

- Aggregates and extends multiple endpoint security functions by providing host intrusion prevention, distributed firewall, malicious mobile code protection, operating system integrity assurance, and audit log consolidation all within a single agent.
- Provides preventive protection against entire classes of attacks including port scans, buffer overflows, Trojan horses, malformed packets, and e-mail worms.
- Offers "zero update" prevention for known and unknown attacks

- Provides industry-leading protection for UNIX and Windows servers and Windows desktops allowing customers to patch systems on their own schedules.
- Open and extensible architecture offers the capability to define and enforce security according to corporate policy.
- Scalable to thousands of agents per manager to support large enterprise deployments.

For specific information on the host-based IDS management functionality of VMS, refer to: the Management Center for Cisco Security Agents Datasheet.

VPN Router Management

CiscoWorks VMS includes functions for the setup and maintenance of large deployments of VPN connections and provides users with a point-and-click interface for setting up and deploying connections. This application is intended for scalable configuration of site-to-site VPN connections in a hub-and-spoke topology for centralized, multidevice configuration and deployment of Internet Key Exchange (IKE) and IP Security (IPsec) tunneling policies on VPN routers.

Major features include:

- Wizard-based interface for the creation of IKE and VPN tunneling policies.
- Hierarchical inheritance and Smart Rules hierarchy to reflect the organizational and common setup of devices and simplified device management
- IKE-KA (IKE Keepalive) or generic routing encapsulation (GRE) with Open Shortest Path First (OSPF) and Enhanced Interior Gateway Routing Protocol (EIGRP) for failover routing scenarios.
- Centralized role-based access control model allows for centralized management of users and accounts.

For specific information on the VPN router management functionality of VMS, refer to: http://www.cisco.com/en/US/products/sw/cscowork/ps3994/index.html

Security Monitoring

CiscoWorks VMS provides integrated monitoring to reduce the number of security monitoring consoles, reduce the number of events to monitor, and provide a broader view of security status.

- Integrated monitoring is used to capture, store, view, correlate, and report on events from many of the devices in the SAFE Blueprint such as Cisco network IDSs, switch IDSs, host IDSs, firewalls, and routers.
- Event correlation is used to identify attacks that are not easily recognizable from a single event. A flexible notification scheme and automated responses to critical events also aid in quick action.
- The event viewer can read both real-time and historical events.
- Events are color-coded and administrators can quickly isolate problems. Administrators can also define thresholds and time periods when rules can be triggered to provide notification.
- On-demand and scheduled reports facilitate ongoing monitoring.

For specific information on the security monitoring component of VMS, refer to: http://www.cisco.com/en/US/products/sw/cscowork/ps3991/index.html

VPN Monitoring

CiscoWorks VMS offers a Web-based management tool that allows network administrators to collect, store, and view information on IPsec VPN connections for remote-access or site-to-site VPN terminations. Multiple devices can be viewed from an easy-to-use dashboard that is configured using a Web browser. This dashboard provides the following capabilities:

- Provides data on system resources related to real-time memory usage, percent CPU usage per device, and active tunnel and active sessions. This data simplifies the identification of devices with potential performance problems and devices with the highest usage.
- Enables viewing of current and long-term packet rates and packet dropped percentage which can aid in determining where excess capacity can be tapped or quickly identify bottlenecks and device throughput problems.
- Enables identification of the devices with the most persistent problems through the event log; key device and VPN statistics are evaluated against a set of global and device-specific thresholds, and exceptions are recorded in the event log.
- Provides graphing of important common metrics. Device performance comparisons provide a global view of short-term trends in VPN performance, enabling administrators to identify problem areas before they become critical failures.

For specific information on the VPN monitoring component of VMS, refer to: http://www.cisco.com/en/US/products/sw/cscowork/ps2326/index.html

Operational Management

CiscoWorks VMS provides the operational management for the network, allowing network managers to perform the following:

- Quickly build a complete network inventory
- Manage device credentials information
- Monitor and report on hardware, software, configuration, and inventory changes
- Manage and deploy configuration changes and software image updates to multiple devices
- Monitor and troubleshoot critical LAN and WAN resources
- Quickly identify devices that can be used for VPNs, if upgraded with the appropriate Cisco IOS Software
- Discover which VPN devices have hardware encryption modules
- Graphically compare configurations of VPN devices
- Isolate IPsec-related problems by running customized Syslog reports

For specific information on the operational management functionality of VMS, refer to: http://www.cisco.com/en/US/products/sw/cscowork/ps2073/index.html

Server Specifications (Minimum requirements)

Server Hardware

- PC-compatible computer with 1 GHz or faster Pentium processor
- Sun UltraSPARC 60 MP with 440 MHz or faster processor
- Sun UltraSPARCIII (Sun Blade 2000 Workstation or Sun Fire 280R Workgroup Server)

- CD-ROM drive
- 100BASE-T or faster connection
- 1 GB RAM
- 9 GB available disk drive space
- 2 GB virtual memory
- Color monitor with video card capable of 16-bit color

Server Operating System

CiscoWorks VMS requires the following operating systems:

- Windows 2000 Professional, Server, and Advanced Server (Service Pack 3)

Note: Support for Advanced Server requires that Terminal Services be turned off.

Sun Solaris 2.8 with patches:

109742 has been replaced by 108528-13

109322 has been replaced by 108827-15

109279 has been replaced by 108528-13

108991 has been replaced by 108827-15

Java Requirements

Sun Java plug-in 1.3.1-b24

Client Requirements

Hardware

- PC-compatible computer with 300 MHz or faster Pentium processor
- Solaris SPARCstation or Sun Ultra 10

Client Operating System

- Windows 2000 Server or Professional Edition with Service Pack 3, or Windows XP SP1 with Microsoft VM.
- Solaris 2.8

Client Browser

- Internet Explorer 6.0 Service Pack 1, on Windows operating systems
- Netscape Navigator 4.79, on Windows 2000 Server or Professional Edition with Service Pack 3, or Windows XP; Netscape Navigator 4.76 on Solaris 2.8

The CiscoWorks Management Center for Firewalls, and CiscoWorks Management Center for VPN Routers, are supported on Internet Explorer 6.0, but not on Netscape Navigator. In addition to supporting Internet Explorer The Management Center for IDS and the Monitoring Center for Security are also supported on Netscape Navigator.

6.186

Service and Support

CiscoWorks products are eligible for coverage under the Cisco Software Application Service (SAS) program. This service program offers customers contract-based 24-hour access to the Cisco Technical Assistance Center (TAC), full Cisco.com privileges, and software maintenance updates. A SAS contract ensures that customers have easy access to the information and services needed to stay current with newly supported device packages, patches, and minor updates. For further information about service and support offerings, contact your local sales office.

Ordering Information

CiscoWorks VMS is available for purchase through regular Cisco sales and distribution channels worldwide. CiscoWorks VMS includes all the necessary components needed for an independent installation on a Microsoft Windows or Sun Solaris workstation.

For More Information

For more information, go to http://www.cisco.com/warp/public/cc/pd/wr2k/vpmnso/prodlit/ or send e-mail to ciscoworks@cisco.com

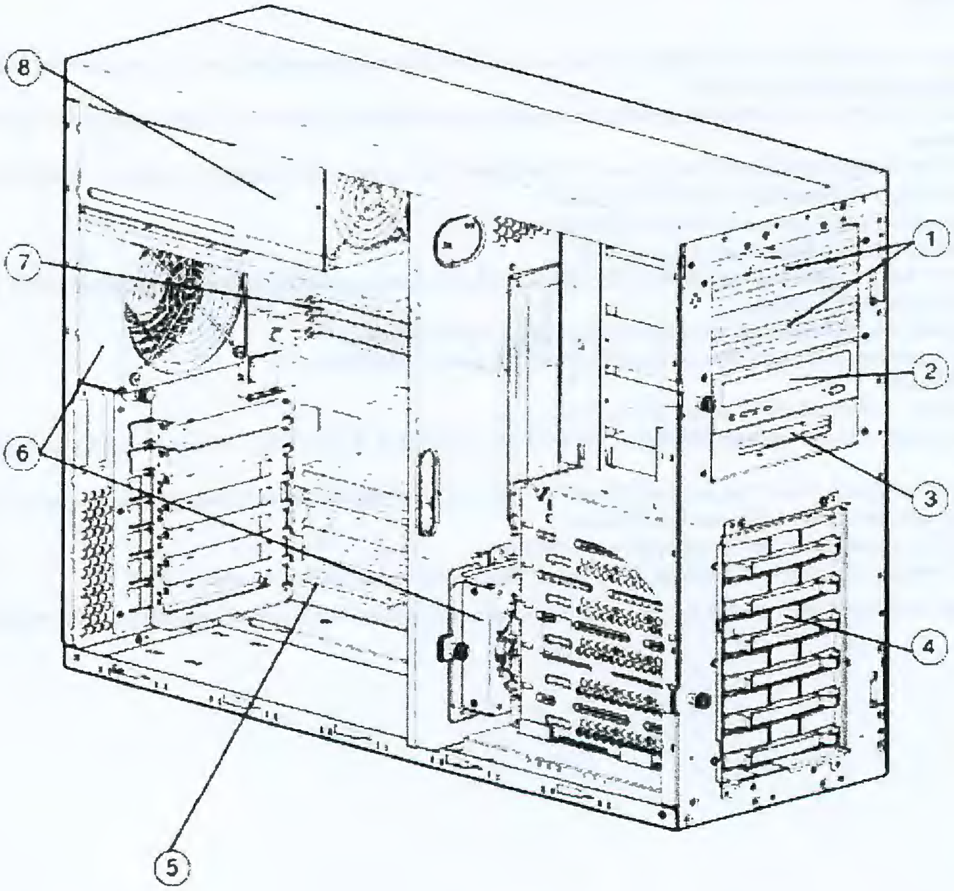
Apêndice EL

Overview



1. Two Removable Media Bays
2. 48X Max IDE (ATAPI) CD-ROM Drive
3. 1.44 Floppy Drive
4. Six 1" Hot Plug Drive Bays
5. Five expansion slots(four 64-bit/100-MHz PCI-X, one 32-bit/33-MHz PCI)
6. System fan
7. DIMM sockets for up to 8GB of memory, optionally interleaved
8. Optional 2nd Power Supply for hot-pluggable 1+1 redundancy

What's New

- Now available with Intel®Xeon 2.8 GHz Processors with 533MHz system bus.

At A Glance

- The ProLiant ML350 G3 is an expandable rack or tower platform delivering affordable 2-way performance and essential availability to corporate workgroups and growing businesses
- Intel Xeon 2.4 GHz or 2.8 GHz processors (dual processor capability) with 512-KB level 2 cache standard (full speed) and Hyper-Threading Technology
- ServerWorks Grand Champion LE Chipset with 533-MHz Front Side Bus for 2.8GHz processor models or 400-MHz FSB for models < 2.8 GHz
- Integrated Dual Channel Wide Ultra3 SCSI Adapter
- Smart Array Controller (standard in Array Models only)
- NC7760 PCI Gigabit Server Adapter (embedded)
- 512MB of 2-way interleaving capable PC2100 DDR SDRAM, with Advanced ECC capabilities (Array models only; 256MB standard on other models): Expandable to 8GB
- Flexible memory configurations allow interleaving (2x1) or non-interleaving
- Five available expansion slots: four 64-bit/100-MHz PCI-X, one 32-bit/33-MHz PCI
- Two USB ports
- Standard 6 x 1" Wide Ultra320 ready Hot Plug Drive Cage
- Internal storage capacity of up to 880GB (6 x 146.8 GB 1"), 1.174-TB (2 x 146.8 GB 1" + 6 x 146.8 GB 1") with optional 2-bay hot plug drive cage option
- 500W Hot-Pluggable Power Supply (standard) and an optional 500W Hot-Pluggable Redundant Power Supply (1+ 1) available
- Tool-free entry to chassis and access to components
- RBSU (ROM based setup utility) support, redundant ROM
- Insight Manager, SmartStart, ROM-based BIOS Setup Utility, and Automatic Server Recovery (ASR-2)
- Protected by HP Services, including a three-yeor, next business day, on-site, limited global warranty and extended Pre-Failure Warranty.

Standard Features

Processor *One of the following depending on Model:*	Intel Xeon Processor 2.8 GHz/533-512KB Intel Xeon Processor 2.4 GHz/400-512KB
Cache Memory	Integrated 512-KB Level 2 cache (full speed)
Upgradability	Upgradable to dual processing
Chipset	ServerWorks Grand Champion LE Chipset with 400-MHz or 533-MHz Front Side Bus (model dependent) NOTE: For more information regording ServerWorks, please see the following URL: http://www.serverworks.com/products/overview.html NOTE: This Web site is available in English only.

Memory
(One of the following depending on model)

2-way interleaving capable PC2100 DDR SDRAM running at 200MHz on 400MHz models or 266MHz on 533MHz models with Advanced ECC capabilities

Standard (Non-Array Models)	256MB
Standard (Array Models)	512MB
Maximum	8 GB

Network Controller

NC7760 Gigabit Server Adapter (embedded)

Expansion Slots

I/O (5 Total, 5 Available)		PCI Voltage:
64-bit/100MHz, PCI	4 (4 available) (Array model has 3 available)	3.3 Volt or universal cards
32-bit/33MHz, PCI	1 (1 available)	5 Volt or universal cards

Storage Controller

Integrated Dual Channel Wide Ultra3 SCSI Adapter
Smart Array 641 Controller (2.8 GHz Array Models Only)

Storage

Diskette Drives	1.44 MB
CD-ROM	48x IDE (ATAPI) CD-ROM Drive
Hard Drives	None
Maximum Internal Storage	1.174 TB GB (6 x 146.8 GB 1" with standard internal hot plug drive cage + (2 x 146.8 GB 1") with optional ML3xx Two Bay Hot Plug SCSI Drive Cage)
External Storage	Two external SCSI knockouts available, optional ProLiant ML350 Internal to External SCSI Cable Option Kit required ● HD68 Internal to External SCSI Cable Option Kit PN 159547-B22 ● VHDCI Internal to External SCSI Cable Option Kit PN 333370-B21

Standard Features

Interfaces	Parallel	1
	Serial	1
	Pointing Device (Mouse)	1
	Graphics	1
	Keyboard	1
	Network RJ-45	1
	USB	2 NOTE: Please see the following URL for additional information regarding USB support: http://www.compaq.com/products/servers/platforms/usb-support.html. NOTE: This Web site is available in English only.
	External SCSI knockouts	2

Graphics	Integrated ATI RAGE XL Video Controller with 8-MB SDRAM Video Memory

Form Factor

Tower or rack (5U)

NOTE: Rack models (and rack conversion kit) support:

- Square hole racks from 27' - 32' deep (including Compaq/HP 7000, 9000, 10000 and H9 series)
- Square or round hole racks, from 24" - 35" deep (including HP Rack System /E and HP Systems, with an adjustment)
- Telco racks with 3rd part option kit from Rack Solutions

http://www.racksolutions.com/compaq/products.htm

NOTE: This Web site is available in English only.

Standard Features

ProLiant Essentials Foundation Pack Software

Insight Manager 7

Insight Manager 7 helps maximize system uptime and performance and reduces the cost of maintaining the IT infrastructure by providing proactive notification of problems before those problems result in costly downtime and reduced productivity. Insight Manager 7 is easy to set up and provides rapid access to detailed fault and performance information gathered by the Management Agents. One-click-access to the Remote Insight Lights Out Edition II board allows systems administrators to take full graphical control of ProLiant servers in remote locations or lights-out data centers. Finally, Insight Manager 7 in concert with the Version Control Agents and Version Control Repository Manager enables systems administrators to version manage and update system software across groups of ProLiant servers.

Management Agents

The Management Agents form the foundation for HP's Intelligent Manageability strategy. They provide direct, browser-based access to in-depth instrumentation built into HP servers, workstations, desktops, and portables, and send alerts to Insight Manager 7 and other enterprise management applications in case of subsystem or environmental failures. For additional information about the Management Agents and other management products from HP, please visit the management Web site at http://www.hp.com/servers/manage.

SmartStart

SmartStart is a tool that simplifies server setup, providing a rapid way to deploy reliable and consistent server configurations. For more information, please visit the SmartStart website at http://www.hp.com/servers/manage.
SmartStart version supported (minimum): SmartStart 5.50

ActiveUpdate

ActiveUpdate is a web-based application that keeps IT managers directly connected to HP for proactive notification and delivery of the latest software updates.

ROMPaq, support software, and configuration utilities

The latest software, drivers, and firmware fully optimized and tested for your ProLiant server and options.

Survey Utility and diagnostics utilities

The most advanced configuration analysis, reporting and troubleshooting utilities used by HP and at your fingertips.

Optional Proliant Essentials Value Packs

Optional software offerings that selectively extend the functionality of an Adaptive Infrastructure to address specific business problems and needs:

- Rapid Deployment Pack – an automated solution for multi-server deployment and provisioning, enabling companies to quickly and easily adapt to changing business demands.
- Workload Management Pack – provides easier management of complex environments, improving overall server utilization and enabling Windows 2000 customers for the first time to confidently deploy multiple applications on a single multiprocessor ProLiant Server.
- Performance Management Pack – a performance management solution that identifies and explains hardware performance bottlenecks on ProLiant servers and attached options enabling users to better utilize their valuable resources.

NOTE: Flexible and volume quantity license kits are available for ProLiant Essentials Value Packs. Refer to http://www.hp.com/servers/proliantessentials or the various ProLiant Essentials Value Pack product QuickSpecs for more information.
NOTE: For more information regarding ProLiant Essentials Software, please see the following URL: http://www.hp.com/servers/proliantessentials
NOTE: These Web sites are available in English only.

Industry Standard Compliance

ACPI V1.0B Compliant
PCI 2.2 Compliant
PXE Support
WOL Support
PCI-X 1.0 Compliant
Novell Certified
Microsoft Logo certifications

Standard Features

Manageability

Insight Manager 7
Redundant ROM
System Firmware Update
ROMPaq
Remote Insight Lights-Out Edition II (optional)
ProLiant RBSU (ROM-Based Setup Utility)
Automatic Server Recovery-2 (ASR-2)
Drive Parameter Tracking (with Smart Array Controller)
Dynamic Sector Repairing (with Smart Array Controller)
Pre-Failure Warranty (covers processors, memory and hard drives)

Security

Power-on password
Setup password
Diskette boot control
Parallel and serial interface control
Disk configuration lock
Power switch security

Server Power Cords

One Lowline NEMA power cord and one Highline IEC Power cord ship standard
Tower models ship with standard country specific power cords.
Rack models ship with IEC cables. Depending on the country, some also ship with country specific power cords
Redundant power supply options ship with country specific power cords with the exception of the -B21 Rack SKU which ships with an IEC cable only.

Power Supply

500 Watts, Power Factor Correction (PFC), Hot Plug 100 to 240 VAC Rated Input Voltage (Auto-sensing), CE Mark Compliant
Optional 2nd Power Supply for hot-pluggable 1 + 1 redundancy.

System Fans

2 fans ship standard, 2 fans total supported (does not include power supply fans)

Required Cabling

For required cabling information, refer to the HP Web site at http://www.hp.com/servers/proliantML350.
NOTE: This Web site is available in English only.

OS Support

Microsoft Windows NT® Server 4.0 and Terminal Server 4.0
Microsoft BackOffice Small Business Server 2000
Microsoft Windows 2000 Server and Advanced Server
Windows Server 2003
Novell NetWare 5.1, 6.0
Novell NetWare Small Business Suite 6.0
SCO OpenServer 5.0.6a
SCO OpenUnix 8 SCO UnixWare 7.1.1
IBM OS/2 Warp Server for e-business
LINUX (Red Hat, 2.1 Advanced Server, Red Hat 8.0 and Red Hat 7.3, SuSE, SLES7, UnitedLinux 1.0)
NOTE: For a more complete and up-to-date listing of supported OSs and versions, please visit our OS Support Matrix at: ftp://ftp.compaq.com/pub/products/servers/os-support-matrix-310.pdf
NOTE: Optional hardware may be required to support some operating systems.
NOTE: For an up-to-date listing of the latest drivers available for the ProLiant ML350, please see: http://www.compaq.com/support/files/server/us/index.html.
NOTE: These Web sites are available in English only.

Rack Airflow Requirements

- Rack 9000 and 10000 series Cabinets
  The increasing power of new high-performance processor technology requires increased cooling efficiency for rack-mounted servers. The 9000 and 10000 Series Racks provide enhanced airflow for maximum cooling, allowing these racks to be fully loaded with servers using the latest processors.
- Rack 7000 series Cabinets
  When installing a server with processors running at speeds of 550 MHz or greater in Rack 7000 series racks with glass doors (165753-001 (42U), and 163747-001 (22U)), the new processar technology requires the installation of HP's new High Airflow Rack Door Inserts (327281-B21 (42U), 327281-B22 (42U 6 pack), or 157847-B21 (22U)) to promote enhanced airflow for maximum cooling.

CAUTION: If a third-party rack is used, observe the following additional requirements to ensure adequate airflow and to prevent damage to the equipment:

- ○ Front and rear doors: If your 42U server rack includes closing front and rear doors, you must allow 830 square inches (5,350 sq cm) of hole evenly distributed from top to bottom to permit adequate airflow (equivalent to the required 64 percent open area for ventilation).
- ○ Side: The clearance between the installed rack component and the side panels of the rack must be a minimum of 2.75 inches (7 cm).

CAUTION: Always use blanking panels to fill all remaining empty front panel U-spaces in the rock. This arrangement ensures proper airflow. Using a rack without blanking panels results in improper cooling that can lead to thermal damage.

NOTE: For additional information, refer to the Setup and Installation Guide or the Documentation CD provided with the server, or to the server documentation located in the Support section at the following URL:
http://www5.hp.com/servers/proliantml350
NOTE: This Web site is available in English only.

Installation of Server into Telco Racks

ML350 G3 rack model support: Support for all 2-post Telco racks requires the use of the rack kit and an additional option kit from Rack Solutions. http://www.racksolutions.com/compaq
NOTE: This Web site is available in English only.

HP Factory Express Capabilities

HP Factory Express gives you the flexibility to choose from a full menu of factory capabilities all in one manufacturing facility, in one process, with one touch giving you full control and access to HP's World class manufacturing facility anytime. This approach provides you the speed to deploy your IT needs, with total quality assurance, reliability, and predictability to lower your total cost of ownership by letting HP install, rack, and customize your software and hardware options for you.

Service and Support

HP Services provides a three-year, limited warranty, including Pre-Failure Warranty (coverage of hard drives, memory and processors) fully supported by a worldwide network of resellers and service providers and lifetime toll-free 7 x 24 hardware technical phone support. In addition, available service offerings include:
NOTE: Limited Warranty includes 3 year Parts, 3 year Labor, 3-year on-site support.

A full range of HP Care Pack packaged hardware and software services:

- Installation and start up
- Extended coverage hours and enhanced response times
- System management and performance services
- Availability and recovery services

NOTE: For more infomation, visit http://www.hp.com/services/carepack.

Please see the following URL regarding Warranty Information For Your HP Products:

NOTE: These Web sites are available in English only.

NOTE: Certain restrictions and exclusions apply. Consult the Customer Support Center at 1-800-345-1518 for details.

Models

ML350T03 X2.8-512KB/533, 256MB *311523-001*	Processor(s)	(1) Intel Xeon Processor 2.8 GHz Processor standard (up to 2 supported)
	Cache Memory	Integrated 512-KB Level 2 cache per processor
	Memory	256 MB Advanced ECC PC2100 DDR SDRAM DIMM (Standard) to 8 GB (Maximum)
	Network Controller	NC7760 PCI Gigabit Server Adapter (Integrated/Embedded)
	Storage Controller	Integrated Dual Channel Wide Ultra3 SCSI Adapter
	Hard Drive	None ship standard
	Internal Storage	1.174 TB maximum hot plug (with optional drive cage & hard drives)
	Optical Drive	48x IDE (ATAPI) CD-ROM Drive
	Form Factor	Tower (5U)

ML350R03 X2.8-512KB/533, 256MB *311524-001*	Processor(s)	(1) Xeon 2.8 GHz Processor standard (up to 2 supported)
	Cache Memory	Integrated 512-KB Level 2 cache per processor
	Memory	256 MB Advanced ECC PC2100 DDR SDRAM DIMM (Standard) to 8 GB (Maximum)
	Network Controller	NC7760 PCI Gigabit Server Adapter (Integrated/Embedded)
	Storage Controller	Integrated Dual Channel Wide Ultra3 SCSI Adapter
	Hard Drive	None ship standard
	Internal Storage	1.174 TB maximum hot plug (with optional drive cage & hard drives)
	Optical Drive	48x IDE (ATAPI) CD-ROM Drive
	Form Factor	Rack (5U)

ML350T03 X2.8-512KB/533, 512MB Array *311525-001*	Processor(s)	(1) Intel Xeon Processor 2.8 GHz Processor standard (up to 2 supported)
	Cache Memory	Integrated 512-KB Level 2 cache per processor
	Memory	512 MB Advanced ECC PC2100 DDR SDRAM DIMM (Standard) to 8 GB (Maximum)
	Network Controller	NC7760 PCI Gigabit Server Adapter (Integrated/Embedded)
	Storage Controller	Integrated Dual Channel Wide Ultra3 SCSI Adapter
	RAID Controller	Smart Array 641
	Hard Drive	None ship standard
	Internal Storage	1.174 TB maximum hot plug (with optional drive cage & hard drives)
	Optical Drive	48x IDE (ATAPI) CD-ROM Drive
	Form Factor	Tower (5U)

ML350R03 X2.8-512KB/533, 512MB Array *311526-001*	Processor(s)	(1) Xeon 2.8 GHz Processor standard (up to 2 supported)
	Cache Memory	Integrated 512-KB Level 2 cache per processor
	Memory	512 MB of Advanced ECC PC2100 DDR SDRAM DIMM (Standard) to 8 GB (Maximum)
	Network Controller	NC7760 PCI Gigabit Server Adapter (Integrated/Embedded)
	Storage Controller	Integrated Dual Channel Wide Ultra3 SCSI Adapter
	RAID Controller	Smart Array 641
	Hard Drive	None ship standard
	Internal Storage	1.174 TB maximum hot plug (with optional hard drive cage)
	Optical Drive	48x IDE (ATAPI) CD-ROM Drive
	Form Factor	Rack (5U)

Models

ML350T03 X2.4-512KB/400, 256MB *269786-001*	Processor(s)	(1) Intel Xeon Processor 2.4 GHz Processor standard (up to 2 supported)
	Cache Memory	Integrated 512-KB Level 2 cache per processor
	Memory	256 MB of Advanced ECC PC2100 DDR SDRAM DIMM Memory Kit (Standard) to 8 GB (Maximum)
	Network Controller	NC7760 PCI Gigabit Server Adapter (Integrated/Embedded)
	Storage Controller	Integrated Dual Channel Wide Ultra3 SCSI Adapter
	Hard Drive	None ship standard
	Internal Storage	1.174 TB maximum hot plug (with optional hard drive cage)
	Optical Drive	48x IDE (ATAPI) CD-ROM Drive
	Form Factor	Tower (5U)

ML350R03 X2.4-512KB/400, 256MB *269787-001*	Processor(s)	(1) Xeon 2.4 GHz Processor standard (up to 2 supported)
	Cache Memory	Integrated 512-KB Level 2 cache per processor
	Memory	256 MB of Advanced ECC PC2100 DDR SDRAM DIMM Memory Kit (Standard) to 8 GB (Maximum)
	Network Controller	NC7760 PCI Gigabit Server Adapter (Integrated/Embedded)
	Storage Controller	Integrated Dual Channel Wide Ultra3 SCSI Adapter
	Hard Drive	None ship standard
	Internal Storage	1.174 TB maximum hot plug (with optional hard drives & drive cage)
	Optical Drive	48x IDE (ATAPI) CD-ROM Drive
	Form Factor	Rack (5U)

Options

ProLiant ML350 G3 Unique Options	Hot Plug Redundant Power Supply Option Kit	283655-001
	Hot Plug Redundant Power Supply Option Kit (cable) NOTE: PN 283655-B21 SKU contains the 2nd power supply with an IEC power cable. Only purchase if connecting to PDU/UPS that supports IEC cables. All other SKUs contain country specific power cables.	283655-B21
	Intel Xeon 2.80 GHz-512KB Processor Option Kit NOTE: The 2.8 GHz processor option kit (PN 314763-B21) supports ProLiant ML350 G3 systems with 533 MHz front side bus only. This kit cannot be used in 400 MHz front side bus systems such as those with 2.4 GHz, 2.2GHz or 2.0 GHz processors.	314763-B21
	Intel Xeon 2.40 GHz-512KB Processor Option Kit NOTE: This processor option kit (PN 257913-B21) supports the ProLiant ML350 G3 servers.	257913-B21
	Intel Xeon 2.20 GHz-512KB Processor Option Kit NOTE: This processor option kit (PN 283702-B21) supports the ProLiant ML350 G3 servers.	283702-B21
	Intel Xeon 2.0 GHz-512KB Processor Option Kit NOTE: This processor option kit (PN 283701-B21) supports the ProLiant ML350 G3 servers.	283701-B21
	ProLiant ML350 G3 Tower to Rack Conversion Kit (CPQ brand)	290683-B21
ProLiant Essentials Value Pack Software	Rapid Deployment Pack, 1 User, V1.x NOTE: This license allows 1 server to be managed and deployed via the Deployment Server.	267196-B21
	Rapid Deployment Pack, 10 Users, V1.x NOTE: This license allows 10 servers to be managed and deployed via the Deployment Server.	269817-B21
	Flexible Quantity License Kit	302127-B21
	License-Only - for use with a Master License Agreement	302128-B21
	ProLiant Essentials Workload Management Pack 2.0 (Featuring Compaq Resource Partitioning Manager version 2.0)	303284-B21
	ProLiant Essentials Performance Management Pack Flexible License	306697-B21
	NOTE: Flexible and volume quantity license kits are available for ProLiant Essentials Value Packs. Refer to http://www.hp.com/servers/proliantessentials or the various ProLiant Essentials Value Pack product QuickSpecs for more information. NOTE: For more information regarding ProLiant Essentials Software, please see the following URL: http://www.hp.com/servers/proliantessentials. NOTE: These Web sites are available in English only.	
HP NetServer Transition Services	HP NetServer to ProLiant integration and assessment service NOTE: HP identifies current levels of NetServer support, services, and management. This service helps maximize customer's ability to add ProLiant platforms into their current environment.	304164-002
	HP TopTools to Insight Manager 7 installation and startup service NOTE: Provides on-site review, installation and configuration services for Insight Manager 7. HP will also re-create, as closely as possible, the views and reports from the customer's current TopTools configuration. This service assures a smooth transition to the ProLiant Essentials software.	304163-002
	HP NetServer to ProLiant Essentials Rapid Deployment Pack installation and startup service NOTE: Install and configure Rapid Deployment Pack in a test environment, then deploy a server image to a maximum of 250 systems in the production environment. This service helps to assure successful system deployment.	304162-002

Processors	Intel Xeon 2.80 GHz-512KB Processor Option Kit NOTE: The 2.8 GHz processor option kit (PN 314763-B21) supports ProLiant ML350 G3 systems with 533 MHz front side bus only. This kit cannot be used in 400 MHz front side bus systems such as thhose with 2.4 GHz, 2.2GHz or 2.0 GHz processors.	314763-B21
	Intel Xeon 2.40 GHz-512KB Processor Option Kit NOTE: This processor option kit supports ProLiant ML350 G3 servers with 400 MHz front side bus only. This kit (PN 257913-B21) cannot be used in 533 MHz front side bus systems such as the 2.8 GHz systems.	257913-B21
	Intel Xeon 2.20 GHz-512KB Processor Option Kit NOTE: This processor option kit supports ProLiant ML350 G3 servers with 400 MHz front side bus only. This kit (PN 283702-B21) cannot be used in 533 MHz front side bus systems such as the 2.8 GHz systems.	283702-B21
	Intel Xeon 2.0 GHz-512KB Processor Option Kit NOTE: This processor option kit supports ProLiant ML350 G3 servers with 400 MHz front side bus only. This kit (PN 283701-B21) cannot be used in 533 MHz front side bus systems such as the 2.8 GHz systems.	283701-B21
Memory (DIMMs)	NOTE: The ML350 G3 supports both interleaved and non-interleaved memory configurations. Base models ship standard with one 256MB DIMM or one 512MB DIMM (Array models). For best performance automatically invoke interleaving by populating memory in identical pairs. If 1GB of total memory is desired odd three 256MB DIMMs to the base configuration. If 1.5GB of memory is desired add one 256MB DIMM (to pair with the standard DIMM) and two 512MB DIMMs. Interleaving and installation of memory in pairs is not required. Add any combination of memory DIMMs below to operate in non-interleaved mode. NOTE: Each SDRAM Memory kit contains one (1) DIMM.	
	128MB of Advanced ECC PC2100 DDR SDRAM DIMM Memory Kit (1 x 128 MB)	287494-B21
	256MB of Advanced ECC PC2100 DDR SDRAM DIMM Memory Kit (1 x 256 MB)	287495-B21
	512MB of Advanced ECC PC2100 DDR SDRAM DIMM Memory Kit (1 x 512 MB)	287496-B21
	1024MB of Advanced ECC PC2100 DDR SDRAM DIMM Memory Kit (1 x 1024 MB)	287497-B21
	2048MB of Advanced ECC PC2100 DDR SDRAM DIMM Memory Kit (1 x 2048 MB)	301044-B21
Internal Storage	ML3xx Two Bay Hot Plug SCSI Drive Cage NOTE: The drive cage option kit (PN 244059-B21) has one 1" drive bay and one 1.6" drive bay. It installs in two available removable media bays.	244059-B21
Optical Drives	16X DVD-ROM Drive Option Kit (Carbon)	217053-B21
	CD-RW/DVD-ROM 48X Combo Drive Option Kit	3[illegible]6-B21
Hard Drives	*Ultra320 – Universal Hot Plug*	
	146.8-GB 10,000 rpm U320 Universal Hard Drive (1")	286716-B22
	72.8-GB 10,000 rpm U320 Universal Hard Drive (1")	286714-B22
	36.4-GB 10,000 rpm U320 Universal Hard Drive (1")	286713-B22
	72.8-GB 15,000 rpm U320 Universal Hard Drive (1")	286778-B22
	36.4-GB 15,000 rpm U320 Universal Hard Drive (1")	286776-B22
	18.2-GB 15,000 rpm U320 Universal Hard Drive (1")	286775-B22
	NOTE: All U320 Universal Hard Drives are backward compatible to U2 or U3 speeds. U320 drives require an optional U320 Smart Array Controller or U320 SCSI HBA to support U320 transfer rates	
	NOTE: Please see the Wide Ultra320 Universal Hot Plug QuickSpecs for additional technical information on the hard drives Support details, please see the following: http://www.compaq.com/products/quickspecs/[illegible]531[illegible]53[illegible]

Options

Tape Drives

NOTE: In order to install certain tape drives internally, you may need to remove the rails that come standard on the drives and then re-insert the screws in the mounting holes. To ensure proper fit, install the mounting screws as described in the tape option kit.

Internal and External DAT Tape Drives

Internal 12/24-GB DAT Drive (Opal)	295513-B22

NOTE: Please see the 12/24-GB DAT Drive QuickSpecs for additional options such as cassettes and for on up-to-date listing of the latest O/S Support details, please see the following:
http://www5.compaq.com/products/quickspecs/10239_na/10239_na.HTML

HP StorageWorks 20/40-GB DAT DDS-4 Tape Drive, Internal (Carbon)	157769-B22
HP StorageWorks 20/40-GB DAT DDS-4 Tape Drive, External (Carbon)	157770-002
HP StorageWorks Internal 20/40-GB DAT, Hot Plug (Carbon)	215488-B21

NOTE: Please see the 20/40-GB DAT Tape Drive QuickSpecs for additional options such as host bus adapters, controllers, cassettes, and for on up-to-date listing of the latest O/S Support details, please see the following:
http://www5.compaq.com/products/quickspecs/10426_na/10426_na.HTML

Internal and External DAT 72 Tape Backup Drive

HP StorageWorks DAT 72 Tape Drive Internal (Carbon)	Q1525A
HP StorageWorks DAT 72 Tape Drive, External (Carbon)	Q1527A
HP StorageWorks DAT 72h Internal Hot Plug (Carbon)	Q1529A

NOTE: Please see the DAT 72 Tape Drive QuickSpecs for additional options such as adapters, controllers, and cassettes, and for on up-to-date listing of the latest O/S Support details, please see the following:
http://www5.compaq.com/products/quickspecs/11597_na/11597_na.HTML

Internal and External LTO Ultrium Tape Drives

HP StorageWorks Ultrium 215 Tape Drive for ProLiant, Internal (Carbon)	Q1543A
HP StorageWorks Ultrium 215 Tape Drive for ProLiant, External (Carbon)	Q1544A

NOTE: Please see the HP StorageWorks Ultrium 230 Tape Drive QuickSpecs for additional options such as controllers, and other related items, and for on up-to-date listing of the latest O/S Support details, please see the following:
http://h18006.www1.hp.com/products/quickspecs/11678_na/11678_na.html

HP StorageWorks LTO Ultrium 230 Tape Drive, Internal (Carbon)	Q1515A
HP StorageWorks LTO Ultrium 230 Tape Drive, External (Carbon)	Q1516A

NOTE: Please see the HP StorageWorks LTO Ultrium QuickSpecs for additional options such as data and cleaning cartridges, and for on up-to-date listing of the latest O/S Support details, please see the following:
http://www5.compaq.com/products/quickspecs/11415_na/11415_na.HTML

HP StorageWorks Ultrium 460 tape drive for ProLiant, Internal (Carbon)	Q1518A
HP StorageWorks Ultrium 460 tape drive for ProLiant, External (Carbon)	Q1519A

NOTE: Please see the HP StorageWorks Ultrium 460 Tape Drive QuickSpecs for additional options such as controllers, and other related items, and for on up-to-date listing of the latest O/S Support details, please see the following:
http://www5.compaq.com/products/quickspecs/11530_na/11530_na.HTML

Internal and External AIT Tape Drives

NOTE: The Internal AIT Hot Plug Drives are supported in hot plug drive bays only. When installing a non hot plug AIT tape drive into an ML350 ProLiant server use the special screw included with the drive kit proper fit in the removable media bay.

HP StorageWorks Internal AIT 35-GB, LVD Tape Drive (Carbon)	216884-B21
HP StorageWorks External AIT 35-GB, LVD Tape Drive (Carbon)	216885-001
HP StorageWorks Internal AIT 35-GB, LVD, Hot Plug (Carbon)	216886-B21

NOTE: Please see the AIT 35-GB, LVD Tape Drive QuickSpecs for additional options such as adapters, controllers, and cassettes, and for an up-to-date listing of the latest O/S Support details, please see the following:
http://www5.compaq.com/products/quickspecs/10712_na/10712_na.HTML

HP StorageWorks AIT 50-GB Tape Drive, Internal (Carbon)	157766-B22
HP StorageWorks AIT 50-GB Tape Drive, External (Carbon)	157767-002
HP StorageWorks Internal AIT 50-GB, Hot Plug (carbon)	215487-B21
HP StorageWorks Rackmount AIT 50-GB, 3U (Single Drive)	274333-B21

NOTE: Please see the AIT 50-GB Tape Drive QuickSpecs for additional options such as adapters, controllers, and cassettes, and for an up-to-date listing of the latest O/S Support details, please see the following:
http://www5.compaq.com/products/quickspecs/10425_na/10425_na.HTML

HP StorageWorks Internal AIT 100-GB Tape Drive (Carbon)	249189-B21
HP StorageWorks External AIT 100-GB Tape Drive (Carbon)	249160-001
HP StorageWorks Internal AIT 100-GB, Hot-Plug (Carbon)	249161-B21

HP StorageWorks SDLT 160/320, External (carbon)	257319-001

NOTE: Please see the SDLT 160/320GB Tape Drive QuickSpecs for additional options such as adapters, controllers, and media, and for an up-to-date listing of the latest O/S Support details, please see the following:
http://www5.compaq.com/products/quickspecs/11406_na/11406_na.HTML

Internal and External DAT Autoloader

20/40-GB DAT 8 Cassette Autoloader Internal (Opal)	166504-B21
20/40-GB DAT 8 Cassette Autoloader External (Opal)	166505-001

NOTE: Please see the 20/40-GB DAT DDS-4 8 Cassette Autoloader QuickSpecs for additional options such as adapters, controllers, and cassettes, and for an up-to-date listing of the latest O/S Support details, please see the following:
http://www5.compaq.com/products/quickspecs/10518_na/10518_na.HTML

AIT Autoloader

HP StorageWorks AIT 35GB Autoloader, Rackmount (carbon)	280349-001
HP StorageWorks AIT 35GB Autoloader Tabletop (carbon)	292355-001

NOTE: Please see the HP StorageWorks AIT 35GB Autoloader QuickSpecs for additional options such as adapters, controllers, and cassettes, and for an up-to-date listing of the latest O/S Support details, please see the following:
http://www5.compaq.com/products/quickspecs/11404_na/11404_na.HTML

HP StorageWorks 1/8 Autoloader

HP StorageWorks 1/8 Autoloader, Tabletop, Ultrium 230	C9572CB
HP StorageWorks 1/8 Autoloader, Tabletop, DLT VS80	C9264CB
HP StorageWorks 1/8 Autoloader, Rackmount kit	C9266R

NOTE: Please see the HP StorageWorks 1/8 Autoloader QuickSpecs for additional options such as adapters, controllers, and cassettes, and for an up-to-date listing of the latest O/S Support details, please see the following:
http://www5.compaq.com/products/quickspecs/11496_na/11496_na.HTML

SSL1016 tape autoloader

SSL1016 DLT1 tape autoloader (includes two 8-cartridge magazines and a barcode reader)	3308[illegible]21

NOTE: Please see the SSL1016 DLT1 tape autoloader Quick Specs for additional information:
http://h18000.www1.hp.com/products/quickspecs/11626_na/11626_na.HTML

SSL1016 SDLT 160/320 tape autoloader (includes two 8-cartridge magazines and a barcode reader)	330816-B21

NOTE: Please see the SSL1016 SDLT160/320 tape autoloader Quick Specs for additional information:
http://h18000.www1.hp.com/products/quickspecs/11609_na/11609_na.HTML

Add-on drives and accessories

SSL1016 DLT/SDLT 8-cartridge magazine	268664-B22

Rackmount Tape Drive Kits

3U Rackmount Kit	274338-B21

NOTE: The 3U Rackmount Kit (PN 274338-B21) can support up to (2) full-height or (4) half-height tape drives and compatible with multiple Single-Ended and LVD SCSI Tape Drives including the 12/24-GB DAT, 20/40-GB DAT, DAT 72-GB, 20/40-GB DAT DDS-4 8 Cassette Autoloader, AIT 35GB LVD, AIT 50GB, AIT 100-GB, 40/80-GB DLT, DLT VS 40/80-GB, SDLT 110/220-GB, SDLT 160/320-GB, Ultrium 215, Ultrium 230 and Ultrium 460 Tape Drives.

5U Rackmount Kit	274339-B21

NOTE: The 5U Rackmount Kit (PN 274339-B21) can support up to (4) full-height tape drives and is compatible with DLT/SDLT/LTO tape drives including the 40/80-GB DLT, SDLT 110/220, SDLT 160/320, Ultrium 230, and Ultrium 460 Tape Drives.

NOTE: Please see the Rackmount Tape Drive Kits QuickSpecs for additional information regarding these kits, please see the following:
http://www5.compaq.com/products/quickspecs/10854_na/10854_na.HTML

Tape Storage Enclosure Cable Kits

LVD Cable Kit, VHDCI/HD68	168048-B21

NOTE: For use with the 3U RM Storage Enclosure and DLT Tape Array III only.

LVD Cable Kit, HD68/HD68	242381-B21

NOTE: For use with the 3U RM Storage Enclosure and DLT Tape Array III only.

Options

Tape Automation

StorageWorks SSL2000 small system library

SSL2020 – AIT50 based library with up to 2 drives and 20 slots

HP ProLiant ML350 G3 Array Models

The ML350 G3 supports both interleaved and non-interleaved memory configurations. Array models ship standard with one 512MB DIMM, non-interleaved. For best performance automatically invoke interleaving by populating memory in identical pairs. Interleaving memory and installing in pairs is not required. Add any combination of memory DIMMs to operate in non-interleaved mode.

Standard Memory

512MB (expandable to 8GB) of 2-way interleaving capable PC2100 DDR SDRAM running at 200MHz on 400MHz models or 266MHz on 533MHz models, with Advanced ECC capabilities (1x 512MB)

NOTE: Advanced ECC Memory - ECC protection provides the ability to detect and correct single bit memory errors while Advanced ECC extends this coverage to include protection against multiple simultaneous errors on a DIMM. Advanced ECC detects and corrects 4bit memory errors that occur within a single DRAM chip on a DIMM. Advanced ECC algorithms work in combination with industry standard ECC DIMMS.

Standard Memory Plus Optional Memory

Up to 6.7 GB of total memory can be implemented with the installation of three optional PC2100-MHz Registered ECC DDR SDRAM DIMMs.

Standard Memory Replaced with Optional Memory

Up to 8.2 GB of total memory can be implemented with the removal of the standard 512-MB DIMM and the optional installation of PC2100-MHz Registered ECC DDR SDRAM DIMMs.

NOTE: Charts do not represent all possible memory configurations.

		Slot 1	Slot 2	Slot 3	Slot 4
Standard	512 MB	512 MB	Empty	Empty	Empty
Optional	6656 MB	512 MB	2048 MB	2048 MB	2048 MB
Maximum	8192 MB	2048 MB	2048 MB	2048 MB	2048 MB
2x1 Interleaved Memory (Recommended)		Pair 1		Pair 2	
	Total Memory	Slot 1	Slot 2	Slot 3	Slot 4
Recommended Configurations for Array Models	1 GB	512 MB	512 MB	Empty	Empty
	1.5 GB	512 MB	512 MB	256 MB	256 MB
	2 GB	512 MB	512 MB	512 MB	512 MB

Following are memory options available from HP:

● 128MB of Advanced ECC PC2100 DDR SDRAM DIMM Memory Kit (1 x 128 MB)	287494-B21
● 256MB of Advanced ECC PC2100 DDR SDRAM DIMM Memory Kit (1 x 256 MB)	287495-B21
● 512MB of Advanced ECC PC2100 DDR SDRAM DIMM Memory Kit (1 x 512 MB)	287496-B21

NOTE: To invoke interleaving in your array model, order this kit for a total of 1-GB of interleaved memory.

● 1024MB of Advanced ECC PC2100 DDR SDRAM DIMM Memory Kit (1 x 1024 MB)	287497-B21
● 2048MB of Advanced ECC PC2100 DDR SDRAM DIMM Memory Kit (1 x 2048 MB)	301044-B21

Memory

HP ProLiant ML350 G3 Non-Array Models
The ML350 G3 supports both interleaved and non-interleaved memory configurations. Base models ship standard with one 256MB DIMM, non-interleaved. For best performance automatically invoke interleaving by populating memory in identical pairs. Interleaving memory and installing in pairs is not required. Add any combination of memory DIMMs to operate in non-interleaved mode.

Standard Memory
256MB (expandable to 8GB) of 2-way interleaving capable PC2100 DDR SDRAM running at 200MHz on 400MHz models or 266MHz on 533MHz models with Advanced ECC capabilities (1x 256MB)

NOTE: Advanced ECC Memory - ECC protection provides the ability to detect and correct single bit memory errors while Advanced ECC extends this coverage to include protection against multiple simultaneous errors on a DIMM. Advanced ECC detects and corrects 4bit memory errors that occur within a single DRAM chip on a DIMM. Advanced ECC algorithms work in combination with industry standard ECC DIMMS.

Standard Memory Plus Optional Memory
Up to 6.4 GB optional memory is available with the installation of PC2100-MHz Registered ECC DDR SDRAM DIMMs.

Standard Memory Replaced with Optional Memory
Up to 8.2 GB of memory is available with the removal of the standard 256-MB of memory and the optional installation of PC2100-MHz Registered ECC DDR SDRAM DIMM installed.

NOTE: Charts do not represent all possible memory configurations

Memory					
		Slot 1	Slot 2	Slot 3	Slot 4
Standard	256 MB	256 MB	Empty	Empty	Empty
Optional	6400 MB	256 MB	2048 MB	2048 MB	2048 MB
Maximum	8192 MB	2048 MB	2048 MB	2048 MB	2048 MB

Recommended Configurations for Base Models	Total Memory Desired	1	2	3	4
	512 MB	256 MB	256 MB	Empty	Empty
	1 GB	256 MB	256 MB	256 MB	256 MB
	1.5 GB	256 MB	256 MB	512 MB	512 MB

	Compatibility	IEEE 802.3 10Base-T	
		IEEE 802.3ab 1000Base-T	
		IEEE 80.3u 100Base-TX	
	Data Transfer Method	32-bit bus-master PCI	
	Network Transfer Rate	10Base-T(Half-Duplex)	10 Mb/s
		10Base-T(Full-Duplex)	20 Mb/s
		100Base-TX(Half-Duplex)	100 Mb/s
		100Base-TX(Full-Duplex)	200 Mb/s
		1000Base-TX	1000Mb/s
	Connector	RJ-45	
	Cable Support	10Base-T	Categories 3, 4 or 5 UTP; up to 328 ft (100 m)
		10/100/1000Base-TX	Category 5 UTP; up to 328 ft (100 m)

Integrated Dual Channel Wide Ultra3 SCSI Adapter	Drives Supported	Up to 28 SCSI devices (14 per channel)
	Data Transfer Method	64-bit PCI bus-master
	SCSI Channel Transfer Rate	80 MB/s per channel
	Maximum Transfer Rate per PCI Bus (peak)	133 MB/s per channel
	SCSI Protocols	Wide Ultra2 SCSI Wide-Ultra SCSI-3 Fast SCSI-2
	Electrical Protocol	Low Voltage Differential (LVD)
	SCSI Termination	Active Termination
	External SCSI Connectors	Two 80-Pin VHDCI connectors
	Internal SCSI Connectors	Two 68-Pin Wide-Ultra SCSI-3 connectors

Smart Array 641 Controller (NOTE: The Smart Array 641 Controller ships standard with the 2.8 GHz Array Models only)	Protocol	Ultra320 SCSI
	SCSI Electrical Interface	Low Voltage Differential (LVD)
	Drives Supported	Up to 6 Ultra 320, Ultra3 and Ultra2 SCSI hard drives
	SCSI Port Connectors SA-641	one internal SCSI port
	Data Transfer Method	64-Bit PCI bus-master
	PCI Bus Speed	64-bit, 133-MHz PCI-X (1 GB/s maximum bandwidth)
	PCI	3.3 volt PCI slot compatibility only
	Simultaneous Drive Transfer Channels	Two
	Channel Transfer Rate	320-MB/s total; 320-MB/s per channel
	Software upgradeable Firmware	Yes
	Cache Memory	64-MB DRAM used for code, transfer buffers, and non-battery backed read cache
	Logical Drives Supported	32
	Maximum Capacity	880.8 GB (6 X 146.8 GB)
	Memory Addressing	64-bit, supporting servers memory greater than 4 GB
	RAID Support	RAID 5 (Distributed Data Guarding) RAID 1+ 0 (Striping & Mirroring) RAID 1 (Mirroring) RAID 0 (Striping)
	Upgradeable Firmware	2-MB Flashable ROM
	Disk Drive and Enclosure Protocol Support	Ultra 320, Ultra2 and Ultra3
	Warranty	Maximum: The remaining warranty of the HP server product in which it is installed (to a maximum three-year limited warranty) Minimum: One-year, on-site limited warranty Pre-Failure Warranty: Drives attached to the Smart Array Controller and monitored under Insight Manager are supported by a Pre-Failure (replacement) Warranty. For complete details, consult the HP Support Center or refer to your HP Server Documentation.

TechSpecs

Video Controller	Controller Chip	ATI RAGE XL
	Video DRAM	8 MB Video SDRAM
	Data Transfer Method	32-bit PCI
	Support Resolution	Supported Color Depths:
	640 x 480	16.7M, 64K, 256, 16
	800 x 600	16.7M, 64K, 256, 16
	1024 x 768	16.7M, 64K, 256, 16
	1152 x 864	16.7M, 64K, 256, 16
	1280 x 1024	16.7M, 64K, 256, 16
	1600 x 1200	64K, 256, 16
	Connector	VGA

Apêndice EM

GLOSSARY

A

Address book A record of people who can receive e-mail or pager notification as part of the enforcement of a security policy. The address book contains the names of the contacts as well as e-mail and pager addresses.

Agent The aspect of the Host Sensor system that is installed on each host in your network. An agent serves as a protective layer surrounding a computer's operating system kernel identifying and preventing suspected breaches of security and malicious attacks.

Agent Group A defined set of agents. Agent groups are created and modified from the **Agent Management** view of the Host Sensor system.

All Agents Group Default group to which all agents belong. Agents cannot be deleted from this group.

Attack An attempted breach of system security. Successful attacks range in severity from someone having an unauthorized view of data on your system to destroying or stealing data or shutting down your system.

B

Back orifice A remote administration tool that can provide unwanted access to and control of a computer by way of its Internet link. BO runs on Widows 95/98 and Windows NT.

Backbone In a LAN, the lines used to connect building to building, or to connect to a WAN. In a WAN, the set of paths to which local or regional networks connect.

Backdoor A planned security breach in an application that can allow unauthorized access to data.

Brute force A hacking method used to find passwords or encryption keys by trying every possible combination of characters until the code is broken.

Buffer overflow attack The method of overfilling a software buffer in order to insert and execute some other code with elevated privileges, often a shell from which further commands can be issued.

C

Camping out A hacking technique of breaking into a system and then finding a safe place from which to monitor the system, store information, or re-enter the system at some later time.

CERT Computer Emergency Response Team. Established in 1988 by the Defense Advanced Research Projects Agency, CERT is chartered to facilitate the Internet community's response to computer security events. www.cert.org.

Ciphertext An encrypted form of plaintext.

Console user Console users have full access to Host Sensor system functionality, with the exception of user management.

Console The GUI application that provides monitoring and management of the Host Sensor system.

D

DARPA Defense Advanced Research Projects Agency. Department of Defense agency responsible for the development of military technology. Funded much of the development of the Internet, including Berkeley UNIX and TCP/IP.

Database The repository of all data necessary to the valid operation of the Host Sensor system, as well as all data collected and reported by agents.

Datagram See packet.

Decryption The process of converting encrypted data back into its original form.

Denial of Service An attack method whereby a computer is overwhelmed with bogus requests, causing it to crash or keeping it from honoring legitimate requests.

DNS Domain Name System. A system on the Internet that maps host names to IP Addresses for the purpose of making network connections. DNS also makes the reverse map (IP Address to host name) for the purpose of authentication.

Domain installation The type of installation the Host Sensor system uses if you are operating under a Windows NT Domain architecture and want the Host Sensor server to retrieve user group information from the Primary Domain Controllers in your network.

E

Encryption The conversion of data from plaintext to ciphertext in order to keep the contents secure.

Event Recognition of a signature by an agent (security event); any of a defined set of Host Sensor system activities (system event).

Exception The mechanism for overriding security policies to minimize false positive alerts. Exceptions are defined for specific security events.

F

False positive A security event triggered by a benign process rather than an attack.

Finger A program that displays information about users logged on to a local or remote system.

Firewall A set of programs installed on a gateway server, designed to protect the resources of that network from users on other networks. A firewall filters and routes incoming traffic, and makes outgoing requests (to the Internet, for instance) on behalf of local workstations.

Fragmentation The IP process in which a packet is divided into smaller pieces (fragments) to pass over a network. The fragments are reassembled by the IP layer at the destination.

H

Host Any computer on the Internet that has full two-way access to other computers on the Internet.

Host-based security system A security application that functions by virtue of being installed on and protecting each node (host) in a network.

I

ICMP An extension to IP that allows for the generation of error messages and test packets.

IP address A 32-bit number that identifies each computer sending or receiving information via packets across the Internet. An IP Address has two parts: one identifying the network, the other identifying the specific server or workstation.

L

LAN Local Area Network. A network of servers, workstations and peripheral devices usually confined to a single building or other geographically limited area.

Local installation The type of installation the Host Sensor system uses if you are operating in a workgroup environment.

M

Mode The manner in which an agent has been set to protect its host. There are four possible modes for an agent: **On-Protecting, On-Warning, Off-Protecting, Off-Warning.**

N

Network A series of nodes connected by communication paths. Networks can interconnect with one another and contain subnetworks.

New Agents Group Agent group comprised of newly installed agents making their first contact with the server. Agents remain part of the **New Agents** group until they are removed manually.

Notification An alert dispatched by the Host Sensor system as defined in a security policy. There are four methods of notification: e-mail, pager, SNMP trap, spawned process.

NT registry A database that stores the configuration data of a computer operating under Windows NT. Stored data include attached hardware, system settings and programs to be started along with the operating system.

O

Off-Protecting Agent is deactivated and performs no security measures; the agent is in protection mode when it is reactivated.

Off -Warning Agent is deactivated and performs no security measures; the agent is in warning mode when it is reactivated.

On-Protecting Agent detects signatures, logs events and carries out all security measures.

On-Warning Agent detects signatures and logs events, but does not carry out security measures.

P

Packet A unit of data routed from an origin to a destination on the Internet. Any file sent from one place to another on the Internet is divided into packets by the TCP layer of TCP/IP at the point of origin. The TCP layer at the destination reassembles the packets into the original file.

Packet filter A part of a firewall, a packet filter examines incoming packets in order to permit or deny entry to the network.

Packet sniffer A sniffer on a TCP/IP network that examines the contents of all packets on that network. See **Sniffer.**

Packet switching A method of sending data through a network based on the destination address contained within each packet.

PGP Pretty Good Privacy. A technique for encrypting messages that uses the public key method. The pubic key is distributed to those from whom you wish to receive encrypted messages; the private key is held by you to decrypt messages. Developed by Philip Zimmerman; freely available from the Massachusetts Institute of Technology.

Ping Packet InterNet Groper. A program used to test whether a host is operating. Ping sends an ICMP echo request and waits for a reply.

Ping attack The method of overwhelming a network with ping commands.

Ping of death A hacking technique used to cause a denial of service by sending a large ICMP packet to a target. As the target is attempting to reassemble the packet, the size of the packet overflows the buffer and can cause the target to reboot or hang.

Plaintext Ordinary, readable text. Opposite of ciphertext.

Port scanning A hacking technique used to check TCP/IP ports to reveal what services are available in order to plan an exploit involving those services, and to determine the operating system of a particular computer.

Protection mode The mode in which an agent monitors activity on its host and carries out security measures.

Protocol A formal description of the set of rules and conventions that govern how devices on a network exchange information.

PSN Packet Switch Node. A dedicated computer used to accept, route and forward packets in a packet switched network.

publickey A file generated during installation of the Host Sensor system. This file must be copied to the Cisco HIDS Agent installation folder on each host, and is used by the agent to facilitate encrypted communication with the server.

Public key encryption A system of encrypting electronic files using a pair of keys: a public key used to encrypt a file, and a private key used to decrypt a file.

R

Reaction The response by an agent when intercepting a signature. There are four possible reactions: ignore the attack, log the attack in the database, prevent the specific illegal operation from taking place, and end the process that is performing the attack.

Remote login A terminal emulation program that allows a user to log on to a remote computer.

Router The path that network traffic follows from its origin to its destination.

S

Samba A program that implements the SMB protocol for UNIX systems, allowing UNIX and NT systems to share files and directories.

Security event The recognition of a signature by an agent.

Security level Definition of the danger implied by a signature. Signatures are given one of four security levels: **Info**, **Low**, **Medium**, and **High**.

Security policy The definition of reactions taken by agents when recognizing signatures, and the notifications that will be made in those cases.

Server An NT service that provides communication between agents and the database, and the database and the console.

Signature The description of a security threat or attack methodology.

Smurf attack A Denial of Service attack that floods its target with replies to ICMP echo (PING) requests. A smurf attack sends PING requests to internet broadcast addresses, which forward the PING requests to up to 255 hosts on a subnet. The return address of the PING request is spoofed to be the address of the attack target. All hosts receiving the PING requests reply to the attack target, flooding it with replies.

Sniffer An application that monitors and analyzes network traffic. Sniffers are used by network managers to detect problems with network traffic. They are also used by hackers to steal information. Sniffers are difficult to detect and can be inserted almost anywhere in a network (a primary reason for their popularity among hackers).

SNMP A network management protocol widely used in TCP/IP networks that provides the means to monitor and control network devices, as well as manage configuration, performance and security.

SNMP Trap A method of notification included in a security policy.

Snooping Passively observing a network.

Spawned process A method of notification included in a security policy. Any process that can be started from the Windows **Start>Run** menu can be used.

Spoofing Forging something, such as an IP Address to hide one's location and identity.

State Describes the manner in which an agent is actually functioning (Current State), or will be functioning after its next communication with the server (Requested State). The console recognizes six different states for an agent: On-Protecting, On-Warning, Off-Protecting, Off-Warning, Not connected, No license.

Stub network A network that carries packets to and from local hosts.

SYN flood A hacking technique used to cause a denial of service. SYN packets are sent from a client with a spoofed IP address and are sent at a rate faster than the TCP stack on the host is set to time out. As the client address is spoofed, the client sends no SYN-ACK, but continues to flood the host with SYN packets, tying up the resources of the host.

System All components of the Host Sensor.

System administrator This account has full access to Host Sensor system functionality including user management.

System event Any of a defined set of Host Sensor system activities.

T

TCP/IP Transmission Control Protocol/ Internet Protocol. The basic communication language of the Internet. The TCP layer divides outgoing data into packets and assembles incoming packets into the original file. The IP layer handles the address in each packet so that it arrives at the appropriate destination.

Telnet The user command and TCP/IP protocol for accessing a remote computer. Telnet allows you to log on to the remote computer as a user.

Testing group A specific agent group designated to receive a Test version of Host Sensor agent software.

TFN/Trinoo Tribal Flood Network. Distributed Denial of Service attacks based on TCP/IP architecture that use a large number of computers to simultaneously attack a target. The attack originates from a single computer controlling several master computers, which in turn each control a number of daemons (other compromised computers). The masters maintain a list of responding daemons, signaling them to initiate the attack. Trinoo floods the target with UDP packets. TFN uses SYN flood, UDP flood, ICMP flood or smurf attack.

Trojan horse Harmful or malicious code masked by apparently innocuous code. In addition to corrupting data or giving away passwords, a trojan horse can open a back door to a system, providing further unwanted access.

U

User group Any set of users defined on a Primary Domain Controller.

V

Version A release of Cisco IDS Host Sensor agent software. Any number of versions can be maintained on a server.

Version, Default A release of Host Sensor agent software that has been tested in the network environment and designated as Default. This version is distributed to all agents not in the testing group. There can be only one version designated as Default.

Version, New A release of Host Sensor agent software that is newer than the Default version.

Version, Old A release of Host Sensor agent software that is older than the Default version.

Version, Test A release of Host Sensor software designated as Test and distributed to a specific group of agents in order to check its functionality in a specific network environment. There can be only one version designated as Test.

W

WAN Wide Area Network. A data communications network that serves a broad geographic area.

Warning Mode The mode in which an agent can monitor activity on its host without carrying out security measures.

Worm A program that seeks to replicate itself from one computer to another, often damaging or stealing data in the process.

CISCO SYSTEMS

Product Bulletin No. 1928

Cisco **Content Switching Module** Software Version 3.1(1) for the Cisco Catalyst 6500 Switch and the Cisco 7600 Internet Router

New Features

New features of the Cisco CSM Software Version 3.1(1) Content Switching Module for the Cisco Catalyst® 6500 Switch and the Cisco 7600 Internet Router include the following:

- *Virtual IP (VIP) connection watermarks*—The VIP connection watermark feature allows the Web-hosting provider to limit the number of connections going through a particular virtual server or set of virtual servers. By using this feature, the network administrator allows a fair distribution of connection resources among all virtual servers. When a virtual server reaches the configured maximum connection limit, no new connections are established to that virtual server until it drops below the connection watermark again. This feature allows Cisco CSM customers to have a shared CSM environment, whether between multiple customers or many departments with an enterprise, without fear that one group will consume all the resources. This feature also can be configured to protect against denial-of-service (DoS) attacks.
- *Backup server farm*—The backup server farm feature allows the administrator to specify one or more backup servers that will be used when all primary servers in a server farm are unavailable because of health probes or connection thresholds. If configured, when the Cisco CSM receives a connection that matches a policy associated with a server farm in which all the servers are currently down, the CSM load balances this connection to the configured backup server farm. The backup server farm also can be configured to be a Hypertext Transfer Protocol (HTTP) redirect so that clients are redirected to a remote location.
- *Optional port for health probing*—Some of the Cisco CSM supported health probes require that the CSM probe real servers on a specific TCP or User Datagram Protocol (UDP) port. In earlier implementations of Cisco CSM Software, the network administrator cannot explicitly specify a server port when configuring a health probe. Instead, the port is inherited from the virtual servers that are using the server farm with which the probe is associated. This feature allows the administrator to override the real and virtual server port information by explicitly specifying a port to probe in the health probe configuration.

- *IP reassembly*—In Cisco CSM 1.x Software releases, all IP fragments are dropped by the CSM. In Cisco CSM 2.x Software releases, the UDP fragments of a datagram are reassembled as long as the first fragment of the datagram is received by the Cisco CSM before all other fragments. In 3.1(1), the Cisco CSM can handle UDP fragments and assemble them, regardless of the order in which they were received.
- *Toolkit Command Language (TCL) scripting*—To support more flexible health-probing functionality, this feature gives the administrator the ability to upload and execute TCL scripts on the Cisco CSM. The administrator can create a "script probe" that the Cisco CSM periodically executes for each real server in any server farm associated with the probe. Depending upon the exit code of such a script, the real server is considered healthy, suspect, or failed. A wide variety of probing functions are possible using the flexibility of the TCL scripting environment. The Cisco CSM also supports execution of custom TCL scripts that are not directly associated with a particular server health probe. A "standalone script" dynamically executes a task at a specified interval.
- *Extended Markup Language application programming interface (XML API) configuration*—Users can now automate programmatic configuration of the Cisco CSM via a documented XML API. When the network administrator enables this feature, a network management device may connect to the CSM and "push" new configurations to it. The network management device pushes configuration commands to the Cisco CSM using the standard HTTP protocol by sending an XML document in the data portion of an HTTP POST. The full Document Type Definition (DTD) can be found documented in the appendix of the Cisco CSM Installation and Configuration Guide.
- *Simple Network Management Protocol/Management Information Base (SNMP/MIB)*—The Cisco CSM now has full SNMP/MIB support. In this release, the Cisco CSM supports two Read Only MIBs: CISCO-SLB-MIB and CISCO-SLB-EXT-MIB, which are available at ftp://ftp.cisco.com/pub/mibs/. Traps can be sent based on real server, virtual server, and fault tolerant state changes.
- *Global server load balancing (GSLB)*—GSLB has increased in popularity as a method for disaster recovery. In this release the Cisco CSM supports GSLB in which the CSM can be configured to act as an authoritative Domain Name System (DNS) server. The Cisco CSM then collects load information from other Cisco CSMs in the network and load balances incoming traffic across these geographically dispersed CSMs.
- *Resource usage display*—A show command has been added to the Cisco CSM that includes multiple parameters for determining how loaded the CSM is at a given moment. The output of this command indicates the CPU usage on each of the processing modules within the Cisco CSM hardware, memory usage, and other related information.
- *HTTP method parsing*—Every HTTP request contains an HTTP method, a URL, and other information such as HTTP headers. This new feature allows the user not only to match HTTP headers, but also to configure policies that match particular HTTP "methods," such as GET, HEAD, and POST, and to make a load-balancing decision based on this information.
- *Real server names*—The real server configuration on the Cisco CSM now includes assigning an ASCII string name in addition to the current options of IP address and port. This creates a friendlier way to reference real servers, mapping an IP address to a name. It also allows all instances of the real server to be removed from service on a global level with one command, regardless of how many server farms to which a real server belongs.
- *Non-TCP connection state redundancy*—The Cisco CSM currently supports connection state redundancy for TCP protocols. This functionality has been extended to include non-TCP protocols.

- *Reverse sticky*—In a firewall load-balancing environment, this feature allows multiple connections between the same two devices to be stuck to the same firewall based on the IP addresses of the first incoming connection, regardless of the load-balancing algorithm used and regardless of which of the two devices originated the connection. This feature is especially important for firewall load-balancing scenarios where the load balancers on the two sides of the "sandwich" are not both Cisco CSMs. As an example, when using Cisco IOS® SLB on one side of the sandwich and the Cisco CSM on the other, the hash algorithms are not the same; therefore, new connections originated by the receiving device might not be load balanced to the same firewall from which the first connection was received. With the Cisco CSM reverse sticky feature configured, the receiving Cisco CSM sets up a sticky entry for connections opened in the opposite direction. This way, after the first connection between two specific devices has been set up on the two Cisco CSMs in the firewall load-balancing sandwich, all subsequent connections are load balanced to the same firewall, regardless of which of the two devices originates them.
- *Unidirectional idle timeout*—This feature allows the user to configure unidirectional timers for specific virtual servers; for flows matching those virtual servers, the Cisco CSM monitors only one direction of the flow. This feature is particularly useful in UDP streaming environments, where unidirectional flows are common and long idle timers are not optimal; unidirectional timers for this kind of flows allow the Cisco CSM to ignore the silent direction of the flow and time out the flow based on only the other direction.
- *SSL service module ID*—The Cisco CSM now has a configurable sticky option that allows the CSM to continue to provide stickiness based on Secure Sockets Layer (SSL) ID, even during SSL ID renegotiation when the Cisco CSM is paired with the SSL Services Module for the Cisco Catalyst 6500. Though the renegotiation process is encrypted, usually making it impossible to use SSL ID effectively for stickiness, the Cisco CSM is able to work in conjunction with the Cisco SSL Services Module, when this feature is configured. This ensures that the stickiness is not broken, even if a SSL ID renegotiation occurs. The result is that the same SSL Service Module is always selected for the same client.

Orderable Product Numbers

Table 1 gives part numbers for ordering Cisco CSM Software.

Table 1 Cisco CSM Part Numbers

Cisco CSM Software Version	Hardware Part Number	Software Part Number	Hardware Requirements	Native Cisco IOS Software Release	Added Features
3.1(1)	WS-X6066-SLB-APC	SC6k-3.1.1-CSM	Supervisor IA with Multilayer Switch Feature Card (MSFC) and Policy Feature Card (PFC) or Supervisor II with MSFC 2	12.1(13)E	• VIP connection watermarks • Backup serverfarm • Optional port for probing • IP reassembly • Scriptable health checks • XML API for configuration • SNMP/MIB support • GSLB • Resource usage display • HTTP method parsing • Real server names • Non-TCP connection state redundancy • Reverse IP sticky • SSL services module ID • Unidirectional idle timeout
2.1(4)	WS-X6066-SLB-APC	SC6k-2.1.4-CSM	Supervisor IA with MSFC and PFC or Supervisor II with MSFC 2	12.1(8)EX	• Firewall load balancing • Non-TCP load balancing • URL hashing • HTTP 1.1 persistence • Full stateful failover • Generic header parsing • SNMP server health traps • Multiple Cisco CSMs in a chassis • Virtual private network/IP Security (VPN/IPSec) load balancing
2.2(4)	WS-X6066-SLB-APC	SC6k-2.2.4-CSM	Supervisor IA with MSFC and PFC or Supervisor II with MSFC 2	12.1(11)E	• Increased VLAN limit • Return code checking • Inband health monitoring • Configuration pending timeout value • Real-Time Streaming Protocol (RTSP) support

Cisco Catalyst 6500 Series Switch

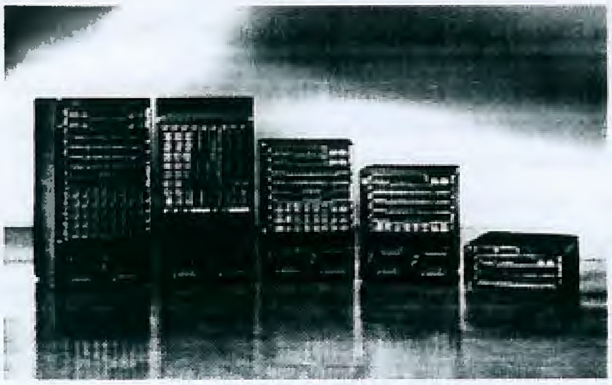
The Catalyst 6500 Series sets the new standard for IP communications and application delivery in enterprise campus and service provider networks by maximizing user productivity and enhancing operational control while providing unprecedented investment protection. As Cisco's premier intelligent multilayer modular switch, the Catalyst[®] 6500 Series delivers secure, converged services, end-to-end, from the wiring closet to the core, to the data center, to the WAN edge.

Ideal for enterprises and service providers seeking to reduce their total cost of ownership, the Cisco Catalyst 6500 Series delivers scalable performance and port density across a range of chassis configurations and LAN/WAN/MAN interfaces. Available in 3-, 6-, 9-, and 13-slot chassis, Cisco Catalyst 6500 Series switches feature an unparalleled range of integrated services modules, including multigigabit network security, content switching, telephony, and network analysis modules.

By taking advantage of a forward-thinking architecture that uses a common set of modules and operating system software across all Cisco Catalyst 6500 Series chassis, the Catalyst 6500 Series delivers a high level of operational consistency that optimizes IT infrastructure usage and enhances return on investment. From 48-port to 576-port 10/100/1000 Ethernet wiring closets to hundreds-of-Mpps network cores supporting up to 192 1-Gbps or 32 10-Gbps trunks, the Cisco Catalyst 6500 Series provides an optimal platform that maximizes network uptime with stateful failover capability between redundant routing and forwarding engines.

With numerous industry-firsts and industry-leading features to its credit, the Catalyst 6500 Series supports three generations of modules that continue to demonstrate the Catalyst 6500 value and Cisco's commitment to innovation. Cisco's new generation of Catalyst 6500 Series modules and Supervisor Engine 720 incorporate 11 new Cisco-developed application specific integrated circuits (ASICs)—extending Cisco's leadership in networking while providing unparalleled investment protection.

Figure 1
Cisco Catalyst 6500 Series Chassis



Cisco Catalyst 6500 Series Benefits

The Cisco Catalyst 6500 Series provides market-leading services, performance, port densities, and availability with investment protection for enterprise and service provider markets. These include:

- *Maximum network uptime*—With platform, power supply, supervisor engine, switch fabric, and integrated network services redundancy provides one- to three-second stateful failover and delivers application and services continuity in a converged network environment, minimizing disruption of mission-critical data and services
- *Comprehensive network security*—Integrates proven, multigigabit Cisco security solutions, including intrusion detection, firewall, VPN, and SSL into existing networks
- *Scalable performance*—Provides up to 400 Mpps performance with distributed forwarding architecture
- *Forward-Thinking architecture with investment protection*—Supports three generations of interchangeable, hot-swappable modules in the same chassis, optimizing IT infrastructure usage, maximizing return on investment, and reducing total cost of ownership
- *Operational consistency*—Features 3-, 6-, 9-, and 13-slot chassis configurations sharing a common set of modules, Cisco IOS Software, Cisco Catalyst Operating System Software, and network management tools that can be deployed anywhere in the network
- *Unparalleled services integration and flexibility*—Integrates advanced services such as security and content with converged networks, provides the widest range of interfaces and densities, from 10/100 and 10/100/1000 Ethernet to 10 Gigabit and from DS0 to OC-48, and performs in any deployment end to end

Operational Consistency in End-to-End Cisco Catalyst 6500 Series Deployments

- Features 3-, 6-, 9-, and 13-slot chassis configurations that share a common set of modules, software, and network management tools
- Deploys anywhere in the network—from the wiring closet to the core, to the data center, to the WAN edge
- Shares WAN port adapters with Cisco 7xxx router Series for reduced sparing and training costs
- Offers choice of Cisco IOS Software and Cisco Catalyst Operating System Software supported on all supervisor engines, providing smooth migration from Cisco Catalyst 5000 Series and Cisco 7500 Series deployments

Maximum Network Uptime and Network Resiliency

- Provides packet-loss protection and the fastest recovery from network disruption
- Features fast, one- to three-second stateful failover between redundant supervisor engines
- Offers optional, redundant high-performance Cisco Catalyst 6500 Series Supervisor Engine 720, passive backplane, multimodule Cisco EtherChannel® technology, IEEE 802.3ad link aggregation, IEEE 802.1s/w, Hot Standby Router Protocol/Virtual Router Redundancy Protocol (HSRP/VRRP) high-availability features

Integrated High-performance Security and Network Management

Integrated gigabit-per-second services modules, deployed where external devices would not be feasible, simplify network management and reduce total cost of ownership. These include:

- Gigabit firewall—provides access protection
- High-performance intrusion detection system (IDS)—provides intrusion detection protection
- Gigabit Network Analysis Module—provides a more manageable infrastructure and full Remote Monitoring (RMON) support
- High-performance SSL—provides high-performance, secure e-commerce traffic termination
- Gigabit VPN and standards-based IP Security (IPSec)—support lower cost Internet and intracampus connections

Content-and Application-Aware Layers 2 Through 7 Switching Services

- Integrated content switching module (CSM) brings high-performance, feature-rich server and firewall load balancing to the Cisco Catalyst 6500 Series, ensuring a safer and more manageable infrastructure with unprecedented control
- Integrated multigigabit SSL acceleration combined with CSM provides a high-performance e-commerce solution
- Integrated multigigabit firewall and CSM provide a secure, high-performance, data-center solution
- Software features such as Network Based Application Recognition (NBAR) enhance network management and control of bandwidth utilization

Scalable Performance

- Delivers the industry's highest LAN switch performance, 400 Mpps, using the distributed Cisco Express Forwarding dCEF720 platform
- Supports a mix of Cisco Express Forwarding (CEF) implementations and switch fabric speeds for optimal wiring closet, core, data center, and WAN edge deployments, as well as service provider networks

Rich Layer 3 Services

- Multiprotocol Layer 3 routing supports traditional network requirements and provides a smooth transition mechanism in the enterprise
- Provides hardware support for enterprise-class and service-provider-scale routing tables
- Provides IPv6 support in hardware (using Supervisor Engine 720) with an unparalleled high-performance suite of services
- Provides hardware support for large enterprise-class and service-provider-scale routing tables
- Provides MPLS support in hardware to enable VPN services within the enterprise and facilitate smooth integration with new high-speed service provider core infrastructures and Metro Ethernet deployments

Enhanced Data Voice, and Video Services

- Provides integrated IP communications throughout all Cisco Catalyst 6500 Series platforms
- Provides 10/100 and 10/100/1000 line cards, field upgradable with inline power using a daughter card and offering future support for IEEE 802.3af to protect today's investments
- Provides dense T1/E1 and foreign Exchange Station (FXS) voice-over-IP (VoIP) gateway interfaces for public switched telephone network (PSTN) access and traditional phone, fax, and private branch exchange (PBX) connections
- Supports high-performance IP multicast video and audio applications
- Provides integrated management necessary to effectively deploy a scalable enterprise-converged network

Highest Level of Interface Flexibility, Scalability, and Density

- Provides the port densities and interface choices that large mission-critical wiring closets, enterprise core, and distribution networks require
- Supports up to 576 voice 10/100/1000 Gigabit-over-copper ports with inline power per system
- Provides up to 192 Gigabit Ethernet ports

16.126
L

- Features the industry's first 10 Gigabit Ethernet, Channelized OC-48 dense OC-3 Packet over Synchronous Optical Network (SONET) (PoS)
- Provides investment protection by using Cisco 7xxx Series port adapters on the Cisco Catalyst 6500 Series FlexWAN Line Card, supporting T1/E1 through OC-48 WAN interfaces
- Chassis sizes range from 3-slot (Cisco Catalyst 6503 Switch) to 13-slot (Cisco Catalyst 6513 Switch)

High-Speed WAN Interfaces

- Provides high-speed WAN, ATM, and SONET interfaces compatible with other core routers
- Provides single-device management for WAN aggregation and for campus and metro connectivity

Maximum Investment Protection

- Highly flexible modular architecture supports multiple generations of modules that are fully interoperable with each other in the same chassis
- Upgradable supervisor engines can add Layer 3 routing or forwarding capabilities over time
- Cisco IOS Software and Cisco Catalyst Operating System Software are supported across all supervisor eng
- Field-upgradable inline power for 10/100 Mbps and 10/100/1000 Mbps Ethernet modules for "pay as you go" IP telephony and wireless computing
- A steady stream of new services modules adds to the deployment options
- Includes Cisco Catalyst 6500 Series network security, content switching, and voice capabilities
- Future modules will increase performance, port density, and include additional services

Ideal for Metro Ethernet WAN Services

- 802.1Q and 802.1Q tunneling (QinQ) providing point-to-point and multipoint Ethernet services
- EoMPLS in MPLS backbones for superior network scaling providing virtual LAN (VLAN) translation capability
- Layer 2 and Layer 3 QoS enables tiered Ethernet service offerings through rate limiting and traffic shaping
- Superior high-availability features include enhanced Spanning Tree Protocol, IEEE 802.1s, IEEE 802.1w, and Cisco EtherChannel IEEE 802.3ad link aggregation

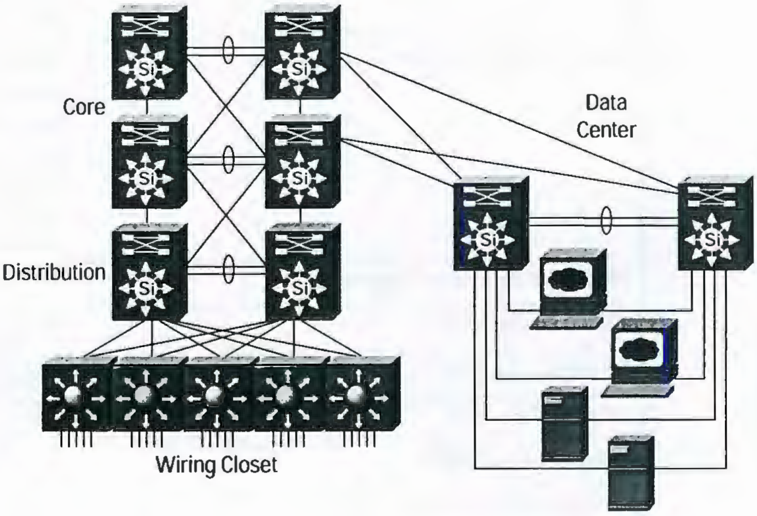
Deployment Scenarios

The Cisco Catalyst 6500 Series delivers secure converged services for campus, Internet service provider (ISP), metro edge, and research and grid computing networks.

- *Campus networks*—Features 10/100 and 10/100/1000 autosensing modules that provide inline power for the wiring closet, along with robust high availability, security, and manageability features; world-class networking software; high-performance Gigabit and 10 Gigabit interface modules; and network management for the distribution and core

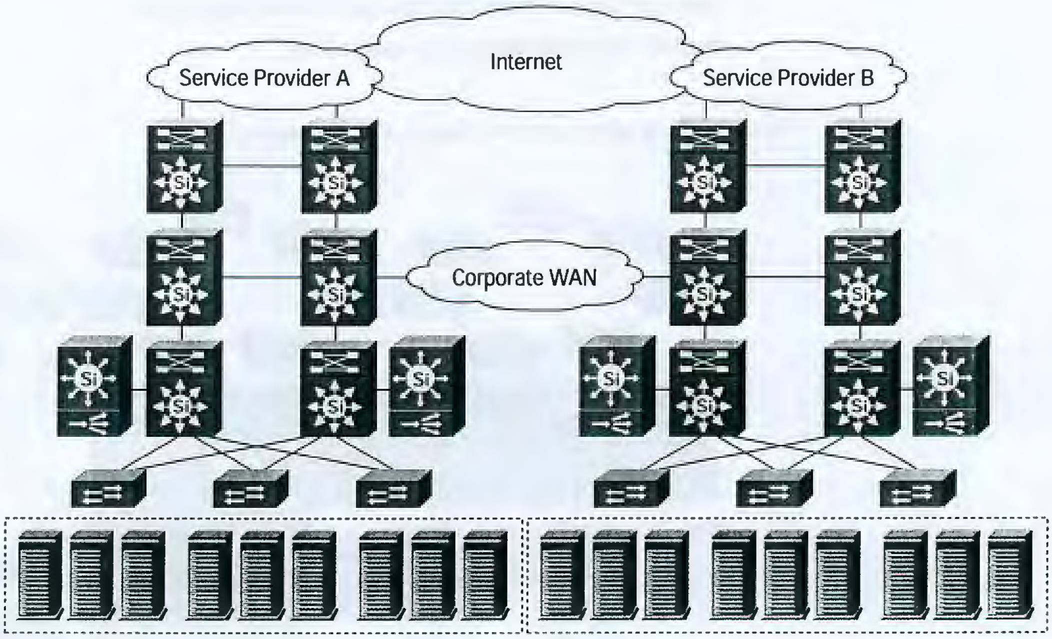
Figure 2

Deployment Scenarios for Catalyst 6500 Series Switches in Campus Networks



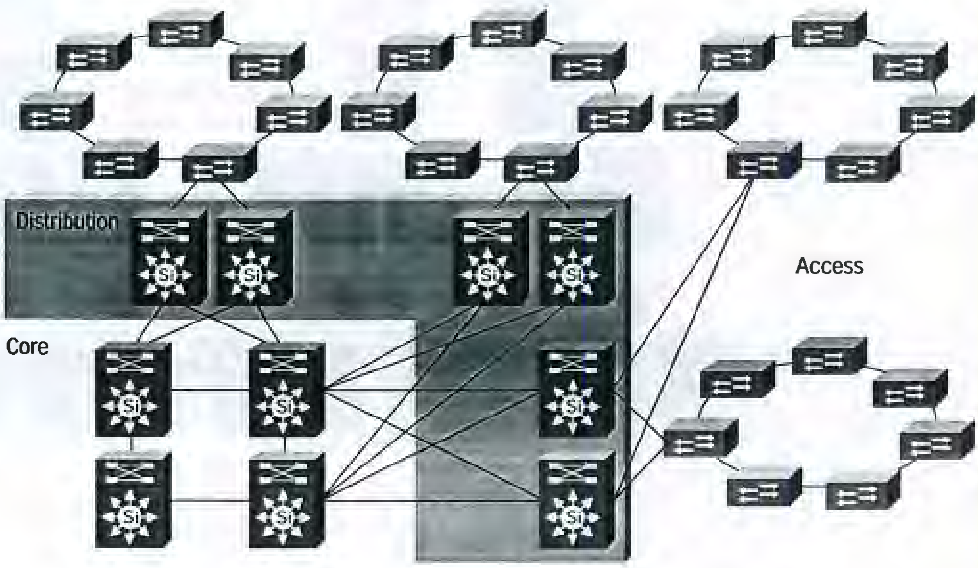
- [*ISP network*—Provides robust high-availability, security, and manageability features; world-class networking software; high-performance Gigabit and 10 Gigabit interface modules; and network management for the most demanding service provider networking environments requiring Multiprotocol Label Switching (MPLS), Multicast, IP Version 6 (IPv6), an extensive set of WAN interfaces, and hierarchical traffic shaping.

Figure 3
Deployment Scenarios for Catalyst 6500 Series Switches in ISP Networks



- *Metro edge*—Features edge-, distribution-, and core-layer interfaces for point-to-point and multipoint Ethernet services for metro and inter-metro network deployments with the following features:
  - High-performance 10-Gigabit Ethernet uplinks
  - 802.1Q tunneling
  - Ethernet over MPLS (EoMPLS)
  - Layer 2 and Layer 3 QoS
  - Network Equipment Building Standards (NEBS) compliance
  - Security, high availability, and manageability

Figure 4
Deployment Scenarios for Catalyst 6500 Series Switches in Metro Edge



- *Grid computing network*—Provides high-speed optical interface modules and world-class software required to handle high-volume traffic and build and manage large-scale networks

System Overview

Modular Architecture

The Cisco Catalyst 6500 Series is a modular system that can grow as customer requirements expand and technology evolves, allowing customers to upgrade and reconfigure systems by adding new modules, replacing existing modules, and adding and redeploying systems. Throughout the Cisco Catalyst 6500 Series, modules are:

- *Configurable*—Separately, simplifying the addition of new services
- *Interoperable*—In the same chassis, providing flexible design options
- *Interchangeable*—Among Cisco Catalyst 6500 Series systems, simplifying sparing and network expansion
- *Hot-swappable*—Without requiring a chassis to be powered off, providing fast upgrade and repair
- *Upgradable*—As newer modules come along, providing investment protection

Cisco Catalyst 6500 Series Hardware-Forwarding Architectures

Cisco Catalyst 6500 Series modules use one of three forwarding technologies, each having a different architecture with different characteristics and capabilities:

- *Cisco Express Forwarding (CEF)*—Scaling to 30 Mpps, this technology uses a central CEF Cisco Express Forwarding engine located on the supervisor engine's policy feature card (PFC) daughter and CEF forwarding tables located on the supervisor engine. The supervisor engine makes all forwarding decisions for all interface modules centrally. For more information see *How Cisco Express Forwarding Works.*
- *Accelerated Cisco Express Forwarding (aCEF)*—Suited for high-performance enterprise environments, this technology uses the aCEF engine and aCEF tables located on the interface module, along with the central CEF engine located on the supervisor engine's PFC daughter card and central CEF forwarding tables located on the supervisor engine. The interface module makes high-volume forwarding decisions locally, and the supervisor engine makes the rest of the forwarding decisions centrally. For more information see *How Accelerated Cisco Express Forwarding (aCEF) Works.*
- *Distributed Cisco Express Forwarding (dCEF)* —Suited for the most demanding environments, this technology uses the dCEF engine located on the interface module's distributed forwarding card (DFC) daughter card and the dCEF table, a local copy of the supervisor engine's central CEF table located on the interface module's DFC. The interface module makes all the forwarding decisions locally, and provides maximum performance and scalability. For more information see *How Distributed Cisco Express Forwarding (dCEF) Works*

Cisco Catalyst 6500 Series Switching Architectures

Cisco developed the following switching architectures for Cisco Catalyst 6500 modules to allow platforms to scale in any deployment:

- 32-Gbps bus—Allowing access to a central shared bus
- 256-Gbps switch fabric—Located on the switch fabric module (SFM)
- 720 Gbps switch fabric—Located on Cisco Catalyst 6500 Series Supervisor Engine 720

Cisco Catalyst 6500 Series Modules

Cisco Catalyst 6500 Series interfacecmodules support the following forwarding technology and switch fabric combinations:

- *Classic Interface Modules*—Use the centralized CEF engine located on the supervisor engine's PFC, connect to the 32-Gbps switching bus only, and forward packets at up to 15 Mpps
- *CEF256 Interface Modules*—Use the centralized CEF engine located on the supervisor engine's PFC, connect to both the 256-Gbps fabric located on the supervisor engine with a single 8-Gbps full-duplex fabric connection and the 32-Gbps switching bus, and forward packets at up to 30 Mpps
- *dCEF256 Interface Modules*—Use the distributed CEF engine on the DFC (located on the interface module), connect to a 256-Gbps fabric located on the supervisor engine or a Switch Fabric Module with 16-Gbps full-duplex fabric connections, and forward packets at up to 210 Mpps
- *aCEF720 Interface Modules*—Use the accelerated CEF engine on the DFC3 (located on the interface module), connect to the 720-Gbps fabric located on the supervisor engine with 40-Gbps full-duplex fabric connections, and forward packets at up to 400 Mpps, peak performance
- *dCEF720 Interface Modules*—Use the distributed CEF engine on the DFC3 (located on the interface module), connect to the 720-Gbps fabric located on the supervisor engine with dual 20-Gbps full-duplex fabric connections, and forward packets at up to 400 Mpps, sustained performance

Note: All Performance numbers refer to IPv4 forwarding.

Cisco Catalyst 6500 Series Module Types

In the Cisco Catalyst 6500 Series architecture, special-purpose modules perform separate tasks—allowing the feature set to evolve quickly and allowing customers to add new features and enhanced performance by adding new modules. The Cisco Catalyst 6500 Series features the following types of special-purpose modules:

- *Supervisor engines*—Perform the control functions and make the forwarding decisions for packets routed to other networks
- *Ethernet interface modules*—Provide IEEE-standard receive and forwarding interfaces and forward packets within the defined network
- *WAN interface modules*—Provide the receive and forwarding interface at the WAN edge
- *Services modules*—Support multigigabit security, application-aware Layer 4 through 7 content switching, network management, and voice gateway services to traditional phones, fax machines, PBXs, and the PSTN
- *Switch Fabric Modules (SFMs)*—Pass network traffic from interface module to the supervisor engine or to another interface

Cisco Catalyst 6500 Series Supervisor Engines

The supervisor engines for the Cisco Catalyst 6500 Series support different forwarding technologies and achieve different forwarding rates, depending on the configuration of the supervisor engine and the capability of a particular interface module.

Supervisor engines can be configured with optional factory-installed daughter cards—a Policy Feature Card (PFC) providing hardware-based Layer-2 forwarding, and a Multilayer Switch Feature Card (MSFC) providing Layer 3 capabilities.

A supervisor engine performs control operations centrally on processors that run either Cisco IOS Software or Cisco Catalyst Operating System Software while special-purpose application-specific integrated circuits (ASICs) perform bridging and routing (based on Cisco Express Forwarding), QoS marking and policing, and access control. The same ASICs are used on the DFCs, daughter cards that can be installed on certain interface modules to distribute forwarding in a decentralized fashion to achieve system forwarding rates of up to 400 Mpps (Table 2).

For additional information about the following Cisco Catalyst 6500 Series supervisor engines visit: http://www.cisco.com/en/US/products/hw/switches/ps708/products_data_sheets_list.html

Table 2 Cisco Catalyst 6500 Supervisor Engines

Feature	Supervisor Engine 1	Supervisor Engine 2	Supervisor Engine 7
Solution and market	Wiring closet	Enterprise distribution, core, and WAN edge; service provider WAN and Internet edge	Enterprise core and data center; service provider metro; wireless; national research networks; grid computing
Fabric architectures supported	Centralized forwarding only—engine located on supervisor engine's PFCx daughter card	Centralized CEF—engine located on supervisor engine's PFCx daughter card; Distributed CEF—engine located on interface module's DFC daughter card	Centralized CEF—engine located on Supervisor Engine 720's PFC3 daughter card; Distributed CEF—engine located on interface module's DFC3 daughter card; Accelerated CEF—engine located on interface module's ASICs
Fabric connections	32-Gbps shared bus connection to modules	16 Gbps per slot; Dual-fabric connection to modules at 8 Gbps full duplex per channel	40 Gbps per slot; Dual-fabric connection to modules at 20 Gbps full duplex per channel
Performance maximum (Mpps)	15 Mpps	210 Mpps	Sustained 400 Mpps—dCEF720 Peak 400 Mpps—aCEF720
DFC modules	Not supported	DFC	DFC3

Table 2 Cisco Catalyst 6500 Supervisor Engines

Feature	Supervisor Engine 1	Supervisor Engine 2	Supervisor Engine 720
Route processor	On MSFC2 daughter card (optional)	On MSFC2 daughter card (optional)	MSFC3 integrated
PFC modules	PFC daughter card (optional)	PFC2 integrated	PFC3 integrated

Ethernet Interface Modules

Cisco Catalyst 6500 Series Ethernet interface modules, designed for wiring closet, distribution and core, and data center applications, as well as service provider and Metro Ethernet environments, use one of the following types of Ethernet interfaces:

- *10/100 Mbps over copper and 10/100/1000 Mbps Ethernet over copper*—For wiring closets providing 10/100- and 10/100/1000-Mbps performance with auto-negotiation and inline power for voice; up to 48 ports/module; includes Classic and CEF256 interface modules.
- *100 Mbps over fiber*—For secure wiring closets and long-haul router and switch interconnects; up to 24 ports per module; includes Classic and CEF256 interface modules.
- *1 Gbps*—For distribution and core layers and for data centers providing 1-Gbps performance in a 48-port module; includes Classic CEF256, and dCEF256 interface modules.
- 10 Gbps—For distribution and core layers providing 10-Gbps performance in 1-port or 2-port module; includes CEF256, aCEF720, and dCEF720 interface modules.

For more information, visit:
http://www.cisco.com/en/US/products/hw/switches/ps708/products_data_sheets_list.html

WAN Interface Modules

The Cisco Catalyst 6500 Series and Cisco 7600 Series support several WAN interfaces using two technologies:

- *FlexWAN module*—Accepts up to two plug-in port adapters that provide numerous WAN/MAN protocols and features
- *Optical Services Module (OSM)*—A dedicated line card that provides several interfaces, including OC-3/STM-1, OC-12/STM-4, OC-48/STM-16, Channelized T3, Channelized OC-12/STM-4 PoS, Gigabit Ethernet, OC-12/STM-4 ATM, and OC-48/STM-16 Dynamic Packet Transport (DPT)

FlexWAN Module

The FlexWAN module fits inside Cisco Catalyst 6500 Series and Cisco 7600 Series systems and uses Cisco 7200 and 7500 Series port adapters for a wide range of WAN/MAN protocols, including Frame Relay, ATM, PoS, Point-to-Point Protocol (PPP), and High-Level Data Link Control (HDLC). Additionally, the FlexWAN module provides media options such as clear channel and Channelized T1/E1, T3/E3, High-Speed Service Interface (HSSI), OC-3 PoS, and ATM.

- For information about the Cisco Catalyst 6500 Series and Cisco 7600 Series FlexWAN Module, visit: http://www.cisco.com/en/US/products/hw/routers/ps368/products_data_sheet09186a00800923bf.html

Optical Services Modules

OSMs are line cards that provide high-speed WAN connectivity with onboard network processors for distributed-line-rate IP service applications. For more information about OSMs, see the following data sheets:

  Layer 4 Through 7 Services Modules

The Cisco Catalyst 6500 Series offers an extensive set of services modules for Layer 4 through 7 applications, including content services, network monitoring, security, and telephony.

Content Services Modules

- *Content Services Gateway (CSG)*—Enables differentiated billing, user balance enforcement, and activity tracking for customer billing systems. For more information, visit: http://mobiletraining.cisco.com/csg/CSGe_ds_0211.pdf
- *Content Switching Module (CSM)*—Integrates advanced content switching into the Cisco Catalyst 6500 Series to provide high-performance, high-availability load balancing of caches, firewalls, Web servers, and other network devices. For more information, visit:
  http://www.cisco.com/en/US/products/hw/modules/ps2706/products_data_sheet09186a00800887f3.html

Network Monitoring

- *Network Analysis Module (NAM 1 and 2)*—Provides application-level visibility into the network infrastructure for real-time traffic analysis, performance monitoring, and troubleshooting; performs traffic monitoring with embedded Web-based traffic analyzer. For more information, visit:
  http://www.cisco.com/en/US/products/hw/modules/ps2706/products_data_sheet09186a00800a2c89.html

Security Services Modules

- *Firewall Services Module (FWSM)*—The FWSM allows any port in the chassis to operate as a firewall port and integrates stateful firewall security inside the network infrastructure. For more information, visit:
  http://www.cisco.com/en/US/products/hw/modules/ps2706/products_data_sheet09 186a00800c4fe7.html
  Intrusion Detection System Module (IDSM and IDSM-2)—Takes traffic from the switch backplane at wire speed, integrating IDS functions directly into the switch. For more information, visit:
  http://www.cisco.com/en/US/products/hw/modules/ps2706/products_data_sheet09186a0080092341.html

- *IPSec VPN Module (IVSM)*—Provides infrastructure-integrated IPSec VPN services capable of 1.9-Gbps Triple Data Encryption Standard (3DES) performance, 8000 active tunnels, and up to 60 tunnels per second. For more information, visit: http://www.cisco.com/en/US/products/hw/modules/ps2706/products_data_sheet09 186a00800c4fe2.html
- *SSL Services Module (SSM)*—Offloads processor-intensive tasks related to securing traffic with SSL accelerating the performance and increasing the security of Web-enabled applications. For more information, visit: http://www.cisco.com/en/US/products/hw/modules/ps2706/products_data_sheet09186a00800c4fe9.html

Telephony Services Modules

- *Communications Media Module (CMM)*—Provides flexible, high-density T1 and E1 gateways, allowing organizations to connect their existing time-division multiplexing (TDM) networks to their IP communications networks, and providing connectivity to the PSTN. For more information, visit: http://www.cisco.com/en/US/products/hw/modules/ps3115/products_data_sheet09 186a00800e9c1f.html

Switch Fabric Modules

Designed to support distributed forwarding for interface modules that have distributed forwarding capability, the Cisco Catalyst 6500 Series SFM or SFM2, in combination with the Cisco Catalyst 6500 Series Supervisor Engine 2-MSFC2 and DFCs on interface modules, increases available system bandwidth from 32 to 256 Gbps. The SFM/ SFM2 supports the Cisco Catalyst 6500 CEF256 and dCEF256 interface modules.

Designed to support new interface modules with 720 Gbps forwarding capabilities, the Supervisor Engine 720's onboard switch fabric increases available bandwidth to 720 Gbps and enables packet forwarding rates up to 400 Mpps. By using auto-sensing and auto-negotiation, the Supervisor 720 switch fabric is fully interoperable with the 8- and 16-Gbps switch fabric interconnections used by the CEF256 and dCEF256 interface modules. When a CEF256 or dCEF256 interface module is detected, the switch fabric will automatically connect those modules by offering 8-16 Gbps of bandwidth to each module, as applicable.

How Cisco Express Forwarding Works

Cisco Express Forwarding (CEF) is a Layer 3 technology that provides increased forwarding scalability and performance to handle many short-duration traffic flows common in today's enterprise and service provider networks. To meet the needs of environments handling large amounts of short-flow, Web-based, or highly interactive types of traffic, CEF forwards all packets in hardware, and maintains its forwarding rate completely independent of the number of flows going though the switch.

On the Cisco Catalyst 6500 Series, the CEF Layer 3 forwarding engine is located centrally on the supervisor engine's PFC2 or PFC3—the same device that performs hardware-based Layer 2 and 3 forwarding, ACL checking, QoS policing and marking, and NetFlow statistics gathering.

Using the routing table that Cisco IOS Software builds to define configured interfaces and routing protocols, the CEF architecture creates CEF tables and downloads them into the hardware-forwarding engine before any user traffic is sent through the switch. The CEF architecture places only the routing prefixes in its CEF tables—the only information it requires to make the Layer 3 forwarding decisions—relying on the routing protocols to do route selection. By performing a simple CEF table lookup, the switch forwards packets at wire-rate, independent of the number of flows transiting the switch.

CEF-based forwarding requirements: Requires a Cisco Catalyst Supervisor Engine 2 or Catalyst Supervisor Engine 720.

How Accelerated Cisco Express Forwarding (aCEF) Works

Accelerated Cisco Express Forwarding (aCEF) technology uses two forwarding engines working together in a master-slave relationship to accelerate high-rate traffic flows through the switch—a central CEF engine located on the Supervisor Engine 720's PFC3 and a scaled-down distributed aCEF engine located on the interface module.

The central PFC3 makes the initial forwarding decision, with the aCEF engine storing the result and making subsequent packet-forwarding decisions locally. aCEF forwarding works like this:

- As in standard CEF forwarding, the central PFC3 is loaded with the necessary CEF information before any user traffic arrives at the switch.
- As traffic arrives on an aCEF720 interface module, the aCEF engine inspects the packet, and finding that no specific packet forwarding information exists, consults the central PFC3.
- The PFC3 makes a hardware-based forwarding decision for this packet (including Layer 2, Layer 3, ACLs, and QoS).
- The aCEF engine stores the forwarding decision results and makes forwarding decisions locally for subsequent packets based on packet-flow history.
- The aCEF engine handles hardware-based Layer 2 and Layer 3 forwarding, ACLs, QoS marking, and NetFlow.
- The central PFC3 processes any forwarding decisions that the interface module's aCEF engine cannot handle.

aCEF-based forwarding requirements: Requires a Cisco Catalyst Supervisor Engine 720 and aCEF720 (WS-X67xx) class modules.

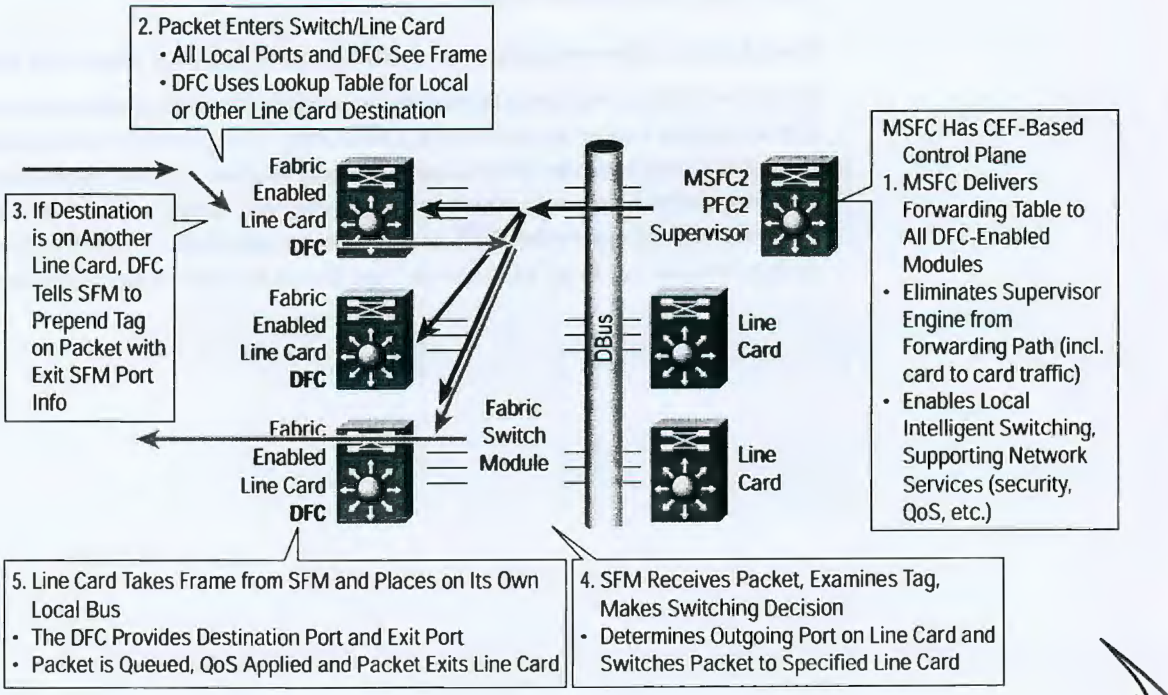
How Distributed Cisco Express Forwarding (dCEF) Works

With Distributed Cisco Express Forwarding (dCEF), forwarding engines located on the interface modules make forwarding decisions locally and in parallel, allowing the Cisco Catalyst 6500 Series to achieve the highest forwarding rates in the industry. With dCEF, forwarding occurs on the interface modules in parallel and system performance scales up to 400 Mpps—the aggregate of all forwarding engines working together.

Using the same ASIC engine design as the central PFCx, DFCs located on the interface modules forward packets between two ports, directly or across the switch fabric, without involving the supervisor engine. With the DFC, each interface module has a dedicated forwarding engine complete with the full forwarding tables. dCEF forwarding works like this:

- As in standard CEF forwarding, the central PFC3 located on the supervisor engine and the DFC engines located on the interface modules are loaded with the same CEF information derived from the forwarding table before any user traffic arrives at the switch.
- As a packet arrives at an interface module, its DFC engine inspects the packet and uses the information in the CEF table (including Layer 2, Layer 3, ACLs, and QoS) to make a completely hardware-based forwarding decision for that packet.
- The dCEF engine handles all hardware-based forwarding for traffic on that module, including Layer 2 and Layer 3 forwarding, ACLs, QoS policing and marking, and NetFlow.
- Because the DFCs make all the switching decisions locally, the supervisor engine is freed from all forwarding responsibilities and can perform other software-based functions, including routing, management, and network services.

Figure 6
Distributed Cisco Express Forwarding Packet Flow



Fabric Enabled Line Card DFC
Fabric Enabled Line Card DFC
Fabric Enabled Line Card DFC
Fabric Switch Module
DBus
MSFC2 PFC2 Supervisor
Line Card
Line Card

2. Packet Enters Switch/Line Card
- All Local Ports and DFC See Frame
- DFC Uses Lookup Table for Local or Other Line Card Destination

3. If Destination is on Another Line Card, DFC Tells SFM to Prepend Tag on Packet with Exit SFM Port Info

MSFC Has CEF-Based Control Plane
1. MSFC Delivers Forwarding Table to All DFC-Enabled Modules
- Eliminates Supervisor Engine from Forwarding Path (incl. card to card traffic)
- Enables Local Intelligent Switching, Supporting Network Services (security, QoS, etc.)

5. Line Card Takes Frame from SFM and Places on Its Own Local Bus
- The DFC Provides Destination Port and Exit Port
- Packet is Queued, QoS Applied and Packet Exits Line Card

4. SFM Receives Packet, Examines Tag, Makes Switching Decision
- Determines Outgoing Port on Line Card and Switches Packet to Specified Line Card

dCEF-based forwarding requirements: Requires a Cisco Catalyst Supervisor Engine 720 for the dCEF720 interface module; requires either a Catalyst Supervisor Engine 720 or a Catalyst Supervisor Engine 2-MSFC2 and a SFM for the dCEF256 interface module.

Cisco IOS Software and Catalyst Operating System Software

Cisco Catalyst 6500 Series switches offer two operating modes of software, the Cisco Catalyst Operating System Software with optional Cisco IOS Software on the MSFC, and Cisco IOS Software for the supervisor engines. Each operating mode can be deployed at different hierarchies of the network, depending on the network's requirements. These software solutions for the Cisco Catalyst 6500 Series switches provide full Layer 2 through 4 switching and routing functions at high performances.

Today, either of these operating modes can be deployed in an entire network environment, or the operating modes can vary within an environment to meet different requirements. One operating mode is not a replacement for another, but is recommended for varying feature requirements.

- Cisco IOS Software for the Cisco Catalyst 6500 Series
- Cisco Catalyst Operating System Software with optional Cisco IOS Software on the MSFC

Cisco IOS Software for the Cisco Catalyst 6500 Series

Cisco IOS Software for the Cisco Catalyst 6500 Series supervisor engines requires the MSFC on the supervisor engine. It provides integrated multilayer functions in a single image and is optimized for core, distribution, Internet access, and data center deployments. Cisco IOS Software combined with the performance of the Cisco Catalyst 6500 Series offers the necessary features for a high-performance Layer 3-enabled deployment, including support for a distributed architecture with the ability to scale the switch to 400 Mpps throughput. Additionally, Cisco IOS Software provides operational ease of use by offering a single image and configuration file to be deployed across the Cisco Catalyst 6500 Series switches.

Cisco Catalyst Operating System Software with Optional Cisco IOS Software on the MSFC

Cisco Catalyst Operating System Software is the premier software for the wiring closet on Cisco Catalyst 6500 Series switches offering high-performance Layer 2 forwarding. It is optimized to deliver the high availability, enhanced security, and integrated inline power support necessary for mission-critical wiring closet deployments. Cisco Catalyst Operating System Software can also be extended to the distribution and core layers of the network when coupled with Cisco IOS Software on the MSFC, providing robust and advanced Layer 3 and Layer 4 functions. This operating mode is often referred to as "hybrid mode." See Table 3 for software and hardware deployment options.

Table 3 Software and Hardware Deployment Options

Network Performance	Wiring Closet	Distribution/ Data Center	Core	WAN Edge
Highest-performance Cisco IOS Software end-to-end	Cisco IOS Software; Supervisor Engine 2-MSFC2; CEF256 interface modules	Cisco IOS Software; Supervisor Engine 720; dCEF720 and aCEF720 interface modules	Cisco IOS Software; Supervisor Engine 720; dCEF720 interface modules	Cisco IOS Software; Supervisor Engine 2-MSFC2; dCEF720 and aCEF720 interface modules

Cisco IOS Software and Cisco Catalyst Operating System Software Shared Features

All Cisco Catalyst 6500 Series supervisor engines, including the new Supervisor Engine 720, take advantage of the industry-leading software and management capabilities of the Cisco Catalyst 6500 Series. Customers can apply their knowledge of Cisco Catalyst Operating System Software, Cisco IOS Software, CiscoWorks, and other graphical and Web-based network management tools without the need to learn a new command-line interface (CLI) or management system.

Cisco Catalyst 6500 Series Chassis

Cisco Catalyst 6500 Series chassis can be deployed in the wiring closet, the distribution and core layers, the data center, and the WAN edge, providing the power and features required for end-to-end deployment for the enterprise campus, the ISP network, metro, and research computing networks.

Chassis Applications

The Cisco Catalyst 6500 Series provides a selection of chassis, including 3-, 6-, 9-, and 13-slot models with slots arranged horizontally and a 9-slot model with slots arranged vertically, with front-to-back airflow. Typical applications for Cisco Catalyst 6500 Series chassis include:

- *3-slot chassis*—Low-density, wiring-closet chassis sharing interface modules and supervisor engines with larger chassis for common sparing; low-density, high-performance specialized services modules chassis for network security and management; low-density, high-end chassis providing connectivity to the WAN edge
- *6- and 9-slot chassis*—Traditional chassis for the wiring closet, distribution and core, data center, and WAN
- *13-slot chassis*—Highest-capacity chassis for Ethernet connectivity, with slots to spare for services modules providing network security and management

Chassis Configuration

All Cisco Catalyst 6500 Series chassis are NEBS Level-3 compliant and use common power supplies. The 6- and 9-slot chassis require a 1000W or 1300W power supply and the 13-slot chassis requires a 2500W or 4000W power supply. The 3-slot chassis requires a 950W power supply. When ordering a Cisco Catalyst 6500 Series switch, use the online Cisco Dynamic Configuration Tool to assist you in selecting the chassis, power supplies, power cables, and fan trays that will meet your requirements. The tool is available at: http://www.cisco.com/appcontent/apollo/configureHomeGuest.html

Power

All Cisco Catalyst 6500 chassis hold up to two load-sharing, fault-tolerant, hot-swappable AC or DC power supplies. Only one supply is required to operate a fully loaded chassis. If a second supply is installed, it operates in a load-sharing capacity. The power supplies are hot-swappable—a failed power supply can be removed without powering off the system.

Cisco Catalyst 6500 Series switch power supplies are available in five power ratings:

- 950W AC input (Cisco Catalyst 6503 chassis)
- 1000W AC input
- 1300W AC and DC input
- 2500W AC and DC input
- 4000W AC input

Table 4 outlines the power requirements and heat dissipation for the three different models of power supplies available for the Cisco Catalyst 6500 Series switch.

Table 4 Power Supply VAC and VDC requirements

Power Supply	AC Input Voltage/Current	DC Input Voltage/Current
950W	100 to 240 VAC (10% for full range); 15 A	-48 VDC to –60 VDC continuous; 38 A @ –48 VDC, 30 A @ –60 VDC
1000W	100 to 240 VAC (10% for full range); 12 A @ 100 VAC, 6 A @ 240 VAC	Not supported
1300W	100 to 240 VAC (10% for full range); 17.25 A @ 100 VAC, 8 A @ 200 VAC	–48 VDC to –60 VDC continuous; 38 A @ –48 VDC, 30 A @ –60 VDC

2500W	100 to 120 VAC, 200 to 240 VAC (10% for full range);
	16 A maximum at 200 VAC at 2500 W output;
	16 A maximum at 100 VAC at 1300 W output
		–48 VDC to –60 VDC continuous;
		80 A @ –40.5 VDC, 70 A @ –48 VDC,
		55 A @ –60 VDC

4000W	100 to 240 VAC (10% for full range); 23 A	Not supported

Fan Trays

Chassis that have a Supervisor Engine 720 installed require a high-speed fan tray. See Table 5 for part number information.

Table 5 Catalyst 6500 Chassis Fan Tray Part Numbers

Catalyst 6500 Chassis	Normal Speed Fan— Fan Tray Part Number	High Speed Fan— Fan Tray Part Number

Technical Support Services

Whether your company is a large organization, a commercial business, or a service provider, Cisco is committed to maximizing the return on your network investment. Cisco offers a portfolio of technical support services to help ensure that your Cisco products operate efficiently, remain highly available, and benefit from the most up-to-date system software.

The Cisco Technical Support Services organization offers the following features, providing network investment protection and minimal downtime for systems running mission-critical applications:

- Provides Cisco networking expertise online and on the telephone
- Creates a proactive support environment with software updates and upgrades as an ongoing integral part of your network operations, not merely a remedy when a failure or problem occurs
- Makes Cisco technical knowledge and resources available to you on demand
- Augments the resources of your technical staff to increase productivity
- Complements remote technical support with onsite hardware replacement

Cisco Technical Support Services include:

- Cisco SMARTnet™ support
- Cisco SMARTnet Onsite support
- Cisco Software Application Services, including Software Application Support and Software Application Support plus Upgrades

Data Sheet

Cisco Catalyst 6500 Series
Gigabit Ethernet Modules

The Cisco Catalyst® 6500 Series Switch—the premier modular multilayer switch—delivers secure converged services from the wiring closet to the core, to the data center, to the WAN edge.

Designed to complement the many roles that the Cisco Catalyst 6500 Series plays in a network, Cisco Catalyst 6500 Series Gigabit Ethernet modules offer the broadest selection of media, densities, performance, interoperability, and chassis deployments for enterprises and service providers. *These modules are ideal for* gigabit to the desktop, gigabit uplinks, aggregation of high-density 10/100 interfaces, Metro Ethernet links; and backbone and high-speed server farm or data center connections. The Cisco Catalyst 6500 Series Gigabit Ethernet modules offer the following features:

- Flexible configurations for any deployment—Provide flexible port densities, media choices, and performance speeds for any deployment requirement
- Choice of media and connector type—Available in multimode fiber or single-mode fiber using MT-RJ and modular GBIC and SFP optics supporting station-to-station distances up to 100 km

Note: For information about 10/100/1000 copper interface modules with auto-negotiation, see the Cisco Catalyst 6500 Series 10/100 and 10/100/1000 Ethernet Data Sheet

- High port densities—From 8 up to 16 ports per module, up to 256 ports per system
- Scalable and predictable performance—Provide a selection of switch fabric connections and throughput: 32 Gbps bandwidth/15 Mpps (Classic interface modules), 256 Gbps bandwidth/30 Mpps (CEF256 interface modules), and 256 Gbps bandwidth/210 Mpps (dCEF256 interface modules)
- Operational consistency—Supported in all Catalyst 6500 3-, 6-, 9-, and 13-slot chassis running Cisco IOS® Software and Cisco Catalyst Operating System Software; interoperable with all other interfaces and services modules; and forward-compatible with all Catalyst 6500 supervisor engines
- Maximum network uptime and resiliency—Support Cisco enhanced Per-Virtual LAN (VLAN) Spanning Tree Plus (PVST+) protocol, IEEE 802.1w Rapid Spanning Tree Protocol (RSTP) and IEEE 802.1s Multiple Spanning Tree (MST) protocol, Per-VLAN Rapid Spanning Tree (PVRST) protocol, Hot Standby Router Protocol (HSRP), Virtual Router Redundancy Protocol (VRRP), Cisco EtherChannel®, and IEEE 802.3ad link aggregation for fault-tolerant connectivity

- Superior traffic management—Available with large per-interface buffers and multiple-priority queues for traffic prioritization and policing, allowing for tight service-level agreement (SLA) enforcement
- Extensive management tools—Support CiscoWorks network management platform, Simple Network Management Protocol (SNMP) versions 1, 2, and 3 and four RMON groups (statistics, history, alarms, and events)

WS-X6516A-GBIC

Gigabit Ethernet Applications

Gigabit Ethernet interface modules are used in distribution and core layers, and in data-center applications (Table 1).

Table 1 Cisco Catalyst 6500 Series Gigabit Interface Module Applications

Primary Applications	Product Number	Interface Module Class	Ports/ Connector/ Interface	Queues per Port (Tx = Transmit, Rx = Receive)[1]	Buffer Size
Data center and server farm	WS-X6816-GBIC	dCEF256	16, GBIC	Tx–1p2q2t Rx–1p1q4t	512 KB per port
Data center and server farm	WS-X6516A-GBIC	CEF256	16, GBIC	Tx–1p2q2t Rx–1p1q4t	1 MB per port
Base server farm	WS-X6408A-GBIC	Classic	8, GBIC	Tx–1p2q2t Rx–1p1q4t	512 KB per port
Base server farm	WS-X6316-GE-TX	Classic	16, RJ-45, 1000	Tx–1p2q2t Rx–1p1q4t	512 KB per port
Base server farm	WS-X6516-GBIC[1]	CEF256	16, GBIC	Tx–1p2q2t Rx–1p1q4t	512 KB per port
Base server farm	WS-X6416-GBIC	Classic	16, GBIC	Tx–1p2q2t Rx–1p1q4t	512 KB per port
Base server farm	WS-X6416-GE-MT	Classic	16, MT-RJ, MM	Tx–1p2q2t Rx–1p1q4t	512 KB per port

[1] **Queues Legend:** 1p2q2t = 1 priority queue, 2 round robin queues, 2 thresholds

Gigabit Ethernet Interface Modules

The Cisco Catalyst 6500 Classic, CEF256, and dCEF26 interface modules provide Gigabit Ethernet with a choice of speeds and forwarding rates.

Classic Interface Modules

Suited for wiring closet applications, Classic interface modules use the supervisor engine for centralized Layer 2 and Layer 3 forwarding, and forward packets up to 15 Mpps over a 32-Gbps shared bus.

Capable of operating in the same chassis with the Cisco Catalyst 6500 Series Supervisor Engine 1A, Supervisor Engine 2, and Supervisor Engine 720, Catalyst Classic interface modules do not support distributed forwarding and cannot be upgraded with a Distributed Forwarding Card (DFC).

Table 2 provides more information about Catalyst Classic interface modules.

CEF256 Interface Modules

Suited for distribution and core layers and for data-center and Web-hosting applications, CEF256 interface modules use the centralized CEF engine located on the supervisor engine's policy feature card (PFC) and forward packets up to 30 Mpps over a dedicated 8-Gbps full-duplex switch fabric connection.

Capable of operating in the same chassis with the Cisco Catalyst 6500 Series Supervisor Engine 1A, Supervisor Engine 2, and Supervisor Engine 720, CEF256 interface modules support distributed forwarding when upgraded with a DFC (Table 2).

Table 2 CEF256 Interface Module Distributed Forwarding Upgrade Requirements

Supervisor Engine	Switch Fabric	Distributed Forwarding Card
Supervisor Engine 2 MSFC2/PFC2	Separate switch fabric module (SFM)	Requires WS-F6K-DFC upgrade
Supervisor Engine 720	Supervisor Engine 720 integrates a 720 Gbps switch fabric *Note:* A Supervisor Engine 720 and an SFM cannot occupy the same chassis	Requires WS-F6K-DFC3 upgrade; will not interoperate with WS-F6K-DFC

dCEF256 Interface Modules

Suited for distribution and core layers, for data-center and Web-hosting applications, and for several high-performance service provider applications, the dCEF256 interface modules use the dCEF engine and tables located on the interface module to perform all forwarding.

dCEF256 interface modules require a Cisco Catalyst 6500 Series Supervisor Engine 720 or a Supervisor Engine 2 with a Multilayer Switch Feature Card 2 (MFSC2) and SFM. Supervisor Engine 720 requires a WS-F6K-DFC3 upgrade; and Supervisor Engine 2-MFSC2 operates with the WS-F6K-DFC supplied with the dCEF256 interface module.

Table 3 Interface Module Class Comparison: Classic, CEF256, and dCEF256

Feature	Classic	CEF256	dCEF256
Performance maximum (Mpps)	15	30	210
Forwarding engine/ location	Centralized CEF Engine; located on supervisor engine's PFCx	Centralized CEF Engine; located on supervisor engine's PFCx	Distributed CEF Engine; located on interface module's DFCx

Supervisor engine supported	Supervisor Engine 1A;
	Supervisor Engine 2;
	Supervisor Engine 720
		Supervisor Engine 1A (15 Mpps maximum);
		Supervisor Engine 2;
		Supervisor Engine 720
			Supervisor Engine 2;
			Supervisor Engine 720

DFC modules integrated/ upgrade requirements	Not supported	None integrated; upgrade with WS-F6K-DFC3 for Supervisor Engine 720 *or* upgrade with WS-F6K-DFC for Supervisor Engine 2-MSFC2	DFC integrated; DFC3 field upgrade (requires Supervisor Engine 720)
Fabric connections	32 Gbps shared bus connection (on Supervisor Engine 1A, Supervisor Engine 2, and Supervisor Engine 720)	Single 8-Gbps channel connection to switch fabric (on Supervisor Engine 720 or Supervisor Engine 2-MSFC2 with SFM) *and* 32-Gbps shared bus connection	Dual 8-Gbps full-duplex serial channel connections to switch fabric (on Supervisor Engine 720 or Supervisor Engine 2-MSFC2 with SFM)
Slot requirements	Can occupy any slot in any chassis	Can occupy any slot in any chassis	Can occupy any slot in any Cisco Catalyst 6503, 6506, 6509, 6509-NEB, or 6509-NEB-A chassis, or any Cisco 7603, 7606, 7609, or OSR-7609 chassis; can only occupy slots 9 through 13 in a 6513, or 7613 chassis
Receive queue structure	1p1q4t	1p1q4t	1p1q4t
Transmit queue structure	1p2q2t	1p2q2t	1p2q2t
Scheduler	Weighted Round Robin (WRR)	WRR	WRR
Buffer size	512 KB	512 KB or 1 MB (WS-X6516a)	512 KB

Legend: 1p2q2t = one strict priority queue, two round-robin queues, and two different thresholds

Cisco Catalyst Classic Gigabit Ethernet Copper Interface Modules

Designed for distribution and core layers and for data-center and Web-hosting applications, Cisco Catalyst Classic copper interface modules provide line-rate Gigabit Ethernet forwarding with the following operational advantages:

Forwarding architecture—Use centralized CEF forwarding

Forwarding performance—Forward packets up to 15 Mpps per system

Fabric connection—Provide a 32-Gbps shared bus connection

Supervisor engine—Work with Supervisor Engine 1A, Supervisor Engine 2, or Supervisor Engine 720

Distributed forwarding upgrade—None; Classic interface modules cannot be upgraded for distributed forwarding

Slot requirements—None; can occupy any slot in any Cisco Catalyst 6500 Series chassis

Table 4 Classic Gigabit Ethernet Copper Interface Modules

Product	Ports/Interface/ Connectors	Port Density/ Chassis Model	Maximum Distance/ Cable Type
WS-X6316-GE-TX	16 ports; 1000BASE-T; RJ-45	192 ports (Cisco Catalyst 6513); 128 ports (Cisco Catalyst 6509)	100 meters; Category 5 cable

Cisco Catalyst Classic Gigabit Ethernet Optical Interface Modules

Designed for distribution and core layers and for data-center and Web-hosting applications, Cisco Catalyst Classic optical interface modules provide line-rate Gigabit Ethernet forwarding with the following operational advantages:

Forwarding architecture—Use centralized CEF forwarding

Forwarding performance—Forward packets up to 15 Mpps per system

Optics—Supports hot-pluggable gigabit interface converters (GBICs)

Fabric connection—Provide a 32-Gbps shared bus connection

Supervisor engine—Work with Supervisor Engine 1A, Supervisor Engine 2, or Supervisor Engine 720

Distributed forwarding upgrade—None; Classic interface modules cannot be upgraded for distributed forwarding

Slot requirements—Can occupy any slot in any Cisco Catalyst 6500 Series chassis

Table 5 Classic Gigabit Ethernet Optical Interface Modules

Product	Transceiver Type	Ports/Interface/ Connectors	Port Density/ Chassis Model	Maximum Distance/ Cable Type
WS-X6408A-GBIC	GBIC	8 ports; 1000BASE-SX, -LX/LH, -ZX; SC	96 ports (Cisco Catalyst 6513); 64 ports (Cisco Catalyst 6509)	550 m: 1000BASE-SX 10 km: LX/LH 100 km: ZX
WS-X6416-GBIC	GBIC	16 ports; 1000BASE-SX, -LX/LH, -ZX; SC	192 ports (Cisco Catalyst 6513); 128 ports (Cisco Catalyst 6509)	550 m: 1000BASE-SX 10 km: LX/LH 100 km: ZX
WS-X6416-GE-MT	MT-RJ	16 ports; 1000BASE-SX; MT-RJ	192 ports (Cisco Catalyst 6513); 128 ports (Cisco Catalyst 6509)	550 m: 1000BASE-SX

6089

Cisco Catalyst CEF256 Gigabit Ethernet Optical Interface Modules

Designed for data center and server farm applications, Cisco Catalyst CEF256 optical interface modules provide line-rate Gigabit Ethernet forwarding with the following operational advantages:

Forwarding architecture—Uses the central CEF engine located on the supervisor engine

Forwarding performance—Forwards packets up to 30 Mpps per system and up to 15 Mpps per slot if upgraded to support distributed forwarding

Optics—Supports hot-pluggable GBICs

Fabric connection—Connects to the switch fabric using one 8-Gbps full-duplex connection and the 32-Gbps shared bus

Supervisor engine—Works with Supervisor Engine 1A, Supervisor Engine 2, or Supervisor Engine 720

Distributed forwarding upgrade—Optional; upgrade is required only to perform distributed forwarding; requir WS-F6K-DFC3 upgrade to operate with Supervisor Engine 720; requires a WS-F6K-DFC upgrade and an SFM to operate with Supervisor Engine 2-MFSC2

Slot requirements—Can occupy any slot in any Catalyst 6500 Series chassis

Port densities—192 ports: Catalyst 6513 chassis; 128 ports: Catalyst 6509 chassis

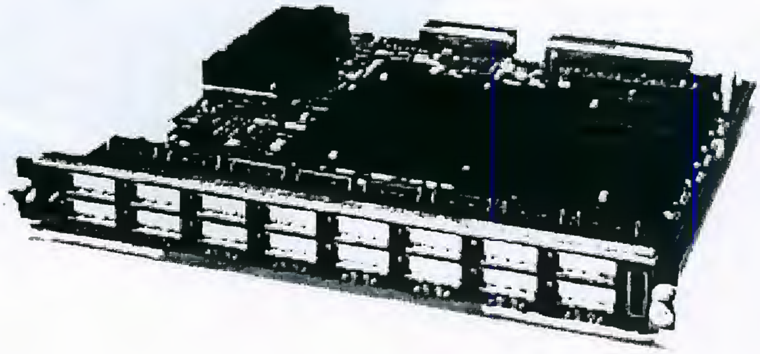
Note: Supervisor Engine 720 communicates with a CEF256 interface module in 256-Gbps mode. Supervisor Engine 720 and SFM cannot operate in the same chassis.

Table 6 CEF256 Gigabit Ethernet Optical Interface Modules

Product	Transceiver Type	Ports/Interface/ Connectors	Port Density/ Chassis Model	Maximum Distance/ Cable Type
WS-X6516-GBIC	GBIC	16 ports; 1000BASE-SX, -LX/LH, -ZX; SC	192 ports (Cisco Catalyst 6513); 128 ports (Cisco Catalyst 6509)	550 m: 1000BASE-SX 10 km: LX/LH 100 km: ZX
WS-X6516A-GBIC	GBIC	16 ports; 1000BASE-SX, -LX/LH, -ZX; SC	192 ports (Cisco Catalyst 6513); 128 ports (Cisco Catalyst 6509)	550 m: 1000BASE-SX 10 km: LX/LH 100 km: ZX

Figure 3

CEF256 Gigabit Ethernet Optical Interface Modules
WS-X6516A-GBIC



Cisco Catalyst dCEF256 Gigabit Ethernet Optical Interface Modules

Designed for distribution and core layers and for data-center and Web-hosting applications, Cisco Catalyst dCEF256 optical interface modules provide line-rate Gigabit Ethernet forwarding with the following operational advantages:

Forwarding architecture—Use the dCEF engine and dCEF tables located on the interface module

Forwarding performance—Forward packets up to 24 Mpps per slot when interface modules have dual-fabric connections

Optics—Support hot-pluggable GBICs over single-mode fiber

Fabric connection—Connect using dual 8-Gbps full-duplex serial channel connections to fabric on a Supervisor Engine 720 or a SFM

Supervisor engine—Work with Supervisor Engine 2 with a SFM or Supervisor Engine 720

Distributed forwarding—Include a DFC when operating with Supervisor Engine 2 or a DFC3 when operating with Supervisor Engine 720

Slot requirements—Can occupy any slot in any Cisco Catalyst 6500 Series chassis except the 6513 chassis where they must be installed in slots 9 through 13 (the only slots on the chassis with dual fabric connections)

Ordering Information

Table 9 provides part number information for Catalyst 6500 Series chassis.

Table 9 Catalyst 6500 Series Chassis Part Numbers

Product Number	Description
WS-X6316-GE-TX	16-port Classic Gigabit Ethernet interface module for the Cisco Catalyst 6000 Series switches; RJ-45
WS-X6408-GBIC	8-port Classic Gigabit Ethernet interface module for the Cisco Catalyst 6000 Series switches; requires GBICs
WS-X6408A-GBIC	8-port Classic Gigabit Ethernet interface module for the Cisco Catalyst 6000 Series switches with enhanced QoS; requires GBICs
WS-X6416-GBIC	16-port Classic Gigabit Ethernet interface module for the Cisco Catalyst 6000 Series switches; requires GBICs
WS-X6416-GE-MT	16-port Classic Gigabit Ethernet interface module for the Cisco Catalyst 6000 Series switches; MT-RJ
WS-X6516-GBIC	16-port CEF256 Gigabit Ethernet interface module for the Cisco Catalyst 6500 Series switches with single fabric channel interface; requires GBICs; upgradable to support distributed forwarding through the addition of the distributed forwarding daughter card (WS-F6K-DFC)
WS-F6K-DFC	Distributed forwarding daughter card for CEF26 interface modules
WS-X6816-GBIC	16-port dCEF256 Gigabit Ethernet interface module for the Cisco Catalyst 6500 Series switches with dual fabric channel interfaces and distributed forwarding; requires GBICs
WS-X6816A-GBIC	16-port dCEF256 Gigabit Ethernet interface module for the Cisco Catalyst 6500 Series switches with dual fabric channel interfaces and distributed forwarding; requires GBICs
GLC-SX-MM	1000BASE-SX SFP (multimode only) Dual LC connector
GLC-SX-MM=	1000BASE-SX SFP (multimode only) spare Dual LC connector
GLC-LH-SM	1000BASE-LX SFP (single mode only) Dual LC connector
GLC-ZX-SM	1000BASE-ZX SFP (single mode only) Dual LC connector
WS-G5484	1000BASE-SX SX GBIC (multimode only)
WS-G5485	1000BASE-LX/LH LH GBIC (single mode or multimode)
WS-G5487	1000BASE-ZX ZX GBIC (single mode only)

Specifications

Standard Protocols

- IEEE 802.1d, IEEE 802.1p, IEEE 802.1q, IEEE 802.1s, IEEE 802.1w, IEEE 802.3x, IEEE 802.3z, IEEE 802.3ab, and IEEE 802.3ad,
- 1000BASE-X (GBIC), 1000BASE-SX, 1000BASE-LX/LH, 1000BASE-ZX, CWDM

Physical Specification

- Occupies one slot in the Cisco Catalyst 6500 Series chassis
- Dimensions (H x W x D): 1.2 x 14.4 x 16 in. (3.0 x 35.6 x 40.6 cm)

Environmental Conditions

- Operating temperature: 32 to 104 F (0 to 40 C)
- Storage temperature: –40 to 167 F (–40 to 75 C)
- Relative humidity: 10 to 90%, noncondensing
- Operating altitude: –60 to 4000 m
- Mean time between failure (MTBF): seven years for system configuration

Safety Compliance

Cisco Catalyst 6500 Series Gigabit Ethernet interface modules, when installed in a system, comply with the following compliance and safety standards:

- UL 1950
- CSA C22.2 No.950
- EN 60950
- EN 60825-1
- IEC 60950
- IEC 60825-1
- TS 001
- CE marking
- AS/NZS 3260
- 21CFR1040

EMC Compliance

Cisco Catalyst 6500 Series Gigabit Ethernet modules, when installed in a system, comply with the following EMI standards:

- FCC Part 15 (CFR 47) Class A
- VCCI
- EN55022
- EN55024
- CISPR 22
- CE marking
- AS/NZS 3548

Network Management

- ETHERLIKE-MIB (RFC 1643)
- IF-MIB (RFC 1573)
- Bridge MIB (RFC 1493)
- CISCO-STACK-MIB
- CISCO-VTP-MIB
- CISCO-CDP-MIB

- RMON MIB (RFC 1757)
- CISCO-PAGP-MIB
- CISCO-STP-EXTENSIONS-MIB
- CISCO-VLAN-BRIDGE-MIB
- CISCO-VLAN-MEMBERSHIP-MIB
- ENTITY-MIB (RFC 2037)
- HC-RMON
- RFC1213-MIB (MIB-II)
- SMON-MIB

Maximum Station-to-Station Cabling Distance

- 1000BASE-SX: 62.5 um multimode fiber: up to 275 m
- 1000BASE-SX: 50 um multimode fiber: up to 550 m
- 1000BASE-LX: 62.5 um multimode fiber: up to 550 m
- 1000BASE-LX: 50 um multimode fiber: up to 550 m
- 1000BASE-LX: 9/10 um single-mode fiber: up to 5 km[1]
- 1000BASE-LH: 62.5 um multimode fiber: up to 550 m
- 1000BASE-LH: 50 um multimode fiber: up to 550 m
- 1000BASE-LH: 9/10 um single-mode fiber: up to 10 km
- 1000BASE-ZX: 9/10 um single-mode fiber: up to 70 km
- 1000BASE-ZX: disposition shifted fiber: up to 100 km
- 1000BASE-T: Category 5 cable: up to 100 m
- 10/100/1000BASE-T: Category 5 cable: up to 100 m

Indicators and Interfaces

- Status: green (operational); red (faulty); orange (module booting or running diagnostics)
- Link good: green (port active); orange (disabled); off (not active or not connected); blinking orange (failed diagnostic and disabled)
- 1000BASE-SX: GBIC (female, multimode)
- 1000BASE-LX/LH: GBIC (female, multimode)
- 1000BASE-LX/LH: GBIC (female, single mode)
- 1000BASE-ZX: GBIC (female, single mode)
- 1000BASE-ZX: GBIC (female, dispersion shifted)
- 1000BASE-SX: MT-RJ (female, multimode)
- 1000BASE-T: RJ-45
- 10/100/100BASE-T: RJ-45

[1] Cisco 1000BASE-LX/LH interfaces fully comply with the IEEE 802.3z 1000BASE-LX standard. However, their higher quality allows them to reach 10 km over single-mode fiber versus the 5 km specified in the standard.

6033

Technical Support Services

Whether your company is a large organization, a commercial business, or a service provider, Cisco is committed to maximizing the return on your network investment. Cisco offers a portfolio of technical support services to help ensure that your Cisco products operate efficiently, remain highly available, and benefit from the most up-to-date system software.

The Cisco Technical Support Services organization offers the following features, providing network investment protection and minimal downtime for systems running mission-critical applications:

- Provides Cisco networking expertise online and on the telephone
- Creates a proactive support environment with software updates and upgrades as an ongoing integral part of your network operations, not merely a remedy when a failure or problem occurs
- Makes Cisco technical knowledge and resources available to you on demand
- Augments the resources of your technical staff to increase productivity
- Complements remote technical support with onsite hardware replacement

Cisco Technical Support Services include:

- Cisco SMARTnet™ support
- Cisco SMARTnet Onsite support
- Cisco Software Application Services, including Software Application Support and Software Application Support plus Upgrades

Data Sheet

Cisco Catalyst 6500 Series
10/100 and 10/100/1000 **Ethernet** Interface Modules

As Cisco's premier modular multilayer switch, the Catalyst® 6500 Series delivers secure, converged services from the wiring closet to the core, to the data center, to the WAN edge.

The Cisco Catalyst® 6500 Series provides the broadest selection of 10/100 and 10/100/1000 Ethernet media, inline power options, densities, performance, interoperability, and chassis deployments. Equally suited for basic wiring closets, small campus distribution/core layers, and high performance data centers, Catalyst 6500 10/100 and 10/100/1000Mbps modules scale from 16-ports up to 576-ports in a single Catalyst 6500 chassis. Catalyst 6500 10/100 and 10/100/1000Mbps modules feature include:

- Proven and widely deployed Cisco AVVID wiring closet solution—Establish the Cisco Catalyst 6500 Series as the most widely deployed IP telephony port-enabled campus switch platform
- Choice of media and connector types—Available in copper unshielded twisted-pair (UTP), shielded twisted-pair (STP) using RJ-45 or RJ-21, multimode fiber (62.5/125 micron), and single-mode fiber using MT-RJ 100FX and 10FL
- IP phone and wireless access point support—Support inline power field upgrade (copper only), NIC/Phone auto-detection (phone discovery), and voice VLANs
- Simplified network operation with cable fault detection—Test cabling using Time Domain Reflectometer (TDR) that sends signals down the cable to identify faults in each twisted pair (available for 10/100/1000 copper
- Range of port densities—Available with 16 up to 48 ports per module; with up to 576 10/100/1000Base-TX ports, 288 ports of 100-Base-FX, or 10BASE-FL (per 13-slot chassis configured with 12 interface modules)
- Scalable and predictable performance—Provide a selection of switch fabric connections and throughput: 32 Gbps bandwidth/15 Mpps (Classic interface modules), 256 Gbps bandwidth/30 Mpps (CEF256 interface modules) and 256 Gbps bandwidth/210 Mpps(dCEF256 interface modules)
- IEEE 802.3 triple-speed autonegotiation—Allow switches to negotiate speed (10, 100, and now 1000 Mbps) and duplex mode (half or full) with attached devices
- Superior traffic management—Available with large 1-MB-per-interface buffers and up to 8 transmit queues for traffic prioritization and policing

- Operational consistency—Supported in all Catalyst 6500 3-, 6-, 9-, and 13-slot chassis running Cisco IOS® Software and Cisco Catalyst Operating System Software; interoperable with all other interfaces and services modules; and forward-compatible with all Catalyst 6500 supervisor engines
- Maximum network uptime and resiliency—Support Cisco enhanced Per-Virtual LAN (VLAN) Spanning Tree Plus (PVST+) protocol, IEEE 802.1w Rapid Spanning Tree Protocol (RSTP) and IEEE 802.1s Multiple Spanning Tree (MST) protocol, Per-VLAN Rapid Spanning Tree (PVRST) protocol, Hot Standby Router Protocol (HSRP), Virtual Router Redundancy Protocol (VRRP), Cisco EtherChannel®, and IEEE 802.3ad link aggregation for fault-tolerant connectivity
- Extensive management tools—Support CiscoWorks network management platform; Simple Network Management Protocol (SNMP) versions 1, 2, and 3; and four Remote Monitoring (RMON) groups (statistics, history, alarms, and events)

The newest members of the Cisco Catalyst 6500 Series 10/100/1000 product family—the Classic interface module WS-X6148-GE-TX and the CEF256 interface module WS-X6548-GE-TX—provide 10/100/1000 Gigabit netwo access using standard RJ-45 connectors (Figure 1).

Figure 1

Cisco Catalyst 6500 Series 10/100 and 10/100/1000 Ethernet Interface Modules with Cisco Inline Power

The Cisco Catalyst 6500 Series delivered the first 10/100BASE-T Ethernet switching modules that provided inline power for converged data and voice traffic. Cisco Catalyst Classic interface modules support voice functionality on each interface port, allowing customers to build campus multiservice data and voice networks for wiring closets with the following features:

- Inline power—Provides 48-volt DC power (for Cisco Inline Power and IEEE 802.3af standard inline power when it becomes available) over standard Category 5 unshielded twisted-pair (UTP) cable up to 100 meters for IP phones and wireless access points
- Phone discovery—Detects the presence of an IP phone and supplies inline power automatically
- Auxiliary VLAN using 802.1Q—Segments IP phones and data endpoints into separate logical networks automatically
- AutoQoS

Cisco Catalyst Inline Power and IEEE 802.3af Inline Power

The Inline Power feature gives network administrators centralized power control. It works over existing Category 5 UTP installations and helps to ensure that building power outages will not affect network telephony connections, providing greater network availability—when Cisco Catalyst 6500 Series switches are configured with uninterruptible power supply (UPS) systems.

10/100 and 10/100/1000 Ethernet interface modules shipping today support the Cisco Inline Power feature or support the IEEE 802.3af standard, or both, allowing 802.3af capability to be added later through an upgrade. The Cisco Catalyst Inline Power feature implementation passes the required domestic and international safety regulations and compliance measures.

Phone Discovery

The Cisco phone discovery feature eases network management burdens by automating the Inline Power feature. With phone discovery, the Cisco Catalyst switch detects the presence of an IP phone and supplies inline power automatically, eliminating the need to manually enable ports for inline power. The phone discovery mechanism is intelligent enough to differentiate between an IP phone and a network interface card (NIC), and will not supply inline power to NICs or other devices not designed to use inline power. With this feature, network administrators can depend on automatic and centralized control of inline power that is safe to deploy and maintain.

Auxiliary VLAN

The unique Auxiliary VLAN feature offered by Cisco provides automatic VLAN configuration for IP phones. It places phones into their own VLANs automatically, simplifying the task of overlaying a voice topology onto a data network. It allows network administrators to easily segment phones into separate logical networks, even though the data and voice infrastructure is physically the same—greatly simplifying the task of managing a multiservice network and identifying and troubleshooting network problems.

The Auxiliary VLAN feature maintains VLAN assignments, even when phones are moved to new locations. When a user plugs a phone into the switch, the switch provides the phone with the necessary VLAN information.

AutoQoS

Network administrators can assign IP phones to separate IP subnets and VLANs to allow separate quality of service (QoS) or security policies for IP phones. By deploying AutoQoS that configures QoS on voice ports automatically, the administrative task of configuring QoS to establish end-to-end traffic prioritization is greatly simplified.

Cisco Catalyst 6500 Series 10/100 and 10/100/1000 Modules

Two classes of Cisco Catalyst 6500 Series 10/100 and 10/100/1000 Ethernet interface modules—Classic and CEF256—provide a choice of speeds and forwarding rates (Table 4).

Classic 10/100 and 10/100/1000 Interface Modules

Suited for wiring closet applications, Classic 10/100 and 10/100/1000 modules use the supervisor's centralized forwarding engine for Layer 3 forwarding, and forward packets up to 15 Mpps.

Capable of operating in the same chassis with Supervisor Engine 1A, Supervisor Engine 2, and Supervisor Engine 720, Classic Series modules do not support distributed forwarding and cannot be upgraded with a Distributed Forwarding Card (DFC).

CEF256 10/100 and 10/100/1000 Interface Modules

Suited for premier wiring closet, distribution and core layers, data-center, and Web-hosting applications, CEF256 10/100 and 10/100/1000 interface modules use the centralized CEF engine located on the supervisor engine's policy feature card (PFC) and forward packets up to 30 Mpps.

Capable of operating in the same chassis with Supervisor Engine 1A, Supervisor Engine 2, and Supervisor Engine 720, CEF256 interface modules can also support distributed forwarding (Table 2).

Table 3 CEF256 10/100 and 10/100/1000 Switch Fabric DFC Upgrade Requirements

Supervisor Engine	Switch Fabric	DFC
Supervisor Engine 2 MSFC2/PFC2	Separate switch fabric module (SFM)	Requires WS-F6K-DFC upgrade
Supervisor Engine 720	Supervisor Engine 720 contains a switch fabric	Requires WS-F6K-DFC3 upgrade; will not work with WS-F6K-DFC3, or WS-F6K-DFC

Table 4 provides a comparison of the interface module classes available for 10/100 and 10/100/1000 Ethernet interface modules.

Table 4 Classic and CEF256 10/100 and 10/100/1000 Interface Module Comparison

Feature	Classic Interface Modules	CEF256 Interface Modules
Performance/ Forwarding Rate (Mpps)	32 Gbps; 15 Mpps per system	256 Gbps; Up to 30 Mpps per system (15 Mpps per slot for slots upgraded with DFC to support distributed forwarding)
Forwarding Engine Architecture	Supervisor engine CPU makes forwarding decision	Centralized CEF engine located on supervisor's PFCx daughter card makes forwarding decision upgradeable to dCEF switching with optional WS-F6K-DFC or WS-F6K-DFC3
Supervisor Engine Supported	Supervisor Engine 1A, Supervisor Engine 2, Supervisor Engine 720	Supervisor Engine 1A, Supervisor Engine 2, Supervisor Engine 720
DFC Upgrade Requirements	Not supported	None integrated; Supervisor Engine 2—WS-F6K-DFC upgrade; SupervisorEngine 720—WS-F6K-DFC3 upgrade
Fabric Connections	32 Gbps shared bus connection (on Supervisor Engine1A, Supervisor Engine 2, and Supervisor Engine 720)	Single 8-Gbps channel connection to switch fabric [on Supervisor Engine 720 or Supervisor Engine 2-MSFC2 with Switch Fabric Module (SFM)] and 32-Gbps shared bus connection
Slot Requirements	Can occupy any slot in any chassis	Can occupy any slot in any chassis
Scheduler	Weighted Round Robin (WRR)	WRR

6075

Cisco Catalyst Classic 10/100/1000 Voice Interface Modules

Suited for wiring closet applications, Cisco Catalyst Classic 10/100/1000 voice interface modules (Table 5) provide access to the desktop through standard RJ-45 connectors with the following operational advantages:

Forwarding architecture—Centralized CEF forwarding

Forwarding performance—Forward packets up to 15 Mpps per system

Fabric connection—Provide a 32-Gbps shared bus connection

Supervisor engine—Work with Supervisor Engine 1A, Supervisor Engine 2, or Supervisor Engine 720

Distributed forwarding upgrade—None; Classic interface modules cannot be upgraded for distributed forwarding

Slot requirements—Can occupy any slot in any Cisco Catalyst 6500 Series chassis

Time Domain Reflectometer (TDR)—Tests cabling by sending signals down the cable to identify faults in each twisted pair

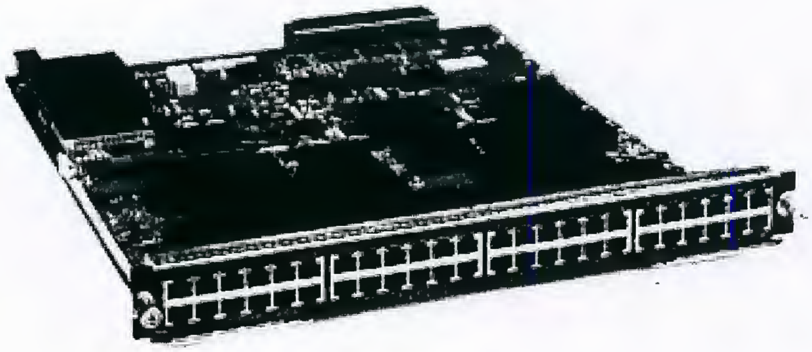
Transmit queue structure—1p2q2t = 1 strict priority queue, 2 round robin queues, 2 thresholds

Receive queue structure—1q2t = 1 round robin queue, 2 thresholds

Table 5 Classic 10/100/1000 Voice Interface Modules

Product	Ports/ Interface/ Connectors	Port Density/ Chassis Model	Maximum Distance/ Cable Type	Inline Power for Voice Availability/ Upgrade Capability
WS-X6148-GE-TX	48-port;10/100/ 1000BASE-TX; RJ-45	576 ports (Cisco Catalyst 6513); 384 ports (Cisco Catalyst 6509)	100 meters; Category 5 cable	Cisco Inline Power; upgradable to 802.3af
WS-X6148V-GE-TX	48-port; 10/100/ 1000BASE-TX; RJ-45	576 ports (Cisco Catalyst 6513); 384 ports (Cisco Catalyst 6509)	100 meters; Category 5 cable	Cisco Inline Power; upgradable to 802.3af

Figure 2
Classic 10/100/1000 Voice Interface Modules
WS-X6148V-GE-TX



Cisco Catalyst CEF256 10/100/1000 Voice Interface Modules

Suited for wiring closet applications, Cisco Catalyst CEF256 10/100/1000 voice interface modules provide access to the desktop through standard RJ-45 connectors and line-rate 10/100/1000 Ethernet forwarding (Table 6) with the following operational advantages:

Forwarding architecture—Use the central CEF engine located on the supervisor engine

Forwarding performance—Forward packets up to 30 Mpps per system and up to 15 Mpps per slot if upgraded to support distributed forwarding

Fabric connection—Connect to the switch fabric through one 8-Gbps connection and the 32-Gbps shared bus

Supervisor engine—Work with Supervisor Engine 1A, Supervisor Engine 2, or Supervisor Engine720

Distributed forwarding upgrade—Optional; upgrade is required only to perform distributed forwarding; requires a WS-F6K-DFC3 upgrade to operate with a Supervisor Engine 720; requires a WS-F6K-DFC upgrade to operate with a Supervisor Engine2/MFSC2 and a Switch Fabric Module

Slot requirements—Can occupy any slot in any Cisco Catalyst 6500 Series chassis

Time Domain Reflectometer (TDR)—Tests cabling by sending signals down the cable to identify faults in each twisted pair

Transmit queue structure—1p2q2t = 1 priority queue, 2 round robin queues, 1 threshold

Receive queue structure—1q2t = 1 round robin queue, 2 thresholds

Cisco Catalyst Classic 10/100 Copper Voice Modules

Designed for deployment in wiring closets, high-density Cisco Catalyst Classic 10/100 interface modules come with a selection of inline power capabilities and provide line-rate 10/100 Ethernet forwarding with the following operational advantages:

- Voice-ready modules with Cisco Inline Power and upgradable to 802.3af—Available in 48-port RJ-45 and RJ-21 configurations (WS-X6148-RJ45V and WS-X6148-RJ21V)
- Voice-ready modules with Cisco Inline Power and not upgradable to 802.3af—Available in 48-port RJ-45 and RJ-21 configurations (WS-X6348-RJ45V and WS-X6348-RJ21V)
- Voice-capable modules upgradable to Cisco Inline Power or 802.3af—Available in 48-port RJ-45 and RJ-21configurations (WS-X6148-RJ-45 and WS-X6148-RJ-21)

Note: These modules are designed to fully support future upgrades to the IEEE 802.3af inline power standard currently underway, providing maximum investment protection.

Forwarding architecture—Use centralized CEF forwarding

Forwarding performance—Forwards packets up to 15 Mpps per system

Fabric connection—Connect to the switch fabric using a 32-Gbps shared bus connection

Supervisor engine—Work with Supervisor Engine 1A, Supervisor Engine 2, or Supervisor Engine 720

Distributed forwarding upgrade—None; Classic interface modules cannot be upgraded for distributed forwarding

Slot requirements—Can occupy any slot in any Cisco Catalyst 6500 Series chassis

Transmit queue structure—2q2t = two round robin queues and two thresholds

Receive queue structure—1q4t = one round robin queue and four thresholds

Cisco Catalyst CEF256 10/100 Copper Modules

Designed for small campus distribution and core layers and for data-center and Web-hosting applications where voice capability is not required, Cisco Catalyst CEF256 twisted-pair interface modules provide line-rate 10/100 Ethernet forwarding with the following operational advantages:

Forwarding architecture—Use the central CEF engine located on the supervisor engine

Forwarding performance—Forward packets up to 30 Mpps per system and up to 15 Mpps per slot for slots upgraded to support distributed forwarding

Fabric connection—Connect to the switch fabric using a single 8-Gbps switch fabric channel and a 32-Gbps shared bus

Supervisor engine—Work with Supervisor Engine 1A, Supervisor Engine 2, or Supervisor Engine 720

Distributed forwarding upgrade—Only required to perform distributed forwarding; require a WS-F6K-DFC3 upgrade to operate with Supervisor Engine 720; require a WS-F6K-DFC upgrade to operate with Supervisor Engine 2/ MFSC2 and an SFM

Slot requirements—Can occupy any slot in any Cisco Catalyst 6500 Series chassis

Transmit queue structure—1p3q1t = 1 priority queue, 3 round robin queues, 1 threshold

Receive queue structure—1p1q4t = 1 priority queue, 1 round robin queue, 4 thresholds

Catalyst Classic 100FX and 10FL Fiber Interface Modules

Designed for deployment in wiring closets where optical interfaces are required, the Cisco Catalyst Classic fiber interface modules provide 10/100 Ethernet forwarding with the following operational advantages:

Forwarding architecture—Use centralized CEF forwarding

Forwarding performance—Forward packets up to 15 Mpps per system

Fabric connection—Connect to the switch fabric using a 32-Gbps shared bus connection

Supervisor engine—Work with Supervisor Engine 1A, Supervisor Engine 2, or Supervisor Engine 720

Distributed forwarding upgrade—None; Classic interface modules cannot be upgraded for distributed forwarding

Slot requirements—Can occupy any slot in any Cisco Catalyst 6500 Series chassis

Transmit queue structure—2q2t = 2 round robin queues, 2 thresholds

Receive queue structure—1q4t = 1 round robin queue, 4 thresholds

Note: No inline power support for voice is available for 100FX/10FL fiber modules.

Cisco Catalyst CEF256 100FX Fiber Modules

Designed for small campus distribution and core layers and for data-center and Web-hosting applications, Cisco Catalyst dCEF256 fiber interface modules provide line-rate 100FX Ethernet forwarding with the following operational advantages:

Forwarding architecture—Use the central CEF engine located on the supervisor engine

Forwarding performance—Forward packets up to 30 Mpps per system and up to 15 Mpps per slot for slots upgraded to support distributed forwarding

Fabric connection—Connect to the switch fabric using one 8-Gbps connection and the 32-Gbps shared bus

Supervisor engine—Work with Supervisor Engine 1A, Supervisor Engine 2, or Supervisor Engine 720

Distributed forwarding upgrade—Only required to perform distributed forwarding; require a WS-F6K-DFC3 upgrade to operate with Supervisor Engine 720; require a WS-F6K-DFC upgrade to operate with Supervisor Eng 2/MFSC2 and a Switch Fabric Module

Slot requirements—Can occupy any slot in any Cisco Catalyst 6500 Series chassis

Transmit queue structure—1p3q1t = 1 priority queue, 3 round robin queues, 1 threshold

Receive queue structure—1p1q2t = 1 priority queue, 1 round robin queue, 2 thresholds

Note: No inline power support for voice is available for 100FX fiber modules.

- Gigabit Ethernet: 1000BASE-TX
- IEEE 802.1d, IEEE 802.1p, IEEE 802.1q, IEEE 802.1s, IEEE 802.1w, IEEE 802.3x, IEEE 802.3z, IEEE 802.3ab, IEEE 802.3ad

Physical Specification

- Occupies one slot in a Cisco Catalyst 6500 Series chassis
- Dimensions (H x W x D): 1.2 x 14.4 x 16 in. (3.0 x 35.6 x 40.6 cm)

Environmental Conditions

- Operating temperature: 32 to 104 F (0 to 40 C)
- Storage temperature: –40 to 167 F (–40 to 75 C)
- Relative humidity: 10 to 90%, noncondensing
- Operating altitude: –60 to 4000 m

Safety Compliance

- UL 1950
- CSA-C22.2 No. 950
- EN 60950
- IEC 950
- AS/NZS 3260
- IEC 825

- EN 60825
- 21CFR1040

EMC Compliance

- FCC Part 15 (CFR 47) Class A
- VCCI Class A with UTP, Class B with STP
- EN55022 Class A with UTP, Class B with STP
- CISPR 22 Class A with UTP, Class B with STP
- CE marking
- AS/NZS 3548 Class A with UTP, Class B with STP

Network Management

- SMON-MIB

Inline Power Specifications

- Output power per port: 48V DC power
- Pin assignment: 1, 2, 3, 6

Maximum Station-to-Station Cabling Distance

- 10/100BASE-TX, 100BASE-TX Fast Ethernet, and 10/100/1000: Category 5, 5e, and 6 UTP: 328 ft. (100 m), 100-ohm STP: 328 ft. (100 m); half or full duplex
- 100BASE-FX Fast Ethernet: 62.5/125-micron multimode fiber: 400-m half duplex, 2-km half or full duplex

- 100BASE-FX Fast Ethernet: 8/125-micron single-mode fiber: 10-km half or full duplex
- 10BASE-FL Ethernet: 62.5/125-micron multimode fiber: 2-km half or full duplex
- Maximum power: off (maximum power condition not reached); on (maximum power condition reached; no more phones will receive inline power from this module)

Indicators and Interfaces

- Status: green (operational); red (faulty); orange (module booting or running diagnostics)
- Link good: green (port active); orange (disabled); off (not active or not connected); blinking orange (failed diagnostic and disabled)
- 10/100/1000: RJ-45 (female)
- 10/100BASE-TX and 100BASE-TX: RJ-45 (female)
- 100BASE-FX: MT-RJ (female, multimode)
- 100BASE-FX: MT-RJ (female, single mode)
- 10BASE-FL: MT-RJ (female, multimode)

Cisco Technical Support Services

Whether your company is a large organization, a commercial business, or a service provider, Cisco is committed to maximizing the return on your network investment. Cisco offers a portfolio of technical support services to help ensure that your Cisco products operate efficiently, remain highly available, and benefit from the most up-to-date system software.

The Cisco Technical Support Services organization offers the following features, providing network investment protection and minimal downtime for systems running mission-critical applications:

- Provides Cisco networking expertise online and on the telephone
- Creates a proactive support environment with software updates and upgrades as an ongoing integral part of your network operations, not merely a remedy when a failure or problem occurs
- Makes Cisco technical knowledge and resources available to you on demand
- Augments the resources of your technical staff to increase productivity
- Complements remote technical support with onsite hardware replacement

Cisco Technical Support Services include:

- Cisco SMARTnet™ support
- Cisco SMARTnet Onsite support
- Cisco Software Application Services, including Software Application Support and Software Application Support plus Upgrades

For more information, visit:

http://www.cisco.com/en/US/products/svcs/ps3034/serv_category_home.html

CHAPTER 6

Configuring EtherChannel

This chapter describes how to use the command-line interface (CLI) to configure EtherChannel on the Catalyst 6500 series switches. The configuration tasks in this chapter apply to Ethernet, Fast Ethernet, and Gigabit Ethernet switching modules and the uplink ports on the supervisor engine.

Note For complete syntax and usage information for the commands used in this chapter, refer to the *Catalyst 6500 Series Command Reference* publication.

This chapter consists of these sections:

Note You can use the commands in the following sections on all Ethernet ports in the Catalyst 6500 series switches.

Understanding How EtherChannel Works

EtherChannel aggregates the bandwidth of up to eight compatibly configured ports into a single logical link. A Catalyst 6500 series switch supports a maximum of 128 EtherChannels. All Ethernet ports on all modules, including those on a standby supervisor engine, support EtherChannel with no requirement that ports be contiguous or on the same module. All ports in each EtherChannel must be the same speed.

Note With software releases 6.3(1) and later, due to the port ID handling by the spanning tree feature, the maximum supported number of EtherChannels is 126 for a 6- or 9-slot chassis and 63 for a 13-slot chassis.

Note The network device to which a Catalyst 6500 series switch is connected may impose its own limits on the number of ports in an EtherChannel.

If a link within an EtherChannel fails, traffic previously carried over the failed link switches to the remaining links within the EtherChannel. Inbound broadcast and multicast packets on one link in an EtherChannel are blocked from returning on any other link of the EtherChannel.

You can configure EtherChannels as trunks. After a channel is formed, configuring any port in the channel as a trunk applies the configuration to all ports in the channel. Identically configured trunk ports can be configured as an EtherChannel.

Understanding EtherChannel Frame Distribution

EtherChannel distributes frames across the links in a channel by reducing part of the binary pattern formed from the addresses in the frame to a numerical value that selects one of the links in the channel.

EtherChannel frame distribution is based on a Cisco-proprietary hashing algorithm. The algorithm is deterministic; given the same addresses and session information, you always hash to the same port in the channel, preventing out-of-order packet delivery.

The address may be a source, a destination, or a combination of two IP addresses, two MAC addresses, or two TCP/UDP port numbers depending on the policy adopted through the **ip**, **mac**, or **session** options of the **set port channel all distribution** command. See the "Configuring EtherChannel Load Balancing" section on page 6-11 for detailed information.

Note The **set port channel all distribution session** command is supported on Supervisor Engine 2 only.

EtherChannel frame distribution is not configurable on all supervisor engines. Enter the **show module** command on a supervisor engine to determine if EtherChannel frame distribution is configurable on your switch. If the display shows the "Sub-Type" to be "L2 Switching Engine I WS-F6020," then EtherChannel frame distribution is not configurable on your Catalyst 6500 series switch; the switch uses source and destination Media Access Control (MAC) addresses.

EtherChannel frame distribution is configurable with all other switching engines. The default is to use source and destination IP addresses.

Port Aggregation Control Protocol and Link Aggregation Control Protocol

Port Aggregation Control Protocol (PAgP) and Link Aggregation Control Protocol (LACP) are two different protocols that allow ports with similar characteristics to form a channel through dynamic negotiation with adjoining switches. PAgP is a Cisco-proprietary protocol that can be run only on Cisco switches and those switches released by licensed vendors. LACP, which is defined in IEEE 802.3ad, allows Cisco switches to manage Ethernet channeling with devices that conform to the 802.3ad specification.

Note MAC address notification settings are ignored on PAgP and LACP EtherChannel ports.

To use PAgP, see the "Understanding the Port Aggregation Protocol" section on page 6-5. To use LACP, see the "Understanding the Link Aggregation Control Protocol" section on page 6-12.

EtherChannel Configuration Guidelines

If improperly configured, some EtherChannel ports are disabled automatically to avoid network loops and other problems. Follow these guidelines to avoid configuration problems.

Note Except where specifically differentiated, these guidelines apply to both PAgP and LACP.

These sections provide EtherChannel configuration guidelines:

- Guidelines for Port Configuration, page 6-3
- Guidelines for VLAN and Trunk Configuration, page 6-4
- EtherChannel Interaction with Other Features, page 6-4

Guidelines for Port Configuration

Follow these port configuration guidelines:

- You can have a maximum of eight compatibly configured ports per EtherChannel; the ports do not have to be contiguous or on the same module.

  Note To configure the EtherChannel across different modules, you must put the ports in the same administrative group using the **set port channel** *port_list admin_group* command.

- All ports in an EtherChannel must use the same protocol; you cannot run two protocols on one module.
- PAgP and LACP are not compatible; both ends of a channel must use the same protocol.

  Note Switches can be configured manually with PAgP on one side and LACP on the other side in the **on** mode.

- You can change the protocol at any time, but this change causes all existing EtherChannels to reset to the default channel mode for the new protocol.
- Configure all ports in an EtherChannel to operate at the same speed and duplex mode (full duplex only for LACP mode).
- Enable all ports in an EtherChannel. If you disable a port in an EtherChannel, it is treated as a link failure and its traffic is transferred to one of the remaining ports in the EtherChannel.
- A port cannot belong to more than one channel group at the same time.
- Ports with different port path costs, set by the **set spantree portcost** command, can form an EtherChannel as long as they are otherwise compatibly configured. Setting different port path costs does not, by itself, make ports incompatible for the formation of an EtherChannel.

6058

- PAgP and LACP manage channels differently. When all the ports in a channel get disabled, PAgP removes them from its internal channels list; **show** commands do not display the channel. With LACP, when all the ports in a channel get disabled, LACP does not remove the channel; **show** commands continue to display the channel even though all its ports are down. To determine if a channel is actively sending and receiving traffic with LACP, use the **show port** command to see if the link is up or down.
- LACP does not support half-duplex links. If a port is in active/passive mode and becomes half duplex, the port is suspended (and a syslog message is generated). The port is shown as "connected" using the **show port** command and as "not connected" using the **show spantree** command. This discrepancy is because the port is physically connected but never joined spanning tree. To get the port to join spanning tree, either set the duplex to full or set the channel mode to off for that port.

  With software releases 7.3(1) and later, LACP behavior for half-duplex links has changed and affected ports are no longer suspended. Instead of suspending a port, LACP PDU transmission (if any) is suppressed. If the port is part of a channel, the port is detached from the channel but still functions as a nonchannel port. A syslog message is generated when this condition occurs. Normal LACP behavior is reenabled automatically when the link is set back to full duplex.

Guidelines for VLAN and Trunk Configuration

Follow these VLAN and trunk-related guidelines:

- Assign all ports in an EtherChannel to the same VLAN, or configure them as trunk ports.
- If you configure the EtherChannel as a trunk, configure the same trunk mode on all the ports in the EtherChannel. Configuring ports in an EtherChannel in different trunk modes can have unexpected results.
- An EtherChannel supports the same allowed range of VLANs on all the ports in a trunking EtherChannel. If the allowed range of VLANs is not the same for a port list, the ports do not form an EtherChannel even when set to the **auto** or **desirable** mode with the **set port channel** command.
- Do not configure the ports in an EtherChannel as dynamic VLAN ports. Doing so can adversely affect switch performance.
- Ports with different VLAN cost configurations cannot form a channel.

EtherChannel Interaction with Other Features

Follow these guidelines associated with EtherChannel's interaction with other features:

- An EtherChannel will not form with ports that have different GARP VLAN Registration Protocol (GVRP), GARP Multicast Registration Protocol (GMRP), and QoS configurations.
- An EtherChannel will not form with ports where the port security feature is enabled. You cannot enable the port security feature for ports in an EtherChannel.
- An EtherChannel will not form if one of the ports is a SPAN destination port.
- An EtherChannel will not form if protocol filtering is set differently on the ports.
- Cisco Discovery Protocol (CDP) runs on the physical port even after the port is added to a channel.
- VLAN Trunking Protocol (VTP) and Dual Ring Protocol (DRiP) run on the channel.
- During fast switchover to the standby supervisor engine, all channeling ports are cleared on its channeling configuration and state, and the links are pulled down temporarily to cause partner ports to reset. All ports are reset to the nonchanneling state.

- Ports with different dot1q port types cannot form a channel.
- Ports with different jumbo frame configurations cannot form a channel.
- Ports with different dynamic configurations cannot form a channel.
- During high-availability switchover to the standby supervisor engine, all channeling ports remain operational. Ports are reset only if there are events missing during the switchover.

Note With software releases 6.3(1) and later, a PAgP-configured EtherChannel is preserved even if it contains only one port (this does not apply to LACP-configured EtherChannels). In software releases prior to 6.3(1), traffic was disrupted when you removed a 1-port channel from spanning tree and then added it to spanning tree as an individual port.

Note With software releases 6.3(1) and later, due to the port ID handling by the spanning tree feature, the maximum number of EtherChannels is 126 for a 6- or 9-slot chassis and 63 for a 13-slot chassis.

Understanding the Port Aggregation Protocol

Note Use the information in these sections if you are configuring EtherChannel using PAgP. If you are using LACP, see the "Understanding the Link Aggregation Control Protocol" section on page 6-12.

These sections describe PAgP:

- PAgP Modes, page 6-5
- PAgP Administrative Groups, page 6-6
- PAgP EtherChannel IDs, page 6-7

PAgP Modes

PAgP facilitates the automatic creation of EtherChannels by exchanging packets between Ethernet ports. PAgP packets are exchanged only between ports in **auto** and **desirable** modes. Ports configured in **on** or **off** mode do not exchange PAgP packets. The protocol learns the capabilities of port groups dynamically and informs the other ports. After PAgP identifies correctly matched EtherChannel links, it groups the ports into an EtherChannel. The EtherChannel is then added to the spanning tree as a single bridge port.

EtherChannel includes four user-configurable modes: **on**, **off**, **auto**, and **desirable**. Only **auto** and **desirable** are PAgP modes. You can modify the **auto** and **desirable** modes with the **silent** and **non-silent** keywords. By default, ports are in **auto silent** mode.

6050

Table 6-1 describes the EtherChannel modes available in PAgP.

Table 6-1 EtherChannel Modes Available in PAgP

Mode	Description
on	Mode that forces the port to channel without PAgP. With the **on** mode, a usable EtherChannel exists only when a port group in **on** mode is connected to another port group in **on** mode.
off	Mode that prevents the port from channeling.
auto	PAgP mode that places a port into a passive negotiating state, in which the port responds to PAgP packets it receives but does not initiate PAgP packet negotiation. (Default)
desirable	PAgP mode that places a port into an active negotiating state, in which the port initiates negotiations with other ports by sending PAgP packets.
silent	Keyword that is used with the **auto or desirable** mode when no traffic is expected from the other device to prevent the link from being reported to the Spanning Tree Protocol as down. (Default)
non-silent	Keyword that is used with the **auto** or **desirable** mode when traffic is expected from the other device.

Both the **auto** and **desirable** modes allow ports to negotiate with connected ports to determine if they can form an EtherChannel, based on criteria such as port speed, trunking state, and VLAN numbers.

Ports can form an EtherChannel when they are in different PAgP modes as long as the modes are compatible. For example:

- A port in **desirable** mode can form an EtherChannel successfully with another port that is in **desirable** or **auto** mode.
- A port in **auto** mode can form an EtherChannel with another port in **desirable** mode.
- A port in **auto** mode cannot form an EtherChannel with another port that is also in **auto** mode, because neither port will initiate negotiation.

When configurable, EtherChannel frame distribution can use MAC addresses, IP addresses, and Layer 4 port numbers. You can specify either the source or the destination address or both the source and destination addresses and Layer 4 port numbers. The mode you select applies to all EtherChannels configured on the switch. Use the option that provides the greatest variety in your configuration. For example, if the traffic on a channel is going to a single MAC address only, using source addresses, IP addresses, or Layer 4 port numbers as the basis for frame distribution may provide better frame distribution than selecting MAC addresses as the basis.

PAgP Administrative Groups

Configuring an EtherChannel creates an administrative group, designated by an integer between 1 and 1024, to which the EtherChannel belongs. When an administrative group is created, you can assign an administrative group number or let the next available administrative group number be assigned automatically. Forming a channel without specifying an administrative group number creates a new automatically numbered administrative group. An administrative group may contain a maximum of eight ports.

PAgP EtherChannel IDs

Each EtherChannel is automatically assigned a unique EtherChannel ID. Use the **show channel group** *admin_group* command to display the EtherChannel ID.

Configuring EtherChannel Using PAgP

These sections describe how to configure EtherChannel using PAgP:

- Specifying the EtherChannel Protocol, page 6-7
- Configuring an EtherChannel, page 6-8
- Setting the EtherChannel Port Mode, page 6-8
- Setting the EtherChannel Port Path Cost, page 6-8
- Setting the EtherChannel VLAN Cost, page 6-9
- Configuring EtherChannel Load Balancing, page 6-11
- Displaying EtherChannel Traffic Utilization, page 6-11
- Displaying Outgoing Ports for a Specified Address or Layer 4 Port Number, page 6-12
- Disabling an EtherChannel, page 6-12

Note Before you configure the EtherChannel, see the "EtherChannel Configuration Guidelines" section on page 6-3.

Specifying the EtherChannel Protocol

Note The default protocol is PAgP.

Note You can specify only one protocol, PAgP or LACP, per module.

To specify the EtherChannel protocol, perform this task in privileged mode:

Task	Command
Specify the EtherChannel protocol.	**set channelprotocol [pagp | lacp]** *mod*

This example shows how to specify the PAgP protocol for module 3:

```
Console> (enable) set channelprotocol pagp 3
Channeling protocol set to PAGP for module(s) 3.
Console> (enable)
```

6059

Configuring an EtherChannel

To configure EtherChannel on a group of Ethernet ports, perform this task in privileged mode:

Task	Command
Configure the EtherChannel on the desired ports.	**set port channel** *mod/ports...* [*admin_group*] **set port channel** *mod/ports...* **mode** {**on** | **off** | **desirable** | **auto**} [**silent** | **non-silent**]

This example shows how to configure a seven-port EtherChannel in a new administrative group:

```
Console> (enable) set port channel 2/2-8 mode desirable
Ports 2/2-8 left admin_group 1.
Ports 2/2-8 joined admin_group 2.
Console> (enable)
```

Setting the EtherChannel Port Mode

To set a port's EtherChannel mode, perform this task in privileged mode:

Task	Command
Set a port's EtherChannel mode.	**set port channel** *mod/ports...* [*admin_group*] **set port channel** *mod/port* **mode** {**on** | **off** | **desirable** | **auto**} [**silent** | **non-silent**]

This example shows how to set port 2/1 to **auto** mode:

```
Console> (enable) set port channel 2/1 mode auto
Ports 2/1 channel mode set to auto.
Console> (enable)
```

Setting the EtherChannel Port Path Cost

Note You accomplish this task using a global command that configures both LACP and PAgP.

The channel path cost is achieved by adjusting the port costs of each port belonging to the channel. If you do not specify the cost, it is updated based on the current port costs of the channeling ports. You may address one channel or all channels.

To set the EtherChannel port path cost, perform this task in privileged mode:

	Task	Command
Step 1	Use the administrative group number to display the EtherChannel ID.	**show channel group** *admin_group* or **show lacp-channel group** *admin_key*
Step 2	Use the EtherChannel ID to set the EtherChannel port path cost.	**set spantree channelcost** {*channel_id* | **all**} *cost*

Note When you enter the **set spantree channelcost** command, it does not appear in the configuration file. The command causes a "set spantree portcost" entry to be created for each port in the channel. See the "Configuring the PVST+ Port Cost" section in Chapter 8, "Configuring Spanning Tree," for information on using the **set spantree portcost** command.

This example shows how to set the EtherChannel port path cost for channel ID 768:

```
Console> (enable) show channel group 20
Admin Port  Status     Channel   Channel
group                  Mode      id
----- ----- ---------- --------- --------
  20    1/1 notconnect on             768
  20    1/2 connected  on             768

Admin Port  Device-ID                       Port-ID                   Platform
group
----- ----- ------------------------------- ------------------------- ----------
  20    1/1
  20    1/2  066510644(cat26-lnf(NET25))     2/1                       WS-C6009
Console> (enable)

Console> (enable) set spantree channelcost 768 12
Port(s) 1/1,1/2 port path cost are updated to 31.
Channel 768 cost is set to 12.
Warning:channel cost may not be applicable if channel is broken.
Console> (enable)
```

Setting the EtherChannel VLAN Cost

Note You accomplish this task using a global command that configures both LACP and PAgP.

The EtherChannel VLAN cost feature provides load balancing of VLAN traffic across multiple channels configured with trunking.

You enter the **set spantree channelvlancost** command to set the initial spanning tree costs for all VLANs in the channel. The **set spantree channelvlancost** command provides an alternate cost for some of the VLANs in the channel (assuming you are trunking across the channel). This command allows you to have up to two different spanning tree costs assigned per channel; some VLANs in the channel can have the "vlancost" while the remaining VLANs in the channel have the "cost."

The **set spantree channelvlancost** command creates a "set spantree portvlancost" entry to the configuration file for each port in the channel. Once you have entered the **set spantree channelvlancost** command, you must enter the **set spantree portvlancost** command for at least one port in the channel, specifying the VLAN or VLANs that you want associated with each port. The following examples show what occurs when each command is entered:

```
Console> (enable) set spantree channelvlancost 856 10
Port(s) 3/47-48 vlan cost are updated to 16.
Channel 856 vlancost is set to 10.
```

The following commands are added to the configuration file:

- **set spantree portvlancost 3/47 cost 16**
- **set spantree portvlancost 3/48 cost 16**

Now you have to add the desired VLANs to the above created commands by entering the following:

```
Console> (enable) set spantree portvlancost 3/47 cost 16 1-1005
Port 3/47 VLANs 1025-4094 have path cost 19.
Port 3/47 VLANs 1-1005 have path cost 16.
Port 3/48 VLANs 1-1005 have path cost 16.
```

To set the EtherChannel VLAN cost, perform this task in privileged mode:

	Task	Command
Step 1	Use the administrative group number to display the EtherChannel ID.	**show channel group** *admin_group* or **show lacp-channel group** *admin_key*
Step 2	Use the EtherChannel ID to set the EtherChannel VLAN cost.	**set spantree channelvlancost** *channel_id cost*
Step 3	Configure the port cost for the desired VLANs on each port.	**set spantree portvlancost** {*mod/port*} [**cost** *cost*] [*vlan_list*]

This example shows how to set the EtherChannel VLAN cost for channel ID 856:

```
Console> (enable) show channel group 22
Admin Port  Status     Channel   Channel
group                  Mode      id
----- ----- ---------- --------- --------
   22   1/1 notconnect on             856
   22   1/2 connected  on             856

Admin Port  Device-ID                       Port-ID                   Platform
group
----- ----- ------------------------------- ------------------------- ----------
   22   1/1
   22   1/2  066510644(cat26-lnf(NET25))     2/1                       WS-C6009
Console> (enable)

Console> (enable) set spantree channelvlancost 856 10
Port(s) 3/47-48 vlan cost are updated to 16.
Channel 856 vlancost is set to 10.
Console> (enable) set spantree portvlancost 3/47 cost 16 1-1005
Port 3/47 VLANs 1025-4094 have path cost 19.
Port 3/47 VLANs 1-1005 have path cost 16.
Port 3/48 VLANs 1-1005 have path cost 16.
Console> (enable)
```

Configuring EtherChannel Load Balancing

The load-balancing policy (frame distribution) can be based on a MAC address (Layer 2), an IP address (Layer 3), or a port number (Layer 4). These policies can be activated, respectively, by the **mac**, **ip** and **session** keywords. The load balancing can be based solely on the source address (**source** keyword), destination address (**destination** keyword), or both source and destination addresses (**both** keyword).

If a packet does not belong to a selected category, the next lower level category is considered. If the hardware cannot support the frame distribution method selected, a "Feature not supported" error message is displayed.

To configure EtherChannel load balancing, perform this task in privileged mode:

Task	Command
Configure EtherChannel load balancing.	**set port channel all distribution** {**ip** | **mac** | **session**} [**source** | **destination** | **both**]

Note The **set port channel all distribution session** command option is supported on Supervisor Engine 2 only.

This example shows how to configure EtherChannel to use MAC source addresses:

```
Console> (enable) set port channel all distribution mac source
Channel distribution is set to mac source.
Console> (enable)
```

Displaying EtherChannel Traffic Utilization

To display the traffic utilization on the EtherChannel ports, perform this task:

Task	Command
Display traffic utilization.	**show channel traffic**

This example shows how to display traffic utilization on EtherChannel ports:

```
Console> (enable) show channel traffic
ChanId Port  Rx-Ucst Tx-Ucst Rx-Mcst Tx-Mcst Rx-Bcst Tx-Bcst
------ ----- ------- ------- ------- ------- ------- -------
   808  2/16   0.00%   0.00%  50.00%  75.75%   0.00%   0.00%
   808  2/17   0.00%   0.00%  50.00%  25.25%   0.00%   0.00%
   816  2/31   0.00%   0.00%  25.25%  50.50%   0.00%   0.00%
   816  2/32   0.00%   0.00%  75.75%  50.50%   0.00%   0.00%
Console> (enable)
```

6050

Displaying Outgoing Ports for a Specified Address or Layer 4 Port Number

To display the outgoing port used in an EtherChannel for a specific address or Layer 4 port number, perform this task:

<table>
<tr><th>Task</th><th>Command</th></tr>
<tr><td>Display the outgoing port for a specified address or Layer 4 port number.</td><td><b>show channel hash</b> <i>channel_id src_ip_addr</i> [<i>dest_ip_addr</i>] | <i>dest_ip_address</i> | <i>src_mac_addr</i> [<i>dest_mac_addr</i>] | <i>dest_mac_addr</i> | <i>src_port dest_port</i> | <i>dest_port</i></td></tr>
</table>

This example shows how to display the outgoing port for the specified source and destination IP addresses:

```
Console> (enable) show channel hash 808 172.20.32.10 172.20.32.66
Selected channel port:2/17
Console> (enable)
```

Disabling an EtherChannel

To disable an EtherChannel, perform this task in privileged mode:

Task	Command
Disable an EtherChannel.	**set port channel** *mod/port* **mode off**

This example shows how to disable an EtherChannel:

```
Console> (enable) set port channel 2/2-8 mode off
Ports 2/2-8 channel mode set to off.
Console> (enable)
```

Understanding the Link Aggregation Control Protocol

Note Use the information in these sections if you are configuring EtherChannel using LACP. If you are using PAgP, see the "Understanding the Port Aggregation Protocol" section on page 6-5.

This section contains the following descriptions:

- LACP Modes, page 6-13
- LACP Parameters, page 6-13

LACP Modes

You may manually turn on channeling by setting the port channel mode to **on**, and you may turn off channeling by setting the port channel mode to **off**.

If you want LACP to handle channeling, use the **active** and **passive** channel modes. To start automatic EtherChannel configuration with LACP, you need to configure at least one end of the link to **active** mode to initiate channeling, because ports in **passive** mode passively respond to initiation and never initiate the sending of LACP packets.

Table 6-2 describes the EtherChannel modes available in LACP.

Table 6-2 EtherChannel Modes Available in LACP

Mode	Description
on	Mode that forces the port to channel without LACP. With the **on** mode, a usable EtherChannel exists only when a port group in **on** mode is connected to another port group in **on** mode.
off	Mode that prevents the port from channeling.
passive	LACP mode that places a port into a passive negotiating state, in which the port responds to LACP packets it receives but does not initiate LACP packet negotiation. (Default)
active	LACP mode that places a port into an active negotiating state, in which the port initiates negotiations with other ports by sending LACP packets.

LACP Parameters

The parameters used in configuring LACP are as follows:

- System priority

  Each switch running LACP must be assigned a system priority that can be specified automatically or through the CLI (see the "Specifying the System Priority" section on page 6-15). The system priority is used with the switch MAC address to form the system ID and is also used during negotiation with other systems.

- Port priority

  Each port in the switch must be assigned a port priority that can be specified automatically or through the CLI (see the "Specifying the Port Priority" section on page 6-15). The port priority is used with the port number to form the port identifier. The port priority is used to decide which ports should be put in standby mode when there is a hardware limitation that prevents all compatible ports from aggregating.

- Administrative key

  Each port in the switch must be assigned an administrative key value that can be specified automatically or through the CLI (see the "Specifying an Administrative Key Value" section on page 6-16). The ability of a port to aggregate with other ports is defined with the administrative key. A port's ability to aggregate with other ports is determined by these factors:

  - Port physical characteristics, such as data rate, duplex capability, and point-to-point or shared medium
  - Configuration constraints that you establish

When enabled, LACP always tries to configure the maximum number of compatible ports in a channel, up to the maximum allowed by the hardware (eight ports). If LACP is not able to aggregate all the ports that are compatible (for example, the remote system might have more restrictive hardware limitations), then all the ports that cannot be actively included in the channel are put in hot standby state and are used only if one of the channeled ports fails.

You can configure different channels with ports that have been assigned the same administrative key. For example, if eight ports are assigned the same administrative key, you may configure four ports in a channel using LACP **active** mode and the remaining four ports in a manually configured channel using the **on** mode. An administrative key is meaningful only in the context of the switch that allocates it; there is no global significance to administrative key values.

Configuring EtherChannel Using LACP

These sections describe how to configure EtherChannel using LACP:

- Specifying the EtherChannel Protocol, page 6-14
- Specifying the System Prior ty, page 6-15
- Specifying the Port Priority, page 6-15
- Specifying an Administrative Key Value, page 6-16
- Changing the Channel Mode, page 6-17
- Specifying the Channel Path Cost, page 6-17
- Specifying the Channel VLAN Cost, page 6-17
- Configuring Channel Load Balancing, page 6-17
- Clearing LACP Statistics, page 6-18
- Displaying EtherChannel Traffic Utilization, page 6-18
- Displaying Outgoing Ports for a Specified Address or Layer 4 Port Number, page 6-18
- Disabling an EtherChannel, page 6-19
- Displaying Spanning Tree-Related Information for EtherChannels, page 6-19

Note Before you configure the EtherChannel, see the "EtherChannel Configuration Guidelines" section on page 6-3.

Specifying the EtherChannel Protocol

Note The default protocol is PAgP.

Note You can specify only one protocol, PAgP or LACP, per module.

To specify the EtherChannel protocol, perform this task in privileged mode:

Task	Command
Specify the EtherChannel protocol.	**set channelprotocol [pagp | lacp]** *mod*

This example shows how to specify the LACP protocol for modules 2 and 3:

```
Console> (enable) set channelprotocol lacp 2,3
Mod 2 is set to LACP protocol.
Mod 3 is set to LACP protocol.
Console> (enable)
```

Use the **show channelprotocol** command to display the protocols for all modules.

Specifying the System Priority

Note Although this command is a global option, the command applies only to modules on which LACP is enabled; it is ignored on modules running PAgP.

The system priority value must be a number in the range of 1 through 65535, where higher numbers represent lower priority. The default priority is 32768.

To specify the system priority, perform this task in privileged mode:

Task	Command
Specify the system priority.	**set lacp-channel system-priority** *value*

This example shows how to specify the system priority as 20000:

```
Console> (enable) set lacp-channel system-priority 20000
LACP system priority is set to 20000
Console> (enable)
```

Use the **show lacp-channel sys-id** command to display the LACP system ID and system priority.

Specifying the Port Priority

The port priority value must be a number in the range of 1 through 255, where higher numbers represent lower priority. The default priority is 128.

To specify the port priority, perform this task in privileged mode:

Task	Command
Specify the port priority.	**set port lacp-channel** *mod/ports* **port-priority** *value*

This example shows how to specify the port priority as 10 for ports 1/1 to 1/4 and 2/6 to 2/8:

```
Console> (enable) set port lacp-channel 1/1-4,2/6-8 port-priority 10
Port(s) 1/1-4,2/6-8 port-priority set to 10.
Console> (enable)
```

Use the **show lacp-channel group** *admin_key* **info** command to display the port priority.

Specifying an Administrative Key Value

Note When the system or module configuration information stored in NVRAM is cleared, the administrative keys are assigned new values automatically. For modules, each group of four consecutive ports, beginning at the 1st, 5th, 9th and so on, are assigned a unique administrative key. Across the module, ports must have unique administrative keys. After NVRAM is cleared, the channel mode of the ports is set to "passive."

You can specify an administrative key value to a set of ports or the system automatically selects a value if you do not specify the parameter *admin_key*. In both cases, the admin_key value can range from 1 through 1024.

If you choose a value for the administrative key, and this value has already been used in the system, then all the ports originally associated with the previously assigned admin_key value are moved to another automatically assigned value, and the modules and ports that you specified in the command are assigned the admin_key value that you specified.

The maximum number of ports to which an administrative key can be assigned is eight.

The default mode for all ports being assigned the administrative key is passive. However, if the channel was previously assigned a particular mode (see the "Changing the Channel Mode" section on page 6-17), assigning the administrative key will not affect it,and the channel mode that you specified previously is maintained.

To specify the administrative key value, perform this task in privileged mode:

Task	Command
Specify the administrative key value.	**set port lacp-channel** *mod/ports* [*admin_key*]

This example shows how to assign ports 4/1 to 4/4 the same administrative key, with the system picking its value automatically:

```
Console> (enable) set port lacp-channel 4/1-4
Port(s) 4/1-4 are assigned to admin key 96.
Console> (enable)
```

This example shows how to assign ports 4/4 to 4/6 the administrative key 96 (you specify the 96). In this example, the administrative key was previously assigned to another group of ports by the system (see the previous example):

```
Console> (enable) set port lacp-channel 4/4-6 96
Port(s) 4/1-3 are moved to admin key 97.
Port(s) 4/4-6 are assigned to admin key 96.
Console> (enable)
```

This example shows the system response when more than eight ports are assigned the same administrative key value (the request is denied, and no ports are assigned administrative key 123):

```
Console> (enable) set port lacp-port channel 2/1-2,4/1-8 123
No more than 8 ports can be assigned to an admin key.
Console> (enable)
```

Use the **show lacp-channel group** command to display administrative key values for ports.

Changing the Channel Mode

You can change the channel mode for a set of ports that were previously assigned the same administrative key (see the "Specifying an Administrative Key Value" section on page 6-16).

To change the channel mode, perform this task in privileged mode:

Task	Command
Change the channel mode.	**set port lacp-channel** *mod/ports* **mode [on | off | active | passive]**

This example shows how to change the channel mode for ports 4/1 and 4/6, setting it to **on**. The administrative key for ports 4/1 and 4/6 is unchanged.

```
Console> (enable) set port lacp-channel 4/1,4/6 mode on
Port(s) 4/1,4/6 channel mode set to on.
Console> (enable)
```

Use the **show lacp-channel group** *admin_key* command to display the channel mode for ports.

Specifying the Channel Path Cost

You can accomplish this task using a global command that configures both LACP and PAgP. For more information, see the "Setting the EtherChannel Port Path Cost" section on page 6-8.

Specifying the Channel VLAN Cost

You can accomplish this task using a global command that configures both LACP and PAgP. For more information, see the "Setting the EtherChannel VLAN Cost" section on page 6-9.

Configuring Channel Load Balancing

You can accomplish this task using a global command that configures both LACP and PAgP. For more information, see the "Configuring EtherChannel Load Balancing" section on page 6-11.

Clearing LACP Statistics

To clear LACP statistics, perform this task in privileged mode:

Task	Command
Clear LACP statistics.	**clear lacp-channel statistics**

This example shows how to clear LACP statistics:

```
Console> (enable) clear lacp-channel statistics
LACP channel counters are cleared.
Console> (enable)
```

Displaying EtherChannel Traffic Utilization

To display the traffic utilization on the EtherChannel ports, perform this task:

Task	Command
Display traffic utilization.	**show lacp-channel traffic**

This example shows how to display traffic utilization on EtherChannel ports:

```
Console> (enable) show lacp-channel traffic
ChanId Port  Rx-Ucst Tx-Ucst Rx-Mcst Tx-Mcst Rx-Bcst Tx-Bcst
------ ----- ------- ------- ------- ------- ------- -------
   808  2/16   0.00%   0.00%  50.00%  75.75%   0.00%   0.00%
   808  2/17   0.00%   0.00%  50.00%  25.25%   0.00%   0.00%
   816  2/31   0.00%   0.00%  25.25%  50.50%   0.00%   0.00%
   816  2/32   0.00%   0.00%  75.75%  50.50%   0.00%   0.00%
Console> (enable)
```

Displaying Outgoing Ports for a Specified Address or Layer 4 Port Number

To display the outgoing port used in an EtherChannel for a specific address or Layer 4 port number, perform this task:

Task	Command
Display the outgoing port for a specified address or Layer 4 port number.	**show lacp-channel hash** *channel_id src_ip_addr* [*dest_ip_addr*] | *dest_ip_address* | *src_mac_addr* [*dest_mac_addr*] | *dest_mac_addr* | *src_port dest_port* / *dest_port*

This example shows how to display the outgoing port for the specified source and destination IP addresses:

```
Console> (enable) show lacp-channel hash 808 172.20.32.10 172.20.32.66
Selected channel port:2/17
Console> (enable)
```

Disabling an EtherChannel

To disable an EtherChannel, perform this task in privileged mode:

Task	Command
Disable an EtherChannel.	**set port lacp-channel** *mod/port* **mode off**

This example shows how to disable an EtherChannel:

```
Console> (enable) set port lacp-channel 2/2-8 mode off
Port(s) 2/2-8 channel mode set to off.
Console> (enable)
```

Displaying Spanning Tree-Related Information for EtherChannels

You can display the channel ID and the truncated port list for all ports that are channeling. Ports that are not channeling are identified by their port number.

To display spanning tree-related information for EtherChannels, perform this task:

Task	Command
Display spanning-tree related information for EtherChannels.	**show spantree** *mod/port*

These examples show how to display spanning tree-related information for EtherChannels:

```
Console> show spantree 4/6
Port                     Vlan Port-State    Cost  Priority Portfast   Channel_id
------------------------ ---- ------------- ----- -------- ---------- ----------
 4/6                     1    not-connected     4       32 disabled   0
Console>

Console> show spantree 4/7
Port                     Vlan Port-State    Cost  Priority Portfast   Channel_id
------------------------ ---- ------------- ----- -------- ---------- ----------
4/7-8                    1    blocking          3       32 disabled   770
Console>
```

Apêndice ES

CHAPTER 4

Configuring Content Switching

This chapter describes how to configure content switching and contains these sections:

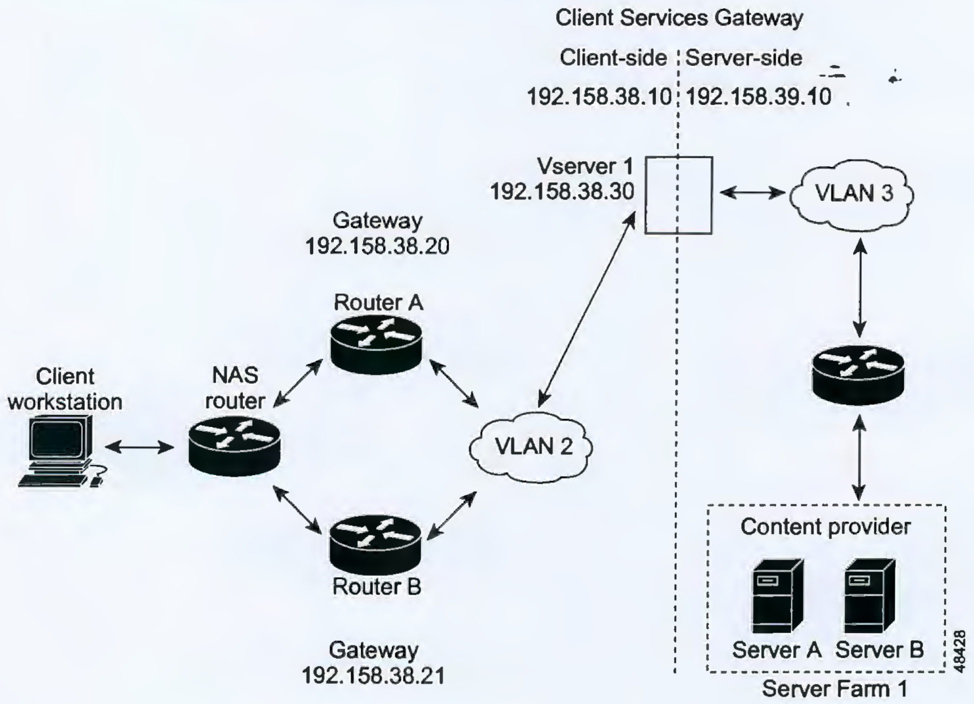
- Configuring the Single Subnet (Bridge) Mode, page 4-2
- Configuring the Secure (Router) Mode, page 4-4
- Configuring Fault Tolerance, page 4-5
- Configuring HSRP, page 4-9

Note All examples assume that the **ip slb mode csm** command has been entered as described in Chapter 3, "Configuring the Content Switching Module."

Configuring the Single Subnet (Bridge) Mode

In the single subnet (bridge) mode configuration, the client-side and server-side VLANs are on the same subnets. Figure 4-1 shows how the single subnet (bridge) mode configuration is set up.

Figure 4-1 Single Subnet (Bridge) Mode Configuration



Note	The addresses in Figure 4-1 refer to the steps in the following task table.

Note	You configure single subnet (bridge) mode by assigning the same IP address to the CSM client and server VLANs.

To configure content switching for the single subnet (bridge) mode, perform this task:

	Command	Purpose
Step 1	`Router(config-module-csm)# vlan database`	Enters the VLAN mode[1].
Step 2	`Router(vlan)# vlan 2`	Configures a client-side VLAN[2].
Step 3	`Router(vlan)# vlan 3`	Configures a server-side VLAN.
Step 4	`Router(vlan)# exit`	Exits to have the configuration take effect.
Step 5	`Router(config-module-csm)# vlan 2 client`	Creates the client-side VLAN 2 and enters the SLB VLAN mode[1].

	Command	Purpose
Step 6	`Router(config-slb-vlan-client)# ip addr 192.158.38.10 255.255.255.0`	Assigns the CSM IP address on VLAN 2.
Step 7	`Router(config-slb-vlan-client)# gateway 192.158.38.20`	Defines the client-side VLAN gateway to Router A.
Step 8	`Router(config-slb-vlan-client)# gateway 192.158.38.21`	Defines the client-side VLAN gateway to Router B.
Step 9	`Router(config-slb-vserver)# vlan 3 server`	Creates the server-side VLAN 3 and enters the SLB VLAN mode.
Step 10	`Router(config-slb-vlan-client)# ip addr 192.158.38.10 255.255.255.0`	Assigns the CSM IP address on VLAN 3.
Step 11	`Router(config-slb-vlan-client)# exit`	Exits the submode.
Step 12	`Router(config-module-csm)# vserver VIP1`	Creates a virtual server and enters the SLB *vserver* mode.
Step 13	`Router(config-slb-vserver)# virtual 192.158.38.30 tcp www`	Creates a virtual IP address.
Step 14	`Router(config-slb-vserver)# serverfarm farm1`	Associates the virtual server with the server farm[3].
Step 15	`Router(config-module-csm)# inservice`	Enables the server.

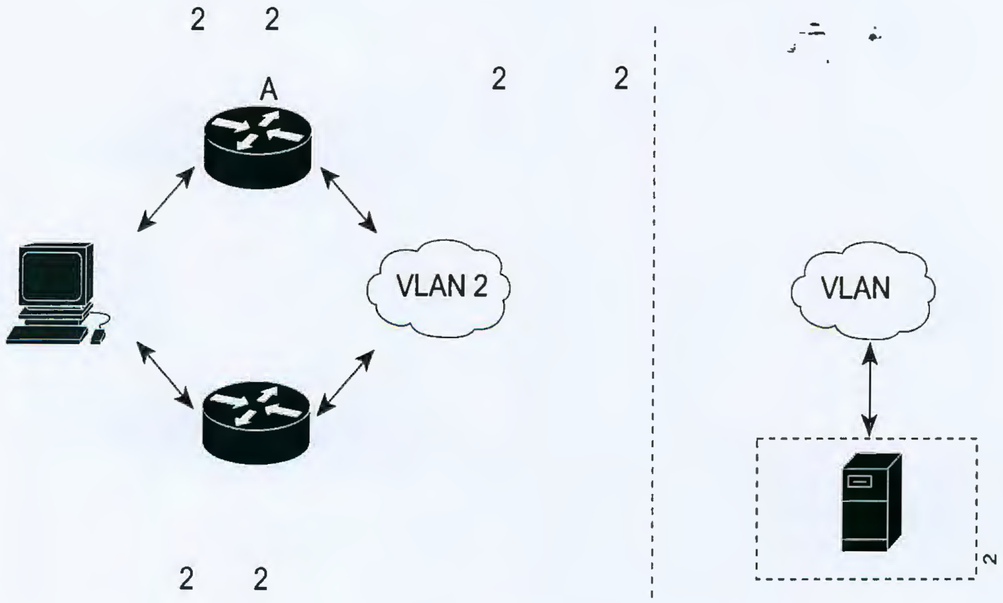
1. Enter the **exit** command to leave a mode or submode. Enter the **end** command to return to the menu's top level.
2. The **no** form of this command restores the defaults.
3. This step assumes that the server farm has already been configured. (See the "Configuring Server Farms" section on page 3-12.)

Note Set the server's default routes to Router A's gateway (192.158.38.20) or Router B's gateway (192.158.38.21).

Configuring the Secure (Router) Mode

In secure (router) mode, the client-side and server-side VLANs are on different subnets. Figure 4-2 shows how the secure (router) mode configuration is set up.

Figure 4-2 Secure (Router) Mode Configuration



Note The addresses in Figure 4-2 refer to the steps in the following task table.

To configure content switching in secure (router) mode, perform this task:

	Command	Purpose
Step 1	`Router(config-module-csm)# vlan database`	Enters the VLAN mode[1].
Step 2	`Router(vlan)# vlan 2`	Configures a client-side VLAN[2].
Step 3	`Router(vlan)# vlan 3`	Configures a server-side VLAN.
Step 4	`Router(vlan)# exit`	Exits to have the configuration take effect.
Step 5	`Router(config-module-csm)# vlan 2 client`	Creates the client-side VLAN 2 and enters the SLB VLAN mode.
Step 6	`Router(config-slb-vlan-client)# ip addr 192.158.38.10 255.255.255.0`	Assigns the CSM IP address on VLAN 2.
Step 7	`Router(config-slb-vlan-client)# gateway 192.158.38.20`	Defines the client-side VLAN gateway to Router A.
Step 8	`Router(config-slb-vlan-client)# gateway 192.158.38.21`	Defines the client-side VLAN gateway to Router B.

	Command	Purpose
Step 9	`Router(config-module-csm)# vlan 3 server`	Creates the server-side VLAN 3 and enters the SLB VLAN mode.
Step 10	`Router(config-slb-vlan-server)# ip addr 192.158.39.10 255.255.255.0`	Assigns the CSM IP address on VLAN 3.
Step 11	`Router(config-slb-vlan-server)# exit`	Exits the submode.
Step 12	`Router(config-module-csm)# vserver VIP1`	Creates a virtual server and enters the SLB *vserver* mode.
Step 13	`Router(config-slb-vserver)# virtual 192.158.38.30 tcp www`	Creates a virtual IP address.
Step 14	`Router(config-slb-vserver)# serverfarm farm1`	Associates the virtual server with the server farm[3].
Step 15	`Router(config-module-csm)# inservice`	Enables the server.

1. Enter the **exit** command to leave a mode or submode. Enter the **end** command to return to the menu's top level.
2. The **no** form of this command restores the defaults.
3. This step assumes that the server farm has already been configured. (See the "Configuring Server Farms" section on page 3-12.)

Note Set the server's default routes to the CSM's IP address (192.158.39.10).

Configuring Fault Tolerance

This section describes a fault-tolerant configuration. In this configuration, two separate Catalyst 6500 series chassis each contain a CSM.

Note You can also create a fault-tolerant configuration with two CSMs in a single Catalyst 6500 series chassis. You also can create a fault-tolerant configuration in either the secure (router) mode or nonsecure (bridge) mode.

In the secure (router) mode, the client-side and server-side VLANs provide the fault-tolerant (redundant) connection paths between the CSM and the routers on the client side and the servers on the server side. In a redundant configuration, two CSMs perform active and standby roles. Each CSM contains the same IP, virtual server, server pool, and real server information. From the client-side and server-side networks, each CSM is configured identically. The network sees the fault-tolerant configuration as a single CSM.

Note When you configure multiple fault-tolerant CSM pairs, do not configure multiple CSM pairs to use the same FT VLAN. Use a different FT VLAN for each fault-tolerant CSM pair.

Configuring fault tolerance requires the following:

- Two CSMs that are installed in the Catalyst 6500 series chassis.
- Identically configured CSMs. One CSM is configured as the active; the other is configured as the standby.
- Each CSM connected to the same client-side and server-side VLANs.

- Communication between the CSMs provided by a shared private VLAN.
- A network that sees the redundant CSMs as a single entity.
- Connection redundancy by configuring a link that has a 1-GB per-second capacity. Enable the calendar in the switch Cisco IOS software so that the CSM state change gets stamped with the correct time.

  The following command enables the calendar:

  ```
  Cat6k-2# conf t
  Cat6k-2(config)# clock timezone WORD offset from UTC
  Cat6k-2(config)# clock calendar-valid
  ```

Because each CSM has a different IP address on the client-side and server-side VLAN, the CSM can issue health monitor probes (see the "Configuring Probes for Health Monitoring" section on page 6-1) to the network and receive responses. Both the active and standby CSMs send probes while operational. If the passive CSM assumes control, it knows the status of the servers because of the probe responses it has received.

Connection replication supports both non-TCP connections and TCP connections. Enter the **replicate csrp** {**sticky** | **connection**} command in the virtual server mode to configure replication for the CSMs.

Note The default setting for the **replicate** command is disabled.

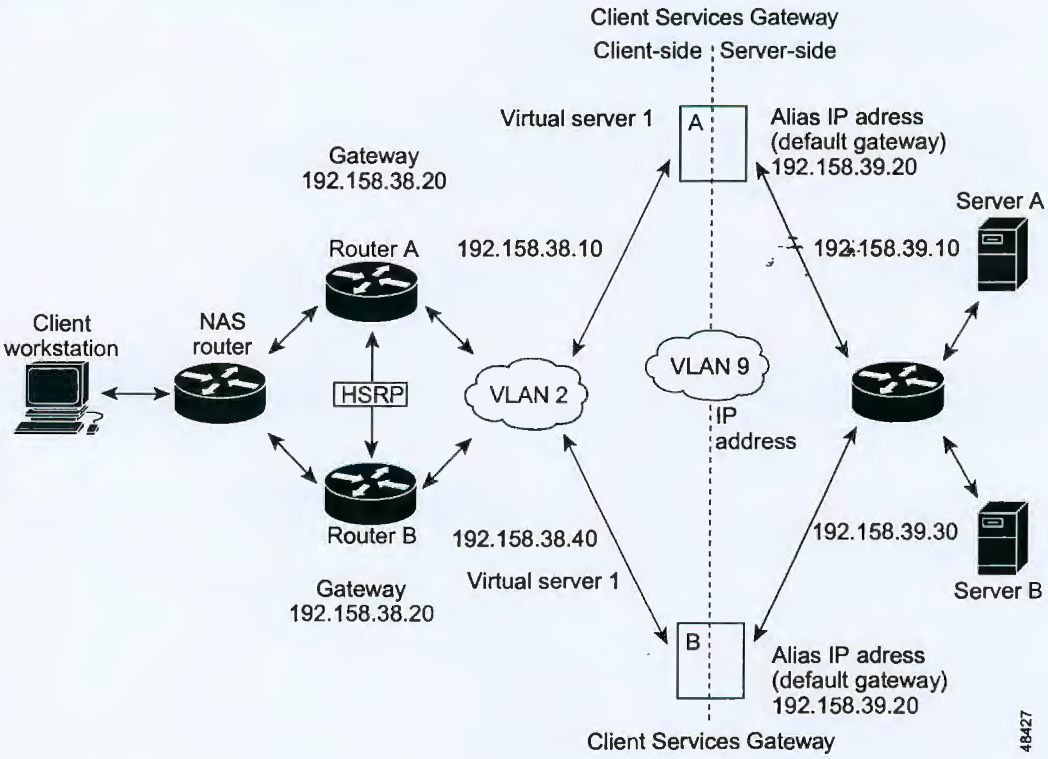
To use connection replication for connection redundancy, use these commands:

```
Cat6k-2# conf t
Cat6k-2(config)# no ip igmp snooping
```

If no router is present on the server-side VLAN, then each server's default route points to the aliased IP address.

Figure 4-3 shows how the secure (router) mode fault-tolerant configuration is set up.

Figure 4-3 Fault-Tolerant Configuration



Note The addresses in Figure 4-3 refer to the steps in the following two task tables.

To configure the active (A) CSM for fault tolerance, perform this task:

	Command	Purpose
Step 1	`Router(config-module-csm)# vlan 2 client`	Creates the client-side VLAN 2 and enters the SLB VLAN mode[1].
Step 2	`Router(config-slb-vlan-client)# ip addr 192.158.38.10 255.255.255.0`	Assigns the content switching IP address on VLAN 2.
Step 3	`Router(config-slb-vlan-client)# gateway 192.158.38.20`	(Optional) Defines the client-side VLAN gateway for an HSRP enabled gateway.
Step 4	`Router(config-module-csm)# vserver vip1`	Creates a virtual server and enters the SLB vserver mode.

	Command	Purpose
Step 5	Router(config-slb-vserver)# **virtual 192.158.38.30 tcp www**	Creates a virtual IP address.
Step 6	Router(config-module-csm)# **inservice**	Enables the server.
Step 7	Router(config-module-csm)# **vlan 3 server**	Creates the server-side VLAN 3 and enters the SLB VLAN mode.
Step 8	Router(config-slb-vlan-server)# **ip addr 192.158.39.10 255.255.255.0**	Assigns the CSM IP address on VLAN 3.
Step 9	Router(config-slb-vlan-server)# **alias ip addr 192.158.39.20 255.255.255.0**	Assigns the default route for VLAN 3.
Step 10	Router(config-slb-vlan-server) **vlan 9 ft**	Defines VLAN 9 as a fault-tolerant VLAN.
Step 11	Router(config-module-csm)# **ft group** *ft-group-number* **vlan 9**	Creates the content switching active and standby (A/B) group VLAN 9.
Step 12	Router(config-module-csm)# **vlan database**	Enters the VLAN mode[1].
Step 13	Router(vlan)# **vlan 2**	Configures a client-side VLAN 2[2].
Step 14	Router(vlan)# **vlan 3**	Configures a server-side VLAN 3.
Step 15	Router(vlan)# **vlan 9**	Configures a fault-tolerant VLAN 9.
Step 16	Router(vlan)# **exit**	Enters the **exit** command to have the configuration take affect.

[1] Enter the **exit** command to leave a mode or submode. Enter the **end** command to return to the menu's top level.

[2] The **no** form of this command restores the defaults.

To configure the standby (B) CSM for fault tolerance, perform this task (see Figure 4-3):

	Command	Purpose
Step 1	Router(config-module-csm)# **vlan 2 client**	Creates the client-side VLAN 2 and enters the SLB VLAN mode[1].
Step 2	Router(config-slb-vlan-client)# **ip addr 192.158.38.40 255.255.255.0**	Assigns the Content Switching IP address on VLAN 2.
Step 3	Router(config-module-csm) **vlan 9 ft**	Defines VLAN 9 as a fault-tolerant VLAN.
Step 4	Router(config-slb-vlan-client)# **gateway 192.158.38.20**	Defines the client-side VLAN gateway.
Step 5	Router(config-module-csm)# **vserver vip1**	Creates a virtual server and enters the SLB *vserver* mode.
Step 6	Router(config-slb-vserver)# **virtual 192.158.38.30 tcp www**	Creates a virtual IP address.
Step 7	Router(config-module-csm)# **inservice**	Enables the server.
Step 8	Router(config-module-csm)# **vlan 3 server**	Creates the server-side VLAN 3 and enters the SLB *vlan* mode.
Step 9	Router(config-slb-vserver)# **ip addr 192.158.39.30 255.255.255.0**	Assigns the CSM IP address on VLAN 3.
Step 10	Router(config-slb-vserver)# **alias 192.158.39.20 255.255.255.0**	Assigns the default route for VLAN 2.

	Command	Purpose

Step 11	`Router(config-module-csm)# ft group`
	`ft-group-number vlan 9`
		Creates the CSM active and standby (A/B) group VLAN 9.

Step 12	`Router(config-module-csm)# show module csm`
	`module ft`
		Displays the state of the fault tolerant system.

1. Enter the **exit** command to leave a mode or submode. Enter the **end** command to return to the menu's top level.

Configuring HSRP

This section provides an overview of a Hot Standby Router Protocol (HSRP) configuration (see Figure 4-4) and describes how to configure the CSMs with HSRP and CSM failover on the Catalyst 6500 series switches.

HSRP Configuration Overview

Figure 4-4 shows that two Catalyst 6500 series switches, Switch 1 and Switch 2, are configured to route from a client-side network (10.100/16) to an internal CSM client network (10.6/16, VLAN 136) through an HSRP gateway (10.100.0.1). The configuration shows the following:

- The client-side network is assigned an HSRP group ID of HSRP ID 2.
- The internal CSM client network is assigned an HSRP group ID of HSRP ID 1.

Note HSRP group 1 must have tracking turned on so that it can track the client network ports on HSRP group 2. When HSRP group 1 detects any changes in the active state of those ports, it duplicates those changes so that both the HSRP active (Switch 1) and HSRP standby (Switch 2) switches share the same knowledge of the network.

In the example configuration, two CSMs (one in Switch 1 and one in Switch 2) are configured to forward traffic between a client-side and a server-side VLAN:

- Client VLAN 136

  Note The client VLAN is actually an internal CSM VLAN network; the actual client network is on the other side of the switch.

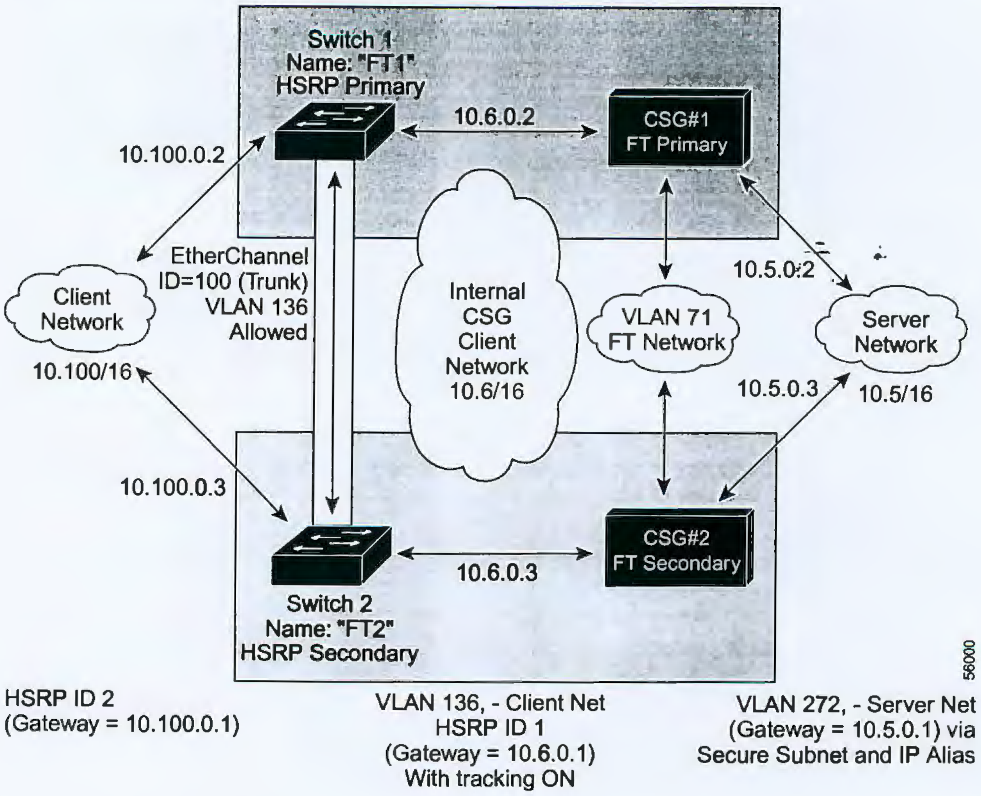
- Server VLAN 272

  The actual servers on the server network (10.5/1) point to the CSM server network through an aliased gateway (10.5.0.1), allowing the servers to run a secure subnet.

  In the example configuration, an EtherChannel is set up with trunking enabled, allowing traffic on the internal CSM client network to travel between the two Catalyst 6500 series switches. The setup is shown in Figure 4-4.

  Note EtherChannel protects against a severed link to the active switch and a failure in a non-CSM component of the switch. EtherChannel also provides a path between an active CSM in one switch and another switch, allowing CSMs and switches to fail over independently, providing an extra level of fault tolerance.

Figure 4-4 HSRP Configuration



Creating the HSRP Gateway

This procedure describes how to create an HSRP gateway for the client-side network. The gateway is HSRP ID 2 for the client-side network.

Note In this example, HSRP is set on Fast Ethernet ports 3/6.

To create an HSRP gateway, follow these steps:

Step 1 Configure Switch 1—FT1 (HSRP active) as follows:

```
Router(config)#interface FastEthernet3/6
Router(config)#ip address 10.100.0.2 255.255.0.0
Router(config)#standby 2 priority 110 preempt
Router(config)#standby 2 ip 10.100.0.1
```

Step 2 Configure Switch 2—FT2 (HSRP standby) as follows:

```
Router(config)#interface FastEthernet3/6
Router(config)#ip address 10.100.0.3 255.255.0.0
Router(config)#standby 2 priority 100 preempt
Router(config)#standby 2 ip 10.100.0.1
```

Creating Fault-Tolerant HSRP Configurations

This section describes how to create a fault-tolerant HSRP secure-mode configuration. To create a nonsecure-mode configuration, enter the commands described with these exceptions:

- Assign the same IP address to both the server-side and the client-side VLANs.
- Do not use the **alias** command to assign a default gateway for the server-side VLAN.

To create fault-tolerant HSRP configurations, follow these steps:

Step 1 Configure VLANs on HSRP FT1 as follows:

```
Router(config)# module csm 5
Router(config-module-csm)# vlan 136 client
Router(config-slb-vlan-client)# ip address 10.6.0.245 255.255.0.0
Router(config-slb-vlan-client)# gateway 10.6.0.1
Router(config-slb-vlan-client)# exit

Router(config-module-csm)# vlan 272 server
Router(config-slb-vlan-server)# ip address 10.5.0.2 255.255.0.0
Router(config-slb-vlan-server)# alias 10.5.0.1 255.255.0.0
Router(config-slb-vlan-server)# exit

Router(config-module-csm)# vlan 71 ft

Router(config-module-csm)# ft group 88 vlan 71
Router(config-slb-ft)# priority 30
Router(config-slb-ft)# preempt
Router(config-slb-ft)# exit

Router(config-module-csm)# interface Vlan136
ip address 10.6.0.2 255.255.0.0
standby 1 priority 100 preempt
standby 1 ip 10.6.0.1
standby 1 track Fa3/6 10
```

Step 2 Configure VLANs on HSRP FT2 as follows:

```
Router(config)# module csm 6
Router(config-module-csm)# vlan 136 client
Router(config-slb-vlan-client)# ip address 10.6.0.246 255.255.0.0
Router(config-slb-vlan-client)# gateway 10.6.0.1
Router(config-slb-vlan-client)# exit

Router(config-module-csm)# vlan 272 server
Router(config-slb-vlan-server)# ip address 10.5.0.3 255.255.0.0
Router(config-slb-vlan-server)# alias 10.5.0.1 255.255.0.0
Router(config-slb-vlan-server)# exit

Router(config-module-csm)# vlan 71 ft
Router(config-module-csm)# ft group 88 vlan 71
Router(config-slb-ft)# priority 20
Router(config-slb-ft)# preempt
Router(config-slb-ft)# exit

Router(config-module-csm)# interface Vlan136
ip address 10.6.0.3 255.255.0.0
standby 1 priority 100 preempt
standby 1 ip 10.6.0.1
standby 1 track Fa3/6 10
```

Note To allow tracking to work, preempt must be on.

Step 3 Configure EtherChannel on both switches as follows:

```
Router(console)# interface Port-channel100
Router(console)# switchport
Router(console)# switchport trunk encapsulation dot1q
Router(console)# switchport trunk allowed vlan 136
```

Note By default, all VLANs are allowed on the port channel.

Step 4 To prevent problems, remove the server and FT CSM VLANs as follows:

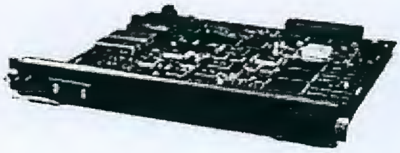
```
Router(console)# switchport trunk remove vlan 71
Router(console)# switchport trunk remove vlan 272
```

Step 5 Add ports to the EtherChannel as follows:

```
Router(console)# interface FastEthernet3/25
Router(console)# switchport
Router(console)# channel-group 100 mode on
```

Apêndice E1

Cisco **Catalyst 6500** Series Content Switching Module

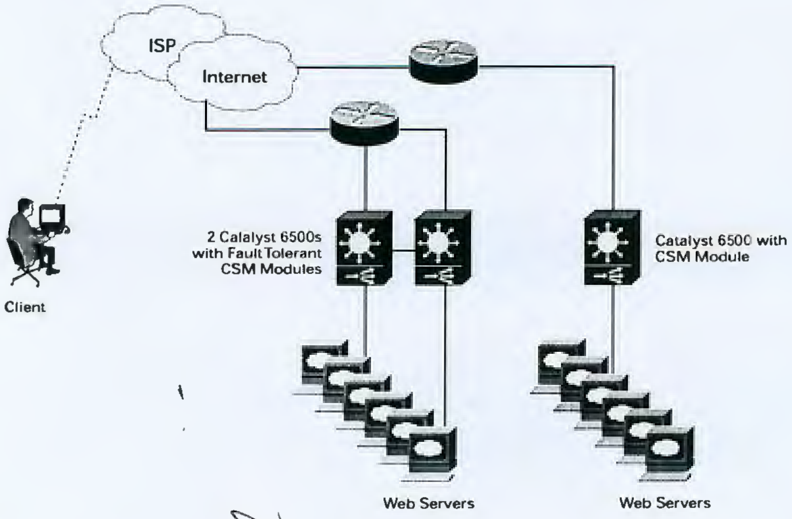


The Cisco Content Switching Module (CSM) is a Cisco Catalyst® 6500 line card that balances client traffic to farms of servers, firewalls, Secure Sockets Layer (SSL) devices, or virtual private network (VPN) termination devices. The Cisco CSM provides a high-performance, cost-effective load-balancing solution for enterprise and Internet service provider (ISP) networks. The Cisco CSM meets the demands of high-speed content delivery networks, tracking network sessions and server load conditions in real time and directing each session to the most appropriate server. Fault-tolerant Cisco CSM configurations maintain full state information and provide true hitless failover required for mission-critical functions.

The Cisco CSM provides the following key benefits (refer to Figure 1):

- Market-leading performance—The Cisco CSM establishes up to 165,000 Layer 4 connections per second (depending on software version) and provides high-speed content switching while maintaining 1 million concurrent connections.
- Outstanding price/performance value for large data centers and ISPs—The Cisco CSM features a low connection cost and occupies a small footprint. It slides into a slot in a new or existing Cisco Catalyst 6500 and enables all ports in the Cisco Catalyst 6500 for Layer 4–7 content switching.
- Multiple Cisco CSMs can be installed in the same Cisco Catalyst 6500.
- Ease of configuration—The Cisco CSM uses the same Cisco IOS® command-line interface (CLI) that is used to configure the Cisco Catalyst 6500 Switch.

Figure 1. The Cisco CSM



Content Switching Module Key Features

Firewall Load Balancing

The Cisco CSM allows you to scale firewall protection by distributing traffic across multiple firewalls on a per-connection basis, while ensuring that all packets belonging to a particular connection go through the same firewall. Both stealth and regular firewalls are supported.

URL and Cookie-Based Load Balancing

The Cisco CSM allows full regular expression pattern matching for policies based on URLs, cookies, and Hypertext Transfer Protocol (HTTP) header fields. The Cisco CSM supports any URL or cookie format—allowing it to load balance existing Web content without requiring URL/cookie format changes.

High Performance

The Cisco CSM performs up to 165,000 new Layer 4 TCP connection setups per second, depending on software version. These connections can be spread across 4096 virtual servers (16,384 real servers) and all the ports in a Cisco Catalyst 6500, or they can be focused on a single port. This provides a benefit over competitors who use distributed architectures that require use of all the ports in order to gain maximum performance.

Network Configurations

The Cisco CSM supports many different network topology types. A Cisco CSM can operate in a mixed bridged and routed configuration, allowing traffic to flow from the client side to the server side on the same or on different IP subnets.

IP Protocol Support

The Cisco CSM accommodates a wide range of common IP protocols—including TCP and User Datagram Protocol (UDP). Additionally, the Cisco CSM supports higher-level protocols, including HTTP, File Transfer Protocol (FTP), Telnet, Real-Time Streaming Protocol (RTSP), Domain Name System (DNS), and Simple Mail Transfer Protocol (SMTP).

User Session Stickiness

Whenever encryption or e-commerce is involved, it is important that the end user is consistently directed to the same server-that is, the server where the user's shopping cart is located or the encryption tunnel terminates. Cisco CSM User Session Stickiness provides the ability to consistently bring users back to the same server-based on SSL session ID, IP address, cookie, or HTTP redirection.

Load-Balancing Algorithms

The Cisco CSM supports the following load-balancing algorithms:

- Round robin
- Weighted Round Robin
- Least connections
- Weighted least connections
- Source and/or destination IP hash (subnet mask also configurable)
- URL hashing

Quality of Service

Providing differentiated levels of service to end users is important when generating revenue from content. The Cisco CSM takes advantage of the robust quality of service (QoS) of the Cisco Catalyst 6500, enabling traffic differentiation as follows:

- Correctly prioritizes packets based on Layer 7 rules
- Directs users who are paying more for services to faster or less loaded servers

High Availability

The Cisco CSM continually monitors server and appliation availability using health monitoring probes, inband health monitoring, return code checking, and the Dynamic Feedback Protocol (DFP). When a real server or gateway failure occurs, the Cisco CSM redirects traffic to a different location. Servers can be added and removed without disrupting service—systems can easily be scaled up or down.

Connection Redundancy

Optionally, two Cisco CSMs can be configured in a fault-tolerant configuration to share state information about user sessions and provide connection redundancy. If the active Cisco CSM fails, open connections are handled by the standby CSM without interruption, and users experience hitless failover—an important requirement for e-commerce sites and sites where encryption is used.

Global Server Load Balancing

The CSM offers multiple options for building a global or geographical load balanced environment. The CSM can act as an authoritative DNS and perform GSLB among geographically dispersed CSMs for the purposes of disaster recovery or for small GSLB environments with 2-4 locations. In addition, the CSM can report load information for it's Virtual IPs into the Global Site Selector (GSS), an appliance designed for advanced GSLB scaling up to 128 sites. With the many different GSLB options the CSM offers the ability to scale GSLB capabilities as growth demands.

Configuration Limits

- Total virtual LANs (VLANs) (client and server): 256
- Virtual servers: 4000
- Server farms: 4000

- Real servers: 16,000
- Probes: 4000
- Access control list (ACL) items: 16,000

Performance Summary
Connections
1,000,000 concurrent TCP connections
165,000 connection setups per second—Layer 4
Throughput
Total combined throughput of 4 Gigabits per second (client to server and server to client)
Cisco Catalyst Switch Platform Requirements
Cisco IOS Software only—Cisco Catalyst Operating System is not supported
Not fabric enabled—Functions as a bus-enabled line card
Multilayer Switch Feature Card (MSFC) or MSFC2
Physical Specifications
Occupies slot in the Cisco Catalyst 6500 chassis
Dimensions (H x W x D): 1.2 x 14.4 x 16 in. (3.0 x 35.6 x 40.6 cm)
Weight: 5 lb (2.27 kg)
Operating Environment
Operating temperature: 32 to 104.5°F (0 to 40°C)
Nonoperating temperature: –40 to 158°F (–40 to 70°C)
Operating relative humidity: 10 to 90% (noncondensing)
Nonoperating relative humidity: 5 to 95% (noncondensing)
Operating and nonoperating altitude: Sea level to 10,000 ft (3050m)
Agency Approvals
Emissions: FCC Part 15 (CFR 47) Class A, ICES-003 Class A, EN55022 Class A, CISPR22 Class A, AS NZS 3548 Class A
Safety: CE Marking according to UL 1950, CSA 22.2 No. 950, EN 60950, IEC 60950, TS 001, AS/NZS 3260

CHAPTER 13

Configuring EtherChannels

This chapter describes how to configure EtherChannels on the Catalyst 6500 series switch Layer 2 or Layer 3 LAN ports.

Note

- For complete syntax and usage information for the commands used in this chapter, refer to the *Catalyst 6500 Series Switch Cisco IOS Command Reference* publication.
- The commands in the following sections can be used on all LAN ports in Catalyst 6500 series switches, including the ports on the supervisor engine and a redundant supervisor engine.
- Release 12.1(13)E and later releases support the IEEE 802.3ad Link Aggregation Control Protocol (LACP).
- The WS-X6548-GE-TX and WS-X6548V-GE-TX fabric-enabled switching modules do not support more than 1 Gbps of traffic per EtherChannel, except when the switch is operating in truncated mode.
- The WS-X6148-GE-TX and WS-X6148V-GE-TX switching modules do not support more than 1 Gbps of traffic per EtherChannel.

This chapter consists of these sections:

- Understanding How EtherChannels Work, page 13-1
- EtherChannel Feature Configuration Guidelines and Restrictions, page 13-5
- Configuring EtherChannels, page 13-6

Understanding How EtherChannels Work

These sections describe how EtherChannels work:

- EtherChannel Feature Overview, page 13-1
- Understanding How EtherChannels Are Configured, page 13-2
- Understanding Port Channel Interfaces, page 13-4
- Understanding Load Balancing, page 13-5

602
D

EtherChannel Feature Overview

An EtherChannel bundles individual Ethernet links into a single logical link that provides the aggregate bandwidth of up to eight physical links.

A Catalyst 6500 series switch supports a maximum of 64 EtherChannels (256 with Release 12.1(2)E and earlier). You can form an EtherChannel with up to eight compatibly configured LAN ports on any module in a Catalyst 6500 series switch. All LAN ports in each EtherChannel must be the same speed and must all be configured as either Layer 2 or Layer 3 LAN ports.

Note The network device to which a Catalyst 6500 series switch is connected may impose its own limits on the number of ports in an EtherChannel.

If a segment within an EtherChannel fails, traffic previously carried over the failed link switches to the remaining segments within the EtherChannel. When a failure occurs, the EtherChannel feature sends a trap that identifies the switch, the EtherChannel, and the failed link. Inbound broadcast and multicast packets on one segment in an EtherChannel are blocked from returning on any other segment of the EtherChannel.

Understanding How EtherChannels Are Configured

These sections describe how EtherChannels are configured:

- EtherChannel Configuration Overview, page 13-2
- Understanding Manual EtherChannel Configuration, page 13-3
- Understanding PAgP EtherChannel Configuration, page 13-3
- Understanding IEEE 802.3ad LACP EtherChannel Configuration, page 13-3

EtherChannel Configuration Overview

You can configure EtherChannels manually or you can use the Port Aggregation Control Protocol (PAgP) or, with Release 12.1(13)E and later, the Link Aggregation Control Protocol (LACP) to form EtherChannels. The EtherChannel protocols allow ports with similar characteristics to form an EtherChannel through dynamic negotiation with connected network devices. PAgP is a Cisco-proprietary protocol and LACP is defined in IEEE 802.3ad.

PAgP and LACP do not interoperate with each other. Ports configured to use PAgP cannot form EtherChannels with ports configured to use LACP. Ports configured to use LACP cannot form EtherChannels with ports configured to use PAgP.

Table 13-1 lists the user-configurable EtherChannel modes.

Table 13-1 EtherChannel Modes

Mode	Description
on	Mode that forces the LAN port to channel unconditionally. In the **on** mode, a usable EtherChannel exists only when a LAN port group in the **on** mode is connected to another LAN port group in the **on** mode. Because ports configured in the **on** mode do not negotiate, there is no negotiation traffic between the ports. You cannot configure the **on** mode with an EtherChannel protocol.
auto	PAgP mode that places a LAN port into a passive negotiating state, in which the port responds to PAgP packets it receives but does not initiate PAgP negotiation. (Default)
desirable	PAgP mode that places a LAN port into an active negotiating state, in which the port initiates negotiations with other LAN ports by sending PAgP packets.
passive	LACP mode that places a port into a passive negotiating state, in which the port responds to LACP packets it receives but does not initiate LACP negotiation. (Default)
active	LACP mode that places a port into an active negotiating state, in which the port initiates negotiations with other ports by sending LACP packets.

Understanding Manual EtherChannel Configuration

Manually configured EtherChannel ports do not exchange EtherChannel protocol packets. A manually configured EtherChannel forms only when you enter configure all ports in the EtherChannel compatibly.

Understanding PAgP EtherChannel Configuration

PAgP supports the automatic creation of EtherChannels by exchanging PAgP packets between LAN ports. PAgP packets are exchanged only between ports in **auto** and **desirable** modes.

The protocol learns the capabilities of LAN port groups dynamically and informs the other LAN ports. Once PAgP identifies correctly matched Ethernet links, it facilitates grouping the links into an EtherChannel. The EtherChannel is then added to the spanning tree as a single bridge port.

Both the **auto** and **desirable** modes allow PAgP to negotiate between LAN ports to determine if they can form an EtherChannel, based on criteria such as port speed and trunking state. Layer 2 EtherChannels also use VLAN numbers.

LAN ports can form an EtherChannel when they are in different PAgP modes if the modes are compatible. For example:

- A LAN port in **desirable** mode can form an EtherChannel successfully with another LAN port that is in **desirable** mode.
- A LAN port in **desirable** mode can form an EtherChannel with another LAN port in **auto** mode.
- A LAN port in **auto** mode cannot form an EtherChannel with another LAN port that is also in **auto** mode, because neither port will initiate negotiation.

Understanding IEEE 802.3ad LACP EtherChannel Configuration

Release 12.1(13)E and later releases support IEEE 802.3ad LACP EtherChannels. LACP supports the automatic creation of EtherChannels by exchanging LACP packets between LAN ports. LACP packets are exchanged only between ports in **passive** and **active** modes.

The protocol learns the capabilities of LAN port groups dynamically and informs the other LAN ports. Once LACP identifies correctly matched Ethernet links, it facilitates grouping the links into an EtherChannel. The EtherChannel is then added to the spanning tree as a single bridge port.

Both the **passive** and **active** modes allow LACP to negotiate between LAN ports to determine if they can form an EtherChannel, based on criteria such as port speed and trunking state. Layer 2 EtherChannels also use VLAN numbers.

LAN ports can form an EtherChannel when they are in different LACP modes as long as the modes are compatible. For example:

- A LAN port in **active** mode can form an EtherChannel successfully with another LAN port that is in **active** mode.
- A LAN port in **active** mode can form an EtherChannel with another LAN port in **passive** mode.
- A LAN port in **passive** mode cannot form an EtherChannel with another LAN port that is also in **passive** mode, because neither port will initiate negotiation.

LACP uses the following parameters:

- LACP system priority—You must configure an LACP system priority on each switch running LACP. The system priority can be configured automatically or through the CLI (see the "Configuring the LACP System Priority and System ID" section on page 13-9). LACP uses the system priority with the switch MAC address to form the system ID and also during negotiation with other systems.

  Note The LACP system ID is the combination of the LACP system priority value and the MAC address of the switch.

- LACP port priority—You must configure an LACP port priority on each port configured to use LACP. The port priority can be configured automatically or through the CLI (see the "Configuring Channel Groups" section on page 13-7). LACP uses the port priority with the port number to form the port identifier. LACP uses the port priority to decide which ports should be put in standby mode when there is a hardware limitation that prevents all compatible ports from aggregating.
- LACP administrative key—LACP automatically configures an administrative key value equal to the channel group identification number on each port configured to use LACP. The administrative key defines the ability of a port to aggregate with other ports. A port's ability to aggregate with other ports is determined by these factors:
  - Port physical characteristics, such as data rate, duplex capability, and point-to-point or shared medium
  - Configuration restrictions that you establish

On ports configured to use LACP, LACP tries to configure the maximum number of compatible ports in an EtherChannel, up to the maximum allowed by the hardware (eight ports). If LACP cannot aggregate all the ports that are compatible (for example, the remote system might have more restrictive hardware limitations), then all the ports that cannot be actively included in the channel are put in hot standby state and are used only if one of the channeled ports fails. You can configure an additional 8 standby ports (total of 16 ports associated with the EtherChannel).

Understanding Port Channel Interfaces

Each EtherChannel has a numbered port channel interface. Release 12.1(5)E and later releases support a maximum of 64 port channel interfaces, numbered from 1 to 256.

Note Releases 12.1(4)E1, 12.1(3a)E4, and 12.1(3a)E3 support a maximum of 64 port channel interfaces, numbered from 1 to 64. Releases 12.1(2)E and earlier support a maximum of 256 port channel interfaces, numbered from 1 to 256.

The configuration that you apply to the port channel interface affects all LAN ports assigned to the port channel interface.

After you configure an EtherChannel, the configuration that you apply to the port channel interface affects the EtherChannel; the configuration that you apply to the LAN ports affects only the LAN port where you apply the configuration. To change the parameters of all ports in an EtherChannel, apply the configuration commands to the port channel interface, for example, Spanning Tree Protocol (STP) commands or commands to configure a Layer 2 EtherChannel as a trunk.

Understanding Load Balancing

An EtherChannel balances the traffic load across the links in an EtherChannel by reducing part of the binary pattern formed from the addresses in the frame to a numerical value that selects one of the links in the channel.

EtherChannel load balancing can use MAC addresses or IP addresses. With a PFC2, EtherChannel load balancing can also use Layer 4 port numbers. EtherChannel load balancing can use either source or destination or both source and destination addresses or ports. The selected mode applies to all EtherChannels configured on the switch.

Use the option that provides the balance criteria with the greatest variety in your configuration. For example, if the traffic on an EtherChannel is going only to a single MAC address and you use the destination MAC address as the basis of EtherChannel load balancing, the EtherChannel always chooses the same link in the EtherChannel; using source addresses or IP addresses might result in better load balancing.

EtherChannel Feature Configuration Guidelines and Restrictions

When EtherChannel interfaces are configured improperly, they are disabled automatically to avoid network loops and other problems. To avoid configuration problems, observe these guidelines and restrictions:

- All Ethernet LAN ports on all modules, including those on a redundant supervisor engine, support EtherChannels (maximum of eight LAN ports) with no requirement that the LAN ports be physically contiguous or on the same module.
- Configure all LAN ports in an EtherChannel to use the same EtherChannel protocol; you cannot run two EtherChannel protocols in one EtherChannel.
- Configure all LAN ports in an EtherChannel to operate at the same speed and in the same duplex mode.
- LACP does not support half-duplex. Half-duplex ports in an LACP EtherChannel are put in the suspended state.

- Enable all LAN ports in an EtherChannel. If you shut down a LAN port in an EtherChannel, it is treated as a link failure and its traffic is transferred to one of the remaining ports in the EtherChannel.
- An EtherChannel will not form if one of the LAN ports is a Switched Port Analyzer (SPAN) destination port.
- For Layer 3 EtherChannels, assign Layer 3 addresses to the port channel logical interface, not to the LAN ports in the channel.
- For Layer 2 EtherChannels:
  - Assign all LAN ports in the EtherChannel to the same VLAN or configure them as trunks.
  - If you configure an EtherChannel from trunking LAN ports, verify that the trunking mode is the same on all the trunks. LAN ports in an EtherChannel with different trunk modes can operate unpredictably.
  - An EtherChannel supports the same allowed range of VLANs on all the LAN ports in a trunking Layer 2 EtherChannel. If the allowed range of VLANs is not the same, the LAN ports do not form an EtherChannel.
  - LAN ports with different STP port path costs can form an EtherChannel as long they are compatibly configured with each other. If you set different STP port path costs, the LAN ports are not incompatible for the formation of an EtherChannel.
  - An EtherChannel will not form if protocol filtering is set differently on the LAN ports.
- After you configure an EtherChannel, the configuration that you apply to the port channel interface affects the EtherChannel. The configuration that you apply to the LAN ports affects only the LAN port where you apply the configuration.
- With Release 12.1(12c)E1 and later releases, when QoS is enabled, enter the **no mls qos channel-consistency** port-channel interface command to support EtherChannels that have ports with and without strict-priority queues.

Configuring EtherChannels

These sections describe how to configure EtherChannels:

- Configuring Port Channel Logical Interfaces for Layer 3 EtherChannels, page 13-6
- Configuring Channel Groups, page 13-7
- Configuring EtherChannel Load Balancing, page 13-10

Note

- Make sure that the LAN ports are configured correctly (see the "EtherChannel Feature Configuration Guidelines and Restrictions" section on page 13-5).
- With Release 12.1(11b)E and later, when you are in configuration mode you can enter EXEC mode commands by entering the **do** keyword before the EXEC mode command.

Configuring Port Channel Logical Interfaces for Layer 3 EtherChannels

Note

- When configuring Layer 2 EtherChannels, you cannot put Layer 2 LAN ports into manually created port channel logical interfaces. If you are configuring a Layer 2 EtherChannel, do not perform the procedures in this section (see the "Configuring Channel Groups" section on page 13-7).
- When configuring Layer 3 EtherChannels, you must manually create the port channel logical interface as described in this section, and then put the Layer 3 LAN ports into the channel group (see the "Configuring Channel Groups" section on page 13-7).
- To move an IP address from a Layer 3 LAN port to an EtherChannel, you must delete the IP address from the Layer 3 LAN port before configuring it on the port channel logical interface.

To create a port channel interface for a Layer 3 EtherChannel, perform this task:

	Command	Purpose

Step 1	`Router(config)# interface port-channel number`
	`Router(config)# no interface port-channel number`
		Creates the port channel interface.
		Deletes the port channel interface.

Step 2	`Router(config-if)# ip address ip_address mask`	Assigns an IP address and subnet mask to the EtherChannel.
Step 3	`Router(config-if)# end`	Exits configuration mode.
Step 4	`Router# show running-config interface port-channel number`	Verifies the configuration.

When creating the port channel interface, the *group* number can be one of the following:

- Release 12.1(5)E and later—1 through 256, up to a maximum of 64 port channel interfaces
- Releases 12.1(4)E1, 12.1(3a)E4, and 12.1(3a)E3—1 through 64
- Release 12.1(2)E and earlier—1 through 256

This example shows how to create port channel interface 1:

```
Router# configure terminal
Router(config)# interface port-channel 1
Router(config-if)# ip address 172.32.52.10 255.255.255.0
Router(config-if)# end
```

This example shows how to verify the configuration of port channel interface 1:

```
Router# show running-config interface port-channel 1
Building configuration...

Current configuration:
!
interface Port-channel1
 ip address 172.32.52.10 255.255.255.0
 no ip directed-broadcast
end
Router#
```

Configuring Channel Groups

Note

- When configuring Layer 3 EtherChannels, you must manually create the port channel logical interface first (see the "Configuring Port Channel Logical Interfaces for Layer 3 EtherChannels" section on page 13-6), and then put the Layer 3 LAN ports into the channel group as described in this section.
- When configuring Layer 2 EtherChannels, configure the LAN ports with the **channel-group** command as described in this section, which automatically creates the port channel logical interface. You cannot put Layer 2 LAN ports into a manually created port channel interface.
- For Cisco IOS to create port channel interfaces for Layer 2 EtherChannels, the Layer 2 LAN ports must be connected and functioning.

To configure channel groups, perform this task for each LAN port:

	Command	Purpose
Step 1	`Router(config)# `**`interface`** *`type`*[1] *`slot/port`*	Selects a LAN port to configure.
Step 2	`Router(config-if)# `**`no ip address`**	Ensures that there is no IP address assigned to the LAN port.
Step 3	`Router(config-if)# `**`channel-protocol (lacp | pagp}`**	(Optional) On the selected LAN port, restricts the **channel-group** command to the EtherChannel protocol configured with the **channel-protocol** command.
	`Router(config-if)# `**`no channel-protocol`**	Removes the restriction.

Step 4	`Router(config-if)# `**`channel-group`** *`number`* **`mode`**
	`{active | auto | desirable | on | passive}`
		Configures the LAN port in a port channel and specifies the mode (see Table 13-1 on page 13-2). PAgP supports only the auto and desirable modes. LACP supports only the active and passive modes.

	`Router(config-if)# `**`no channel-group`**	Removes the LAN port from the channel group.

Step 5	`Router(config-if)# `**`lacp port-priority`**
	`priority_value`
		(Optional for LACP) Valid values are 1 through 65535. Higher numbers have lower priority. The default is 32768.

	`Router(config-if)# `**`no lacp port-priority`**	Reverts to the default.
Step 6	`Router(config-if)# `**`end`**	Exits configuration mode.

Step 7	`Router# `**`show running-config interface`** *`type`*[1]
	`slot/port`
	`Router# `**`show interfaces`** *`type`*[1] *`slot/port`*
	`etherchannel`
		Verifies the configuration.

[1] *type* = **ethernet, fastethernet, gigabitethernet,** or **tengigabitethernet**

This example shows how to configure Fast Ethernet ports 5/6 and 5/7 into port channel 2 with PAgP mode **desirable**:

```
Router# configure terminal
Router(config)# interface range fastethernet 5/6 -7
Router(config-if)# channel-group 2 mode desirable
Router(config-if)# end
```

Note See the "Configuring a Range of Interfaces" section on page 6-4 for information about the **range** keyword.

This example shows how to verify the configuration of port channel interface 2:

```
Router# show running-config interface port-channel 2
Building configuration...

Current configuration:
!
interface Port-channel2
 no ip address
 switchport
 switchport access vlan 10
 switchport mode access
end
Router#
```

This example shows how to verify the configuration of Fast Ethernet port 5/6:

```
Router# show running-config interface fastethernet 5/6
Building configuration...

Current configuration:
!
interface FastEthernet5/6
 no ip address
 switchport
 switchport access vlan 10
 switchport mode access
 channel-group 2 mode desirable
end
Router# show interfaces fastethernet 5/6 etherchannel
Port state     = Down Not-in-Bndl
Channel group = 12            Mode = Desirable-Sl     Gcchange = 0

Age of the port in the current state: 04d:18h:57m:19s
```

This example shows how to verify the configuration of port channel interface 2 after the LAN ports have been configured:

```
Router# show etherchannel 12 port-channel
                Port-channels in the group:
                ----------------------

Port-channel: Po12
------------

Age of the Port-channel   = 04d:18h:58m:50s
Logical slot/port   = 14/1          Number of ports = 0
GC                  = 0x00000000      HotStandBy port = null
Port state          = Port-channel Ag-Not-Inuse
Protocol            =   PAgP

Router#
```

Configuring the LACP System Priority and System ID

The LACP system ID is the combination of the LACP system priority value and the MAC address of the switch.

To configure the LACP system priority and system ID, perform this task:

	Command	Purpose
Step 1	`Router(config)# lacp system-priority priority_value`	(Optional for LACP) Valid values are 1 through 65535. Higher numbers have lower priority. The default is 32768.
	`Router(config)# no lacp system-priority`	Reverts to the default.
Step 2	`Router(config)# end`	Exits configuration mode.
Step 3	`Router# show lacp sys-id`	Verifies the configuration.

This example shows how to configure the LACP system priority:

```
Router# configure terminal
Router(config)# lacp system-priority 23456
Router(config)# end
Router(config)#
```

This example shows how to verify the configuration:

```
Router# show lacp sys-id
23456,0050.3e8d.6400
Router#
```

The system priority is displayed first, followed by the MAC address of the switch.

Configuring EtherChannel Load Balancing

To configure EtherChannel load balancing, perform this task:

	Command	Purpose
Step 1	`Router(config)# port-channel load-balance {src-mac | dst-mac | src-dst-mac | src-ip | dst-ip | src-dst-ip | src-port | dst-port | src-dst-port}`	Configures EtherChannel load balancing.
	`Router(config)# no port-channel load-balance`	Reverts to default EtherChannel load balancing.
Step 2	`Router(config)# end`	Exits configuration mode.
Step 3	`Router# show etherchannel load-balance`	Verifies the configuration.

The load-balancing keywords indicate the following information:

- With a PFC2:
  - **src-port**—Source Layer 4 port
  - **dst-port**—Destination Layer 4 port
  - **src-dst-port**—Source and destination Layer 4 port
- With a PFC or PFC2:
  - **src-ip**—Source IP addresses
  - **dst-ip**—Destination IP addresses
  - **src-dst-ip**—Source and destination IP addresses
  - **src-mac**—Source MAC addresses
  - **dst-mac**—Destination MAC addresses
  - **src-dst-mac**—Source and destination MAC addresses

This example shows how to configure EtherChannel to use source and destination IP addresses:

```
Router# configure terminal
Router(config)# port-channel load-balance src-dst-ip
Router(config)# end
Router(config)#
```

This example shows how to verify the configuration:

```
Router# show etherchannel load-balance
Source XOR Destination IP address
Router#
```

Apêndice EV

APPENDIX A

Command Reference

This appendix describes the Content Switching Module (CSM) commands that are unique to server load-balancing (SLB) and Layer 3 switching.

The following commands allow you to set up and monitor SLB on the CSM:

Command	Submode Command
dfp, page A-6	agent, page A-7 manager, page A-8
ft group, page A-9	failover, page A-10 heartbeat-time, page A-11 preempt, page A-12 priority, page A-13
ip slb mode, page A-14	
map cookie, page A-16	match protocol http cookie, page A-17
map dns, page A-19	match protocol dns domain, page A-20
map header, page A-21	match protocol http header, page A-22
map retcode, page A-24	match protocol http retcode, page A-25
map url, page A-26	match protocol http url, page A-27
module csm, page A-29	
natpool, page A-30	
owner, page A-31	address, page A-32 billing-info, page A-33 contact-info, page A-34 maxconns, page A-35

Command	Submode Command
policy, page A-36	client-group, page A-37 cookie-map, page A-38 header-map, page A-39 reverse-sticky, page A-40 reverse-sticky, page A-40 set ip dscp, page A-42 sticky-group, page A-43 url-map, page A-44
probe, page A-45	address (dns), page A-47 address (icmp), page A-48 credentials, page A-49 expect status, page A-50 failed, page A-52 header, page A-53 interval, page A-54 kal-ap-udp, page A-55 name, page A-56 open, page A-58 port, page A-57 receive, page A-59 request, page A-60 retries, page A-61
probe script, page A-62	script, page A-63 failed, page A-64 interval, page A-65 open, page A-66 receive, page A-67 retries, page A-68

dfp

Use the **dfp** command to enter the DFP submode and configure DFP. Use the **no** form of this command to remove the DFP configuration.

dfp [**password** *password* [*timeout*]]

no dfp

Syntax Description

password	(Optional) Keyword to specify a password for MD5 authentication.
password	(Optional) Password value for MD5 authentication. This password must be the same on all DFP manager devices.
timeout	(Optional) Delay period, in seconds, during which both the old password and the new password are accepted; the range is from 0 to 65535.

Defaults

The default timeout value is 180 seconds.

Command Modes

Module CSM configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.

Usage Guidelines

The timeout option allows you to change the password without stopping messages between the DFP agent and its manager.

During a timeout, the agent sends packets with the old password (or null, if there is no old password), and receives packets with either the old or new password. After a timeout expires, the agent sends and receives packets with only the new password; received packets that use the old password are discarded.

If you are changing the password for an entire load-balanced environment, set a longer timeout. The extended timeout allows enough time for you to update the password on all agents and servers before the timeout expires. It also prevents mismatches between agents and servers that have the new password and agents and servers that have the old password.

Examples

This example shows how to initiate DFP agent configuration mode, configure DFP, set the password to *flounder*, and configure a 60-second timeout:

```
SLB-Switch(config-module-csm)# dfp password flounder 60
```

Related Commands

show module csm dfp

agent

Use the **agent** command in the SLB DFP submode to configure the DFP agent to which the CSM is going to communicate. Use the **no** form of this command to remove the agent configuration.

agent *ip-address port* [*keepalive-timeout* [*retry-count* [*retry-interval*]]]

no agent *ip-address port*

Syntax Description

ip-address	IP address of the DFP agent.
port	Port number of the DFP agent.
keepalive-timeout	(Optional) Time period in seconds between keepalive messages; the range is from 1 to 65535.
retry-count	(Optional) Number of consecutive connection attempts or invalid DFP reports received before tearing down the connections and marking the agent as failed; the range is from 0 to 65535.
retry-interval	(Optional) Interval between retries; the range is from 1 to 65535.

Defaults

The *keepalive-timeout* default is 0 (no keepalive message).

Retry count default is 0 seconds (the default allows infinite retries).

The *retry-interval* default is 180 seconds.

Command Modes

SLB DFP configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.

Examples

This example shows how to initiate the DFP agent, configure a 350-second timeout, and configure the number of retries to 270:

```
SLB-Switch(config-slb-dfp)# agent 111.101.90.10 2 350 270
```

Related Commands

dfp
manager
show module csm dfp

manager

Use the **manager** command in SLB DFP submode to set the port where an external DFP can connect to the CSM. Use the **no** form of this command to remove the manager configuration.

manager *port*

no manager

Syntax Description

port	Port number.

Defaults

This command has no default settings.

Command Modes

SLB DFP configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.

Usage Guidelines

This command enables the CSM to listen to DFP connections from an external DFP manager.

Examples

This example shows how to set the DFP manager port:

```
SLB-Switch(config-slb-dfp)# manager 4
```

Related Commands

dfp
agent
show module csm dfp

ft group

Use the **ft group** command to enter the fault-tolerant configuration submode and configure fault tolerance. Use the **no** form of this command to remove the fault-tolerant configuration.

ft group *group-id* **vlan** *vlan-id*

no ft group

Syntax Description

group-id	ID of the fault-tolerant group. Both CSMs must have the same group ID. The range is from 1 to 254.
vlan	Keyword to specify a VLAN ID.
vlan-id	ID of the VLAN over which heartbeat messages are sent. Both CSMs must have the same VLAN ID. The range is from 2 to 4095.

Defaults

This command has no default settings.

Command Modes

Module CSM configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.

Usage Guidelines

A fault-tolerant group is comprised of two Catalyst 6500 series switches each containing a CSM configured for fault-tolerant operation. Each fault-tolerant group appears to network devices as a single device. A network may have more than one fault-tolerant group.

Examples

This example shows how to configure a fault-tolerant group named 123 on VLAN 5:

```
SLB-Switch(config-module-csm)# ft group 123 vlan 5
```

Related Commands

failover
heartbeat-time
preempt
priority
show module csm ft

failover

Use the **failover** command in the SLB fault-tolerant configuration submode to set the time for a standby CSM to wait before becoming an active CSM. Use the **no** form of this command to remove the failover configuration.

failover *failover-time*

no failover

Syntax Description

failover-time	Amount of time the CSM must wait after the last heartbeat message is received before assuming the other CSM is not operating; the range is from 1 to 65535.

Defaults

The default failover time is 3 seconds.

Command Modes

SLB fault-tolerant configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.

Examples

This example shows how to set a failover period of 6 seconds:

```
SLB-Switch(config-slb-ft)# failover 6
```

Related Commands

ft group
show module csm ft

heartbeat-time

Use the **heartbeat-time** command in the SLB fault-tolerant configuration submode to set the time before heartbeat messages are transmitted by the CSM. Use the **no** form of this command to restore the default heartbeat interval.

heartbeat-time *heartbeat-time*

no heartbeat-time

Syntax Description

heartbeat-time	Time interval between heartbeat transmissions in seconds; the range is from 1 to 65535.

Defaults

The default heartbeat time is 1 second.

Command Modes

SLB fault-tolerant configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.

Examples

This example shows how to set the heartbeat time to 2 seconds:

```
SLB-Switch(config-slb-ft)# heartbeat-time 2
```

Related Commands

ft group
show module csm ft

6000.

preempt

Use the **preempt** command in the SLB fault-tolerant configuration submode to allow a higher priority CSM to take control of a fault-tolerant group when it comes online. Use the **no** form of this command to restore the preempt default value.

preempt

no preempt

Syntax Description

This command has no arguments or keywords.

Defaults

The default value is that preempt is not specified.

Command Modes

SLB fault-tolerant configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.

Usage Guidelines

When you enable preempt, the higher priority CSM preempts the other CSM in the fault-tolerant group when the higher priority CSM comes online. When you enable no preempt, the current primary CSM remains the primary CSM when the next CSM comes online.

Note You must set both members of the fault-tolerant CSM pair to preempt for this feature to work.

Examples

This example shows how to set the fault-tolerance mode to preempt:

```
SLB-Switch(config-slb-ft)# preempt
```

Related Commands

ft group
priority
show module csm ft

priority

Use the priority command in the SLB fault-tolerant configuration submode to set the priority of the CSM. Use the **no** form of this command to restore the priority default value.

priority *value*

no priority

Syntax Description

value	Priority of a CSM; the range is from 1 to 254.

Defaults

The default priority value is 10.

Command Modes

SLB fault-tolerant configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.

Usage Guidelines

The CSM with the largest priority value is the primary CSM in the fault-tolerant pair when the modules are both operating.

Examples

This example shows how to set the priority value to 12:

```
SLB-Switch(config-slb-ft)# priority 12
```

Related Commands

ft group
preempt
show module csm ft

ip slb mo e

Use the **ip slb mode** command to configure the switch to operate as a CSM load-balancing device instead of a Cisco IOS SLB load-balancing device. Use the **no** form of this command to remove the **mode** configuration.

ip slb mode {**csm** | **rp**}

no ip slb mode

No pecifying the **no ip slb mode** command is the same as specifying the **rp** mode.

Syntax Descriptim

	Keyword to select the CSM load-balancing mode that allows you to configure a single CSM only and prohibits the use of Cisco IOS SLB load-balancing on the Catalyst 6500 series switch.
	Keyword to select the route processor (Cisco IOS SLB) load-balancing mode and enable module CSM commands for configuring multiple CSMs.

Defaults

default is the **rp** mode.

Command Mo

al configuration submode.

Command Hi ase

	Modification
1)	This command was introduced.
1)	This command now enables **module csm** commands for the **rp** mode.

Usage Guide

s command allows you to change from the Cisco IOS SLB load-balancing mode to the CSM l-balancing mode.

csm mode, all **ip slb** commands apply to a CSM module; Cisco IOS SLB is not available. In **rp** mode e default), **ip slb** commands apply to Cisco IOS SLB; the **module csm** commands are available to nfigure multiple CSMs.

Examples

is example shows how to configure the switch mode:

```
B-Switch(config)# ip slb mode csm
```

Related Commands

module csm
show ip slb mode

map cookie

Use the **map cookie** command to create a cookie map and enter the cookie map configuration submode for specifying cookie match rules. Use the **no** form of this command to remove the cookie maps from the configuration.

map *cookie-map-name* **cookie**

no map *cookie-map-name*

Syntax Description

cookie-map-name	Cookie map instance; the character string is limited to 15 characters.
cookie	Keyword to enter the cookie map submode.

Defaults

This command has no default settings.

Command Modes

Module CSM configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.

Examples

This example shows how to create a cookie map:

```
SLB-Switch(config-module-csm)# map upnready cookie
```

Related Commands

cookie-map (SLB policy configuration submode)
match protocol http cookie
show module csm map

match protocol http cookie

Use the **match protocol http cookie** command in SLB cookie map configuration submode to add cookies to a cookie map. Multiple match rules can be added to a cookie map. Use the **no** form of this command to remove the cookie map name from the cookie map.

match protocol http cookie *cookie-name* **cookie-value** *cookie-value-expression*

Syntax Descriptionn

cookie-name	Cookie name; the range is from 1 to 63 characters.
cookie-value	Keyword to specify a cookie value expression.
cookie-value-expression	Cookie value expression string; the range is from 1 to 255 characters.

Defaults

This command has no default settings.

Command Modes

SLB cookie map configuration submode.

Usage Guidelines

Cookie regular expressions are based on the UNIX filename specification. URL expressions are stored in a cookie map in the form *cookie-name* = *cookie-value-expression*. Cookie expressions allow spaces provided they are escaped or quoted. You must match all cookies in the cookie map.

"*" means zero or more characters

"?" means exactly one character—the [Ctrl + V] key combination must be entered

"\" means escaped character

Bracketed range (for example, [0–9]) means matching any single character from the range

A leading ^ in a range means do not match any in the range

".\a" means alert (ASCII 7)

".\b" means backspace (ASCII 8

".\f" means form-feed (ASCII 12)

".\n" means newline (ASCII 10)

".\r" means carriage return (ASCII 13)

".\t" means tab (ASCII 9)

".\v" means vertical tab (ASCII 11)

".\0" means null (ASCII 0)

".\\" means backslash

".\x##" means any ASCII character as specified in two-digit hexadecimal notation

Command History

Release	Modification
1.1(1)	This command was introduced.

Examples

This example shows how to add cookies to a cookie map:

```
SLB-Switch(config-slb-map-cookie)# match protocol http cookie albert cookie-value 4*
```

Related Commands

cookie-map (SLB policy configuration submode)
map cookie

map dns

Use the **map dns** command to enter the SLB DNS map mode and configure a DNS map. Use the **no** form of this command to remove the DNS map from the configuration.

map *dns-map-name* **dns**

no map *dns-map-name*

Syntax Description

dns-map-name	Name of an SLB dns map; the character string range is from 1 to 15 characters.

Defaults

This command has no default settings.

Command Modes

SLB DNS map configuration submode.

Command History

Release	Modification
3.1(1)	This command was introduced.

Usage Guidelines

Any match of a DNS regular expression in the DNS map results in a successful match. A maximum of 1023 DNS domains can be configured to a map.

Examples

This example shows how to group DNS domains:

```
SLB-Switch(config-module-csm)# map m1 dns
SLB-Switch(config-slb-map-url)# exit
SLB-Switch(config)
```

Related Commands

match protocol dns domain
show module csm map

match protocol dns domain

Use the **match protocol dns domain** command in the SLB DNS map configuration submode to add a DNS domain to a DNS map. Use the **no** form of this command to remove the DNS domain from the URL map.

match protocol dns domain *name*

no match protocol dns domain *name*

Syntax Description

name	Names the DNS domain being mapped..

Defaults

This command has no default settings.

Command Modes

SLB DNS map configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.
3.1(1)	HTTP method parsing support was introduced.

Examples

This example shows how to adds URL expressions to a URL map:

```
SLB-Switch(config-slb-map-url)# match protocol http url Host header-value :XYZ
```

Related Commands

map dns
show module csm map

map header

Use the **map header** command to create a map group for specifying HTTP headers and enter the header map configuration submode. Use the **no** form of this command to remove the HTTP header group from the configuration.

map *name* **header**

no map *name*

Syntax Description

name	Map instance; the character string is from 1 to 15 characters.

Defaults

This command has no default settings.

Command Modes

Module CSM configuration submode.

Command History

Release	Modification
2.1(1)	This command was introduced.

Examples

This example shows how to group HTTP headers and associate them with a Content Switching policy:

```
SLB-Switch(config-module-csm)# map upnready header
SLB-Switch(config-slb-map-header)# match protocol http header Accept header-value *jpeg*
SLB-Switch(config-slb-map-header)# match protocol http header User-Agent header-value *NT*
SLB-Switch(config-slb-map-header)# match protocol http header Host header-value
www.myhome.com
SLB-Switch(config-slb-map-header)# exit
```

Related Commands

header-map (SLB policy configuration submode)
match protocol http header
show module csm map

match protocol http header

Use the **match protocol http header** command in SLB header map configuration submode to specify header fields and values for the CSM to search for when receiving a request. Multiple match rules can be added to a header map. Use the **no** form of this command to remove the header match rule from the header map.

match protocol http header *field* **header-value** *expression*

no match protocol http header *field*

Syntax Description

field	Literal name of the generic field in the HTTP header. The range is from 1 to 63 characters.
header-value	Keyword to specify the header value expression.
expression	Header value regular expression string to compare against the value in the specified field; the range is from 1 to 127 characters.

Defaults

This command has no default settings.

Command Modes

SLB header map configuration submode.

Usage Guidelines

There are predefined fields, for example Accept-Language, User-Agent, or Host.

Header regular expressions are based on the UNIX filename specification. URL expressions are stored in a header map in the form *header-name* = *expression*. Header expressions allow spaces provided that they are escaped or quoted. All headers in the header map must be matched.

"*" means zero or more characters

"?" means exactly one character—the [Ctrl + V] key combination must be entered

"\" means escaped character

Bracketed range (for example, [0–9]) means matching any single character from the range

A leading ^ in a range means don't match any in the range

".\a" means alert (ASCII 7)

".\b" means backspace (ASCII 8

".\f" means form-feed (ASCII 12)

".\n" means newline (ASCII 10)

".\r" means carriage return (ASCII 13)

".\t" means tab (ASCII 9)

".\v" means vertical tab (ASCII 11)

".\0" means null (ASCII 0)

".\\" means backslash

".\x##" means any ASCII character as specified in two-digit hexadecimal notation

Command History

Release	Modification
2.1(1)	This command was introduced.

Examples

This example shows how to specify header fields and values to search upon a request:

```
SLB-Switch(config-slb-map-header)# match protocol http header Host header-value XYZ
```

Related Commands

header-map (SLB policy configuration submode)

map retcode

Use the **map retcode** command to enable return error code checking and enter the return error code map submode. Use the **no** form of this command to remove the return code error checking from the configuration.

map *name* **retcode**

no map *name*

Syntax Description

name	Return error code map instance; the character string is limited to 15 characters.
retcode	Keyword to enter the return error code map submode.

Defaults

This command has no default settings.

Command Modes

Global configuration submode.

Command History

Release	Modification
2.2(1)	This command was introduced.

Examples

This example shows how to enable return error code checking:

```
SLB-Switch(config-module-csm)# map upnready retcode
```

Related Commands

cookie-map (SLB policy configuration submode)
match protocol http cookie
show module csm map

match protocol http retcode

Use the **match protocol http retcode** command in SLB return code map configuration submode to specify return code thresholds, count and log return codes, and send syslog messages for return code events received from the servers. Use the **no** form of this command to remove the return code thresholds.

match protocol http retcode *min max* **action** {**count** | **log** | **remove**} *threshold* [**reset** *seconds*]

no match protocol http retcode *min max*

Syntax Description

min	Minimum number of return codes received before an action is taken.
max	Maximum number of return codes received before an action is taken.
action	Keyword to enable the header value expression.
count	Keyword to increment the statistics of the number of occurrences of return codes received.
log	Keyword to specify where syslog messages are sent when a threshold is reached.
remove	Keyword to specify where the syslog messages are sent when a threshold is reached and the server is removed from service.
threshold	The number of return occurrences before the log or remove action is taken.
reset	(Optional) Keyword to enable the header value expression.
seconds	Number of seconds to wait before the action can take place again.

Defaults

This command has no default settings.

Command Modes

SLB return code map configuration submode.

Usage Guidelines

The *threshold* and **reset** values are not configurable for the **count** action. These commands only are available for the **log** and **remove** actions.

Command History

Release	Modification
2.2(1)	This command was introduced.

Examples

This example shows how to specify return codes values to search for in an HTTP request:

```
SLB-Switch(config-slb-map-retcode)# match protocol http quigly retcode 30 50 action log
400 reset 30
```

Related Commands

map url

Use the **map url** command to enter the SLB URL map mode and configure a URL map. Use the **no** form of this command to remove the URL map from the configuration.

map *url-map-name* **url**

no map *url-map-name*

Syntax Description

url-map-name	Name of an SLB URL map; the character string range is from 1 to 15 characters.

Defaults

This command has no default settings.

Command Modes

SLB URL map configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.

Usage Guidelines

Any match of a URL regular expression in the URL map results in a successful match. A maximum of 1023 URLs can be configured to a map.

Examples

This example shows how to group URLs and associate them with a Content Switching policy:

```
SLB-Switch(config-module-csm)# map m1 url
SLB-Switch(config-slb-map-url)# match protocol http url /index.html
SLB-Switch(config-slb-map-url)# match protocol http url /stocks/csco/
SLB-Switch(config-slb-map-url)# match protocol http url *gif
SLB-Switch(config-slb-map-url)# match protocol http url /st*
SLB-Switch(config-slb-map-url)# exit
SLB-Switch(config)
```

Related Commands

match protocol http url
url-map (SLB policy configuration submode)

match protocol http url

Use the **match protocol http url** command in the SLB URL map configuration submode to add a URL regular expression to a URL map. Multiple match rules can be added to a URL map. Use the **no** form of this command to remove the URL regular expression from the URL map.

match protocol http [**method** *method-expression*] **url** *url-expression*

no match protocol http url [**method** *method-expression*] **url** *url-expressionn*

Syntax Description

method	(Optional) Keyword to specify the method in incoming HTTP requests.
method-expression	Specifies the method expression to match.
url	Keyword to specify the URL in incoming HTTP requests.
url-expression	Regular expression range; the range is from 1 to 255 characters.

Defaults

This command has no default settings.

Command Modes

SLB URL map configuration submode.

Usage Guidelines

URL regular expressions are based on the UNIX filename specification. URL expressions are stored in a cookie map in the form *urln*. URL expressions do not allow spaces and only one of the URLs in the map must be matched.

"*" means zero or more characters

"?" means exactly one character—the [Ctrl + V] key combination must be entered

"\" means escaped character

Bracketed range (for example, [0–9]) means matching any single character from the range

A leading ^ in a range means don't match any in the range

".\a" means alert (ASCII 7)

".\b" means backspace (ASCII 8

".\f" means form-feed (ASCII 12)

".\n" means newline (ASCII 10)

".\r" means carriage return (ASCII 13)

".\t" means tab (ASCII 9)

".\v" means vertical tab (ASCII 11)

".\0" means null (ASCII 0)

".\\" means backslash

".\x##" means any ASCII character as specified in two-digit hexadecimal notation

The method expression may be either one of the standard HTTP 1.1 method names (OPTIONS, GET, HEAD, POST, PUT, DELETE, TRACE, or CONNECT) or a string you specify that must be matched exactly (PROTOPLASM).

Command History

Release	Modification
1.1(1)	This command was introduced.
3.1(1)	HTTP method parsing support was introduced.

Examples

This example shows how to adds URL expressions to a URL map:

```
SLB-Switch(config-slb-map-url)# match protocol http url Host header-value XYZ
```

Related Commands

5323
D.

module csm

Use the **module csm** command to allow the association of load-balancing commands to a specific CSM module and enter the CSM module configuration submode for the specified slot. Use the **no** form of this command to remove the **module csm** configuration.

Note The **module ContentSwitching Module** *slot* command is the full syntax; the **module csm** *slot* command is a valid shortcut.

module csm *slot-number*

no module csm *slot-number*

Syntax Description

slot-number	Slot number where the CSM resides.

Defaults

This command has no default settings.

Command Modes

Global configuration submode.

Command History

Release	Modification
2.1(1)	This command was introduced.

Usage Guidelines

If you want to use the new multiple module configuration, you must change the **ip slb mode** command to **rp**. An existing CSM configuration is migrated to the new configuration when you change the mode from **csm** to **rp**. A prompt appears requesting a slot number. Migrating from a multiple module configuration to a single module configuration is supported. Migrating the Cisco IOS SLB configuration to the CSM configuration is not supported.

Examples

This example shows how to configure a CSM:

```
SLB-Switch(config)# module csm 5
SLB-Switch(config-module-csm)# vserver VS1
```

Related Commands

ip slb mode

natpool

Use the **natpool** command in module CSM configuration submode to configure NAT and create a client address pool. Use the **no** form of this command to remove a **natpool** configuration.

natpool *pool-name start-ip end-ip* {**netmask** *netmask* | **prefix-length** *leading_1_bits*}

no natpool *pool-name*

Syntax Description

pool-name	Name of a client address pool; the character string is from 1 to 15 characters.
start-ip	Starting IP address that defines the range of addresses in the address pool.
end-ip	Ending IP address that defines the range of addresses in the address pool.
netmask	(Optional) Keyword to specify the subnet mask.
netmask	(Optional) Mask for the associated IP subnet.
prefix-length	(Optional) Keyword to specify the subnet mask.
leading_1_bits	(Optional) Mask for the associated IP subnet.

Defaults

This command has no default settings.

Command Modes

Module CSM configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.

Usage Guidelines

If you want to use client NAT, you must create at least one client address pool.

A maximum of 255 NAT pool addresses are available for any CSM.

Examples

This example shows how to configure a pool of addresses with the name **web-clients**, an IP address range from 128.3.0.1 through 128.3.0.254, and a subnet mask of 255.255.0.0:

```
SLB-Switch(config-module-csm)# natpool web-clients 128.3.0.1 128.3.0.254 netmask
255.255.0.0
```

Related Commands

nat client (SLB serverfarm configuration submode)
show module csm natpool

owner

Use the **owner** command in module CSM configuration submode to configure an owner object. Use the **no** form of this command to remove an **owner** configuration.

owner *name*

no owner

Syntax Description

name	Name of the object owner.

Defaults

This command has no default settings.

Command Modes

Module CSM configuration submode.

Command History

Release	Modification
3.1(1)	This command was introduced.

Usage Guidelines

You can define more than one virtual server with the same virtual IP address (VIP) and set the VIP connection watermark level to apply to a single VIP, which may correspond to multiple virtual servers. With the **owner** command, any virtual server has either zero or one owners. A particular owner can be associated with multiple virtual servers (typically, but not necessarily, with the same VIP). The VIP connection watermark applies to a specific owner. Once the sum of the number of open connections to all virtual servers in a particular owner reaches the VIP connection watermark level for that owner, new connections to any of these virtual servers are rejected by the CSM.

Examples

This example shows how to configure an owner object:

```
SLB-Switch(config-module-csm)# owner sequel
```

billing-info

Use the **billing-info** command in the owner configuration submode to configure billing information for an owner object. Use the **no** form of this command to remove an billing information from the configuration.

billing-info *billing-address-information*

no billing-info

Syntax Description

billing-info	Keyword to specify the owner's billing address.
billing-address-information	The owner's billing address.

Defaults

This command has no default settings.

Command Modes

Module CSM configuration submode.

Command History

Release	Modification
3.1(1)	This command was introduced.

Examples

This example shows how to configure an owner object:

```
SLB-Switch(config-owner)# billing-info 300 cordera avenue
```

Related Commands

owner
address

contact-info

Use the **contact-info** command in owner configuration submode to configure an email address for an owner object. Use the **no** form of this command to remove the contact information from the **owner** configuration.

contact-info *string*

no contact-info

Syntax Description

string	The owner's information.

Defaults

This command has no default settings.

Command Modes

Module CSM configuration submode.

Command History

Release	Modification
3.1(1)	This command was introduced.

Examples

This example shows how to configure an owner object:

```
SLB-Switch(config-owner)# contact-info shaggy@angel.net
```

Related Commands

policy

Use the **policy** command to configure policies, associate attributes to a policy, and enter the policy configuration submode. In this submode, you can configure the policy attributes. The policy is associated with a virtual server in virtual server submode. Use the **no** form of this command to remove a **policy**.

policy *policy-name*

no policy *policy-name*

Syntax Description

policy-name	Name of an slb-policy instance; the character string is limited to 15 characters.

Defaults

This command has no default settings.

Command Modes

Module CSM configuration submode.

Command History

Release	Modification
1(1)	This command was introduced.

Usage Guidelines

licies establish rules for balancing connections to servers. They can contain URL maps, cookie maps, ader maps, client groups, sticky groups, DSCP values, and server farms. The order in which policies linked to a virtual server determines the precedence of the policy. When two or more policies match equested URL, the policy with the highest precedence is selected.

u can create up to 12287 SLB policies for a given CSM module.

Note policies should be configured with a server farm.

Examples

example shows how to configure a policy named policy_content:

```
Switch(config-module-csm)# policy policy_content
Switch(config-slb-policy)# serverfarm new_serverfarm
Switch(config-slb-policy)# url-map url_map_1
Switch(config-slb-policy)# exit
```

Related Commands

licy (SLB virtual server configuration submode)
nodule csm owner

client-group

Use the **client-group** command in SLB policy configuration submode to associate an access list with the policy. Use the **no** form of this command to remove access list from the policy.

client-group {*1-99* | *std-access-list-name*}

no client-group

Syntax Description

1-99	Standard IP access list number.
std-access-list-name	Standard access list name.

Defaults

This command has no default settings.

Command Modes

SLB policy configuration submode.

Command History

Release	**Modification**
1.1(1)	This command was introduced.

Usage Guidelines

Only client groups created with the **ip access-list standard** command can be associated with an SLB policy. Only one client-group can be associated with a given SLB policy.

Examples

This example shows how to configure a client group:

```
SLB-Switch(config-slb-policy)# client-group 44
SLB-Switch(config-slb-policy)# exit
```

Related Commands

policy
ip access-list standard
show module csm owner

cookie-map

Use the **cookie-map** command in SLB policy configuration submode to associate a list of cookies with a policy. Use the **no** form of this command to remove a cookie map.

cookie-map *cookie-map-name*

no cookie-map

Syntax Description

cookie-map-name	Name of the cookie list associated with a policy.

Defaults

This command has no default settings.

Command Modes

SLB policy configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.

Usage Guidelines

Only one cookie map can be associated with a policy. Cookie maps are configured using the **map cookie** command. The cookie map name must match the name specified in the **map cookie** command.

Examples

This example shows how to configure a cookie-based SLB policy named policy_content:

```
SLB-Switch(config-module-csm)# policy policy_content
SLB-Switch(config-slb-policy)# serverfarm new_serverfarm
SLB-Switch(config-slb-policy)# cookie-map cookie-map-1
SLB-Switch(config-slb-policy)# exit
SLB-Switch(config)
```

Related Commands

policy
map cookie
show module csm owner

header-map

Use the **header-map** command in SLB policy configuration submode to specify the HTTP header criteria to include in a policy. Use the **no** form of this command to remove a header map.

Note If any HTTP header information is matched, the policy rule is satisfied.

header-map *name*

no header-map

Syntax Description

name	Name of the previously configured HTTP header expression group.

Defaults

This command has no default settings.

Command Modes

SLB policy configuration submode.

Command History

Release	Modification
2.1(1)	This command was introduced.

Usage Guidelines

Only one header map can be associated with a policy. The header map name must match the name specified in the **map header** command on page A-18.

Examples

This example shows how to configure a header-based policy named policy_content:

```
SLB-Switch(config-module-csm)# policy policy_content
SLB-Switch(config-slb-policy)# serverfarm new_serverfarm
SLB-Switch(config-slb-policy)# header-map header-map-1
SLB-Switch(config-slb-policy)# exit
```

Related Commands

policy

show module csm owner

reverse-sticky

Use the **reverse-sticky** command to ensure that the CSM switches connections in the opposite direction back to the original source. Use the **no** form of this command to remove the reverse-sticky option from the policy or the default-policy of a virtual server.

reverse-sticky *group-id*

no reverse-sticky

Syntax Description

group-id	Number identifying the sticky group to which the virtual server belongs; the range is from 0 to 255.

Defaults

The default is **no reverse-sticky**. Sticky connections are not tracked.
The group ID default is 0. The sticky feature is not used for other virtual servers.
The network default is 255.255.255.255.

Command Modes

SLB virtual server configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.
3.1(1)	The **IP reverse-sticky** command is introduced.

Examples

This example shows how to set the IP reverse-sticky feature:

```
SLB-Switch(config-module-csm)# vserver PUBLIC_HTTP
SLB-Switch(config-slb-vserver)# reverse-sticky 60
```

Related Commands

serverfarm

Use the **serverfarm** command in the SLB policy configuration submode to associate a server farm with a policy. Use the **no** form of this command to remove the server farm from the policy.

serverfarm *primary-serverfarm* [**backup** *sorry-serverfarm* [**sticky**]]

no serverfarm

Syntax Description

primary-serverfarm	Character string used to identify the server farm.
backup	(Optional) Keyword set the name of a backup serverfarm.
sorry-serverfarm	(Optional) Backup serverfarm name.
sticky	(Optional) Keyword to associate the backup serverfarm with a virtual server.

Defaults

This command has no default settings.

Command Modes

SLB policy configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.
3.1(1)	The sorry server (backup server) option was added to this command.

Usage Guidelines

Use the **serverfarm** command to configure the server farm. Only one server farm can be configured per policy. The server farm name must match the name specified in the **serverfarm** module CSM configuration submode command. By default, the sticky option does not apply to the backup serverfarm. To remove the backup serverfarm, you can either use the serverfarm command without the backup option or use the **no serverfarm** command.

Examples

This example shows how to associate a server farm named central with a policy:

```
SLB-Switch(config-module-csm)# policy policy
SLB-Switch(config-slb-policy)# serverfarm central backup domino sticky
```

Related Commands

set ip dscp

Use the **set ip dscp** command in the SLB policy configuration submode to mark packets that match the policy with a DSCP value. Use the **no** form of this command to stop marking packets.

set ip dscp *dscp-value*

no set ip dscp

Syntax Description

dscp-value	The range is from 0 to 63.

Defaults

The default is that the CSM does not store DSCP values.

Command Modes

SLB policy configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.

Examples

This example shows how to mark packets to match a policy named policy_content:

```
SLB-Switch(config-module-csm)# policy policy_content
SLB-Switch(config-slb-policy)# set ip dscp 22
```

Related Commands

policy
show module csm owner

sticky-group

Use the **sticky-group** command in the SLB policy configuration submode to associate a sticky group and the sticky group attributes to the policy. Use the **no** form of this command to remove the sticky group from the policy.

sticky-group *group-id*

no sticky-group

Syntax Description

group-id	ID of the sticky group to be associated with a policy.

Defaults

The default is 0, which means that no connections are sticky.

Command Modes

SLB policy configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.

Usage Guidelines

The *group-id* must match the ID specified in the **sticky** command; the range is from 1 to 255.

Examples

This example shows how to configure a sticky group:

```
SLB-Switch(config-module-csm)# policy policy1
SLB-Switch(config-slb-policy)# sticky-group 5
```

Related Commands

url-map

Use the **url-map** command in SLB policy configuration submode to associate a list of URLs with the policy. Use the **no** form of this command to remove the URL map from the policy.

url-map *url-map-name*

no url-map

Syntax Description

url-map-name	Name of the URL list to be associated with a policy.

Defaults

The default is no URL map.

Command Modes

SLB policy configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.

Usage Guidelines

Only one URL map can be associated with a policy. URL maps are configured using the **map url** command.

Examples

This example shows how to associate a list of URLs with a policy named assembly:

```
SLB-Switch(config-module-csm)# policy policy
SLB-Switch(config-slb-policy)# url-map assembly
```

Related Commands

policy
map url
show module csm owner

probe

Use the **probe** command to configure a probe and probe type for health monitoring and to enter the probe configuration submode. Use the **no** form of this command to remove a probe from the configuration.

probe *probe-name* {**http** | **icmp** | **telnet** | **tcp** | **ftp** | **smtp** | **dns** | **kal-ap-upd**}

no probe *probe-name*

Syntax Description

probe-name	Name of the probe; the character string is limited to 15 characters.
http	Keyword to create an HTTP probe with a default configuration.
icmp	Keyword to create an ICMP probe with a default configuration.
telnet	Keyword to create a Telnet probe with a default configuration.
tcp	Keyword to create a TCP probe with a default configuration.
ftp	Keyword to create an FTP probe with a default configuration.
smtp	Keyword to create an SMTP probe with a default configuration.
dns	Keyword to create a DNS probe with a default configuration.
kal-ap-udp	Keyword to create a GSLB target probe.

Defaults

This command has no default settings.

Command Modes

Module CSM configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.

Usage Guidelines

A probe can be assigned to a server farm in serverfarm submode.

When configuring kal-ap-udp type probes, the **port** submode command is not used to specify the destination UDP port to query. Use theCSM environment variable GSLB_KALAP_UDP_PORT instead. The default is port 5002.

Also, to specify probe frequency and the number of retries for KAL-AP, ICMP, HTTP and DNS probes when associated with a GSLB serverfarm environment, the following variables must be used instead of the probe submode commands:

```
GSLB_KALAP_PROBE_FREQ          10
GSLB_KALAP_PROBE_RETRIES       3
GSLB_ICMP_PROBE_FREQ           10
GSLB_ICMP_PROBE_RETRIES        3
GSLB_HTTP_PROBE_FREQ           10
GSLB_HTTP_PROBE_RETRIES        2
GSLB_DNS_PROBE_FREQ            10
GSLB_DNS_PROBE_RETRIES         3
```

5966
D

Examples

This example shows how to configure an HTTP probe named TREADER:

```
SLB-Switch(config-module-csm)# probe TREADER http
```

Related Commands

probe (SLB serverfarm configuration submode)
show module csm probe

address (dns)

Use the **address** command in SLB DNS probe configuration submode to specify an IP address of the real server used by DNS to resolve requests. Use the **no** form of this command to remove the address.

address *ip-address*

no address *ip-address*

Syntax Description

ip-address	Real server IP address.

Defaults

This command has no default settings.

Command Modes

SLB DNS probe configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.

Usage Guidelines

Multiple addresses can be configured for a DNS probe.

Examples

This example shows how to configure an IP address of the DNS server:

```
SLB-Switch(config-slb-probe-dns)# address 101.23.45.36
```

Related Commands

probe
address (icmp)
show module csm probe

address (icmp)

Use the **address** command in SLB ICMP probe configuration submode to specify a destination IP address for health monitoring. Use the **no** form of this command to remove the address.

address *ip-address*

no address

Syntax Description

ip-address	Real server IP address.

Defaults

This command has no default settings.

Command Modes

SLB ICMP probe configuration submode.

Command History

Release	Modification
2.1(1)	This command was introduced.

Usage Guidelines

One address can be configured for an ICMP probe.

Examples

This example shows how to configure an IP address of the real server:

```
SLB-Switch(config-slb-probe-icmp)# address 101.23.45.36
```

Related Commands

probe
address (dns)
show module csm probe

credentials

Use the **credentials** command in the SLB HTTP probe configuration submode to configure basic authentication values for an HTTP probe. Use the **no** form of this command to remove the credentials configuration.

credentials *username* [*password*]

no credentials

Syntax Description

username	Name that appears in the HTTP header.
password	(Optional) Password that appears in the HTTP header.

Defaults

This command has no default settings.

Command Modes

SLB HTTP probe configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.

Usage Guidelines

This command is for HTTP probes.

Examples

This example shows how to configure authentication for an HTTP probe:

```
SLB-Switch(config-slb-probe-http)# credentials seamless abercrombie
```

Related Commands

probe
show module csm probe

expect status

Use the **expect status** command in the SLB HTTP/FTP/Telnet/SMTP probe configuration submode to configure a status code for the probe. Use the **no** form of this command to remove the status code from the configuration.

expect status *min-number* [*max-number*]

no expect status *min-number* [*max-number*]

Syntax Description

min-number	Single status code if *max-number* is not specified.
max-number	(Optional) Maximum status code in a range.

Defaults

The default range is 0 to 999 (any response from the server is valid). Both min-number and max-number can be any number between 0 and 999, as long as max-number is not lower than min-number.

For example:

`expect status 5` is the same as `expect status 5 5`

`expect status 0` specifies a range of 0 to 4

`expect status 900 999` specifies a range of 900 to 999.

You can specify many expected status ranges.

Command Modes

SLB HTTP/FTP/Telnet/SMTP probe configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.

Usage Guidelines

This command is for HTTP, FTP, Telnet, and SMTP probes. You can specify multiple status code ranges with this command by entering one command at a time. If you specify the *max-number* value, this number is used as the minimum status code of a range. If you specify no maximum number, this command uses a single number (*min-number*). If you specify both *min-number* and *max-number* values, this command uses the range between the numbers.

Note When you remove the expect status, you cannot set the range of numbers to 0 or as a range of numbers that includes the values you set for the expect status. The expect status state becomes invalid and does not restore the default range of 0 through 999. To remove the expect status, remove each set of numbers using the **no expect status** command. For example, enter the **no expect status 0 3** command and then enter the **no expect status 34 99** command.

Examples

This example shows how to configure an HTTP probe with multiple status code ranges:

```
SLB-Switch(config-slb-probe-http)# expect status 34 99
SLB-Switch(config-slb-probe-http)# expect status 0 33
SLB-Switch(config-slb-probe-http)#
```

Related Commands

probe
show module csm probe

5960
D.

failed

Use the **failed** command in the SLB probe configuration submode to set the time to wait before probing a failed server. Use the **no** form of this command to reset the time to wait before probing a failed server to default.

failed *failed-interval*

no failed

Syntax Description

failed-interval	Time in seconds before retrying a failed server; the range is from 2 to 65535.

Defaults

The default value for the failed interval is 300 seconds.

Command Modes

SLB probe configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.

Usage Guidelines

This command is used for all probe types.

Examples

This example shows how to configure a failed server probe for 200 seconds:

```
SLB-Switch(config-slb-probe-http)# failed 200
```

Related Commands

probe
show module csm probe

header

Use the **header** command in the SLB HTTP probe configuration submode to configure a header field for the HTTP probe. Use the **no** form of this command to remove the credentials configuration.

header *field-name* [*field-value*]

no header *field-name*

Syntax Description

field-name	Name for the header being defined.
field-value	(Optional) Content for the header.

Defaults

This command has no default settings.

Command Modes

SLB HTTP probe configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.

Usage Guidelines

You can configure multiple headers for each HTTP probe. The length of the *field-name* value plus the length of the *field-value* value plus 4 (for ":", space, and CRLF) cannot exceed 255 characters. This command is for HTTP probes.

Examples

This example shows how to configure a header field for the HTTP probe:

```
SLB-Switch(config-slb-probe-http)# header abacadabra
```

Related Commands

probe
show module csm probe

interval

Use the **interval** command in the SLB probe configuration submode to set the time interval between probes. Use the **no** form of this command to reset the time interval between probes to default.

interval *seconds*

no interval

Syntax Description

seconds	Number of seconds to wait between probes from the end of the previous probe to the beginning of the next probe; the range is from 2 to 65535.

Defaults

The default value for the interval between probes is 120 seconds.

Command Modes

SLB probe configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.

Usage Guidelines

This command is used for all probe types.

Examples

This example shows how to configure a probe interval of 150 seconds:

```
SLB-Switch(config-slb-probe-http)# interval 150
```

Related Commands

probe
show module csm probe

kal-ap-udp

Use the **kal-ap-udp** command in the SLB probe configuration submode to set a probe for a Global Server Load Balancing (GSLB) target for load information. Use the **no** form of this command to remove the GSLB probe.

kal-ap-udp *seconds*

no kal-ap-udp

Syntax Description

seconds	Number of seconds to wait between probes from the end of the previous probe to the beginning of the next probe; the range is from 2 to 65535.

Defaults

The default value for the interval between probes is 120 seconds.

Command Modes

SLB probe configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.

Usage Guidelines

This command is used for all probe types.

Examples

This example shows how to configure a probe interval of 150 seconds:

```
SLB-Switch(config-slb-probe-http)# interval 150
```

Related Commands

probe
show module csm probe

name

Use the **name** command in the SLB DNS probe configuration submode to configure a domain name for the DNS probe. Use the **no** form of this command to remove the name from the configuration.

name *domain-name*

no name

Syntax Description

domain-name	Domain name that the probe sends to the DNS server.

Defaults

This command has no default settings.

Command Modes

SLB DNS probe configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.

Examples

This example shows how to specify the probe name that is resolved by the DNS server:

```
SLB-Switch(config-slb-probe-dns)# name astro
```

Related Commands

probe
show module csm probe

port

Use the **port** command in the SLB probe configuration submode to configure an optional port for the DNS probe. Use the **no** form of this command to remove the port from the configuration.

port *port-number*

no port

Syntax Description

port-number	Sets the port number.

Defaults

The default value for the port number is 0.

Command Modes

This command is available in all SLB probe configuration submodes except ICMP.

Command History

Release	Modification
3.1(1)	This command was introduced.

Usage Guidelines

When the port of a health probe is specified as 0, the health probe uses the configured port number from the real server (if a real server is configured) or the configured port number from the virtual server (if a virtual server is configured and no port is configured for the real server). The default port value is 0. For the ICMP probes, where there is no port number, the port value is ignored. The **port** command is available for all probe types except ICMP.

Examples

This example shows how to specify the port for the DNS server:

```
SLB-Switch(config-slb-probe-dns)# port 63
```

Related Commands

probe
show module csm probe

D.

open

Use the **open** command in the SLB HTTP/TCP/FTP/Telnet/SMTP probe configuration submode to set the time to wait for a TCP connection. Use the **no** form of this command to reset the time to wait for a TCP connection to default.

open *open-timeout*

no open

Syntax Description

open-timeout	Maximum number of seconds to wait for the TCP connection; the range is from 1 to 65535.

Defaults

The default value for the open timeout is 10 seconds.

Command Modes

SLB HTTP/TCP/FTP/Telnet/SMTP probe configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.

Usage Guidelines

This command is not used for any non-TCP probes, for example, ICMP or DNS.

Note There are two different timeout values: open and receive. The open timeout specifies how many seconds to wait for the connection to open (that is, how many seconds to wait for SYN ACK after sending SYN). The receive timeout specifies how many seconds to wait for data to be received (that is, how many seconds to wait for an HTTP reply after sending a GET/HHEAD request). Because TCP probes close as soon as they open without sending any data, the receive timeout is not used.

Examples

This example shows how to configure a time to wait for a TCP connection of 5 seconds:

```
SLB-Switch(config-slb-probe-http)# open 5
```

Related Commands

probe
show module csm probe

receive

Use the **receive** command in the SLB probe configuration submode to set the time to wait for a reply from a server. Use the **no** form of this command to reset the time to wait for a reply from a server to default.

receive *receive-timeout*

no receive

Syntax Description

receive-timeout	Number of seconds to wait for reply from a server; the range is from 1 to 65535.

Defaults

The default value for a receive timeout is 10 seconds.

Command Modes

SLB probe configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.

Usage Guidelines

This command is available for all probe types, except TCP.

Note There are two different timeout values: open and receive. The open timeout specifies how many seconds to wait for the connection to open (that is, how many seconds to wait for SYN ACK after sending SYN). The receive timeout specifies how many seconds to wait for data to be received (that is, how many seconds to wait for an HTTP reply after sending a GET/HHEAD request). Because TCP probes close as soon as they open without sending any data, the receive timeout is not used.

Examples

This example shows how to configures a time to wait for a reply from a server to 5 seconds:

```
SLB-Switch(config-slb-probe-http)# receive 5
```

request

Use the **request** command in the SLB HTTP probe configuration submode to configure the request method used by the HTTP probe. Use the **no** form of this command to remove the request method from the configuration.

request [method {get | head}]] [url *path***]**

no request [method {get | head}] [url *path***]**

Syntax Description

method	(Optional) Keyword to configure a method for the probe request.
get	(Optional) Keyword to direct the server to get this page.
head	(Optional) Keyword to direct the server to get only the header for this page.
url	(Optional) Keyword to direct the server to get the URL for this page.
path	(Optional) A character string up to 255 characters specifying the URL path.

Defaults

The default path is /.
The default method is **get**.

Command Modes

SLB HTTP probe configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.

Usage Guidelines

The CSM supports only the **get** and **head** request methods. It does not support **post** and other methods. This command is for HTTP probes.

Examples

This example shows how to configure a request method for the probe configuration:

```
SLB-Switch(config-slb-probe-http)# request method head
```

Related Commands

probe
show module csm probe

retries

Use the **retries** command in the SLB probe configuration submode to set the number of failed probes that are allowed before marking the server failed. Use the **no** form of this command to reset the number of failed probes allowed before marking a server as failed to default.

retries *retry-count*

no retries

Syntax Description

retry-count	Number of probes to wait before marking a server as failed; the range is from 0 to 65535.

Defaults

The default value for retries is 3.

Command Modes

SLB probe configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.

Usage Guidelines

This command is used for all probe types.

Note Set retries to 2 or more. If retries are set to 1, a single dropped probe packet will bring down the server. A setting of 0 places no limit on the number of probes that are sent. Retries are sent until the system reboots.

Examples

This example shows how to configure a retry count of 3:

```
SLB-Switch(config-slb-probe-http)# retries 3
```

Related Commands

probe script

Use the **probe** *probe-name* **script** command to create a script probe and enter the probe script configuration submode. Use the **no** form of this command to remove the probe from the configuration.

probe *probe_name* **script**

no probe *probe_name* **script**

Syntax Description

probe_name	Names the probe script
script	Keyword that specifies the creation of a probe script.

Defaults

This command has no default settings.

Command Modes

SLB probe script configuration submode.

Usage Guidelines

This command enters a probe sub-mode that is similar to the existing CSM health probe sub-modes (such as HTTP, TCP, DNS, and SMTP). The script probe sub-mode contains the existing probe sub-mode commands **failed, interval, open, receive,** and **retries.**

Command History

Release	Modification
3.1(1)	This command was introduced.

Examples

This example shows how to create a script probe:

```
SLB-Switch(config-module-csm)# ip slb script file tftp://192.168.10.102/csmScripts
SLB-Switch(config-probe-script)# script echoProbe.tcl
SLB-Switch(config-probe-script)# interval 10
SLB-Switch(config-probe-script)# retries 1

script

Use the **script** *script-name* **[arg1 [arg2...]]** command to create a script probe. Use the **no** form of this command to remove the probe from the configuration.

script *script_name* **[arg1 [arg2...]]**

no script *script_name* **[arg1 [arg2...]]**

Syntax Description

script-name	Names the probe script
arg1, arg2	Keyword that specifies ???

Defaults

This command has no default settings.

Command Modes

SLB probe script configuration submode.

Usage Guidelines

This command enters a probe sub-mode that is similar to the existing CSM health probe sub-modes (such as HTTP, TCP, DNS, and SMTP). The script probe sub-mode contains the existing probe sub-mode commands failed, interval, open, receive, and retries.

Command History

Release	Modification
3.1(1)	This command was introduced.

Examples

This example shows how to create a script probe:

```
SLB-Switch(config-module-csm)# ip slb script file tftp://192.168.10.102/csmScripts
SLB-Switch(config-probe-script# script echoProbe.tcl

open

OPL

Use the **open** command in the SLB probe script configuration submode to set the time to wait for a reply from a server. Use the **no** form of this command to reset the time to wait for a reply from a server to default.

open *open-timeout*

no open

Syntax Description

open-timeout	Number of seconds to wait for reply from a server; the range is from 1 to 65535.

Defaults

The default value for a receive timeout is 10 seconds.

Command Modes

SLB probe script configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.

Usage Guidelines

This command is available for all probe types, except TCP.

Note There are two different timeout values: open and receive. The open timeout specifies how many seconds to wait for the connection to open (that is, how many seconds to wait for SYN ACK after sending SYN). The receive timeout specifies how many seconds to wait for data to be received (that is, how many seconds to wait for an HTTP reply after sending a GET/HHEAD request). Because TCP probes close as soon as they open without sending any data, the receive timeout is not used.

Examples

This example shows how to configures a time to wait for a reply from a server to 5 seconds:

```
SLB-Switch(config-slb-probe-http)# open 5
```

real

Use the **real** command in the SLB serverfarm configuration submode to identify a real server that is a member of the server farm and enter the real server configuration submode. Use the **no** form of this command to remove the real server from the configuration.

real *ip-address* [*port*]

no real *ip-address* [*port*]

Syntax Description

ip-address	Real server IP address.
port	(Optional) Port translation for the real server; the range is from 1 to 65535.

Defaults

The default is no port translation for the real server.

Command Modes

SLB serverfarm configuration submode.

Usage Guidelines

Use this command to identify a real server that is a member of the server farm and enter the real server configuration submode.

Note The IP address that you supply provides a load-balancing target for the CSM. This target can be any IP addressable object. For example, the IP addressable object may be a real server, a firewall, or an alias IP address of another CSM.

Command History

Release	Modification
1.1(1)	This command was introduced.

Examples

This example shows how to identify a real server and enter the real server submode:

```
SLB-Switch(config-slb-sfarm)# real 102.43.55.60
SLB-Switch(config-slb-real)#
```

D.

inservice

Use the **inservice** command in the SLB real server configuration submode to enable the real servers. Use the **no** form of this command to remove a real server from service.

inservice

no inservice

Syntax Description

This command has no arguments or keywords.

Defaults

The default for a real server is **no inservice**.

Command Modes

SLB real server configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.

Examples

This example shows how to enable a real server:

```
SLB-Switch(config-slb-sfarm)# real 10.2.2.1
SLB-Switch(config-slb-real)# inservice
```

Related Commands

real (SLB serverfarm submode)
show module csm real

maxconns

Use the **maxconns** command in the SLB real server configuration submode to limit the number of active connections to the real server. Use the **no** form of this command to change the maximum number of connections to its default value.

maxconns *max-conns*

no maxconns

Syntax Description

max-conns	Maximum number of active connections on the real server at any one point in time; the range is from 1 to 4294967295.

Defaults

The default value is the maximum value or infinite (not monitored).

Command Modes

SLB real server configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.

Usage Guidelines

When you specify **minconns**, you must also specify the **maxconns** command.

Examples

This example shows how to limit the connections to a real server:

```
SLB-Switch(config-slb-sfarm)# real 10.2.2.1
SLB-Switch(config-slb-real)# maxconns 4000
```

Related Commands

minconns (real server submode)
real (serverfarm submode)
show module csm real

5940
D.

minconns

Use the **minconns** command in the SLB real server configuration submode to establish a minimum connection threshold for the real server. Use the **no** form of this command to change the minimum number of connections to the default value.

minconns *min-cons*

no minconns

Syntax Description

min-cons	Minimum number of connections allowed on the real server; the range is from 0 to 4294967295.

Defaults

The default value is **no minconns**.

Command Modes

SLB real server configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.

Usage Guidelines

When the **maxconns** threshold is exceeded, the CSM stops sending connections until the number of connections falls below the **minconns** threshold. This value must be lower than the maximum number of connections configured by the **maxconns** command. When you specify **minconns**, you must also specify the **maxconns** command.

Examples

This example shows how to establish a minimum connection threshold for a server:

```
SLB-Switch(config-slb-sfarm)# real 102.2.2.1
SLB-Switch(config-slb-real)# minconns 4000
```

Related Commands

maxconns (real server submode)
real (serverfarm submode)
show module csm real

probe

Use the **probe** command in the SLB real server configuration submode to configure a probe for the real server. Use the **no** form of this command to remove the probe from the configuration.

probe *probe-name* **tag** *string*

no probe

Syntax Description

probe-name	Names the probe.
tag	Keyword to specify a tag for the probe.
string	Specifies a string to identify the probe.

Defaults

This command has no default values.

Command Modes

SLB real server configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.

Examples

This example shows how to configurre a probe for a server:

```
SLB-Switch(config-slb-sfarm)# real 102.2.2.1
SLB-Switch(config-slb-real)# probe mission tag 12345678
```

Related Commands

real (serverfarm submode)
show module csm real

redirect-vserver

Use the **redirect-vserver** command in the SLB real server configuration submode to configure a real server to receive traffic redirected by a redirect virtual server. Use the **no** form of this command to specify that traffic is not redirected to the real server.

redirect-vserver *name*

no redirect-vserver

Syntax Description

name	Name of the virtual server that has its requests redirected.

Defaults

The default is **no redirect-vserver**.

Command Modes

SLB real server configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.

Usage Guidelines

Mapping real servers to redirect virtual servers provides persistence for clients to real servers across TCP sessions. Before using this command, you must create the redirect virtual server in serverfarm submode with the **redirect-vserver** command.

Examples

This example shows how to map a real server to a virtual server:

```
SLB-Switch(config-slb-sfarm)#   real 10.2.2.1
SLB-Switch(config-slb-real)# redirect-vserver timely
```

Related Commands

real (SLB serverfarm configuration submode)
redirect-vserver (SLB serverfarm configuration submode)
show module csm real
show module csm vserver redirect

weight

Use the **weight** command in the SLB real server configuration submode to configure the capacity of the real servers in relation to the other real servers in the server farm. Use the **no** form of this command to change the server's weight to its default capacity.

weight *weighting-value*

no weight

Syntax Description

weighting-value	Value to use for the server farm predictor algorithm; the range is from 1 to 100.

Defaults

The weighting value default is 8.

Command Modes

SLB real server configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.

Examples

This example shows how to configure the weight of a real server:

```
SLB-Switch(config-slb-sfarm)#   real 10.2.2.1
SLB-Switch(config-slb-real)# weight 8
```

Related Commands

redirect-vserver

Use the **redirect-vserver** command to specify the name of a virtual server to receive traffic redirected by the server farm and enter redirect virtual server configuration submode. Use the **no** form of this command to remove the redirect virtual server.

redirect-vserver *name*

no redirect-vserver *name*

Syntax Description

name	Name of the virtual server to receive traffic redirected by the server farm; the virtual server name can be no longer than 15 characters.

Defaults

This command has no default settings.

Command Modes

SLB serverfarm configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.

Examples

This example shows how to name the virtual server:

```
SLB-Switch(config-slb-sfarm)#   redirect-vserver quantico
```

Related Commands

real (SLB serverfarm submode)
redirect-vserver (SLB real server submode)
serverfarm
show module csm serverfarm
show module csm vserver redirect

advertise

Use the **advertise** command in the SLB redirect virtual server configuration mode to allow the CSM to advertise the IP address of the virtual server as host-route. Use the **no** form of this command to stop advertising the host-route for this virtual server.

advertise [**active**]

no advertise

Syntax Description

active	(Optional) Keyword to allow the CSM to advertise the IP address of the virtual server as host-route.

Defaults

The default for network mask is 255.255.255.255 if the network mask is not specified.

Command Modes

SLB redirect virtual server configuration submode.

Usage Guidelines

Without the active option, the CSM always advertises the virtual server IP address whether or not there is any active real server attached to this virtual server.

Command History

Release	Modification
1.1(1)	This command was introduced.

Examples

This example shows how to restrict a client from using the redirect virtual server:

```
SLB-Switch(config-slb-redirect-vs)# advertise 10.5.2.1 exclude
```

Related Commands

vserver
show module csm vserver redirect

client

Use the **client** command in the SLB redirect virtual server configuration mode to restrict which clients are allowed to use the redirect virtual server. Use the **no** form of this command to remove the client definition from the configuration.

client *ip-address* [*network-mask*] [**exclude**]

no client *ip-address* [*network-mask*]

Syntax Description

ip-address	Client's IP address.
network-mask	(Optional) Client's IP mask.
exclude	(Optional) Keyword to specify that the IP address is disallowed.

Defaults

The default for network mask is 255.255.255.255 if the network mask is not specified.

Command Modes

SLB redirect virtual server configuration submode.

Usage Guidelines

The network mask is applied to the source IP address of incoming connections and the result must match the IP address before the client is allowed to use the virtual server. If you do not specify exclude, the IP address and network mask combination is allowed.

Command History

Release	Modification
1.1(1)	This command was introduced.

Examples

This example shows how to restrict a client from using the redirect virtual server:

```
SLB-Switch(config-slb-redirect-vs)# client 10.5.2.1 exclude
```

Related Commands

client-group (SLB policy submode)

idle

Use the **idle** command in the SLB redirect virtual server configuration submode to specify the connection idle timer duration. Use the **no** form of this command to disable the idle timer.

idle *duration*

no idle

Syntax Description

duration	SLB connection idle timer in seconds; the range is from 4 to 65535.

Defaults

The default is 3600.

Command Modes

SLB redirect virtual server configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.

Examples

This example shows how to specify the connection idle timer duration:

```
SLB-Switch(config-slb-redirect-vs)# idle 7
```

Related Commands

inservice

Use the **inservice** command in the SLB redirect virtual server configuration submode to enable the real server for use by the CSM. If this command is not specified, the virtual server is defined but not used. Use the **no** form of this command to disable the virtual server.

inservice

no inservice

Syntax Description

This command has no arguments or keywords.

Defaults

The default is **no inservice**.

Command Modes

SLB redirect virtual server configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.

Examples

This example shows how to enable a redirect virtual server for use by the CSM:

```
SLB-Switch(config-slb-redirect-vs)# inservice
```

Related Commands

redirect-vserver (SLB serverfarm submode)
show module csm vserver redirect

replicate csrp

Use the **replicate csrp** command in the SLB redirect virtual server configuration submode to enable connection redundancy. Use the **no** form of this command to remove connection redundancy.

replicate csrp

no replicate csrp

Syntax Description

This command has no keywords or arguments.

Defaults

The default is **no replicate csrp**.

Command Modes

SLB virtual server configuration submode.

Command History

Release	Modification
2.1(1)	This command was introduced.

Examples

This example shows how to enable connection redundancy:

```
SLB-Switch(config-slb-redirect-vs)# replicate csrp
```

Related Commands

show module csm vserver redirect

5930

ssl

Use the **ssl** command in the SLB redirect virtual server configuration submode to redirect an HTTP request to either HTTPS (SSL)_ or the FTP service. Use the **no** form of this command to reset the redirect of an HTTP request to an HTTP service.

ssl {**https** | **ftp** | *ssl-port-number*}

no ssl

Syntax Description

ssl-port-number	SSL port number; the range is from 1 to 65535.

Defaults

The default is **no ssl** forwarding.

Command Modes

SLB redirect virtual server configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.

Examples

This example shows how to enable SSL forwarding:

```
SLB-Switch(config-slb-redirect-vs)# ssl 443
```

Related Commands

redirect-vserver (SLB serverfarm submode)
show module csm vserver redirect

virtual

Use the **virtual** command in SLB redirect virtual server configuration submode to specify the virtual server's IP address, the protocol used for traffic, and the port the protocol is using. Use the **no** form of this command to reset the virtual server to its defaults.

virtual *v_ipaddress* **tcp** *port*

no virtual *v_ipaddress*

Syntax Description

v_ipaddress	Redirect virtual server's IP address.
tcp	Keyword to specify the protocol used for redirect virtual server traffic.
port	Port number used by the protocol.

Defaults

The default IP address is 0.0.0.0, which prevents packet forwarding.

Command Modes

SLB redirect virtual server configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.

Examples

This example shows how to specify the virtual server's IP address, the protocol for redirect virtual server traffic, and the port number used by the protocol:

```
SLB-Switch(config-slb-redirect)# virtual 130.32.44.50 tcp 80
```

Related Commands

redirect-vserver (SLB serverfarm submode)
show module csm vserver redirect

vlan

5928

Use the **vlan** command in the SLB redirect virtual server submode to define which source VLANs can be accessed on the redirect virtual server. Use the **no** form of this command to remove the VLAN.

vlan {*vlan-number* | **all**}

no vlan

Syntax Description

vlan-number	VLAN the virtual server may access.
all	(Optional) Keyword to specify all VLANs are accessed by the virtual server.

Defaults

The default is all VLANs.

Command Modes

SLB virtual server configuration submode.

Command History

Release	Modification
2.1(1)	This command was introduced.

Examples

This example shows how to specify a VLAN for redirect virtual server access:

```
SLB-Switch(config-slb-redirect-vs)# vlan 5
```

webhost backup

Use the **webhost backup** command in SLB redirect virtual server configuration submode to specify a backup string sent in response to HTTP requests. Use the **no** form of this command to disable the backup string.

webhost backup *backup-string* **[301 | 302]**

webhost backup

Syntax Description

backup-string	String sent in response to redirected HTTP requests; the maximum length is 127 characters.
301	(Optional) Keyword to specify the HTTP status code: "The requested resource has been assigned a new permanent URL."
302	(Optional) Keyword to specify the HTTP status code: "The requested resource resides temporarily under a different URL."

Defaults

The default status code is 302.

Command Modes

SLB redirect virtual server configuration submode.

Usage Guidelines

This command is used in situations where the redirect virtual server has no available real servers. **301** or **302** is used to specify the redirect code. The backup string may include a %p at the end to indicate inclusion of the path in the HTTP redirect location statement field.

Command History

Release	Modification
1.1(1)	This command was introduced.

Examples

This example shows how to specify a backup string that is sent in response to HTTP requests:

```
SLB-Switch(config-slb-redirect-vs)# webhost backup www.mybackup.com%p 301
```

Related Commands

redirect-vserver (SLB serverfarm submode)
show module csm vserver redirect

webhost relocation

Use the **webhost relocation** command in the SLB redirect virtual server configuration submode to specify a relocation string sent in response to HTTP requests. Use the **no** form of this command to disable the relocation string.

webhost relocation *relocation string* [**301** | **302**]

no webhost relocation

Syntax Description

relocation string	String sent in response to redirected HTTP requests; the maximum length is 127 characters.
301	(Optional) Keyword to specify the HTTP status code: "The requested resource has been assigned a new permanent URL."
302	(Optional) Keyword to specify the HTTP status code: "The requested resource resides temporarily under a different URL."

Defaults

The default status code is 302.

Command Modes

SLB redirect virtual server configuration submode.

Usage Guidelines

The backup string may include a %p at the end to indicate inclusion of the path in the HTTP redirect location statement field.

Command History

Release	Modification
1.1(1)	This command was introduced.

Examples

This example shows how to specify a relocation string that is sent in response to HTTP requests:

```
SLB-Switch(config-slb-redirect-vs)# webhost relocation www.myhome1.com%p 301
```

Related Commands

redirect-vserver (SLB serverfarm submode)
show module csm vserver redirect

script file

Use the **script file** command to load scripts into a script file. Use the **no** form of this command to remove the script file command from the configuration.

script file *file-url*

no script file

Syntax Description

file-url	Sets the standard Cisco IOS file name, such as *bootflash:webprobe.tcl*.

Defaults

This command has no default settings.

Command Modes

Module CSM configuration submode.

Usage Guidelines

The file-url is a standard Cisco IOS file name such as *bootflash:webprobe.tcl*.

Command History

Release	Modification
3.1(1)	This command was introduced.

Examples

This example shows how to load scripts into a script file:

```
SLB-Switch(config-module-csm)# script file file-url
```

Related Commands

show module csm script

script task

Use the **script task** command to run a standalone task. Use the **no** form of this command to remove the standalone task from the configuration.

script task *script-index script-name* [**arg1** [**arg2...**]]

no script task *script-index*

Syntax Description

script-index	Used to identify a specific running script. The *script-index* is an integer between 1 and 100.
script-name	Identifies the script by name.
arg1, arg2	(Optoinal) Arguments can be any string to a particular script.

Defaults

This command has no default settings.

Command Modes

Module CSM configuration submode.

Command History

Release	Modification
3.1(1)	This command was introduced.

Examples

This example shows how to run a standalone script:

```
SLB-Switch(config-module-csm)# script task 30 filerun
```

Related Commands

show module csm script

serverfarm

Use the **serverfarm** command to identify a server farm and enter the serverfarm configuration submode. Use the **no** form of this command to remove the server farm from the configuration.

serverfarm *serverfarm-name*

no serverfarm *serverfarm-name*

Syntax Description

serverfarm-name	Character string used to identify the server farm; the character string is limited to 15 characters.

Defaults

This command has no default settings.

Command Modes

Module CSM configuration submode.

Usage Guidelines

Use this command to enter the server farm configuration submode to configure the load-balancing algorithm (predictor), a set of real servers, and the attributes (NAT, probe, and bindings) of the real servers.

Command History

Release	Modification
1.1(1)	This command was introduced.

Examples

This example shows how to identify a server farm named PUBLIC and change the CLI to server farm configuration mode:

```
SLB-Switch(config-module-csm)#   serverfarm PUBLIC
```

Related Commands

reverse-sticky (SLB policy configuration submode)
serverfarm (SLB virtual server configurations submode)
show module csm serverfarm

bindid

Use the **bindid** command in the SLB serverfarm configuration submode to assign a unique ID to allow the DFP agent to differentiate a real server in one server farm versus another server farm. Use the **no** form of this command to disable the bindid.

bindid [*bind-id*]

no bindid

Syntax Description

bind-id	(Optional) Identification number for each binding; the range is from 0 to 65533.

Defaults

The default is 0.

Command Modes

SLB serverfarm configuration submode.

Usage Guidelines

The single real server is represented as multiple instances of itself, each having a different bind identification. DFP uses this identification to identify a given weight for each instance of the real server.

Command History

Release	Modification
1.1(1)	This command was introduced.

Examples

This example shows how to bind a server to multiple virtual servers:

```
SLB-Switch(config-slb-sfarm)# bindid 7
```

Related Commands

dfp
serverfarm
show module csm serverfarm

failaction purge

Use the **failaction purge** command in the SLB serverfarm configuration submode to set the behavior of connections to real servers that have failed. Use the **no** form of this command to disable the behavior of connections to real servers that have failed.

failaction purge

no failaction purge

Syntax Description

This command has no arguments or keywords.

Defaults

The default is **no failaction purge**.

Command Modes

SLB serverfarm configuration submode.

Usage Guidelines

With this command enabled, connections to a real server in the server farm are purged when the real server goes down. This feature is required for VPN load balancing.

Command History

Release	Modification
2.1(1)	This command was introduced.

Examples

This example shows how to set the behavior of connections to real servers that have failed:

```
SLB-Switch(config-slb-sfarm)# failaction purge
```

Related Commands

dfp
serverfarm
show module csm serverfarm

health

Use the **health** command in the SLB serverfarm configuration submode to set the retry attempts to real servers that have failed. Use the **no** form of this command to disable the retries or the time to wait for connections to real servers that have failed.

health retries *count* **failed** *seconds*

no health

Syntax Description

retries	Keyword to specify the number of tries to attempt to failed real servers.
count	Number of probes to wait before marking a server as failed; the range is from 0 to 65534.
failed	Keyword to specify the time to wait to attempt retries to the real servers.
seconds	Time in seconds before retrying a failed server; the range is from 0 to 65535.

Defaults

There are no default settings.

Command Modes

SLB serverfarm configuration submode.

Command History

Release	Modification
2.2(1)	This command was introduced.

Examples

This example shows how to set the behavior of connections to real servers that have failed:

```
SLB-Switch(config-slb-sfarm)# health retries 20 failed 200
```

Related Commands

dfp
serverfarm
show module csm serverfarm

nat client

Use the **nat client** command in SLB serverfarm configuration submode to specify a set of client NAT pool addresses that should be used to perform the NAT function on clients connecting to this server farm. Use the **no** form of this command to remove the NAT pool from the configuration.

nat client *client-pool-name*

no nat client

Syntax Description

client-pool-name	Client pool name.

Defaults

This command has no default settings.

Command Modes

SLB serverfarm configuration submode.

Usage Guidelines

Use this command to enable client NAT. If client NAT is configured, the client address and port number in load-balanced packets are replaced with an IP address and port number from the specified client NAT pool. This client pool name must match the pool name entered from a previous **natpool** command.

Command History

Release	Modification
1.1(1)	This command was introduced.

Examples

This example shows how to specify NAT on the client:

```
SLB-Switch(config-slb-sfarm)# nat client whishers
```

Related Commands

natpool
serverfarm
nat server
predictor
show module csm serverfarm

nat server

Use the **nat server** command in SLB serverfarm configuration submode to specify NAT to servers in this server farm. Use the **no** form of this command to disable server NAT.

nat server

no nat server

Syntax Description

This command has no arguments or keywords.

Defaults

Server NAT is enabled by default.

Command Modes

SLB server farm configuration submode.

Usage Guidelines

Use this command to enable server NAT. If server NAT is configured, the server address and port number in load-balanced packets are replaced with an IP address and port number of one of the real servers in the server farm.

Note The **nat server** command has no effect when **predictor forward** is configured, because no servers can be configured.

Command History

Release	Modification
1.1(1)	This command was introduced.

Examples

This example shows how to specify NAT on the server:

```
SLB-Switch(config-slb-sfarm)# nat server
```

Related Commands

serverfarm
nat client
predictor
show module csm serverfarm

predictor

Use the **predictor** command in the SLB serverfarm configuration submode to specify the load-balancing algorithm for the server farm. Use the **no** form of this command to remove the load-balancing algorithm.

predictor {**roundrobin** | **leastconns** | **hash url** | **hash address** [**source** | **destination**] [*ip-netmask*] | **forward**}]

no predictor

Syntax Description

roundrobin	Keyword to select the next servers in the list of real servers.
leastconns	Keyword to select the server with the least number of connections.
hash url	Keyword to select the server using a hash value based on the URL.
hash address	Keyword to select the server using a hash value based on the source and destination IP addresses.
source	Keyword to select the server using a hash value based on the source IP address.
destination	Keyword to select the server using a hash value based on the destination IP address.
ip-netmask	(Optional) Bits in the IP address to use for the hash. If not specified, 255.255.255.255 is assumed.
forward	Keyword to tell the CSM to forward traffic in accordance with its internal routing tables.

Defaults

The default algorithm is round robin.

Command Modes

SLB serverfarm configuration submode.

Usage Guidelines

Use this command to define the load-balancing algorithm used in choosing a real server in the server farm. If you do not specify the **predictor** command, the default algorithm is **roundrobin**. Using the **no** form of this command changes the predictor algorithm to the default algorithm.

Note The **nat server** command has no effect when **predictor forward** is configured, because no servers can be configured.

The portion of the URL to hash is based on the expressions configured for the virtual server submode command **url-hash**.

No real servers are needed. The server farm is actually a route forwarding policy with no real servers associated with it.

5816
D.

Command History

Release	Modification
1.1(1)	This command was introduced.
2.1(1)	Changed the **ip-hash** to the **hash address source** keyword and added new keyword types of **hash address**, **hash address destination**, **hash url**, and **forward**. In addition, the **http-redirect** command is now hidden.

Examples

This example shows how to specify the load-balancing algorithm for the server farm:

```
SLB-Switch(config-module-csm)# serverfarm PUBLIC
SLB-Switch(config-slb-sfarm)# predictor leastconns
```

Related Commands

probe

Use the **probe** command in the SLB serverfarm configuration submode to associate a probe with a server farm. Use the **no** form of this command to disable a specific probe.

probe *probe-name*

no probe *probe-name*

Syntax Description

probe-name	Probe name associated with the server farm.

Defaults

This command has no default settings.

Command Modes

SLB serverfarm configuration submode.

Usage Guidelines

Each server farm can be associated with multiple probes of the same or different protocols. Protocols supported by the CSM include HTTP, ICMP, TCP, FTP, SMTP, Telnet, and DNS.

Command History

Release	Modification
1.1(1)	This command was introduced.

Examples

This example shows how to associate a probe with a server farm:

```
SLB-Switch(config-slb-sfarm)# probe general
```

Related Commands

probe (Module CSM configuration submode)
serverfarm
show module csm probe

retcode-map

Use the **retcode-map** command in the SLB serverfarm configuration submode to assign a return code map to a server farm. Use the **no** form of this command to disable a specific probe.

retcode-map *retcodemap_name*

no retcode-map

Syntax Description

retcodemap_name	Return code map name associated with the server farm.

Defaults

This command has no default settings.

Command Modes

SLB serverfarm configuration submode.

Command History

Release	Modification
2.2(1)	This command was introduced.

Examples

This example shows how to associate a probe with a server farm:

```
SLB-Switch(config-slb-sfarm)# retcode-map return_stats
```

Related Commands

map retcode (Module CSM configuration submode)
serverfarm
show module csm serverfarm

show module csm arp

Use the **show module csm** *slot* **arp** command to display the CSM ARP cache.

show module csm *slot* **arp**

Syntax Description

slot	Slot where the CSM resides.

Defaults

This command has no default settings.

Command Modes

Privileged EXEC.

Command History

Release	Modification
1.1(1)	This command was introduced as **show ip slb arp**.
2.1(1)	This command was changed to **show module csm** *slot* (for **ip slb mode rp** only).

Examples

This example shows how to display the CSM ARP cache:

```
SLB-Switch# show module csm 4 arp

Internet Address  Physical Interface  VLAN      Type      Status
------------------------------------------------------------------
 10.10.3.100      00-01-64-F9-1A-02   0         VSERVER   local

show module csm conns

Use the **show module csm** *slot* **conns** command to display active connections.

show module csm *slot* **conns** [**vserver** *virtserver-name*] [**client** *ip-address*] [**detail**]

Syntax Description

slot	Slot where the CSM resides.
vserver	(Optional) Keyword to specify the connections associated with a particular virtual server.
virtserver-name	(Optional) Name of the virtual server to be monitored.
client	(Optional) Keyword to specify the connections associated with a particular client IP address.
ip-address	(Optional) IP address of the client to be monitored.
detail	(Optional) Keyword to specify detailed connection information.

Defaults

If no options are specified, the command displays output for all active connections.

Command Modes

Privileged EXEC.

Command History

Release	Modification
1.1(1)	This command was introduced as **show ip slb conns**.
2.1(1)	This command was changed to **show module csm** *slot* (for **ip slb mode rp** only).

Examples

This example shows how to display active connection data:

```
SLB-Switch# show module csm 4 conns
prot vlan source                destination           state
----------------------------------------------------------------------
In  TCP  11   100.100.100.2:1754    10.10.3.100:80        ESTAB
Out TCP  12   100.100.100.2:1754    10.10.3.20:80         ESTAB

In  TCP  11   100.100.100.2:1755    10.10.3.100:80        ESTAB
Out TCP  12   100.100.100.2:1755    10.10.3.10:80         ESTAB

SLB-Switch# show module csm 4 conns detail

    prot vlan source                destination           state
----------------------------------------------------------------------
In  TCP  11   100.100.100.2:1754    10.10.3.100:80        ESTAB
Out TCP  12   100.100.100.2:1754    10.10.3.20:80         ESTAB
    vs = WEB_VIP, ftp = No, csrp = False

In  TCP  11   100.100.100.2:1755    10.10.3.100:80        ESTAB
Out TCP  12   100.100.100.2:1755    10.10.3.10:80         ESTAB
    vs = WEB_VIP, ftp = No, csrp = False
```

D

show module csm dfp

Use the **show module csm** *slot* **dfp** command to display DFP agent and manager information, such as passwords, timeouts, retry counts, and weights.

show module csm *slot* **dfp** [**agent** [**detail** | *ip-address port*] | **manager** [*ip_addr*] | **detail** | **weights**]

Syntax Description

slot	Slot where the CSM resides.
agent	(Optional) Keyword to specify information about a DFP agent.
detail	(Optional) Keyword to specify all data available.
ip_address	(Optional) Agent IP address.
port	(Optional) Agent port number.
manager	(Optional) Keyword to specify the agent and manager connection state and statistics, and the load and health metric sent to DFP manager.
ip_addr	(Optional) IP address of reported weights.
detail	(Optional) Keyword to specify all data available.
weights	(Optional) Keyword to specify information about weights assigned to real servers for load balancing.

Defaults

If no options are specified, the command displays summary information.

Command Modes

Privileged EXEC.

Command History

Release	Modification
1.1(1)	This command was introduced as **show ip slb dfp**.
2.1(1)	Added the virtual server weight display information to report to the DFP manager. This command was changed to **show module csm** *slot* (for **ip slb mode rp** only).

Examples

This example shows all available DFP data:

```
SLB-Switch# show module csm 4 dfp detail
```

This example shows information about weights:

```
SLB-Switch# show module csm 4 dfp weights
```

This example, with no options specified, shows summary information:

```
SLB-Switch# show module csm 4 dfp
```

show module csm ft

Use the **show module csm** *slot* **ft** command to display statistics and counters for the CSM fault-tolerant pair.

show module csm *slot* **ft [detail]**

Syntax Description

detail	(Optional) Keyword to display more detailed information.

Defaults

No values are displayed.

Command Modes

Privileged EXEC.

Command History

Release	Modification
1.1(1)	This command was introduced as **show ip slb ft**.
2.1(1)	This command was changed to **show module csm** *slot* (for **ip slb mode rp** only).

Examples

This example shows how to display the statistics and counters for the CSM fault-tolerant pair:

```
SLB-Switch# show module csm 4 ft
FT group 2, vlan 30
 This box is active
 priority 10, heartbeat 1, failover 3, preemption is off
```

Related Commands

ft group

show module csm map

Use the **show module csm** *slot* **map** command to display information about URL maps.

show module csm *slot* **map [url | cookie | header | retcode] [name** *map-name***] [detail]**

Syntax Description

lot	Slot where the CSM resides.
ırl	(Optional) Keyword to specify only the URL map configuration.
ookie	(Optional) Keyword to specify only the cookie map configuration.
eader	(Optional) Keyword to specify only the header map configuration.
ɛtcode	(Optional) Keyword to specify only the return code map configuration.
ame	(Optional) Keyword to specify the named map.
ap-name	Map name to display.
ɛtail	(Optional) Keyword to specify all data available.

Defaults

is command has no default settings.

Command Modes

vileged EXEC.

Command History

ease	**Modification**
(1)	This command was introduced as **show ip slb map**.
(1)	This command was changed to **show module csm** *slot* (for **ip slb mode rp** only). The header option is added for displaying only header maps.
(1)	This command was changed to include the **retcode** option.

Examples

s example shows how to display URL maps associated with a Content Switching policy:

```
-Switch# show module csm 4 map url
 map UHASH_UMAP
OKIE map UHASH_CMAP1
OKIE map UHASH_CMAP2

show ip slb map detail
L map UHASH_UMAP rules:
aabb*

OKIE map UHASH_CMAP1 rules:
ame:foo  value:*asdgjasgdkjsdkgjsasdgsg*

OKIE map UHASH_CMAP2 rules:
ame:bar  value:*asdgjasgdkjsdkgjsasdgsg*
```

This example shows how to display return code maps:

```
SLB-Switch#show module csm 5 map retcode detail
 RETCODE map HTTPCODES rules:
  return codes:401 to 401  action:log     threshold:5  reset:120
  return codes:402 to 415  action:count   threshold:0  reset:0
  return codes:500 to 500  action:remove  threshold:3  reset:0
  return codes:503 to 503  action:remove  threshold:3  reset:0
```

show module csm memory

Use the **show module csm** *slot* **memory** command to display information about memory use.

show module csm *slot* **memory** [**vserver** *vserver-name*] [**detail**]

Syntax Description

slot	Slot where the CSM resides.
vserver	(Optional) Keyword to specify the virtual server configuration.
vserver-name	(Optional) Option to restrict output to the named virtual server.

Defaults

This command has no default settings.

Command Modes

Privileged EXEC.

Command History

Release	Modification
1.1(1)	This command was introduced as **show ip slb memory**.
2.1(1)	This command was changed to **show module csm** *slot* (for **ip slb mode rp** only). The **detail** keyword no longer has an effect and is hidden or deprecated.

Examples

This example shows how to display the memory usage of virtual servers:

```
SLB-Switch# show module csm 4 memory
slb vserver      total bytes   memory by type
---------------------------------------------------------------------------
WEB_VIP          0             0          0
FTP_VIP          0             0          0
Total(s):                    0          0
Out of Maximum:              261424     261344
```

Related Commands

show module csm natpool

Use the **show module csm** *slot* **natpool** command to display NAT configurations.

show module csm *slot* **natpool** [**name** *pool-name*] [**detail**]

Syntax Description

slot	Slot where the CSM resides.
name	(Optional) Keyword to display a specific NAT pool.
pool-name	(Optional) NAT pool name string to display.
detail	(Optional) Keyword to list the interval ranges currently allocated in the client NAT pool.

Defaults

This command has no default settings.

Command Modes

Privileged EXEC.

Command History

Release	Modification
1.1(1)	This command was introduced as **show ip slb natpool**.
2.1(1)	This command was changed to **show module csm** *slot* (for **ip slb mode rp** only).

Examples

This example shows how to display results of the default **show module csm** *slot* **natpool** command:

```
SLB-Switch# show module csm 4 natpool
nat client B  1.1(1).6  1.1(1).8  Netmask 255.255.255.0
        nat client A  1.1(1).1  1.1(1).5  Netmask 255.255.255.0
```

This example shows how to display results of the **show module csm** *slot* **natpool** command with the **detail** variable:

```
SLB-Switch# show module csm 4 natpool detail
nat client A  1.1(1).1  1.1(1).5  Netmask 255.255.255.0
     Start NAT         Last NAT          Count     ALLOC/FREE
     -------------------------------------------------------
     1.1(1).1:11001    1.1(1).1:16333    0005333    ALLOC
     1.1(1).1:16334    1.1(1).1:19000    0002667    ALLOC
     1.1(1).1:19001    1.1(1).5:65535    0264675    FREE
```

show module csm owner

Use the **show module csm** *slot* **owner** command to display the current connections count for the specified owner objects.

show module csm *slot* **owner** [**name** *owner-name*] [**detail**]

Syntax Description

slot	Slot where the CSM resides.
owner	Keyword to display a specific owner object.
name	(Optional) Keyword to display a specific owner object.
owner-name	(Optional) Owner object name string to display.
detail	(Optional) Keyword to list the virtual servers in an owner group with the vserver's state and current connections count.

Defaults

This command has no default settings.

Command Modes

Privileged EXEC.

Command History

Release	Modification
3.1(1)	This command was introduced.

Usage Guidelines

Detailed information about an owner object lists the virtual servers in that group with each virtual server's state and current connections count.

The MAXCONNS state is displayed for a virtual server when the current connections counter is equal to the configured **maxconns** value. Counters for the number of connections dropped due to the virtual server being in this state are added. The **show module csm** *slot* **stats** and **show module csm** *slot* **vserver detail** command output displays these counters on a global and per-virtual server basis, respectively.

Examples

This example shows how to display results of the default **show module csm** *slot* **owner** command:

```
SLB-Switch# show module csm 4 owner
```

This example shows how to display results of the **show module csm** *slot* **owner** command with the **detail** variable:

```
SLB-Switch# show module csm 4 owner detail
```

show module csm policy

Use the **show module csm** *slot* **policy** command to display a policy configuration.

show module csm *slot* **policy** [**name** *policy-name*]

Syntax Description

slot	Slot where the CSM resides.
name	(Optional) Keyword to display a specific policy.
policy-name	(Optional) Policy name string to display.

Defaults

This command has no default settings.

Command Modes

Privileged EXEC.

Command History

Release	Modification
1.1(1)	This command was introduced as **show ip slb policy**.
2.1(1)	This command was changed to **show module csm** *slot* (for **ip slb mode rp** only).

Examples

This example shows how to display a policy configuration:

```
SLB-Switch# show module csm 4 policy
policy:             PC1_UHASH_T1
sticky group:       20
serverfarm:         SF_UHASH_T1

policy:             PC1_UHASH_T2
sticky group:       30
serverfarm:         SF_UHASH_T2

policy:             PC1_UHASH_T3
url map:            UHASH_UMAP
serverfarm:         SF_UHASH_T3

show module csm probe

Use the **show module csm** *slot* **probe** command to display HTTP or ping probe data.

show module csm *slot* **probe [http | icmp | telnet | tcp | ftp | smtp | dns] [name** *probe_name*] **[detail]**

Syntax Description

slot	Slot where the CSM resides.
http	(Optional) Keyword to display information about the HTTP configuration.
icmp	(Optional) Keyword to display information about the ICMP configuration.
telnet	(Optional) Keyword to display information about the Telnet configuration.
tcp	(Optional) Keyword to display information about the TCP configuration.
ftp	(Optional) Keyword to display information about the FTP configuration.
smtp	(Optional) Keyword to display information about the SMTP configuration.
dns	(Optional) Keyword to display information about the DNS configuration.
name	(Optional) Keyword to display information about the specific probe named.
probe_name	(Optional) Probe name to display.
detail	(Optional) Keyword to display detailed information.

Defaults

This command has no default settings.

Command Modes

Privileged EXEC.

Command History

Release	Modification
1.1(1)	This command was introduced as **show ip slb probe**.
2.1(1)	This command was changed to **show module csm** *slot* (for **ip slb mode rp** only).

Examples

This example shows how to display probe data:

```

Table A-1 describes the fields in the display.

Table A-1 show module csm real Command Field Information

Field	Description
real	Information about each real server is displayed on a separate line.
server farm	Name of the server farm associated to the real server.
weight	Weight assigned to the real server. The weight identifies the capacity of the real server compared to other real servers in the server farm.
state	Current state of the real server: • OUTOFSERVICE—Removed from the load-balancing predictor lists. • FAILED—Removed from use by the predictor algorithms that start the retry timer. • OPERATIONAL—Functioning properly. • MAXCONNS • DFP_THROTTLED • PROBE_FAILED • PROBE_TESTING • TESTING—Queued for assignment. • READY_TO_TEST—Device functioning and ready to test.
conns	Number of connections.

```

Table A-2 describes the fields in the display.

Table A-2 show module csm serverfarms Command Field Information

Field	Description
server farm	Name of the server farm about which information is being displayed. Information about each server farm is displayed on a separate line.
predictor	Type of load-balancing algorithm) used by the server farm.
nat	Shows whether server and client NAT is enabled.
reals	Number of real servers configured in the server farm.

Table A-2 show module csm serverfarms Command Field Information (continued)

Field	Description
redirect	Number of redirect virtual servers configured in the server farm.
bind id	Bind ID configured on the server farm.

This example shows how to display only the details for one server farm:

```
SLB-Switch# show mod csm 5 serverfarm detail
FARM1, predictor = RoundRobin, nat = SERVER, CLIENT(CLNAT1)
 virtuals inservice:4, reals = 2, bind id = 0, fail action = none
 inband health config:retries = 3, failed interval = 200
 retcode map = <none>
 Real servers:
 10.1.0.102, weight = 8, OPERATIONAL, conns = 0
 10.1.0.101, weight = 8, OPERATIONAL, conns = 0
 Total connections = 0

FARM2, predictor = RoundRobin, nat = SERVER, CLIENT(CLNAT1)
 virtuals inservice:2, reals = 1, bind id = 0, fail action = none
 inband health config:<none>
 retcode map = HTTPCODES
 Real servers:
 10.1.0.101, weight = 8, OPERATIONAL, conns = 2
 Total connections = 2
```

show module csm static

Use the **show module csm** *slot* **static** command to display information about server NAT configurations.

show module csm *slot* **static** [**drop** | **nat** {*ip-address* | **virtual**}]

Syntax Description

slot	Slot where the CSM resides.
drop	(Optional) Keyword to display information about real servers configured to drop connections.
nat	(Optional) Keyword to display information about real servers configured to NAT.
ip-address	(Optional) IP address to which to NAT.
virtual	(Optional) Keyword to display information about real servers configured to NAT virtual server IP addresses.

Defaults

This command has no default settings.

Command Modes

Privileged EXEC.

Command History

Release	Modification
1.1(1)	This command was introduced as **show ip slb static**.
2.1(1)	This command was changed to **show module csm** *slot* (for **ip slb mode rp** only).

Examples

This example shows how to display static data:

```
SLB-Switch# show module csm 4 static nat
```

Related Commands

real (SLB static NAT configuration submode)

show module csm static server

Use the **show module csm** *slot* **static server** command to display information about actual servers that are having NAT performed.

show module csm *slot* **static server** [*ip-address*] [**drop** | **nat** {*ip-address* | **virtual**} | **pass-through**]

Syntax Description

slot	Slot where the CSM resides.
ip-address	(Optional) Option to limit output to a specified server address.
drop	(Optional) Keyword to display information about real servers configured to drop connections.
nat	(Optional) Keyword to display information about real servers configured to NAT.
ip-address	(Optional) IP address to NAT.
virtual	(Optional) Keyword to display information about servers configured to NAT virtual server addresses.
pass-through	(Optional) Keyword to display detailed information about real servers with no NAT configured.

Defaults

This command has no default settings.

Command Modes

Privileged EXEC.

Command History

Release	Modification
1.1(1)	This command was introduced as **show ip slb static server**.
2.1(1)	This command was changed to **show module csm** *slot* (for **ip slb mode rp** only).

Examples

This example shows how to display static server data:

```
SLB-Switch# show module csm 4 static server

Server           NAT Type
---------------------------------------------
10.10.3.10       NAT to 100.100.100.100
10.10.3.20       No NAT
10.10.3.30       NAT to 100.100.100.100
10.10.3.40       No NAT
Cat6k-1#
```

show module csm stats

Use the **show module csm** *slot* **stats** command to display SLB statistics.

show module csm *slot* **stats**

Syntax Description

slot	Slot where the CSM resides.

Defaults

This command has no default settings.

Command Modes

Privileged EXEC.

Command History

Release	Modification
1.1(1)	This command was introduced as **show ip slb stats**.
2.1(1)	This command was changed to **show module csm** *slot* (for **ip slb mode rp** only).

Examples

This example shows how to display SLB statistics:

```
SLB-Switch# show module csm 4 stats
Connections Created:        180
Connections Destroyed:      180
Connections Current:        0
Connections Timed-Out:      0
Connections Failed:         0
Server initiated Connections:
      Created:0, Current:0, Failed:0
L4 Load-Balanced Decisions:180
L4 Rejected Connections:    0
L7 Load-Balanced Decisions:0
L7 Rejected Connections:
      Total:0, Parser:0,
      Reached max parse len:0, Cookie out of mem:0,
      Cfg version mismatch:0, Bad SSL2 format:0
L4/L7 Rejected Connections:
      No policy:0, No policy match 0,
      No real:0, ACL denied 0,
      Server initiated:0
Checksum Failures: IP:0, TCP:0
Redirect Connections:0,  Redirect Dropped:0
FTP Connections:            0
MAC Frames:
      Tx:Unicast:1506, Multicast:0, Broadcast:50898,
          Underflow Errors:0
      Rx:Unicast:2385, Multicast:6148349, Broadcast:53916,
          Overflow Errors:0, CRC Errors:0
```

Table A-3 describes the fields in the display.

Table A-3 show module csm stats Command Field Information

Field	Description
Connections Created	Number of connections that have been created since the last time counters were cleared.
Connections Destroyed	Number of connections that have been destroyed since the last time counters were cleared.

show module csm status

Use the **show module csm** *slot* **status** command to display if the CSM is online. If the CSM is online, this command shows the CSM chassis slot location and indicates if the configuration download is complete.

show module csm *slot* **status**

Syntax Description

slot	Slot where the CSM resides.

Defaults

This command has no default settings.

Command Modes

Privileged EXEC.

Command History

Release	Modification
1.1(1)	This command was introduced as **show ip slb status**.
2.1(1)	This command was changed to **show module csm** *slot* (for **ip slb mode rp** only).

Examples

This example shows how to display CSM status:

```
SLB-Switch# show module csm 4 status
SLB Module is online in slot 4.
Configuration Download state:COMPLETE, SUCCESS
```

show module csm sticky

Use the **show module csm** *slot* **sticky** command to display the sticky database.

show module csm *slot* **sticky** [**groups** | **client** *ip_address*]

Syntax Description

slot	Slot where the CSM resides.
groups	(Optional) Keyword to display all of the sticky group configurations.
client	(Optional) Keyword to display the sticky database entries associated with a particular client IP address.
ip_address	(Optional) IP address of the client.

Defaults

If no options are specified, the command displays information about all clients.

Command Modes

Privileged EXEC.

Command History

Release	Modification
1.1(1)	This command was introduced as **show ip slb sticky**.
2.1(1)	This command was changed to **show module csm** *slot* (for **ip slb mode rp** only.

Usage Guidelines

This command only displays the database of clients using IP stickiness; it does not show cookie or SSL.

Examples

This example shows how to display the sticky database:

```
SLB-Switch# show module csm 4 sticky groups
Group  Timeout  Type
---------------------------------------------------------------
20     100      netmask 255.255.255.255
30     100      cookie foo
```

show module csm tech-script

Use the **show module csm** *slot* **tech-script** command to display the status of a script.

show module csm *slot* **tech-script**

Syntax Description

slot	Slot where the CSM resides.

Defaults

If no options are specified, the command displays all information.

Command Modes

Privileged EXEC.

Command History

Release	Modification
3.1(1)	This command was introduced.

Examples

This example shows how to display the technical support information for the CSM:

```
SLB-Switch# show module csm 4 tech-script
```

show module csm tech-support

Use the **show module csm** *slot* **tech-support** command to display technical support information for the CSM.

show module csm *slot* **tech-support [all | processor** *num* **| redirect | slowpath | probe | fpga | core-dump]**

Syntax Description

slot	Slot where the CSM resides.
all	(Optional) Keyword to display all of the available statistics.
processor	(Optional) Keyword to display the IXP statistics for the IXP identified by *num*.
num	(Optional) IXP number.
redirect	(Optional) Keyword to display all of the HTTP redirect statistics
slowpath	(Optional) Keyword to display all of the slowpath statistics.
probe	(Optional) Keyword to display all of the probe statistics.
fpga	(Optional) Keyword to display all of the FPGA statistics.
core_dump	(Optional) Keyword to display all of the most recent statistics for the process (IXP or Power PC) that experienced a core dump.

Defaults

If no options are specified, the command displays all information.

Command Modes

Privileged EXEC.

Command History

Release	Modification
1.1(1)	This command was introduced as **show ip slb tech-support.**
2.1(1)	This command was changed to **show module csm** *slot* (for **ip slb mode rp** only).

Examples

This example shows how to display the technical support information for the CSM:

```
SLB-Switch# show module csm 4 tech-support ?
  all         All tech output
  core-dump   Most recent core dump
  fpga        FPGA info output
  ft          Fault Tolerance info output
  probe       Probe info output
  processor   Processor info output
  redirect    HTTP redirect info output
  slowpath    Slowpath info output

SLB-Switch# show module csm 4 tech-support processor 2

show module csm vlan

Use the **show module csm** *slot* **vlan** command to display the list of VLANs.

show module csm *slot* **vlan [client | server | ft] [id** *vlan-id*] **[detail]**

Syntax Description

slot	Slot where the CSM resides.
client	(Optional) Keyword to display only the client VLAN configuration.
server	(Optional) Keyword to display only the server VLAN configuration.
ft	(Optional) Keyword to display only the fault-tolerant configuration.
id	(Optional) Keyword to display the VLAN.
vlan-id	(Optional) Keyword to display the specified VLAN.
detail	(Optional) Keyword to display the map configuration details.

Defaults

If no options are specified, the command displays information about all VLANs.

Command Modes

Privileged EXEC.

Command History

Release	Modification
1.1(1)	This command was introduced as **show ip slb vlan**.
2.1(1)	This command was changed to **show module csm** *slot* (for **ip slb mode rp** only).

Examples

This example shows how to display the VLAN configurations:

```
SLB-Switch# show module csm 4 vlan

vlan   IP address       IP mask          type
---------------------------------------------------
11     10.10.4.2        255.255.255.0    CLIENT
12     10.10.3.1        255.255.255.0    SERVER
30     0.0.0.0          0.0.0.0          FT

```

show module csm xml stats

Use the **show module csm xml stats** command to display a list of XML statistics.

show module csm xml stats

Defaults

If no options are specified, the command displays information about all clients.

Command Modes

Privileged EXEC.

Command History

Release	Modification
3.1(1)	This command was introduced.

Examples

This example shows how to display the CSM XML statistics:

```
SLB-Switch# show module csm 4 xml stats
XML config:inservice, port = 80, vlan = <all>, client list = <none>
   connection stats:
     current = 0, total = 5
     failed = 2, security failed = 2
   requests:total = 5, failed = 2
```

S878
D

snmp enable traps slb ft

Use the **snmp enable traps slb ft** command to enable or disable fault-tolerant traps. Use the **no** form of this command to disable fault-tolerant traps.

snmp enable traps slb ft

no snmp enable traps slb ft

Defaults

This command has no default settings.

Command Modes

Module CSM configuration submode.

Command History

Release	Modification
3.1(1)	This command was introduced.

Usage Guidelines

A fault-tolerant trap allows the CSM e to send an SNMP trap when the CSM transitions from standby to active after detecting a failure in its fault tolerant peer.

Examples

This example shows how to enable fault tolerant traps:

```
SLB-Switch(config-module-csm)# snmp enable traps slb ft
```

static

Use the **static** command to configure the server NAT behavior and enter the NAT configuration submode. This command configures the CSM to support connections initiated by real servers. Both client NAT and server NAT can exist in the same configuration. Use the **no** form of this command to remove NAT from the CSM configuration.

static {**drop** | **nat** {**virtual** | *ip-address*}}

no static {**drop** | **nat** {**virtual** | *ip-address*}}

Syntax Description

drop	Keyword to drop connections from servers specified in static submode.
virtual	Keyword specifying that the configuration is for NAT.
nat	Keyword to use the server's Virtual IP (VIP) to NAT its source IP address.
ip-address	IP address to be used for NAT.

Defaults

This command has no default settings.

Command Modes

Module CSM configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.

Examples

This example shows how to configure the CSM to support connections initiated by the real servers:

```
SLB-Switch(config-module-csm)# static nat virtual
```

Related Commands

show module csm static

58x0 9

real

Use the **real** command in SLB static NAT configuration submode to specify the address for a real server or the subnet mask for multiple real servers performing server NAT. Use the **no** form of this command to remove the address of a real server or the subnet mask of multiple real servers so they are no longer performing NAT.

real *real-ip-address* [*real-netmask*]

no real *real-ip-address* [*real-netmask*]

Syntax Description

real-ip-address	Real server IP address performing NAT.
real-netmask	(Optional) Range of real servers performing NAT. If not specified, the default is 255.255.255.255 (a single real server).

Defaults

This command has no default settings.

Command Modes

SLB static NAT configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.

Examples

This example shows how to specify the address for a real server:

```
SLB-Switch(config-slb-static)# real 10.0.0.0 255.0.0.0
```

Related Commands

static
show module csm static

sticky

Use the **sticky** command to ensure that connections from the same client that match the same SLB policy use the same real server on subsequent connections. Use the **no** form of this command to remove a sticky group.

sticky *sticky-group-id* {**netmask** *netmask* | **cookie** *name* | **ssl**} [**timeout** *sticky-time*]

no sticky s*ticky-group-id*

Syntax Description

sticky-group-id	ID to identify the sticky group instance; the range is from 1 to 255.
netmask	Keyword to specify the network mask for IP stickiness.
netmask	Network mask number.
cookie	Keyword to specify cookie stickiness.
name	Name of the cookie attached to the *sticky-group-id*.
ssl	Keyword to specify SSL stickiness.
timeout	(Optional) Keyword to specify the sticky duration.
sticky-time	(Optional) Sticky timer duration in minutes; the range is from 0 to 65535.

Defaults

The sticky time default value is 1440 minutes (24 hours).

Command Modes

Module CSM configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.
2.1(1)	Changed the default timeout from 0 to 1440.

Usage Guidelines

Specifying a netmask permits sticky connections based on the masked client IP address.

Use the sticky time option to ensure that connections from the same client that match the same SLB policy use the same real server. If you specify a nonzero value, the last real server that was used for a connection from a client is remembered for *sticky-time* minutes after the end of the client's latest connection. New connections from the client to the virtual server initiated before the sticky time expires and that match SLB policy are balanced to the same real server that was used for the previous connection. A sticky time of 0 means sticky connections are not tracked.

Examples

This example shows how to create an IP sticky group:

```
SLB-Switch(config-module-csm)# sticky 5 netmask 255.255.255.255 timeout 20
```

vlan

Use the **vlan** command to create a client or server VLAN and assign it a VLAN ID and enter the VLAN submode. Use the **no** form of this command to remove the VLAN from the configuration.

vlan *vlan-id* {**client** | **server**}

no vlan *vlan-id*

Syntax Description

vlan-id	Number of the VLAN; the range is from 2 to 4095.
client	Keyword to specify a client-side VLAN.
server	Keyword to specify a server-side VLAN.

Defaults

This command has no default settings.

Command Modes

Module CSM configuration submode.

Usage Guidelines

A database entry should exist for the given VLAN ID.

Command History

Release	Modification
1.1(1)	This command was introduced.
2.1(1)	VLAN type fault-tolerance is deprecated and hidden.

Examples

This example shows how to create a server VLAN and assign it a VLAN ID:

```
SLB-Switch(config-module-csm)# vlan 2 server
```

Related Commands

vlan (SLB vserver submode)
show module csm vlan

15872 D

alias

Use the **alias** command in the SLB VLAN configuration submode to assign multiple IP addresses to the CSM. Use the **no** form of this command to remove an alias IP addresses from the configuration.

alias *ip-address netmask*

no alias *ip-address netmask*

Syntax Description

ip-address	Alias IP address; a maximum of 255 addresses are allowed per VLAN.
netmask	Network mask.

Defaults

This command has no default settings.

Command Modes

SLB VLAN configuration submode.

Usage Guidelines

This command allows you to place the CSM on a different IP network than real servers without using a router.

Command History

Release	Modification
1.1(1)	This command was introduced for server VLANs.
2.1(1)	This command is now available for both client and server VLANs.

Examples

This example shows how to assign multiple IP addresses to the CSM:

```
SLB-Switch(config-slb-vlan-server)# alias 130.21.34.56 255.255.255.0
SLB-Switch(config-slb-vlan-server)# alias 130.22.35.57 255.255.255.0
SLB-Switch(config-slb-vlan-server)# alias 130.23.36.58 255.255.255.0
SLB-Switch(config-slb-vlan-server)# alias 130.24.37.59 255.255.255.0
SLB-Switch(config-slb-vlan-server)# alias 130.25.38.60 255.255.255.0
```

Related Commands

vlan
show module csm vlan

5871
D.

gateway

Use the **gateway** command in the SLB VLAN configuration mode to configure a gateway IP address. Use the **no** form of this command to remove the gateway from the configuration.

gateway *ip-address*

no gateway *ip-address*

Syntax Description

ip-address	IP address of the client-side gateway.

Defaults

This command has no default settings.

Command Modes

SLB VLAN configuration submode.

Usage Guidelines

You can configure up to seven gateways per VLAN with a total of up to 255 gateways for the entire system. A gateway must be in the same network as specified in the **ip address** SLB VLAN command.

Command History

Release	Modification
1.1(1)	This command was introduced for client VLANs.
2.1(1)	This command is now available for both client and server VLANs.

Examples

This example shows how to configure a client-side gateway IP address:

```
SLB-Switch(config-slb-vlan-client)# gateway 130.21.34.56
```

Related Commands

ip address (SLB VLAN configuration submode)
vlan
show module csm vlan

ip address

Use the **ip address** command in the SLB VLAN configuration submode to assign an IP address to the CSM that is used for probes and ARP requests on a VLAN. Use the **no** form of this command to remove the CSM IP address and disable probes and ARP requests from the configuration.

ip address *ip-address netmask*

no ip address

Syntax Description

ip-address	IP address for the CSM; only one management IP address is allowed per VLAN.
netmask	Network mask.

Defaults

This command has no default settings.

Command Modes

SLB VLAN configuration submode.

Usage Guidelines

This command is applicable for both server and client VLANs. Up to 255 unique VLAN IP addresses are allowed per module.

Command History

Release	Modification
1.1(1)	This command was introduced.
2.2.1	Increases maximum number of unique VLAN IP addresses per system form 32 to 255.

Examples

This example shows how to assign an IP address to the CSM:

```
SLB-Switch(config-slb-vlan-client)# ip address 130.21.34.56 255.255.255.0
```

Related Commands

vlan
show module csm vlan

route

Use the **route** command in the SLB VLAN configuration submode to configure networks that are one Layer 3 hop away from the CSM. Use the **no** form of this command to remove the subnet or gateway IP address from the configuration.

route *ip-address netmask* **gateway** *gw-ip-address*

no route *ip-address netmask* **gateway** *gw-ip-address*

Syntax Description

ip-address	Subnet IP address.
netmask	Network mask.
gateway	Keyword to specify that the gateway is configured.
gw-ip-address	Gateway IP address.

Defaults

This command has no default settings.

Command Modes

SLB VLAN configuration submode.

Usage Guidelines

You specify the Layer 3 network's subnet address and the gateway IP address to reach the next-hop router. The gateway address must be in the same network as specified in the **ip address** SLB VLAN command.

Command History

Release	Modification
1.1(1)	This command was introduced for server VLANs.
2.1(1)	This command is now available for both client and server VLANs.

Examples

This example shows how to configure a network to the CSM:

```
SLB-Switch(config-slb-vlan-server)# route 130.21.34.56 255.255.255.0 gateway 120.22.36.40
```

vserver

Use the **vserver** command to identify a virtual server and enter the virtual server configuration submode. Use the **no** form of this command to remove a virtual server from the configuration.

vserver *virtserver-name*

no vserver *virtserver-name*

Syntax Description

virtserver-name	Character string used to identify the virtual server; the character string is limited to 15 characters.

Defaults

This command has no default settings.

Command Modes

Module CSM configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.

Examples

This example shows how to identify a virtual server named PUBLIC_HTTP and change the CLI to virtual server configuration mode:

```
SLB-Switch(config-module-csm)#   vserver PUBLIC_HTTP
```

Related Commands

redirect-vserver (SLB serverfarm submode)
show module csm vserver redirect

advertise

Use the **advertise** command in the SLB t virtual server configuration mode to allow the CSM to advertise the IP address of the virtual server as host-route. Use the **no** form of this command to stop advertising the host-route for this virtual server.

advertise [active]

no advertise

Syntax Description

active	(Optional) Keyword to allow the CSM to advertise the IP address of the virtual server as host-route.

Defaults

The default for network mask is 255.255.255.255 if the network mask is not specified.

Command Modes

SLB virtual server configuration submode.

Usage Guidelines

Without the active option, the CSM always advertises the virtual server IP address whether or not there is any active real server attached to this virtual server.

Command History

Release	Modification
1.1(1)	This command was introduced.

Examples

This example shows how to restrict a client from using the virtual server:

```
SLB-Switch(config-slb-redirect-vs)# advertise 10.5.2.1 exclude
```

Related Commands

redirect-vserver
show module csm vserver redirect

5866
D

client

Use the **client** command in the SLB virtual server configuration mode to restrict which clients are allowed to use the virtual server. Use the **no** form of this command to remove the client definition from the configuration.

client *ip-address* [*network-mask*] [**exclude**]

no client *ip-address* [*network-mask*]

Syntax Description

ip-address	Client's IP address.
network-mask	(Optional) Client's IP mask.
exclude	(Optional) Keyword to specify that the IP address is disallowed.

Defaults

The default for network mask is 255.255.255.255 if the network mask is not specified.

Command Modes

SLB virtual server configuration submode.

Usage Guidelines

The network mask is applied to the source IP address of incoming connections and the result must match the IP address before the client is allowed to use the virtual server. If exclude is not specified, the IP address and network mask combination is allowed.

Command History

Release	Modification
1.1(1)	This command was introduced.

Examples

This example shows how to restrict a client from using the virtual server:

```
SLB-Switch(config-slb-vserver)# client 10.5.2.1 exclude
```

Related Commands

5865
D.

idle

Use the **idle** command in the SLB virtual server configuration submode to control the amount of time the CSM maintains connection information in the absence of packet activity. Use the **no** form of this command to change the idle timer to its default value.

idle *duration*

no idle

Syntax Description

duration	Idle connection timer duration in seconds; the range is from 4 to 65535.

Defaults

The default is 3600.

Command Modes

SLB virtual server configuration submode.

Usage Guidelines

If you do not specify a duration value, the default value is applied.

Command History

Release	Modification
1.1(1)	This command was introduced.

Examples

This example shows how to specify an idle timer duration of 4000:

```
SLB-Switch(config-slb-vserver)# idle 4000
```

Related Commands

vserver
show module csm vserver redirect

5884

D.

inservice

Use the **inservice** command in the SLB virtual server configuration submode to enable the virtual server for load balancing. Use the **no** form of this command to remove the virtual server from service.

inservice

no inservice

Syntax Description

This command has no keywords or arguments.

Defaults

The default is **no inservice**.

Command Modes

SLB virtual server configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.

Examples

This example shows how to enable a virtual server for load balancing:

```
SLB-Switch(config-slb-vserver)# inservice
```

Related Commands

vserver
show module csm vserver redirect

5863
D

owner

Use the **owner** command in the SLB virtual server submode to define an owner that may access the virtual server. Use the **no** form of this command to remove the owner.

owner *owner-name* ***maxconns*** *number*

no maxconns

Syntax Description

owner-name	Name of the owner object.
maxconns	Keyword to set the maximum number of connections for this owner.
number	Maximum number of connections.

Defaults

This command has no default settings.

Command Modes

SLB virtual server configuration submode.

Command History

Release	Modification
3.1(1)	This command was introduced.

Examples

This example shows how to specify an owner for virtual server access:

```
SLB-Switch(config-slb-vserver)# owner madrigal maxconns 1000
```

Related Commands

vserver

parse-length

Use the **parse-length** command in the SLB virtual server configuration submode to set the maximum number of bytes to parse for URLs and cookies. Use the **no** form of this command to restore the default.

parse-length *bytes*

no parse-length

Syntax Description

bytes	Number of bytes; the range is from 1 to 4000.

Defaults

The default is 600.

Command Modes

SLB virtual server configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.

Examples

This example shows how to set the number of bytes to parse for URLs and cookies:

```
SLB-Switch(config-slb-vserver)# parse-length 1000
```

Related Commands

vserver
show module csm vserver redirect

pending

Use the **pending** command in the SLB virtual server configuration submode to set the pending connection timeout. Use the **no** form of this command to restore the default.

pending *timeout*

no pending

Syntax Description

timeout	Seconds to wait before a connection is considered unreachable. Range is from 1 to 65535.

Defaults

The default pending timeout is 30 seconds.

Command Modes

SLB virtual server configuration submode.

Usage Guidelines

This command is used to prevent denial of service (DOS) attacks. The pending connection timeout sets the response time for terminating connections if a switch becomes flooded with traffic. The pending connections are configurable on a per virtual server basis.

Command History

Release	Modification
2.2(1)	This command was introduced.

Examples

This example shows how to set the number to wait for a connection to be made to the server:

```
SLB-Switch(config-slb-vserver)# pending 300
```

Related Commands

vserver
show module csm vserver redirect

persistent rebalance

Use the **persistent rebalance** command in the SLB virtual server configuration submode to enable or disable HTTP 1.1 persistence for connections in the virtual server. Use the **no** form of this command to disable persistence.

persistent rebalance

no persistent rebalance

Syntax Description

This command has no keywords or arguments.

Defaults

The default is **persistent rebalance**.

Command Modes

SLB virtual server configuration submode.

Command History

Release	Modification
2.1(1)	This command was introduced.

Examples

This example shows how to enable the HTTP 1.1 persistence:

```
SLB-Switch(config-slb-vserver)# persistent rebalance
```

Related Commands

vserver
show module csm vserver redirect

replicate csrp

Use the **replicate csrp** command in the SLB virtual server configuration submode to enable connection redundancy. Use the **no** form of this command to disable connection redundancy.

replicate csrp {**sticky** | **connection**}

no replicate csrp {**sticky** | **connection**}

Syntax Description

sticky	Replicate the sticky database to the backup CSM.
connection	Replicate connections to the backup CSM.

Defaults

The default is disabled.

Command Modes

SLB virtual server configuration submode.

Usage Guidelines

Sticky and connection replication can be enabled or disabled separately. For replication to occur, you must enable SLB fault tolerance with the **ft group** command.

Command History

Release	Modification
2.1(1)	This command was introduced.

Examples

This example shows how to enable connection redundancy:

```
SLB-Switch(config-slb-vserver)# replicate csrp connection
```

Related Commands

ft group
vserver
show module csm vserver redirect

5858

serverfarm

Use the **serverfarm** command in SLB virtual server configuration submode to associate a server farm with a virtual server. Use the **no** form of this command to remove a server farm association from the virtual server.

serverfarm *primary-serverfarm* [**backup** *sorry-serverfarm* [**sticky**]]

no serverfarm

Syntax Description

primary-sf	Character string used to identify the server farm.
backup	(Optional) Keyword set the name of a backup serverfarm.
sorry-sf	(Optional) Backup serverfarm name.
sticky	(Optional) Keyword to associate the backup serverfarm with a virtual server.

Defaults

This command has no default settings.

Command Modes

SLB virtual server configuration submode.

Usage Guidelines

The server farm name must match the server farm name specified in a previous module CSM submode **serverfarm** command.

The backup serverfarm can be associated with a policy. A primary serverfarm must be associated with that policy to allow the backup serverfarm to function properly. The backup serverfarm can have a different predictor option than the primary server. When the sticky option is used for a policy, then stickiness can apply to real servers in the backup serverfarm. Once a connection has been balanced to a server in the backup serverfarm, subsequent connections from the same client can be stuck to the same server even when the real servers in the primary serverfarm come back to the operational state. You may allow the sticky attribute when applying the backup serverfarm to a policy.

By default, the sticky option does not apply to the backup serverfarm. To remove the backup serverfarm, you can either use the serverfarm command without the backup option or use the **no serverfarm** command.

Command History

Release	Modification
1.1(1)	This command was introduced.
3.1(1)	The sorry server (backup server) option was added to this command.

Examples

This example shows how to associate a server farm with a virtual server named PUBLIC_HTTP:

```
SLB-Switch(config-slb-vserver)# serverfarm PUBLIC_HTTP back-up seveneleven sticky
```

Related Commands

serverfarm (Module CSM submode)
reverse-sticky (SLB policy submode)
show module csm vserver redirect
vserver

15856

slb-policy

Use the **slb-policy** command in the SLB virtual server configuration submode to associate a load-balancing policy with a virtual server. Use the **no** form of this command to remove a policy from a virtual server.

slb-policy *policy-name*

no slb-policy *policy-name*

Syntax Description

policy-name	Policy associated with a virtual server.

Defaults

This command has no default settings.

Command Modes

SLB virtual server configuration submode.

Usage Guidelines

Multiple load-balancing policies can be associated with a virtual server. URLs in incoming requests are parsed and matched against policies defined in the same order in which they are defined with this command. The policy name must match the name specified in a previous **policy** command.

Note The order of the policy association is important; you should enter the highest priority policy first.

Command History

Release	Modification
1.1(1)	This command was introduced.

Examples

This example shows how to associate a policy with a virtual server.:

```
SLB-Switch(config-slb-vserver)# slb-policy COOKIE-POLICY1
```

Related Commands

vserver
policy
show module csm owner
show module csm vserver redirect

ssl-sticky

Use the **ssl-sticky** command in the SLB virtual server configuration submode to allow SSL sticky operation. Use the **no** form of this command to remove the SSL sticky feature.

ssl-sticky offset *X* **length** *Y*

no ssl-sticky

Syntax Description

offset	Keyword to specify the SSL ID offset.
X	Sets the offset value.
length	Keyword to specify the SSL ID length.
Y	Sets the length.

Defaults

The default is **offset 0** and **length 32.**

Command Modes

SLB virtual server configuration submode.

Usage Guidelines

This feature allows you to stick an incoming SSL connection based only on this special section of the SSL ID specified by the offset and length values. The **ssl-sticky** command was added to ensure that the CSM always load balances an incoming SSL connection to the SSL Termination Engine that generated that SSL ID.

Command History

Release	Modification
3.1(1)	This command was introduced.

Examples

This example shows how to associate a policy with a virtual server.:

```
SLB-Switch(config-slb-vserver)# ssl-sticky offset 0 length 32
```

Related Commands

D

sticky

Use the **sticky** command to ensure that connections from the same client use the same real server. Use the **no** form of this command to change the sticky timer to its default value and remove the sticky option from the virtual server.

sticky *duration* [***group*** *group-id*] [**netmask** *ip-netmask*] [**source** | **destination** | **both**]

no sticky

Syntax Description

duration	Sticky timer duration in minutes; the range is from 1 to 65535.
group	(Optional) Keyword to place the virtual server in a sticky group for connection coupling.
group-id	(Optional) Number identifying the sticky group to which the virtual server belongs; the range is from 0 to 255.
netmask	(Optional) Keyword to specify which part of the address should be used for stickiness.
ip-netmask	(Optional) Network that allows clients to be stuck to the same server.
source	(Optional) Keyword to specify the source portion of the IP address.
destination	(Optional) Destination portion of the IP address.
both	(Optional) Specifies that both the source and destination portions of the IP address are used.

Defaults

The default is **no sticky**. Sticky connections are not tracked.
The group ID default is 0. The sticky feature is not used for other virtual servers.
The network default is 255.255.255.255.

Command Modes

SLB virtual server configuration submode.

Usage Guidelines

The last real server that was used for a connection from a client is stored for the *duration* value after the end of the client's latest connection. If a new connection from the client to the virtual server is initiated during that time, the same real server that was used for the previous connection is chosen for the new connection.

A nonzero sticky group ID must correspond to a sticky group previously created using the **sticky** command. Virtual servers in the same sticky group share sticky state information.

Command History

Release	Modification
1.1(1)	This command was introduced.
3.1(1)	The IP reverse-sticky optional parameters are introduced.

Examples

This example shows how to set the sticky timer duration and places the virtual server in a sticky group for connection coupling:

```
SLB-Switch(config-module-csm)# vserver PUBLIC_HTTP
SLB-Switch(config-slb-vserver)# sticky 60 group 3
```

reverse-sticky

Use the **reverse-sticky** command to ensure that the CSM switches connections in the opposite direction back to the original source. Use the **no** form of this command to remove the reverse-sticky option from the policy or the default-policy of a virtual server.

reverse-sticky *group-id*

no reverse-sticky

Syntax Description

group-id	Number identifying the sticky group to which the virtual server belongs; the range is from 0 to 255.

Defaults

The default is **no reverse-sticky**. Sticky connections are not tracked.
The group ID default is 0. The sticky feature is not used for other virtual servers.
The network default is 255.255.255.255.

Command Modes

SLB virtual server configuration submode.

Command History

Release	Modification
1.1(1)	This command was introduced.
3.1(1)	The **IP reverse-sticky** command is introduced.

Examples

This example shows how to set the IP reverse-sticky feature:

```
SLB-Switch(config-module-csm)# vserver PUBLIC_HTTP
SLB-Switch(config-slb-vserver)# reverse-sticky 60
```

Related Commands

show module csm vserver redirect

url-hash

Use the **url-hash** command in the SLB virtual server configuration submode to set the beginning and ending pattern of a URL to parse URLs for the URL hash load-balancing algorithm. Use the **no** form of this command to remove the hashing from service.

url-hash {**begin-pattern** | **end-pattern**} *pattern*

no url-hash

Syntax Description

begin-pattern	Keyword to specify the beginning of the URL to parse.
end-pattern	Keyword to specify the ending of the URL to parse.
pattern	Pattern string to parse.

Defaults

The default is **no url-hash**.

Command Modes

SLB virtual server configuration submode.

Usage Guidelines

The beginning and ending patterns apply to the URL hashing algorithm that is set using the **predictor** command in the SLB serverfarm submode.

Command History

Release	Modification
2.1(1)	This command was introduced.

Examples

This example shows how to specify a URL pattern to parse:

```
SLB-Switch(config-slb-vserver)# url hash begin pattern lslkjfsj
```

virtual

Use the **virtual** command in the SLB virtual server configuration submode to configure virtual server attributes. Use the **no** form of this command to set the virtual server's IP address to 0.0.0.0 and its port number to zero.

virtual *ip-address* [*ip-mask*] *protocol port-number* [**service ftp** | **rtsp**] [**unidirectional**]

no virtual *ip-address*

Syntax Description

ip-address	IP address for the virtual server.
ip-mask	(Optional) Mask for the IP address to allow connections to an entire network.
protocol	Load-balancing protocol, either TCP, UDP, any, or a number from to 255.
port-number	(Optional) Decimal TCP/UDP port number (0-65535) or port name.
service ftp	(Optional) Keyword to combine connections associated with the same service so that all related connections from the same client use the same real server. FTP data connections are combined with the control session that created them. If you want to configure FTP services, these keywords are required.
service rtsp	(Optional) Keyword to combine connections to the Real Time Streaming Protocol (RTSP) TCP port 554.
unidirectional	(Optional) Sets the data flow to unidirectional.

Defaults

The default IP mask is 255.255.255.255.

Command Modes

SLB virtual server configuration submode.

Usage Guidelines

Clients connecting to the server farm represented by the virtual server use this address to access the server farm. This service option is allowed only if a port number is specified. A port of 0 (or **any**) means that this virtual server handles all ports not specified for handling by another virtual server with the same IP address. The port is used only for TCP or UDP load balancing.

The following TCP port names can be used in place of a number:

XOT—**X25** over TCP (1998)

dns—Domain Name Service (53)

ftp—File Transfer Protocol (21)

https—HTTP over Secure Sockets Layer (443)

matip-a—Mapping of Airline Traffic over IP, Type A (350)

nntp—Network News Transport Protocol (119)

pop2—Post Office Protocol v2 (109)

pop3—Post Office Protocol v3 (110)

smtp—Simple Mail Transport Protocol (25)

telnet—Telnet (23)

www—World Wide Web—Hypertext Transfer Protocol (80)

any—Allows traffic for any port, or the same as specifying a 0.

Command History

Release	Modification
1.1(1)	This command was introduced.
2.1(1)	*ip-netmask*, UDP/arbitrary protocol introduced.
2.2.1	RTSP support introduced.
3.1(1)	Added the idle timeout for unidirectional flows feature.

Examples

This example shows how to create a virtual server and assign it an IP address, protocol, and port:

```
SLB-Switch(config-slb-vserver)# virtual 102.35.44.79 tcp 1 unidirectional
```

Related Commands

vlan

Use the **vlan** command in the SLB virtual server submode to define which source VLANs may access the virtual server. Use the **no** form of this command to remove the VLAN.

vlan *vlan-number*

no vlan

Syntax Description

vlan-number	VLAN that the virtual server may access.

Defaults

The default is all VLANs.

Command Modes

SLB virtual server configuration submode.

Usage Guidelines

The VLAN must correspond to an SLB VLAN previously created with the **vlan** command.

Command History

Release	Modification

client-group

Use the **client-group** command in the SLB XML submode to allow only connections sourced from an IP address matching the client group. Use the **no** form of this command to remove the owner.

client-group [*1-99* | *name*]

no client-group

Syntax Description

1-99	(Optional) Client group number.
name	(Optional) Name of the client group.

Defaults

The default is **no client-group**.

Command Modes

SLB XML configuration submode.

Usage Guidelines

When a client group is specified, only connections sourced from an IP address matching that client group are accepted by the CSM XML configuration interface. If no client group is specified, then no source IP address check is performed. Only one client-group may be specified.

Command History

Release	Modification
3.1(1)	This command was introduced.

Examples

This example shows how to specify a client group:

```
SLB-Switch(config-slb-xml)# client-group domino
```

Related Commands

credentials

Use the **credentials** command in the SLB XML submode to define one or more username and password combinations. Use the **no** form of this command to remove the credentials.

credentials *user-name password*

no credentials *user-name*

Syntax Description

user-name	Name of the credentials user.
password	Password for the credentials user.

Defaults

This command has no default settings.

Command Modes

SLB XML configuration submode.

Usage Guidelines

When one or more credentials commands are specified, the CSM HTTP server authenticates user access.

Command History

Release	Modification
3.1(1)	This command was introduced.

Examples

This example shows how to specify the user and password credentials for access:

```
SLB-Switch(config-slb-xml)# credentials savis XXXXX
```

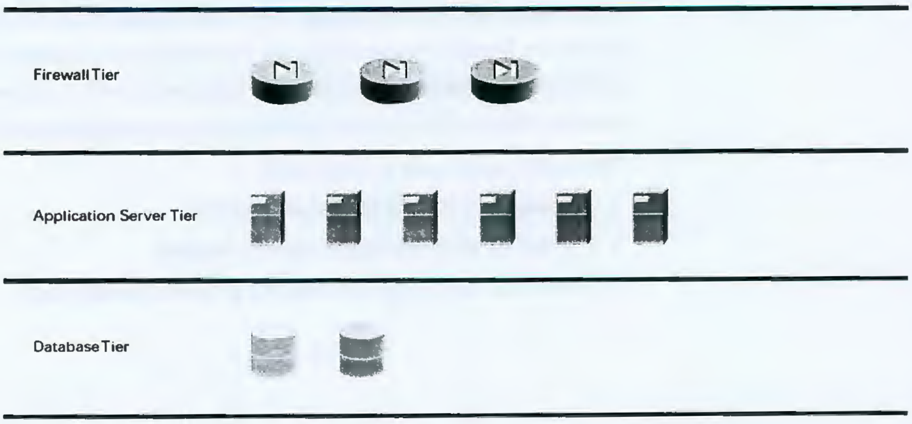
White Paper

Removing Content Switching Performance Barriers: A Discussion of the **Cisco CSM** Pipelined Network Processor Architecture

Introduction

As Web applications become increasingly business-critical—particularly in the areas of e-commerce, customer relationship management (CRM), and employee resource management (ERM) the performance, scalability, security, and availability of the application infrastructure become paramount concerns for IT and network managers. These requirements drive the deployment of Web applications in tiers or layers. Figure 1 shows a typical deployment. In this application, we see a security tier consisting of a layer of firewalls, an application server tier, and a database tier. Each tier may be scaled horizontally by adding additional devices of the appropriate type. As anticipated load on the layer increases, more machines are added to handle the load. In addition, by having multiple devices at each tier, provision is made for functional redundancy. If any device at a given layer fails another device may pick up its work.

Figure 1. Typical Web Application Infrastructure



3840
D

In order for this approach to scaling and failover to work, there must also be a mechanism for intelligently routing messages to and from each of the layers. This is the role fulfilled by content switches. Content switches route messages to individual machines by inspecting the contents of the messages and forwarding them to specific machines based on policies that meet the requirements of the device or application.[1] Content switches monitor the health of each of the devices and provide automatic failover by routing messages to the remaining devices in the tier, this again based on policies set to provide the desired behavior. Because of the critical role they play in enhancing Web application performance, availability, and security, content switches have become an indispensable part of e-business infrastructure.

Network designers building out data centers to support these applications now need to cope with the deployment of firewalls and content switches in addition to their more traditional concerns about routers, LAN switches, and WAN and Internet connectivity. This complexity is accelerating the need for more integrated functions such as firewall and content switching in LAN switches. In addition, the increasing percentage of dynamically generated content in web applications results in a higher load on application servers and databases. This in turn means that a given performance level (in terms of page views or hits per second) requires a greater number of servers, creating greater port density requirements on content switches. The Cisco Content Switching Module for the Catalyst® 6500 Series switch and 7600 Internet router (CSM) was designed to meet these requirements for high density and tight integration with the Layer 2 and Layer 3 infrastructures. In addition, the Cisco CSM sets a new standard for high-end content switching performance. Using a new pipelined network processor architecture, the Cisco CSM achieves better performance by an order of magnitude than previous-generation content switches. The Cisco CSM is especially well suited to deep-packet scanning and inspection operations such as HTTP header matching.[2] In fact, the Cisco CSM turns the Cisco Catalyst 6500 Series switches into the densest, highest performing content switches in the marketplace today—without sacrificing either Layer 2 or Layer 3 performance or burdening the cost of the base platform.

The balance of this paper explores in detail the unique architecture of the Cisco CSM. It will be assumed that the reader has a basic understanding of IP, Transmission Control Protocol (TCP), User Datagram Protocol (UDP), and Hypertext Transfer Protocol (HTTP) (including Secure Socket Layer [SSL] and the concepts of URLs and cookies). It will also be assumed that the reader has a basic level of understanding about the *role* of content switches in a network but not *how* content switches operate to fulfill this role.[3]

This paper will discuss the following:

- An overview of content switch operation
- Categories of processing in content switches
- The Cisco CSM pipelined network processor architecture

[1] The terms "policy" and "policies" as used in this document should be interpreted to mean a generic set of rules or configurable controls that govern the operation of a content switch. They should not be confused with the configuration instructions or keywords used to implement those policies on specific products.

[2] This is especially significant given the overwhelming use of cookies by application server vendors to preserve user session information across multiple HTTP requests. One of the primary requirements for content switches operating in this tier of the infrastructure is to provide session persistence via inspection of these session cookies. Although most content switch benchmarks today do not take into account cookie processing requirements, it is one of the most taxing operations they are asked to perform. The Cisco CSM is especially well suited for these types of operations.

[3] The reader is referred to the Cisco Content Networking homepage at www.cisco.com/go/contentswitch for more information about content switching and its role in web applications.

An Overview of Content Switch Operation

As previously discussed, the primary role of content switches is to route messages to and from specific devices or machines based upon the requirements of the application as well as the devices themselves. These application and device requirements are expressed in terms of policies that are configured on the content switch. For example, when routing messages to a group of firewalls, one might want to balance the load across the available firewalls while at the same time ensuring that all messages associated with a particular application connection traverse the same firewall in both the forward and reverse direction. This is because the firewalls need to be able to statefully inspect all the packets associated with a connection in both directions. When routing messages to application servers, one might be concerned with balancing the load across the application servers, with the additional constraint that all connections from a particular client get routed to the same point-of-contact application server until a particular transaction or set of transactions is complete.[4]

In general, the set of policies that can be implemented in content switches fall into one of the following broad categories:[5]

1. Load balancing policies—these policies describe how connections and requests are to be distributed across an array of servers that are eligible to receive them. These policies are expressed in terms of the criteria that identify the requests to be distributed, the eligible machines capable of handling those requests, and the algorithm(s) to be used to distribute them across the machines. Examples of load-distribution algorithms include: round robin, weighted round robin, least connections, weighted least connections, least loaded, predictive hash, and others. An example of a load-balancing policy might be the following:

   Policy 1:

   For each inbound request where:

   Destination IP address = 192.32.12.3

   Protocol = TCP

   Destination port = 80 (HTTP)

   Balance the load across the following eligible servers:

   IP address 10.10.10.1, port 80

   IP address 10.10.10.2, port 80

   IP address 10.10.10.3, port 80

   Using the following load distribution algorithm:

   Round Robin

[4] The "point of contact" server is the server selected for the first of a series of connections or transactions. It is typically selected with the goal of balancing the load across all servers. Once this server has been selected, this goal becomes secondary to the goal of maintaining "persistence" between this client and server until the requisite set of connections or transactions is complete.

[5] A detailed discussion of the finer points of content switching policies is beyond the scope of this document. The intent here is merely to convey the types of operations performed by content switches to provide context for our architectural discussion. The reader is referred to the CSM documentation for more information.

5838
D.

2. Persistence policies—these policies describe requirements to keep a series of connections or requests coming to the same server in the array until a particular transaction or unit of work is complete. With persistence policies there must be some token passed in each request that can be used by the content switch as the means for maintaining persistence. These tokens are most often IDs that represent a specific server or user session. They are typically found encoded in a URL or cookie or, in the case of secure traffic, in the unique SSL session ID. An example of a persistence policy might be the following:

   Policy 2:

   For each inbound request where:

   Destination IP address = 192.32.12.3

   Protocol = TCP

   Destination port = 80 (HTTP)

   Balance the load across the following eligible servers:IP address 10.10.10.1, port 80

   IP address 10.10.10.2, port 80

   IP address 10.10.10.3, port 80

   Using the following load distribution algorithm:

   Round Robin

   Maintain persistence to selected server using the following token:

   Cookie = “Session-ID”

Note: Note that the persistence policy works in conjunction with a load-balancing policy. The load-balancing policy is used to select the initial point-of-contact server. The server then sets the “Session-ID” cookie to a unique value for this session. The persistence policy alerts the content switch to monitor the setting of this cookie and to maintain an association between this cookie and the point-of-contact server so that subsequent requests received with this cookie are directed to the same server.

3. Server failure policies—these policies are designed to give the operator control over switch behavior in the event of server failure. One can envision, for example, different applications requiring different kinds of treatment. This is particularly true when using persistence policies as described above. What should be done when a server that has a persistent client connection mapped to it fails mid-transaction? Possible options include: reset the connection, issue an HTTP redirect (perhaps to a server that displays an error message), rebalance the connection to a new server using the load-balancing policy, or direct to a special "sorry server" that becomes active if there are no other eligible servers for this policy. An example of a server failure policy follows:

   Policy 3:

   For each inbound request where:

   Destination IP address = 192.32.12.3

   Protocol = TCP

   Destination port = 80 (HTTP)

   Balance the load across the following eligible servers:

   IP address 10.10.10.1, port 80

   IP address 10.10.10.2, port 80

   IP address 10.10.10.3, port 80

   Using the following load distribution algorithm:

   Round Robin

   Maintain persistence to selected server using the following token:

   Cookie = "Session-ID"

   Upon persistent server failure:

   Issue HTTP redirect to 192.32.15.1/failuremessage.htm

5836 D

4. Content-specific policies—these policies are used to specify different treatment for different types of content. One might want to direct all requests for cacheable content, for example, to a set of reverse proxy caches that offload the processing of static images from application servers. Or one might want to partition a web server farm into static and dynamic sections. The following is an example of a content specific policy.

   Policy 4:

   For each inbound request where:

   Destination IP address = 192.32.12.3

   Protocol = TCP

   Destination port = 80 (HTTP)

   URL = "*.GIF, *.JPEG" /* file extensions for cacheable image types

   Balance the load across the following eligible caches:

   IP address 10.10.20.1, port 80

   IP address 10.10.20.2, port 80

   IP address 10.10.20.3, port 80

   Using the following load distribution algorithm:

   URLHash

Note: The URLHash distribution mechanism results in a more optimal cache replacement policy by keeping requests for the same image files on the same caches.

5. Device-specific policies—these policies are used to specify different treatment for different types of devices. Perhaps one wants to direct clients using wireless devices to a set of servers that customize content for that device's specific formatting requirements. Below is an example of a device-specific policy that accomplishes this goal.

   Policy 5:

   Destination IP address = 192.32.12.3

   Protocol = TCP

   Destination port = 80 (HTTP)

   User agent contains the string "Palmscape/PR5" /* Browser = Palm V

   Balance the load across the following eligible wireless gateways:

   IP address 10.10.30.1, port 80

   IP address 10.10.30.2, port 80

   IP address 10.10.30.3, port 80

   Using the following load distribution algorithm:

   Round Robin

5835
D.

Virtual Servers, Real Servers, NAT, and Dispatch Modes

There are a few characteristics of these policies that are worthy of special note. First, note in the above examples that a policy matches a particular destination address, protocol, and port. This information, which represents the servers behind the content switch to the outside world, is known as the virtual server definition. In fact, the Cisco CSM allows a virtual server to consist of an arbitrary range of IP addresses (including all IP addresses), an IP protocol number, a TCP or UDP port number, and an incoming virtual LAN (VLAN).[6]

The actual servers to which connections are forwarded are known as real servers.[7] These are defined by their IP addresses and ports. Content switches essentially accept connections that match virtual servers and direct them to real servers. In the process of doing so, they may modify the packets they forward as follows.

Content switches employ two modes of forwarding: Network Address Translation (NAT) mode (also called directed mode) and dispatch mode. In NAT or directed mode, the destination address is translated[8] from the received destination (the one that matched the virtual) to the address of the target real server. The MAC address is also rewritten. In dispatch mode, only the MAC address is rewritten, and the original destination IP address is preserved. This latter mode is important in order to load balance devices such as firewalls that are designed to transparently screen the traffic but are not necessarily the end recipients of it.[9]

In fact, content switches are commonly required to modify additional fields in packets they forward. In addition to the destination address and MAC address information already cited, common examples include source IP addresses, source and destination ports, sequence numbers, and checksums.

Policies, Protocol Layers, and Delayed Binding

New connections that arrive at a content switch are first classified to determine whether matching policies exist and then processed according to the actions specified by those policies. In the set of policy examples above, Policy 1 is invoked if the destination IP address = 192.32.12.3, the protocol = TCP, and the destination port = 80 (HTTP). The classification of this connection, therefore, can take place at Layers 3 and 4 (IP address, protocol, and port). This classification can take place completely on the initial packet of the TCP connection (the SYN packet).

[6] Valid values for protocol, port, and VLAN include "any" which indicates that the rule will match any value in that field. The VLAN identifier is useful for applying different actions to identical matching criteria based on the ingress VLAN. This is particularly useful for firewall load-balancing applications as well as for transparent caching applications. VLAN identification is also generally useful for security purposes or to separate different networks (such as a service provider environment where the same Cisco CSM is shared among different customers). See the CSM documentation for details.

[7] Real servers are logical constructs separate from physical servers. A real server is identified by an IP address and port. A physical server can host multiple real servers, for example, each represented by a unique IP address and port number combination.

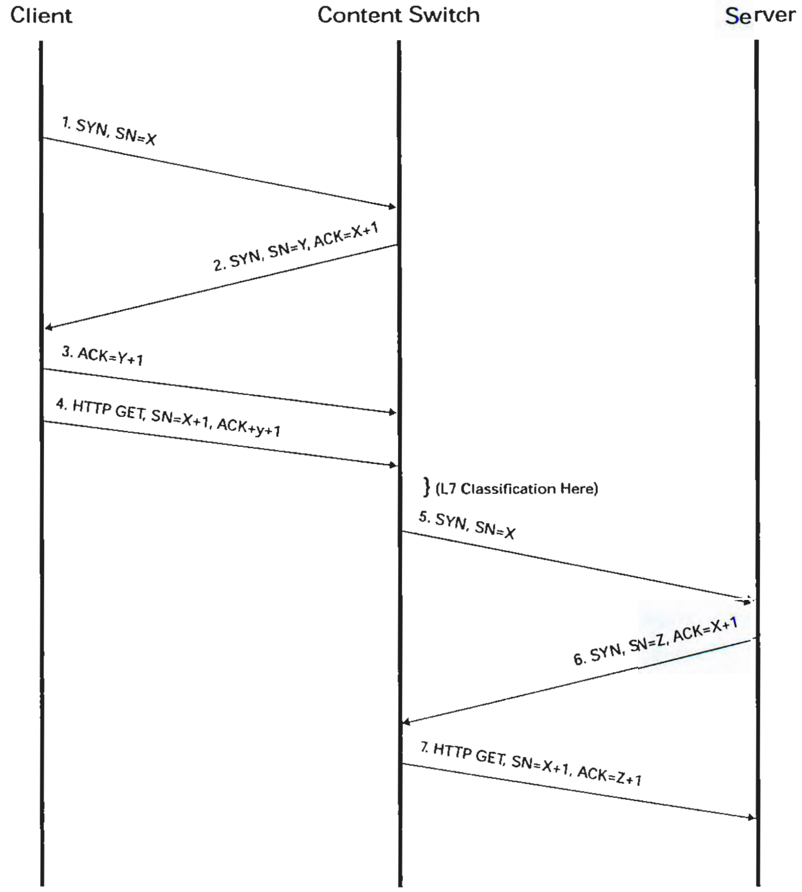
[8] NAT implies that the destination and/or source IP address is translated to a new address. In addition, dependent IP header information (such as the header checksum) will be changed as well.

[9] Dispatch mode has also been used with lower-performing content switching devices, including the Cisco Local Director as well as some third-party content switches. The goal in these types of configurations is to load balance traffic in the client-to-server direction while removing the content switch from the path of traffic in the server-to-client direction. This eliminates the content switch as a bottleneck in the direction of greatest traffic flow. However, this mode of operation significantly complicates and constrains the configuration. For example, loopback addresses must be configured on all the servers, servers must be Layer 2-adjacent to switch, and Address Resolution Protocol (ARP) is turned off on servers. The high performance of the Cisco CSM for both Layer 4 and Layer 7 load balancing effectively removes all motivation to use dispatch mode other than those mentioned above.

5834
D.

Look again at policy examples two through five above. Each of these policies requires additional classification based on data contained in the HTTP header. In examples two and three, the required info is in the "Cookie" header, in example four, the "URL," and in example five, the "User-Agent" header. Because HTTP is considered an application-layer protocol, classification at this layer is referred to as "Layer 7" classification.[10] In order for the classification of these connections and requests to take place properly, a process commonly known as "delayed binding" is used by the content switch to obtain the Layer 7 information required to classify the connection.

Figure 2. Delayed Binding Used for Layer 7 Classification



[10] Layer 7 is the OSI reference model application layer. There is a long-standing debate as to whether this should be called "Layer 5" classification due to the fact that TCP/IP only has five layers, with the fifth being the application layer. While technically incorrect "Layer 7" is the commonly used title.

Delayed binding deals with a "catch 22" situation. The content switch cannot apply Layer 7 policy to the connection until it has received the initial HTTP request and its associated headers (URL, Cookies, User-Agent, etc.) but the client will not send the HTTP information until it believes it has a connection established with the server. The content switch acts as a temporary proxy for the connection until it receives sufficient information to apply its policy, then binds the connection to the correct server as the policy dictates—hence the term "delayed binding." Figure 2 illustrates the process of delayed binding used for Layer 7 classification.

In steps one through three, we see the client establishing a TCP connection with the content switch as a proxy for the server. In step four, the client sends its HTTP request. The content switch now has sufficient data to apply its Layer 7 policy (in this case resulting in the selection of a specific server). In steps five through seven, the content switch establishes a connection with the selected server and forwards the HTTP GET on to that server.[11]

Sequence Number Remapping

The process of delayed binding introduces an additional piece of complexity to the forwarding process—sequence number remapping. For TCP connections, each participating party is responsible for establishing their own initial sequence number. The sequence number is then incremented by one for each byte transmitted over the connection. The receiver is responsible for sending back acknowledgements for each byte received.[12] Because the content switch is acting as a proxy for the initial connection, it must supply an initial sequence number for its side of the connection. The initial sequence number established by the real server is different. This implies that the content switch must translate these sequence numbers in both directions for all packets transferred. In Figure 2, note the sequence numbers and acknowledgments for all participants (client, content switch, and server). In particular, note that the initial sequence number selected by the content switch is different from the initial sequence number set by the server. The content switch must compute the difference between these two initial sequence numbers and maintain that relationship by remapping the sequence numbers for each packet transferred in both directions.[13]

HTTP 1.1 and Connection Remapping

To this point, the terms "connection" and "request" have been used somewhat interchangeably. One might infer from this that there is a one-for-one relationship between HTTP requests and connections. In fact, for earlier versions of HTTP this was true. With the introduction of HTTP 1.1, however, it is possible to transfer a series of HTTP requests and responses over a single TCP connection. For certain types of applications such as caching applications (see discussion on Policy 4 above), one might desire to send each of the requests to a different server based on the load-balancing policy. In these applications it will be necessary to maintain the client side of the connection while "remapping" the server side of that connection to a new server. The content switch is responsible for correctly terminating the old server side connection, re-computing all of the appropriate NAT, port, and sequence number translations that will be applied to the new connection, establishing a connection with the new server, sending the

[11] A valid policy action may be to drop this connection, in which case steps five through seven will never occur. A TCP reset may be issued to the client in this case.

[12] A detailed discussion of the operation of TCP is beyond the scope of this document. For more information please see Richard Stephens' excellent series entitled *TCP/IP Illustrated*, published by Addison Wesley.

[13] The observant reader will have noticed a few of the finer points of this interaction. First, during the delayed binding phase the number of packets exchanged between client and content switch (4) is greater than the number of packets exchanged between content switch and server (3). This is because the TCP specification allows the acknowledgement to be accompanied by data, a fact the content switch takes advantage of. Second, in this example, the client sequence number is preserved without modification from client all the way to server. This is because it is the server side of the connection that is being proxied by the content switch during the delayed binding process.

5832
D

new HTTP request, and then translating all the appropriate fields of subsequent packets associated with the connection in both directions. Effectively, the Layer 7 classification and the server side of the delayed binding process is repeated for each new HTTP request (steps five through seven in Figure 2).[14] The CSM allows the operator to specify whether connection remapping should be turned on or off for a given virtual server. In the event connection remapping is disabled, Layer 7 policy is applied only to the first in the sequence.

Health Checking

Is it important for content switches to detect the failure of servers or processes and route around them. In complex web applications, one might want to verify several layers of infrastructure upon which a target server depends to complete its function (such as a web server, application software, or database) before sending requests to that server. In order to determine that various pieces of application infrastructure are up and available, content switches need to provide flexible capabilities to test various types of servers. There are two different types of health checking offered in the Cisco Catalyst 6500 CSM: active health checking and inband health checking. Active health checking implies that the content switch is actually sending messages to the servers and looking for certain expected results in return. Active health checking is useful for more complex types of verification, such as verifying availability of the database that a particular Java Servlet relies upon to perform its function. Scripting functions also allow the operator to customize active health checking for applications for which canned capabilities don't exist. Active health checks are sent at regular intervals. Failure of the health check results in labeling a particular server or set of servers unavailable. As with all active techniques of this kind, there is a trade-off between the frequency at which health checks are sent (and how quickly a failure can be detected) and the processing requirements associated with them.

With inband health checking, the content switch actually looks at responses to live requests and can immediately take servers out of service if they fail. Inband health checking is a superior means of detecting physical server and process failures on machines to which the content switch is directly communicating. Because the content switch monitors every active connection, it is possible to detect failures much more rapidly than with active health checking. However, the more complex types of health checking are not possible using this mechanism. In practice, it makes sense to leverage both types of capabilities—inband health checks to detect hard server and process failures and active health checks to verify all components required for a particular application are available.[15]

Categories of Processing in Content Switches

Having briefly reviewed content switch operation, this paper now considers the specific types of processing going on inside content switches as they perform these functions. In general, the various tasks to be performed by content switches fall into one of the following three categories:

- Connection processing
- Forwarding processing
- Control processing

Following is a brief description for each as well as an introduction to the types of performance metrics, which will be useful in comparing different content switch architectures.

[14] If the classification indicates the same server may be used for this request as the previous then no remapping is performed. This allows the application to benefit from HTTP 1.1 persistence as appropriate.
[15] Inband health checking is something for which the Cisco CSM is especially well suited due to its superior connection processing capabilities.

Connection Processing

Connection processing may be viewed as any processing associated with the establishment of new connections, the modification of existing connections, or the tearing down of completed connections. Following is a partial list of tasks that can be considered part of connection processing:

- *Detection of new connections:* Is this packet a TCP SYN or a UDP frame with a 5-Tuple for which there is no forwarding state? If so, we may want to set up a connection.
- *Virtual server lookup:* Does this frame match a configured policy in the content switch? If so, can the switch apply its policy yet or does the switch need to do a delayed binding to get Layer 5 information?
- *Delayed binding:* Perform the 3-way handshake and look at the received Layer 7 data. Does this match a configured policy? If so, apply the policy action.
- *TCP state machine and denial of service detection:* The content switch must ensure that packets it is processing are part of a valid TCP connection. This is required both for error-detection purposes as well as to detect any well known denial-of-service attempt that exploits TCP vulnerabilities.
- *Policy matching:* Parse through the Layer 7 data for the required fields and determine whether those fields match the policy database.
- *Frame buffering:* Sometimes the Layer 7 data is not in the first application frame received. This requires the content switch to buffer frames until a match or no-
- match decision can be made.
- *Server selection:* In most applications, the configured policy action will require the selection of a server based on factors such as load balancing, persistence, and failover requirements.[16] The content switch must determine the server based on these requirements.
- *Determine packet transformations:* Should this connection be NATed? Do sequence numbers need to be translated? The content switch must determine which transformations need to be applied and what they are. The connection processing function must inform the forwarding process function of the connection parameters and transformations.
- *Handle new HTTP requests on HTTP 1.1 connections:* For HTTP 1.1 connections in flight, the content switch must detect new HTTP requests and determine whether a new policy action needs to be taken (such as selecting a new server). This also involves recomputing all packet transforms and ensuring the forwarding process is updated with the new information.
- *Manage server side connections:* For connections where delayed binding has been applied, the content switch must perform the correct 3-way handshake with the server, handling correctly any TCP errors. Likewise, for HTTP 1.1 connection remapping functions, the content switch must correctly terminate the old connections and establish the connection to the new server.
- *Inband health checking:* When inband health checking is turned on, the content switch must monitor server response traffic for failure conditions and take servers out of service as appropriate.
- *Terminate connections:* Connections may terminate normally (when a TCP FIN or RESET is received) or abnormally (a server, client, or something in the network path fails so that no packets are received for some timeout period). The content switch must clean up all state and reclaim all resources consumed by the connection.

[16] Other valid policies may involve dropping specific connections, redirecting specific connections, or forwarding to a specific next-hop router.

Connection Processing Performance:

The following metric is most commonly used when looking at connection processing performance:

- *Connections per second (CPS):* For Layer 4 TCP and UDP traffic, this is the rate at which new connections may be processed. For Layer 7 HTTP traffic, this is the rate at which new connections may be established or existing connections modified (as with HTTP 1.1 connection remapping).[17] Note that connection processing does not take place on every packet associated with every connection, rather it takes place only on those packets associated with the beginning and ending of connections as well as on those that signal the potential need for modification of connections in flight. Applications that make use of long-lived connections and few connection modifications will have lower connection processing requirements than those that are short lived or are modified frequently.

Forwarding Processing

Any processing associated with the forwarding of packets that are part of established connections may be viewed as forwarding processing. Following is a partial list of tasks associated with forwarding processing:

- *Classify packets:* Is this packet part of an existing connection? If not, hand the packet over to the connection-processing function. If so, get packet transformation information, next hop, and quality of service (QoS) and type of service (ToS) information.
- *Apply packet transformations:* Including any address changes, port changes, sequence number changes, checksum changes, ToS changes, and Diffserv changes.
- *Queue and transmit packet at required QoS level:* Send the packet on to its destination.

Forwarding Processing Performance:

The following performance metrics are important when discussing forwarding performance:

- *NAT forwarding rate in packets per second (PPS):* As is true for LAN switching, the number of packets per second that can be forwarded is important. Shorter packet sizes require greater packet-per-second handling capacity for a given throughput. Unlike most LAN switches, content switches are typically performing a significant number of packet transformations, or NAT, on the packets they forward.
- *NAT throughput (Mbps):* Likewise, total NAT throughput in megabits per second (irrespective of packet size) should be understood.
- *Simultaneous connections:* Due to the packet transformations that need to be applied (which are unique for each connection), each connection managed and forwarded by a content switch requires its own forwarding table entry and connection state. Every content switch will therefore have a limit (typically due to forwarding table memory size) to the number of simultaneous connections it can manage.[18]

Note that forwarding processing takes place on every packet the content switch must handle, so although this processing is less complex than the processing associated with connection management and control, it happens more frequently. As we shall see, this processing path should be optimized.

[17] Note to testers- as with most performance metrics, this one can be deceiving. The processing associated with matching a simple URL regular expression such as /* will not be the same as that associated with matching a session cookie, for example. Be sure you are making accurate comparisons.

[18] It is important to make accurate comparisons here. Some vendors will talk about connections as uni-directional entities, others as bi-directional entities. The numbers quoted for Cisco CSM capacity in this paper are bi-directional.

5829
D.

Control Processing

Control processing refers to all other processing that is not associated with either connection setup or forwarding but is nonetheless essential to the proper operation, configuration, monitoring, or control of these processes. Control processing is generally asynchronous to the main tasks of the content switch (such as handling connections and forwarding). A partial list of tasks associated with control processing is as follows:

- *System management processes:* Tasks associated with management of configuration files, system images, booting, diagnostics, care and feeding of hardware, and more.
- *Operations management processes:* Tasks associated with management of the running system, including configuration (such as command line, web interface, and application programming interfaces), statistics and Management Information Base (MIB) management, and Simple Network Management Protocol (SNMP).
- *Active health checking:* Scheduling and transmission of health check messages, examining results, moving servers in and out of service as required. The processing associated with this can be quite extensive and includes the following:
  - Formatting queries
  - Establishing and maintaining connections
  - Transmitting and receiving messages
  - Parsing and interpreting replies
  - Taking appropriate action (which may involve notification of several other parts of the system)

Control-Processing Performance:

The following are useful metrics to consider when discussing control-processing performance:

- *Probes per second (PPS):* The number of probes (or active health check messages) a content switch can process per second. Note that processing requirements increase as active health checks become more complex (such as with scripting).
- *Number of probes:* There will typically be memory or configuration limits to the number of health checks that can be configured.

Note that probes have the lowest frequency of all the processing types discussed, yet because of their complexity they may have the highest unit overhead.[19]

Now that the reader is familiar with how content switches operate and the different categories of processing they must perform, this paper will turn to the details of the Cisco CSM architecture—an architecture that is tuned to the specific types of processing tasks that content switching requires.

[19] Note also that this is a strong motivation for inband health checking; however, the additional processing overhead associated with it must be factored into connection processing requirements.

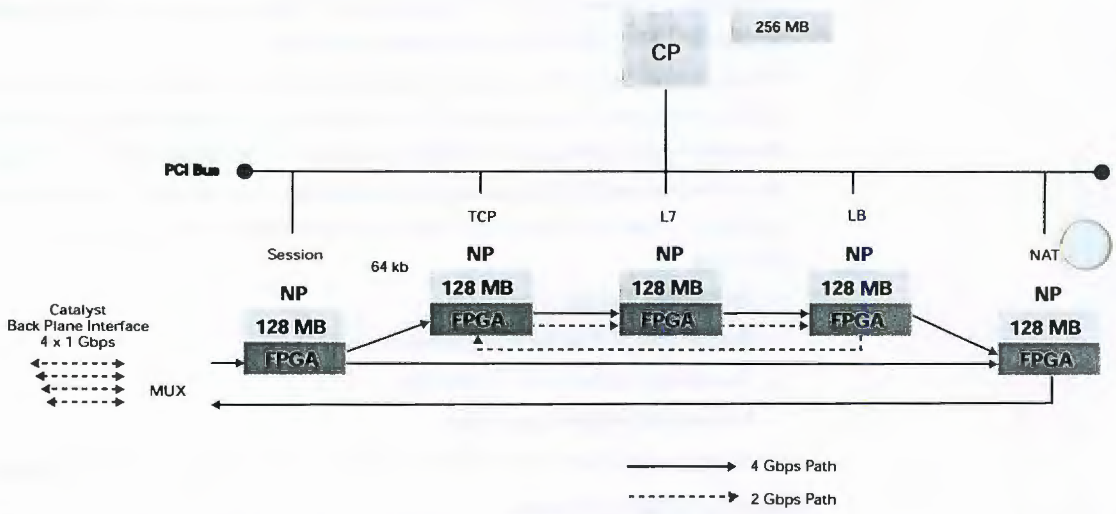
The Cisco CSM Pipelined Network Processor Architecture

The Cisco CSM hardware architecture consists of a series of five field programmable gate arrays (FPGAs) and network processors (NPs), matched in pairs and structured as a dual pipeline (more on this shortly). Figure 3 illustrates the layout of the FPGA and network processor pairs.

Figure 3. CSM Layout



The Cisco CSM has four 1-Gbps, full-duplex connections to the Cisco Catalyst 6500 backplane, which are muxed together to provide a 4-Gbps, full-duplex data path to the CSM processing complex. From a network standpoint, the CSM is configured to participate in and listen to a set of VLANs on the Cisco Catalyst 6500 backplane. Traffic targeted to the CSM arrives via one or more of the 1-Gbps backplane connections shown. Inputs from the backplane are muxed together to present the CSM processing logic with an aggregate 4-Gbps stream of packets. Once processing begins, a packet matching configured policies will traverse one of two 4-Gbps paths through the processing complex. The first is the connection-processing pipeline. The second is the forwarding pipeline. A detailed discussion of these pipelines will be presented in the next section.

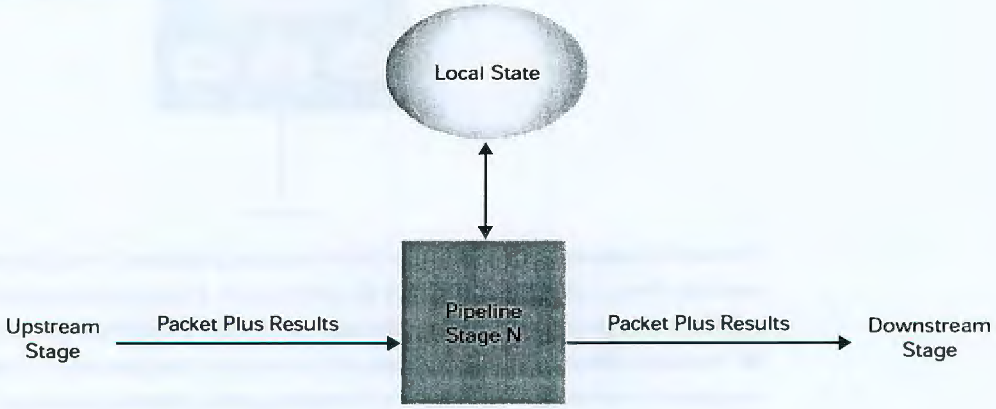
Before moving on to this discussion, a few additional details of the above diagram bear explaining. The first is the separate 2-Gbps path between the pipeline stages labeled TCP, L7, and LB. This path is used for upstream communication between stages. The second is the small chunk of memory (64 KB) shown between the session and TCP pipeline stages. This provides a high-speed, memory-mapped communication path between these stages designed to support high-volume communication.

Each network processor has a connection via a PCI bus to the control processor. The control processor is responsible for the configuration and management of all components on the CSM as well as for the processing associated with certain control tasks (such as active health checking).

Pipeline Overview

The Cisco CSM pipelines consist of a series of linked stages. Each stage consists of a FPGA and network processor pair with associated memory. As packets move through the pipeline, a specific set of operations is performed at each stage. The results of each pipeline stage are then passed along with the packet to the next stage that utilizes those results, the packet itself, and any state it maintains locally about the connection as inputs into its processing. Figure 4 illustrates this idea.

Figure 4. A Pipeline Stage



Note: Each stage of the pipeline may update its own local connection state.

FPGAs

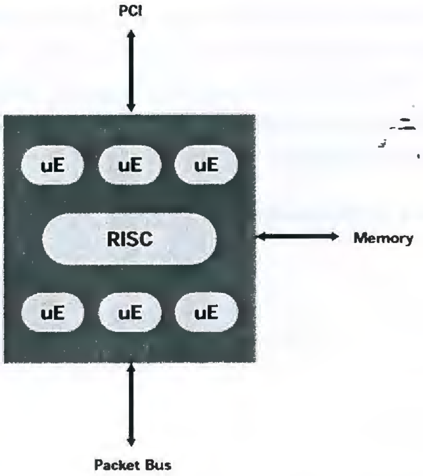
The FPGAs provide an addressable communications fabric between the pipeline stages. Each stage in the pipeline is responsible for determining the downstream stage that should receive the packet next. Note that a stage may "skip" a downstream stage by inserting the address of a further downstream stage as the recipient of its output. Intervening FPGAs at skipped stages merely forward the packet on to the next FPGA unmodified. The network processor at a skipped stage does not see the packet. In this way, latency, bandwidth, and overhead through the system is reduced by bypassing unnecessary processing steps in hardware.

The session-and NAT-stage FPGAs have a few additional functions, which will be explained in the detailed discussion of pipeline stages ahead.

Network Processors

Each network processor has six RISC microengines plus a RISC core, providing a total of over one billion instructions per second. Altogether the network processor pipeline provides over five billion instructions per second, and each network processor has its own dedicated 128-MB pool of high-speed memory. Figure 5 illustrates the Intel IXP 1200 network processor used in the Cisco Catalyst 6500 CSM.

Figure 5. The Intel IXP 1200



The various tasks associated with a particular stage are partitioned across the microengines (uE) in such a way as to maximize the parallelization offered by this architecture. Pipelining maximizes system performance for operations applied to a single packet as it moves through the pipeline. Parallelization maximizes the performance of the system for the many different unrelated packets and connections being processed at the same time. Together they provide exceptional processing performance for forwarding and connection processing.

The Connection and Forwarding Pipelines

Figures 6 and 7 illustrate the connection and forwarding pipelines respectively.

A few observations:

- All packets move through the pipeline in the same direction, entering through the mux from the backplane and leaving through the mux to the backplane.[20]
- There are two stages in common for both pipelines: the "session" stage, and the "NAT" stage.
- It is the session stage that determines which pipeline path the packet will take.

[20] Not all packets that enter will leave because some policies will result in packets being dropped. Other packets may be intended for the module itself (such as ARP, ICMP, and keepalive responses). These are forwarded to the control processor

Figure 6. The Connection Pipeline

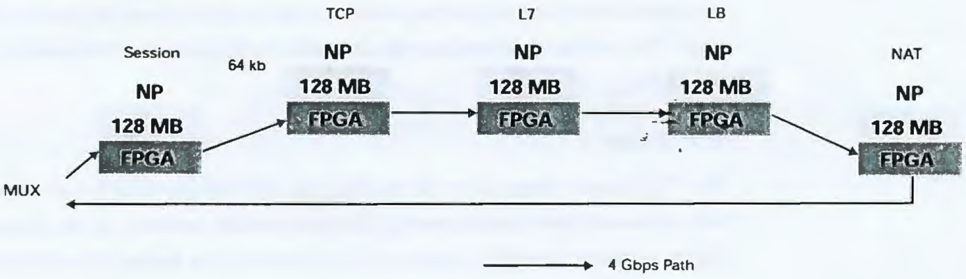


Figure 7. The Forwarding Pipeline

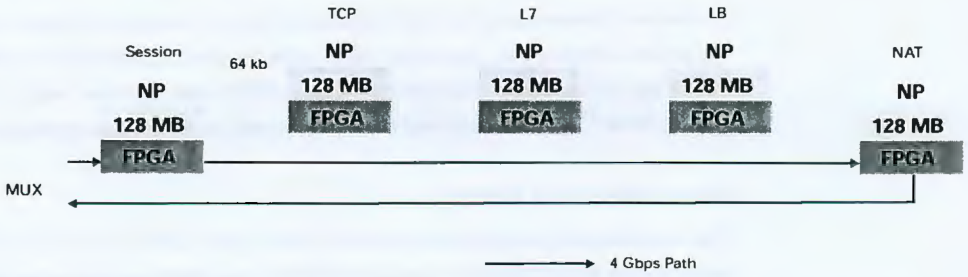

Recalling the earlier discussion about connection and forwarding processing, it is apparent that connection processing is a relatively less frequent task than forwarding processing. This is because connection processing is needed only for the start of connections, the end of connections, and modifications to connections. Packets associated with these events need to be handled differently than those packets that are merely parts of established connections. These only need to be forwarded in accordance with the policy (such as NAT or QoS). The rationale behind the dual pipeline of the Cisco Catalyst 6500 CSM now becomes evident as well: Packets associated with connection-related events are forwarded along the connection pipeline, while packets associated with established connections are forwarded along the forwarding pipeline. Once connections are established, associated packets may be "cut through" along the forwarding pipeline until some new connection-modifying event occurs. This results in much lower processing overhead in the system for the vast majority of packets that must simply be forwarded in accordance with the configured policy.

Following is a brief discussion of each of the individual pipeline stages.

Session Stage

It is the responsibility of the session stage to determine whether the packet indicates the beginning of a connection, the end of a connection, or is part of an existing connection. Packets that are part of an existing connection need only be forwarded over the dedicated 4-Gbps connection to the NAT stage. The connection ID passed with the packet assists the NAT module in quickly locating the correct session entry containing the appropriate packet transformations.

For packets that are determined to require connection processing, the session stage forwards the packet over the connection pipeline path to the TCP stage.

15824

It was mentioned earlier that the session FPGA has some unique functions. The session FPGA essentially preprocesses the received packet for the session network processor. The session network processor receives only that portion of the information from the packet relevant to its decision about the pipeline path selection in an easily digestible form. This substantially reduces the amount of processing that the session network processor has to do to classify the packet.

TCP Stage

The TCP stage is responsible for maintaining TCP session state for all connections. It determines the beginning and end of connections (communicating this information upstream to the session stage), filters denial-of-service attacks, performs delayed binding if required, and forwards the packet on to either the Layer 7 or the load-balancing stage as required.[21]

Layer 7 Stage

Packets are forwarded by the TCP stage to the Layer 7 stage if the Layer 3 and Layer 4 information obtained from the packet indicates that this packet needs to be matched against Layer 7 policies. The Layer 7 stage must parse the packet for relevant fields (such as cookies and URLs) and applies a high-performance regular expression match against them.[22] Packets and results are then passed on to the load-balancing stage.

Load-Balancing Stage

The load-balancing stage receives packets from either TCP or Layer 7 as well as information regarding the virtual server match for this packet. The load-balancing module then applies the configured load-balancing algorithm, persistence policy, or failover policy to the packet. The load-balancing stage then forwards the packet and NAT transformation information to the NAT stage.

NAT Stage

The final stage in the pipeline is the NAT stage, which is responsible for applying all relevant packet transformations to the packets and sending them back to the mux for transmission to the backplane. The NAT stage is also responsible for statistics gathering.

It was previously mentioned that the NAT-stage FPGA had a unique function to perform. Basically this amounts to muxing the inputs received from both pipeline paths and presenting the combined input to the NAT network processor.

[21] Here one sees the benefits of making the FPGAs addressable. The Layer 7 stage can be bypassed for connections that only need processing at Layer 3 or Layer 4.

[22] The regular expression-matching capability of the Cisco CSM itself is quite sophisticated in that not just suffix (*.something) and prefix (something*), but any type of regular expression can be configured, using typical notations (such as range of characters, question marks to indicate a fixed amount of generic characters, negation, OR, and AND). There is no significant impact on the performance when matching against a complex regular expression as opposed to a simple one. See CSM documentation for details.

Control Processing

All control-processing tasks (see above discussion) take place on a dedicated RISC processor within the Cisco Catalyst 6500 CSM. This approach provides dedicated processing cycles for these tasks, enabling the system to scale in terms of control task volume or complexity (such as for active health checking) without negatively impacting performance for connection or forwarding processing.[23]

Cisco Catalyst 6500 CSM Architecture Evaluation

The Cisco Catalyst 6500 CSM architecture makes use of a number of innovative techniques to push content switching to new levels of price performance. Its primary innovation is in the areas of the connection and forwarding pipelines used for connection and forwarding processing respectively. By leveraging the parallel processing capabilities of the selected network processors in a pipeline, the architecture is capable of delivering remarkable performance in both categories. Through the use of a dedicated control processor the architecture performs admirably in this area as well.

The Cisco Catalyst 6500 CSM sets a new standard for content switching in the following dimensions:

- *Features:* The programmability of the selected components yields tremendous flexibility in feature development. The performance offered by the pipeline architecture makes it possible to consider features that were heretofore impractical, such as inband health checking, return error code checking, and deep regular expression matching.
- *Price and performance:* In this dimension the Cisco Catalyst 6500 CSM is without peer, delivering NAT forwarding performance of 4 Gbps and connection performance at rates exceeding 150,000 connections per second. The Cisco Catalyst 6500 CSM can support almost one million simultaneous bi-directional connections. For customers with the highest performance requirements, no other solution will prove as cost-effective.[24]
- *Port density:* A Cisco Catalyst 6500 with CSM can have as many as 528 10/100 ports.
- *Integration with Layer 2 and Layer 3 infrastructure:* Because the Cisco Catalyst 6500 CSM runs in the Cisco Catalyst 6500 with Cisco IOSÒ Software, customers are assured of the highest level of integration with their Layer 2 and Layer 3 infrastructure. They can leverage the industry-leading QoS, Layer 2, and Layer 3 features of the Cisco Catalyst 6500 including any of the network interfaces supported in the Cisco Catalyst 6500 such as packet over SONET (POS) and 10 Gigabit Ethernet modules.

Integration with other data center capabilities: The Cisco Catalyst 6500 CSM supports integrated firewall, intrusion detection, VPN, and in the future, other capabilities as well.

The Cisco Catalyst 6500 CSM is one of several products in the Cisco content switching product line addressing the growing customer demand for scalable Layer 4 to Layer 7 services as a complement to their existing Layer 2 and Layer 3 infrastructure. Cisco content switches enable businesses to build highly available and secure network data centers in support of their Internet and intranet applications. The Cisco Catalyst 6500 CSM provides an integrated services module for the Cisco Catalyst 6500 Series switches and Cisco 7600 Series Internet routers and delivers the highest Layer 4 to Layer 7 performance along with a rich set of application features. The Cisco content switch

[23] The Cisco CSM control processor is separate from the management processor located on the supervisor in the Cisco Catalyst 6500 Series switch itself. The Cisco Catalyst 6500Series switch provides most of the management functions for the Cisco CSM through Cisco IOSÒ Software, such as configuration, command line, and SNMP. The Cisco CSM control processor is therefore free to perform other control tasks such as active health checking.

[24] The Cisco CSM is currently being used with success in the largest production networks, some with server farms in excess of 500 servers driving peaks loads of over 50,000 connections per second and 2 Gbps of NAT throughput.

product line also includes the Cisco CSS 11000 Series content services switches and, the most recent addition to the product line, the Cisco CSS 11500 Series content services switches, which offer a compact modular platform with rich Layer 4 to Layer 7 services for e-business applications.

CiscoWorks LAN Management Solution 2.2 Introduction

CiscoWorks LAN Management Solution (LMS) provides a robust set of applications for maintaining, monitoring, and troubleshooting a broad range of devices in an end-to-end Cisco AVVID (Architecture for Voice, Video and Integrated Data) network. Built upon popular Internet-based standards, CiscoWorks LMS enables network operators to more efficiently and effectively manage the network through a simplified browser-based interface that can be accessed anytime from anywhere within the network. Taking advantage of a Web-based client/server architecture, CiscoWorks LMS can be easily integrated with other popular network management systems or other third-party management solutions running in the network.

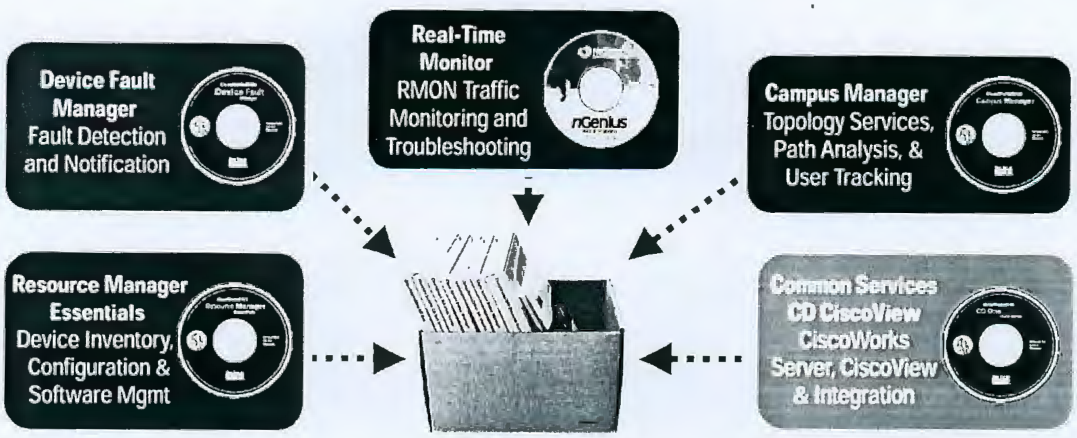
CiscoWorks LMS provides a solid foundation of basic and advanced management applications that complement CiscoWorks products. Other CiscoWorks products include the CiscoWorks Routed WAN Management (RWAN) Solution, which addresses the needs of the WAN with response time and access list management. The IP Telephony Environment Monitor (ITEM) ensures the readiness and manageability of converged networks that support voice over IP (VoIP) and IP telephony traffic and applications. The Cisco VPN/Security Management Solution (VMS) provides an integrated set of Web applications with features that assist in the deployment and monitoring of virtual private network (VPN) and security devices. Together, CiscoWorks products offer leading-edge solutions for improving the accuracy and efficiency of your operations staff, increasing overall availability of your network through proactive planning and maximizing network security.

The Changing Campus LAN

A key part of the business infrastructure, today's LANs are critical systems. The management of local-area networks has evolved from being device centric, to now focusing on managing the convergence of both data and voice traffic over a common infrastructure. As a result, it has become increasingly important to isolate, troubleshoot, and monitor network devices so that connections and services are always available. CiscoWorks LMS delivers advanced discovery technologies, port assignment tools, sophisticated connectivity analysis, configuration management tools, and device and network diagnostic capabilities (including fault management and Remote Monitoring [RMON] traffic monitoring) to help manage the complexities of a converged network.

A Comprehensive Solution

CiscoWorks LMS combines applications and tools for configuring, monitoring, and troubleshooting the campus network. Designed to address the networks powered by Cisco today, it also provides a flexible framework to address the device management needs of networks converging voice, video, and data; networks being protected with Cisco SAFE Blueprint for network security technologies; and networks designed for content migration.



Device Fault Manager
Fault Detection and Notification

CiscoWorks Server, CiscoView & Integration

The CiscoWorks LMS consists of operationally focused tools. These tools include fault management, scalable topology views, sophisticated configuration, Layer 2/3 path analysis, voice-supported path trace, traffic monitoring, end-station tracking workflow application servers management, and device troubleshooting capabilities.

CiscoWorks LMS is built on the CiscoWorks common services foundation. This design facilitates operations workflow between applications by linking data collection, monitoring, and analysis tools—all from a single desktop application. For example, a user complaint of slow response time or a poor IP phone connection can be quickly diagnosed using CiscoWorks LMS Layer 2 path tools that automatically acquire user path information stored in one database, and highlight devices on a topology map. Additionally, switch or router configurations can then be quickly examined, or RMON traffic data can be reviewed to detect anomalies or the need for changes. Those actions may draw information from one or more applications.

CiscoWorks LMS uses Internet standards to tie together best-of-breed tools and to take advantage of their capabilities through data and task integration standards. Using the common information model (CIM) and Extensible Markup Language (XML), the industry standards for data-sharing CiscoWorks LMS offers a means of extracting data and using it with popular network management platform products. With the CiscoWorks LMS, Cisco offers a complete family of dedicated hardware Cisco Catalyst® network analysis modules (NAMs). Cisco Catalyst NAMs provide increased visibility into switched LAN environments comprising 10/100 and Gigabit Ethernet links for comprehensive, end-to-end, seven-layer monitoring of network infrastructures.

Solution Components

The following applications are included in CiscoWorks LMS:

- CiscoWorks Campus Manager—CiscoWorks Campus Manager is a suite of Web-based applications designed for managing networks powered by Cisco switches. These include Layer 2 device and connectivity discovery, workflow application server discovery and management, detailed topology views, virtual LAN/LAN Emulation (VLAN/LANE) and ATM configuration, end-station tracking, Layer2/3 path analysis tools, and IP phone user and path information.
- CiscoWorks Device Fault Manager—CiscoWorks Device Fault Manager provides real-time fault analysis for Cisco devices. It generates "intelligent Cisco traps" through a variety of data collection and analysis techniques. These can be locally displayed, e-mailed, or forwarded to other popular event management systems.
- nGenius Real-Time Monitor—The nGenius Real-Time Monitor is a Web-enabled multiuser traffic management tool set that provides access to network-wide, real-time RMON information for monitoring, troubleshooting, and maintaining network availability. Its applications graphically report and analyze device, link, and port level RMON collected traffic data from RMON-enabled Cisco Catalyst switches and internal network analysis module.
- CiscoWorks Resource Manager Essentials (RME)—CiscoWorks RME provides the tools needed to manage Cisco devices. It includes inventory and device change management, network configuration and software image management, network availability, and syslog analysis.
- CiscoView—CiscoView is a Web-based tool that graphically provides real-time status of Cisco devices. The tool can drill down to display monitoring information on interfaces and access configuration functions.
- CiscoWorks Management Server—The CiscoWorks Management Server provides the common management desktop services and security across the CiscoWorks Family of solutions. It also provides the foundation for integrating with other Cisco and third-party applications.

Key Functions and Applications

Table 1 gives key functions and applications of the CiscoWorks LMS.

Table 1 CiscoWorks LAN Management Solution Key Application/Function

	Product	Management Benefit
Offers intelligent, automatic discovery of Cisco devices to create topology views of the network	CiscoWorks Campus Manager	The Cisco Campus Manager Topology Services functionality discovers Cisco devices and calculates Layer 2 relationships to provide views of the Cisco network by ATM domain, VTP[1] domain, LAN edge view, and a general Layer 2 view.
Gives topology status indications	CiscoWorks Campus Manager	The topology maps indicate the discovery and SNMP[2] status of Cisco devices; these maps also are launching points for other CiscoWorks applications.
Configures, manages, and monitors VLAN[3] and ATM services/networks	CiscoWorks Campus Manager	CiscoWorks Campus Manager provides tools for creating, deleting, and editing VLANs; it provides ATM tools for displaying virtual circuits and for configuring SPVCs/SPVPs.[4]

Table 1 CiscoWorks LAN Management Solution Key Application/Function

	Product	Management Benefit
Discovers end stations and IP phones connected to switch ports and identifies user locations based on user ID	CiscoWorks Campus Manager	The CiscoWorks Campus Manager User Tracking functionality correlates MAC[5] address and IP address to switch port; integration with Microsoft's PDC and Novell's NDS tree provides the user ID for even more efficient user location and tracking.
Traces Layer 2 and Layer 3 connectivity between two points (devices, servers, phones) in the network	CiscoWorks Campus Manager	The CiscoWorks Campus Manager Path Analysis tool performs path analysis for Layer 2 and Layer 3 devices using the device host name or IP address, and shows results on a map display, in a table display, or in a trace display.
Intelligently analyzes fault conditions designed to detect problems before they become network disruptions	CiscoWorks Device Fault Manager	CiscoWorks Device Fault Manager automated fault detection recognizes common problems in networks without forcing users to define their own rules sets, SNMP trap filters, or device polling intervals.
Interprets fault conditions at both the device and VLAN levels	CiscoWorks Device Fault Manager	With the characteristics of over a 100 Cisco routers and switches predefined, new device support is easily added via Cisco.com. Cisco Device Fault Manager simplifies managing both Layer 2 and Layer 3 environments.
Collects RMON/RMON2 statistics from LAN switches, NAMs, and legacy Cisco SwitchProbe® devices	nGenius Real-Time Monitor	nGenius Real-Time Monitor monitors LAN traffic for protocols, applications, and interfaces to apply appropriate filters, reducing costs and increasing performance.
Provides for LAN troubleshooting at network and application packet levels	nGenius Real-Time Monitor	nGenius Real-Time Monitor helps resolve network and application issues by providing total network visibility from the application layer down to the data link layer for virtually any topology that exists today.
Offers detailed software and hardware inventory reporting	Cisco RME	Cisco RME provides accurate Cisco inventory baseline information, including memory, slots, software versions, and boot ROMs needed to make decisions about the network.
Offers automated update engines for device software and configuration changes	Cisco RME	Cisco RME allows software and configuration updates to be sent to selected devices on a scheduled basis; it reduces time and errors involved in network updates.
Offers a consolidated troubleshooting tools device center	Cisco RME	A wide collection of switch and router analysis tools is accessible from a single location; third-party applications can link to the device center.
Offers centralized change audit logging	Cisco RME	A comprehensive change-monitoring log records users and applications that are active on the network.
Offers graphical device management	CiscoView	CiscoView displays a browser representation of Cisco router and switch devices, color-coded to indicate operational states, with access to configuration and monitoring tools.

Table 1 CiscoWorks LAN Management Solution Key Application/Function

	Product	Management Benefit
Provides application access security	CiscoWorks Server	The CiscoWorks desktop controls user access to applications, ensuring that only appropriate classes of users can access tools that change network parameters versus read-only tools.
Offers third-party integration tools (Integration utility)	CiscoWorks Management Server	The CiscoWorks Management Server simplifies the Web integration of third-party and other Cisco management tools.

1. Virtual Trunking Protocol
2. Simple Network Management Protocol
3. Virtual LAN
4. Soft permanent virtual circuits/soft permanent virtual paths
5. Media Access Control

Key Functions and Applications

Deployment Options

Consider the following when installing the CiscoWorks LAN Management Solution:

- All applications do not have to be installed initially; applications not installed initially may be installed later.
- Most applications require the CiscoWorks Management Server from the Common Services CD (formerly CD One), which must be installed first.
- The CiscoWorks Campus Manager application depends on CiscoWorks RME, which is included as part of the CiscoWorks LAN Management Solution.

All solutions can coexist on the same server if they support and operate with the services of Common Services 2.2. However, network managers may want to consider such factors as the number of applications hosted, system resources, and number of devices to be managed in determining if all or a subset of the solutions are installed on the same server.

CiscoWorks solutions offer deployment flexibility. System administrators should use the guidelines given previously when planning the deployment of the various solution bundles. Some components within a solution require the CiscoWorks Management Server and must be installed on that machine. CiscoView and nGenius Real Time Monitor software can be set up on an independent server. The placement of components is a function of performance requirements and the size of the network.

Server System Requirements

Hardware/Operating System

UNIX

- System: Sun UltraSPARCIII (Sun Blade 1000 Workstation or Sun Fire 280R Workgroup Server) running Solaris 2.8 (dual processor system required for hosting multiple management solutions)
- Memory: 1-GB RAM for workstations, 2-GB RAM for servers, 8-MB e-cache

- Available disk: 40-GB internal FC-AL disk drive for workstation and dual drives of this type for server configurations

Windows

- System: IBM PC compatible with 550-MHz or higher Pentium III processor running Microsoft Windows 2000 Advanced Server (with Terminal Services turned off), Server or Professional Edition with Service Pack 2 (dual processor system required for hosting multiple management solutions)
- Memory: 1-GB RAM
- Available disk: 40 GB with 2-GB swap recommended

Note: These system requirements are based on managing 500 devices with CiscoWorks RWAN and LAN Management solutions loaded on a single server. Refer to the Installation documentation for more information on required operating system patches.

Client Browser System Requirements

Hardware/Operating System

UNIX

- System: Sun Ultra 10 running Solaris Version 2.7 or 2.8
- System: HP9000 Series running HP-UX 11.0
- System: IBM RS/6000 workstation running AIX 4.3.3
- Memory: 256 MB

Windows

- System: IBM PC-compatible computer with 300-MHz or higher Pentium processor running Windows XP Professional, Windows 2000 (Advanced Server, Server or Professional) with Service Pack 3
- Memory: 256 MB

Note: Refer to the installation documentation for more information on required operating system patches.

Web Browser

UNIX

- Solaris: Netscape v4.76
- HP-UX: Netscape v4.78, 4.79
- AIX: Netscape v4.78, 4.79

Windows

- Windows 2000/XP: Netscape v4.78, 4.79
- Windows 2000/XP: Internet Explorer v6.0.26

Note: Refer to the Installation documentation for more information on required operating systems patches, browser plug-ins, or Java Virtual Machine (JVM) versions.

Service and Support

CiscoWorks products are covered by the Cisco Software Application Service (SAS) program. This service program offers customers contract-based 7 x 24 access to the Cisco Technical Assistance Center (TAC), full Cisco.com privileges, and software maintenance updates. A Cisco SAS contract ensures that customers have easy access to the information and services needed to stay up-to-date with newly supported device packages, patches, and minor updates. For further information on service and support offerings, contact your local sales office.

Ordering Information

The CiscoWorks LAN Management Solution includes all the necessary components needed for an independent installation on a Microsoft Windows or Sun Solaris Workstation/Server. The products within this solution can be combined with other CiscoWorks products if they support the same CiscoWorks Management Server version, operating environment, and system requirements. Contact your local Cisco representative for available white papers and documentation outlining best practices for implementing a CiscoWorks management solution architecture.

To place an order, contact your Cisco sales representative.

Refer to the CiscoWorks LAN Management Solution individual product data sheets for more information on operating environment and system requirements.

For More Information

For more information on the CiscoWorks LAN Management Solution, visit http://www.cisco.com/en/US/partner/products/sw/cscowork/ps2425/index.html.

CISCO SYSTEMS

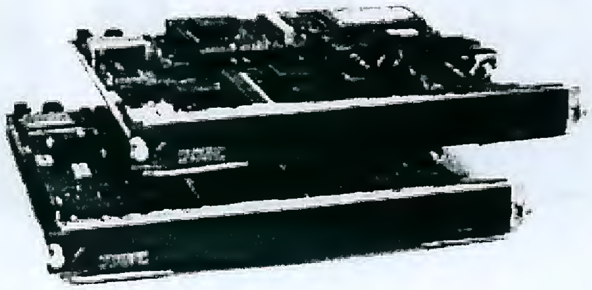
Data Sheet

Cisco Catalyst 6500 Series and Cisco 7600 Series
Network Analysis Module 1 and 2

Second-Generation, High-Performance Network Analysis Modules for Cisco Catalyst 6500 Series and Cisco 7600 Series

Cisco Systems®, the worldwide leader in networking for the Internet, addresses the need for multiservice network management and traffic monitoring in high-capacity switched Ethernet LANs and routed WANs with a new generation of the Network Analysis Module (NAM) for Cisco® Catalyst® 6500 Series switches and Cisco 7600 Series routers. The NAM is an integrated and powerful traffic monitoring service module that occupies a single slot in the chassis and enables network managers to gain application-level visibility into network traffic with the ultimate goal of improving performance, reducing failures, and maximizing returns on network investments.

The second-generation NAMs are available in two hardware versions, NAM-1 and NAM-2, and offer high performance monitoring and crossbar (fabric) connectivity to meet diverse network analysis needs in scalable switching and routing environments running at gigabit speeds. The NAMs come with an embedded, Web-based traffic analyzer, which provides full-scale remote monitoring and troubleshooting capabilities that are accessible through a Web browser.



Application-Level Visibility Built into the Network

The NAMs give network managers visibility into all layers of network traffic by providing application-level Remote Monitoring (RMON) functions based on RMON2 and other advanced Management Information Bases (MIBs). The NAMs add to the built-in Remote Monitoring (mini-RMON) features in Cisco Catalyst 6500 Series switches and Cisco 7600 Series routers that provide port-level traffic statistics at the Media Access Control (MAC) or data link layer. The NAMs provide intelligence to analyze traffic flows for applications, hosts, conversations, and network-based services such as quality of service (QoS) and voice over IP (VoIP).

Integrated Monitoring for LANs and WANs

The NAMS use several data sources from local and remote switches and routers to provide combined visibility into LAN and WAN environments. The NAMs collect data from physical ports, virtual LANs (VLANs), or Cisco EtherChannel®

connections using the Switch Port Analyzer (SPAN) feature. For selective monitoring of large amount of traffic or for traffic from WAN interfaces, VLAN access control list (VACL)-based captures can be used to filter traffic before it is sent to NAM. In addition, the NAMs collect and analyze NetFlow Data Export from local and remote devices to provide broad application-level visibility into the network, including remote WAN segments. The NAMs also collect data from remote switches using the remote SPAN (RSPAN) feature of the Cisco Catalyst switches.

Flexible Deployment Scenarios

The NAMs can be deployed in the Cisco Catalyst 6500 Series at LAN aggregation points (for example, in the core or distribution layer) for proactive monitoring; at service points (for example, in data centers, server farms, or Cisco CallManager clusters in IP telephony networks) where performance is critical; and at important access points (critical clients, IP phone closets) where quick troubleshooting is required. They can also be deployed in Cisco 7600 Series routers at WAN edges or in Catalyst 6500 Series switches connected to WAN routers. When deployed at remote branch offices, the NAMs provide unique advantage to perform remote troubleshooting and traffic analysis through its Web-based Traffic Analyzer without having to send personnel or to haul large amounts of data to the central site. Figure 1 highlights the deployment of NAMs to enable comprehensive traffic monitoring and analysis for performance monitoring, troubleshooting, and capacity planning.

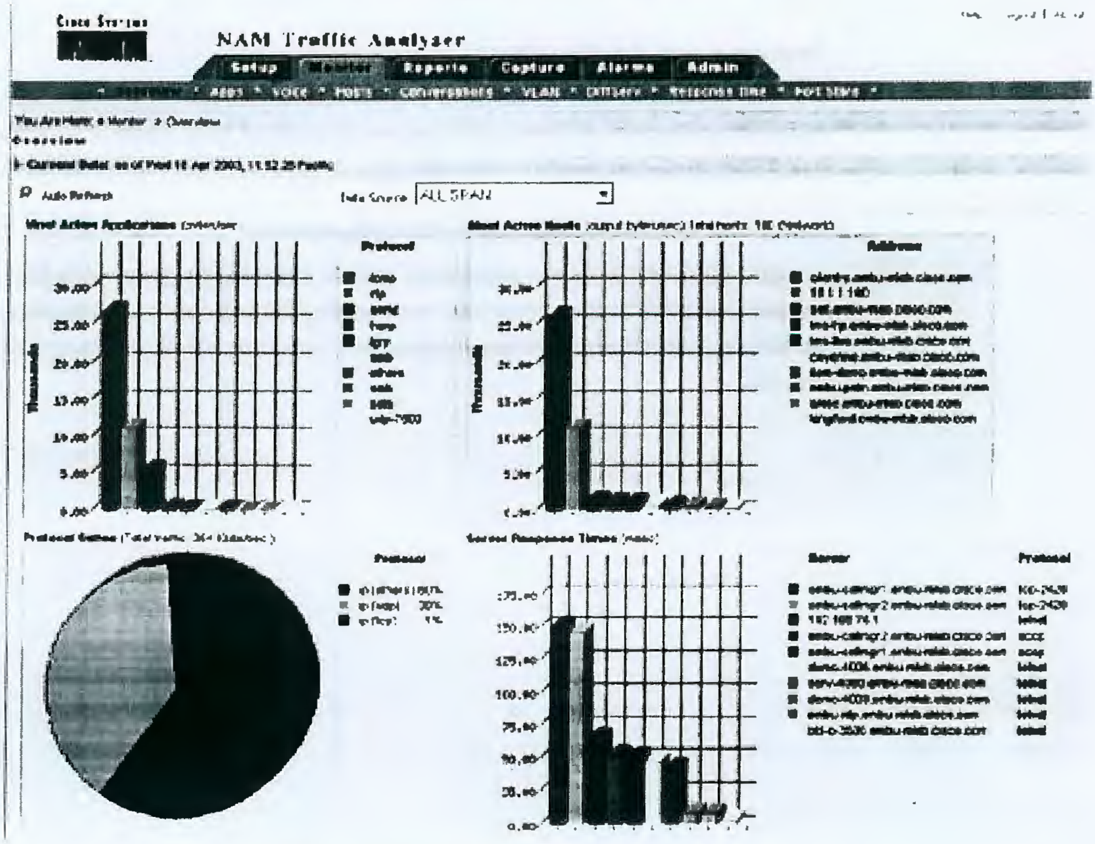
Application Performance Monitoring

Easy to Deploy and Use

The NAMs come with the embedded, Web-based Traffic Analyzer with extensive monitoring and troubleshooting capabilities. Because the NAMs integrate monitoring functions directly into the switch and have complete data collection and data analysis capabilities on board, they are easy to deploy and managers can conveniently access data from anywhere using a Web browser (Figure 2). For security, users can be given role-based access and the Web-browser access can be secured with up to 168-bit encryption.

Figure 2

Web-Based Traffic Monitoring for both LAN and WAN with the embedded NAM Traffic Analyzer



The NAMs also provide the flexibility to use standards-based external applications using the Simple Network Management Protocol (SNMP). NetScout *n*Genius Real-Time Monitor, a component of the CiscoWorks LAN Management Solution (LMS), collects data from NAMs across the network and provides reports on traffic flow.

Major Benefits

- Increase return on network investment—The visibility provided by the NAMs enables better utilization of network resources to meet business objectives. They ease deployment of network-based services and help in capacity planning.
- Reduce productivity loss and revenue loss—Through proactive monitoring and quick troubleshooting capabilities, the NAMs prevent loss due to network degradation and downtime.
- Enhance network security—The NAMs provide investigation and verification capabilities to supplement other security mechanisms such as intrusion detection and firewalls. They can also be used to detect threats by watching anomalies in the network traffic.

Features and Applications

The data collected by the NAMs can be used for several vital management activities, including real-time and historical application monitoring, performance management, fault isolation, troubleshooting, and capacity planr The NAMs also play an active role in managing differentiated services such as voice.

Real-Time and Historical Application Monitoring

Using RMON, RMON2, several extended RMON MIBs, and NetFlow, the NAMs detect the applications on the network and provide detailed real-time and historical information about how these applications utilize the bandwidth, which hosts access those applications, and which client/server pairs generate the most traffic (Figure 3A and 3B).

Performance Management

The NAMs provide valuable information about the delays in server responses to client requests. Using the Application Response Time (ART) MIB, developed by Cisco partner NetScout Systems, the NAMs can identify problems with applications or servers in critical environments such as e-commerce and IP telephony (Figure 4).

Fault Isolation and Troubleshooting

Using the NAMs, network managers can set thresholds and alarms on various network parameters such as increased utilization, severe application response delays, and voice quality degradation, and be alerted to potential problems. The NAMs provide comprehensive views on applications, hosts, voice, quality of service (QoS), and so on, to isolate faults or malfunctions in the network. The NAM Traffic Analyzer can capture and decode packets in real time to aid troubleshooting (Figure 5).

VoIP and QoS Monitoring

The NAMs can analyze voice traffic flows in real time to collect valuable information, including call setup details and voice quality metrics. Network managers can be alerted to voice quality degradation and can isolate potential problems (Figure 6).

The NAMs make the deployment of QoS for voice and other critical services effective by identifying violations of QoS policies. The NAMs support the Differentiated Services Monitoring (DSMON) MIB, which monitors traffic by differentiated services code point (DSCP) allocations defined by QoS policies (Figure 7).

Capacity Planning and Other Extended Applications

The data from the NAMs across the network can be collected by NetScout nGenius Real-Time Monitor, a component of the CiscoWorks LAN Management Solution (LMS) to provide consolidated views of network traffic (Figure 8). The NAMs serve as data sources for several other standards-based applications for a variety of purposes including capacity planning, long-term historical reporting and trending, anomaly-based threat detection, etc.

Primary Advantages

- Integrated with network infrastructure—The NAMs occupy a single slot within the Cisco Catalyst 6500 Series or Cisco 7600 Series chassis and are deployed, managed, and supported as an integral part of the network infrastructure. They do not interfere with switching and routing functions and have their own processing resources. They are managed as a part of the network device using CiscoWorks management tools.
- Complete monitoring solution for LAN, WAN, and network-based services—The NAMs combine the functions of data collection agent and analysis application in one and provide comprehensive monitoring using a variety of data sources including RMON, RMON2 and NetFlow though the embedded Traffic Analyzer.
- Total cost of ownership savings—The integrated nature of the NAM solution saves costs in acquiring network device-specific features like mini-RMON, and in maintenance and technical support. The NAM Traffic Analyzer is embedded in the NAMs at no extra cost.
- Extensible, standards-based solution—The NAMs are compliant with open standards, and can be used with different monitoring applications to meet diverse needs.
- Secure solution—The NAM Traffic Analyzer can be deployed with up to 168-bit encryption, and SNMP can be disabled for fortifying external access to the NAM. The NAMs support Secure Shell (SSH) for secured command-line access.

Network Monitoring Solutions

Cisco Systems offers a wide variety of solutions to provide complete visibility into network infrastructure. The comprehensive Cisco solution includes embedded technologies such as mini-RMON, NetFlow, Service Assurance Agent (SAA), Network-Based Application Recognition (NBAR); NAMs for the Cisco Catalyst 6500 Series and Cisco 7600 Series for value-added traffic analysis. and CiscoWorks network monitoring applications. nGenius Real-Time Monitor, a component of the CiscoWorks LAN Management Solution (LMS), collects mini-RMON data from switches to provide port utilization statistics and uses data from NAMs across the network to provide broad-based analysis and reports on network traffic. Cisco AVVID (Architecture for Voice, Video and Integrated Data) partners extend the Cisco network monitoring solution through a variety of applications that use embedded data sources and NAMs.

Technical Specifications

NAM-1

- High-performance dual processor architecture, 512 MB RAM
- Two data collection interfaces to backplane: 1 for SPAN/VACL data sources, 1 for NetFlow
- Second generation fabric enabled platform with interface to both bus and crossbar based architectures

NAM-2

- Extra high-performance dual processor architecture with hardware-based packet acceleration, 1 GB RAM
- Gigabit monitoring performance
- Three data collection interfaces to backplane: 2 for SPAN/VACL data sources (can be used independently or together), 1 for NetFlow
- Second generation fabric enabled platform with interface to both bus and crossbar based architectures

Supported Platforms

- NAM-1 and NAM-2 can be deployed in any slot in Cisco Catalyst 6500 and 6000 Series switches and Cisco 7600 Series routers [both bus- and crossbar (fabric)-based architectures]; multiple NAMs can be placed in the same chassis
- Supported with Cisco IOS® Software or Cisco Catalyst Operating System on the Supervisor Engine

Supported Topologies and Data Sources

- LAN—Switch Port Analyzer (SPAN) or Remote SPAN (RSPAN), VLAN ACL(VACL)-based captures, NetFlow (v1, v5, v6, v7, v8)
- WAN—NetFlow (v1, v5, v6, v7, v8) from local and remote devices, VLAN ACL (VACL)-based captures for FlexWAN/Optical Service Module (OSM) interfaces (Cisco IOS Software only)

Supported Interfaces and Applications

- HTTP/HTTPS with embedded web based NAM Traffic Analyzer
- SNMP v1, v2 with NetScout nGenius Real Time Monitor and other standards based applications

NAM Traffic Analyzer

- Embedded in NAM Software Version 2.2 and later for NAM-1/NAM-2
- Web based—Requires Microsoft Internet Explorer 5.0 or Netscape 4.7 (minimum)
- Supports Secure Sockets Layer (SSL) security with up to 168-bit encryption
- Role-based user authorization and authentication locally or using TACACS+
- Real-time and historical statistics (up to 100 days) on LAN/WAN traffic and network-based services

NAM Software Version 3.1

- Supports NAM-1 (part number WS-SVC-NAM-1), NAM-2 (WS-SVC-NAM-2) and first-generation NAM (WS-X6380-NAM)
- Supported with Cisco IOS® Software Release 12.1(13)E or Cisco Catalyst Operating System 7.3(1) minimum on the Supervisor Engine

Supported MIB Groups

The NAMs are standards-compliant and support RMON and RMON2 MIBs, as well as several extensions. The major MIB groups supported in the NAMs are:

- MIB-II (RFC 1213)—All groups except Exterior Gateway Protocol (EGP) and transmission
- RMON (RFC 2819)—All groups
- RMON2 (RFC2021)—All groups
- SMON (RFC2613)—DataSourceCaps and smonStats
- DSMON (RFC 3287)
- HC-RMON (RFC 3273)
- Application Response Time (ART)

Supported Protocols

The NAMs provide RMON2 statistics on several-hundred unique protocols, including those defined in RFC 2896, and several Cisco proprietary protocols. In addition, the NAMs can automatically detect unknown protocols and users have the flexibility to customize the protocol directory.

Examples of Protocols Supported by the NAMs for RMON2 Statistics:

- TCP and UDP over IP including IPv6
- VoIP including SCCP(Skinny), RTP/RTCP, MGCP, SIP
- Mobile IP protocols (Both IP in IP and GRE tunnelling)
- Storage area network (SAN) protocols including Fiber Channel over TCP/IP
- AppleTalk, DECnet, Novell, Microsoft
- Database protocols including Oracle, Sybase
- Bridge and router protocols
- Cisco proprietary protocols
- Unknown protocols by TCP/UDP ports, RPC program numbers, etc.

Physical Specifications

- Dimensions (H x W x D): 1.2 x 14.4 x 16 in. (3.0 x 35.6 x 40.6 cm); Occupies any 1 slot in the chassis

Operating Environment

- Operating temperature: 32 F (0 C) to 104 F (40 C)
- Nonoperating and storage temperature: -40 F (-40 C) to 158 F (70 C)
- Operating relative humidity: 10% to 90% (noncondensing)
- Nonoperating relative humidity: 5% to 95% (noncondensing)
- Operating and nonoperating altitude: Sea level to 10,000 ft (3050 m)

Agency Approvals

- Regulatory: CE Marking (89/366/EEC and 73/23/EEC)
- Safety: UL 1950, CAN/CSA-C22.2 No. 950, EN 60950, IEC 60950
- Electromagnetic Emissions: FCC Part 15 (CFR 47) Class A, ICES-003 Class A, EN55022 Class A, CISPR22 Class A, AS/NZS 3548 Class A, VCCI Class A, EN55024, EN50082-1

Ordering Information

Cisco Part Number	Description
WS-SVC-NAM-1	Network Analysis Module-1 for Cisco Catalyst 6500 Series and Cisco 7600 Series
WS-SVC-NAM-2	Network Analysis Module-2 for Cisco Catalyst 6500 Series and Cisco 7600 Series
SC-SVC-NAM-3.1	Network Analysis Module Software v 3.1 for NAM-1, NAM-2 (includes ART, VoIP)

- The use of mini-RMON in Cisco Catalyst 6500 Series and Cisco 7600 Series with NAMs installed does not require the purchase of a separate RMON agent license.
- The Application Response Time (ART) MIB and the VoIP monitoring features are included at no extra cost for the NAM-1 and NAM-2. They require purchase of separate licenses (SC6K-NAM-ART-LIC= and SC6K-NAM-VOIP-LIC=) with the first-generation NAM (WS-X6380-NAM)
- Service Part Numbers for NAM-1 and NAM-2 are CON-xxx-WSSVCNAM1 and CON-xxx-WSSVNAM2 respectively, where "xxx" stands for level of support (for example, xxx= SNT = 8x5x Next Business Day)

CHAPTER 32

Configuring PFC QoS

This chapter describes how to configure quality of service (QoS) as implemented on the policy feature card (PFC) on the Catalyst 6500 series switches.

Note For complete syntax and usage information for the commands used in this publication, refer to the *Catalyst 6500 Series Switch Cisco IOS Command Reference* publication.

This chapter contains these sections:

- Understanding How PFC QoS Works, page 32-1
- PFC QoS Default Configuration, page 32-24
- PFC QoS Configuration Guidelines and Restrictions, page 32-29
- Configuring PFC QoS, page 32-31

Note

- With Release 12.1(13)E and later releases and with an MSFC2, you can configure Network-Based Application Recognition (NBAR) on LAN ports instead of using PFC QoS.
- All ingress and egress traffic on a port that is configured with NBAR is processed in software on the MSFC2.
- The PFC2 provides hardware support for input ACLs on ports where you configure NBAR.
- When PFC QoS is enabled, the traffic through ports where you configure NBAR passes through the ingress and egress queues and drop thresholds. When PFC QoS is enabled, the MSFC2 sets egress CoS equal to egress IP precedence.
- After passing through an ingress queue, all traffic is processed in software on the MSFC2 on ports where you configure NBAR.
- To configure NBAR, refer to this publication:

  http://www.cisco.com/univercd/cc/td/doc/product/software/ios122/122newft/122t/122t8/dtnbarad.htm

Understanding How PFC QoS Works

Typically, networks operate on a *best-effort* delivery basis, which means that all traffic has equal priority and an equal chance of being delivered in a timely manner. When congestion occurs, all traffic has an equal chance of being dropped.

QoS selects network traffic (both unicast and multicast), prioritizes it according to its relative importance, and uses congestion avoidance to provide priority-indexed treatment; QoS can also limit the bandwidth used by network traffic. QoS makes network performance more predictable and bandwidth utilization more effective.

Note On the Catalyst 6500 series switches, queue architecture and QoS queueing features such as Weighted-Round Robin (WRR) and Weighted Random Early Detection (WRED) are implemented with a fixed configuration in Application Specific Integrated Circuits (ASICs). The queueing architecture cannot be reconfigured. For more information, see the "Receive Queues" section on page 32-13 and the "Transmit Queues" section on page 32-21.

These sections describe PFC QoS:

- Hardware Supported by PFC QoS, page 32-2
- QoS Terminology, page 32-3
- PFC QoS Feature Flowcharts, page 32-5
- PFC QoS Feature Summary, page 32-11
- Ingress LAN Port Features, page 32-12
- PFC Marking and Policing, page 32-16
- LAN Egress Port Features, page 32-21
- PFC QoS Statistics Data Export, page 32-24

Hardware Supported by PFC QoS

With Release 12.1(11a)E and later, PFC QoS supports both LAN ports and optical services module (OSM) ports:

- *LAN ports* are Ethernet ports on Ethernet switching modules, except for the 4-port Gigabit Ethernet WAN (GBIC) module (OSM-4GE-WAN). Except for the OSM-4GE-WAN module, OSMs have four Ethernet LAN ports in addition to WAN ports. With earlier releases, PFC QoS supports only LAN ports.
- *OSM ports* are the WAN ports on OSMs. The PFC provides ingress QoS for traffic from OSM ports. For more information, see the following sections:
  - "Ingress OSM Port Features" section on page 32-11
  - "Egress OSM Port Features" section on page 32-12
  - "PFC Marking and Policing" section on page 32-16
  - "Attaching Policy Maps" section on page 32-21
  - "Configuring the Trust State of Ethernet LAN and OSM Ingress Ports" section on page 32-51
- Refer to the following publication for information about additional OSM QoS features:

  http://www.cisco.com/univercd/cc/td/doc/product/core/cis7600/cfgnotes/osm_inst/index.htm
- The PFC does not provide QoS for FlexWAN module ports. Refer to the following publications for information about FlexWAN module QoS features:

QoS Terminology

This section defines some QoS terminology:

- *Packets* carry traffic at Layer 3.
- *Frames* carry traffic at Layer 2. Layer 2 frames carry Layer 3 packets.
- *Labels* are prioritization values carried in Layer 3 packets and Layer 2 frames:
  - Layer 2 class of service (CoS) values, which range between zero for low priority and seven for high priority:

    Layer 2 Inter-Switch Link (ISL) frame headers have a 1-byte User field that carries an IEEE 802.1p CoS value in the three least significant bits.

    Layer 2 802.1Q frame headers have a 2-byte Tag Control Information field that carries the CoS value in the three most significant bits, which are called the User Priority bits.

    Other frame types cannot carry Layer 2 CoS values.

Note On LAN ports configured as Layer 2 ISL trunks, all traffic is in ISL frames. On LAN ports configured as Layer 2 802.1Q trunks, all traffic is in 802.1Q frames except for traffic in the native VLAN.

- Layer 3 IP precedence values—The IP version 4 specification defines the three most significant bits of the 1-byte Type of Service (ToS) field as IP precedence. IP precedence values range between zero for low priority and seven for high priority.
- Layer 3 differentiated services code point (DSCP) values—The Internet Engineering Task Force (IETF) has defined the six most significant bits of the 1-byte IP ToS field as the DSCP. The per-hop behavior represented by a particular DSCP value is configurable. DSCP values range between 0 and 63 (see the "Configuring DSCP Value Maps" section on page 32-64).

Note Layer 3 IP packets can carry either an IP precedence value or a DSCP value. PFC QoS supports the use of either value, since DSCP values are backwards compatible with IP precedence values (see Table 32-1 on page 32-4).

Table 32-1 IP Precedence and DSCP Values

3-bit IP Precedence	6 MSb[1] of ToS						6-bit DSCP	3-bit IP Precedence	6 MSb[1] of ToS						6-bit DSCP
	8	7	6	5	4	3			8	7	6	5	4	3

	0	1	1	1	1	1	31		1	1	1	1	1	1	63

[1] MSb = most significant bit

- *Classification* is the selection of traffic to be marked.
- *Marking*, according to RFC 2475, is the process of setting a Layer 3 DSCP value in a packet; in this publication, the definition of marking is extended to include setting Layer 2 CoS values.
- *Scheduling* is the assignment of Layer 2 frames to a queue. PFC QoS assigns frames to a queue based on Layer 2 CoS values.
- *Congestion avoidance* is the process by which PFC QoS reserves ingress and egress LAN port capacity for Layer 2 frames with high-priority Layer 2 CoS values. PFC QoS implements congestion avoidance with Layer 2 CoS value-based drop thresholds. A drop threshold is the percentage of queue buffer utilization above which frames with a specified Layer 2 CoS value is dropped, leaving the buffer available for frames with higher-priority Layer 2 CoS values.
- *Policing* is limiting bandwidth used by a flow of traffic. Policing is done on the Policy Feature Card (PFC) or on the Policy Feature Card 2 (PFC2) and distributed forwarding cards (DFCs). Policing can mark or drop traffic.

PFC QoS Feature Flowcharts

Figure 32-1 show how traffic flows through the components that support PFC QoS features.

Figure 32-1 Traffic Flow Through PFC QoS Features with PFC2

Note

- The PFC can provide Layer 3 switching for FlexWAN traffic but does not provide PFC QoS for FlexWAN traffic.
- PFC QoS does not change the ToS byte in FlexWAN ingress traffic.
- Traffic that is Layer 3-switched does not go through the MSFC and retains the Layer 2 CoS value assigned by the PFC.

Figure 32-3 through Figure 32-8 show how the PFC QoS features are implemented on the switch components.

PFC QoS Feature Summary

These sections summarize the PFC QoS features:

- Ingress LAN Port Features, page 32-11
- Ingress OSM Port Features, page 32-11
- PFC QoS Features, page 32-11
- Egress LAN Port Features, page 32-12
- Egress OSM Port Features, page 32-12
- MSFC Features, page 32-12

Ingress LAN Port Features

PFC QoS supports classification, marking, scheduling, and congestion avoidance using Layer 2 CoS values at ingress LAN ports. Classification, marking, scheduling, and congestion avoidance at ingress LAN ports do not use or set Layer 3 IP precedence or DSCP values. You can configure ingress LAN port trust states that can be used by the PFC to set Layer 3 IP precedence or DSCP values and the Layer 2 CoS value. See Figure 32-3 and the "Ingress LAN Port Features" section on page 32-12.

Ingress OSM Port Features

PFC QoS associates CoS zero with all traffic received through ingress OSM ports. You can configure ingress OSM port trust states that can be used by the PFC to set Layer 3 IP precedence or DSCP values and the Layer 2 CoS value. You can configure the trust state of each ingress OSM port as follows:

- Untrusted (default)
- Trust IP precedence
- Trust DSCP
- Trust CoS (CoS is always zero because the default port CoS is not configurable on OSM ports.)

PFC QoS Features

On the PFC, PFC QoS supports ingress classification, marking, and policing using policy maps. You can attach one policy map to an ingress port. Each policy map can contain multiple policy-map classes. You can configure a separate policy-map class for each type of traffic received through the ingress port. See the "PFC Marking and Policing" section on page 32-16.

Note

- You can globally disable marking and policing with the **mls qos queueing-only** command (see the Enabling Queueing-Only Mode, page 32-32).
- You can disable marking and policing on a per-interface basis with the **no mls qos** interface command (see the "Enabling or Disabling PFC Features on an Interface" section on page 32-49.

Egress LAN Port Features

PFC QoS supports egress LAN port scheduling and congestion avoidance using Layer 2 CoS values. Egress LAN port marking sets Layer 2 CoS values and Layer 3 DSCP values. See the "LAN Egress Port Features" section on page 32-21.

Egress OSM Port Features

Ingress PFC QoS sets Layer 3 DSCP values that can be used by the OSM egress QoS features.

MSFC Features

PFC QoS marks IP traffic transmitted to the MSFC with rewritten Layer 3 DSCP values. With PFC2, CoS is equal to IP precedence in all traffic sent from the MSFC2 to egress ports; with PFC1, CoS is zero.

Note Traffic that is Layer 3 switched does not go through the MFSC and retains the CoS value assigned by the PFC.

Ingress LAN Port Features

These sections describe ingress LAN port PFC QoS features:

- Ingress LAN Port Trust States, page 32-12
- Marking at Untrusted Ingress LAN Ports, page 32-13
- Marking at Trusted Ingress LAN Ports, page 32-13
- Ingress LAN Port Scheduling and Congestion Avoidance, page 32-13

Ingress LAN Port Trust States

The trust state of an ingress LAN port determines how the port marks, schedules, and classifies received Layer 2 frames, and whether or not congestion avoidance is implemented. You can configure the trust state of each ingress LAN port as follows:

- Untrusted (default)
- Trust IP precedence (not supported on **1q4t** LAN ports except Gigabit Ethernet)
- Trust DSCP (not supported on **1q4t** LAN ports except Gigabit Ethernet)
- Trust CoS (not supported on **1q4t** LAN ports except Gigabit Ethernet)

See the "Configuring the Trust State of Ethernet LAN and OSM Ingress Ports" section on page 32-51. PFC QoS implements ingress LAN port congestion avoidance only on LAN ports configured to trust CoS.

Note Ingress LAN port marking, scheduling, and congestion avoidance use Layer 2 CoS values and does not use or set Layer 3 IP precedence or DSCP values.

Marking at Untrusted Ingress LAN Ports

PFC QoS marks all frames received through untrusted ingress LAN ports with the ingress port CoS value (the default is zero). PFC QoS does not implement ingress port congestion avoidance on untrusted ingress LAN ports.

Marking at Trusted Ingress LAN Ports

When an ISL frame enters the Catalyst 6500 series switch through a trusted ingress LAN port, PFC QoS accepts the three least significant bits in the User field as a CoS value. When an 802.1Q frame enters the switch through a trusted ingress LAN port, PFC QoS accepts the User Priority bits as a CoS value. PFC QoS marks all traffic received in untagged frames with the ingress port CoS value.

Note The ingress port CoS value is configurable for each ingress LAN port (see the "Configuring the Ingress LAN Port CoS Value" section on page 32-52).

Ingress LAN Port Scheduling and Congestion Avoidance

On ingress LAN ports configured to trust CoS, PFC QoS uses Layer 2 CoS-value based receive-queue drop thresholds to avoid congestion (see the "Configuring the Trust State of Ethernet LAN and OSM Ingress Ports" section on page 32-51).

Receive Queues

Enter the **show queueing interface {ethernet | fastethernet | gigabitethernet | tengigabitethernet}** *slot/port* **| include type** command to see the queue structure of a LAN port.

- **1q2t** indicates one standard queue with one configurable tail-drop threshold and one nonconfigurable tail-drop threshold.
- **1q4t** indicates one standard queue with four configurable tail-drop thresholds (usable only on Gigabit Ethernet ports).
- **1p1q4t** indicates one strict-priority queue and one standard queue with four configurable tail-drop thresholds.
- **1p1q0t** indicates one strict-priority queue and one standard queue with no configurable threshold (effectively a tail-drop threshold at 100 percent).
- **1p1q8t** indicates one strict-priority queue and one standard queue with eight configurable WRED-drop thresholds and one non-configurable (100 percent) tail-drop threshold.

Strict-priority queues are queues that are serviced in preference to other queues. PFC QoS services traffic in a strict-priority queue before servicing the standard queue. When PFC QoS services the standard queue, after receiving a packet, it checks for traffic in the strict-priority queue. If PFC QoS detects traffic in the strict-priority queue, it suspends its service of the standard queue and completes service of all traffic in the strict-priority queue before returning to the standard queue.

Scheduling

PFC QoS schedules traffic through the receive queues based on Layer 2 CoS values. In the **1p1q4t**, **1p1q0t** and **1p1q8t** default configurations, PFC QoS assigns all traffic with CoS 5 to the strict-priority queue; PFC QoS assigns all other traffic to the standard queue. In the **1q4t** default configuration, PFC QoS assigns all traffic to the standard queue.

Congestion Avoidance

If an ingress LAN port is configured to trust CoS, PFC QoS implements Layer 2 CoS-value-based receive-queue drop thresholds to avoid congestion in received traffic.

1q2t ingress LAN ports have this default drop-threshold configuration:

- Frames with CoS 0, 1, 2, 3, or 4 go to tail-drop threshold 1, where the switch drops incoming frames when the standard receive-queue buffer is 80 percent full.
- Frames with CoS 5, 6, or 7 go to tail-drop threshold 2, where the switch drops incoming frames when the standard receive-queue buffer is 100 percent full.

1q4t ingress LAN ports have this default drop-threshold configuration:

- Using receive-queue tail-drop threshold 1, the switch drops incoming frames with CoS 0 or 1 when the receive-queue buffer is 50 percent or more full.
- Using receive-queue tail-drop threshold 2, the switch drops incoming frames with CoS 2 or 3 when the receive-queue buffer is 60 percent or more full.
- Using receive-queue tail-drop threshold 3, the switch drops incoming frames with CoS 4 or 5 when the receive-queue buffer is 80 percent or more full.
- Using receive-queue tail-drop threshold 4, the switch drops incoming frames with CoS 6 or 7 when the receive-queue buffer is 100 percent full.

1p1q4t ingress LAN ports have this default drop-threshold configuration:

- Frames with CoS 5 go to the strict-priority receive queue (queue 2), where the switch drops incoming frames only when the strict-priority receive-queue buffer is 100 percent full.
- Frames with CoS 0, 1, 2, 3, 4, 6, or 7 go to the standard receive queue.
  - Using standard receive-queue tail-drop threshold 1, the switch drops incoming frames with CoS 0 or 1 when the receive-queue buffer is 50 percent or more full.
  - Using standard receive-queue tail-drop threshold 2, the switch drops incoming frames with CoS 2 or 3 when the receive-queue buffer is 60 percent or more full.
  - Using standard receive-queue tail-drop threshold 3, the switch drops incoming frames with CoS 4 when the receive-queue buffer is 80 percent or more full.
  - Using standard receive-queue tail-drop threshold 4, the switch drops incoming frames with CoS 6 or 7 when the receive-queue buffer is 100 percent full.

1p1q0t ingress LAN ports have this default drop-threshold configuration:

- Frames with CoS 5 go to the strict-priority receive queue (queue 2), where the switch drops incoming frames only when the strict-priority receive-queue buffer is 100 percent full.
- Frames with CoS 0, 1, 2, 3, 4, 6, or 7 go to the standard receive queue. The switch drops incoming frames when the receive-queue buffer is 100 percent full.

1p1q8t ports have this default drop-threshold configuration:

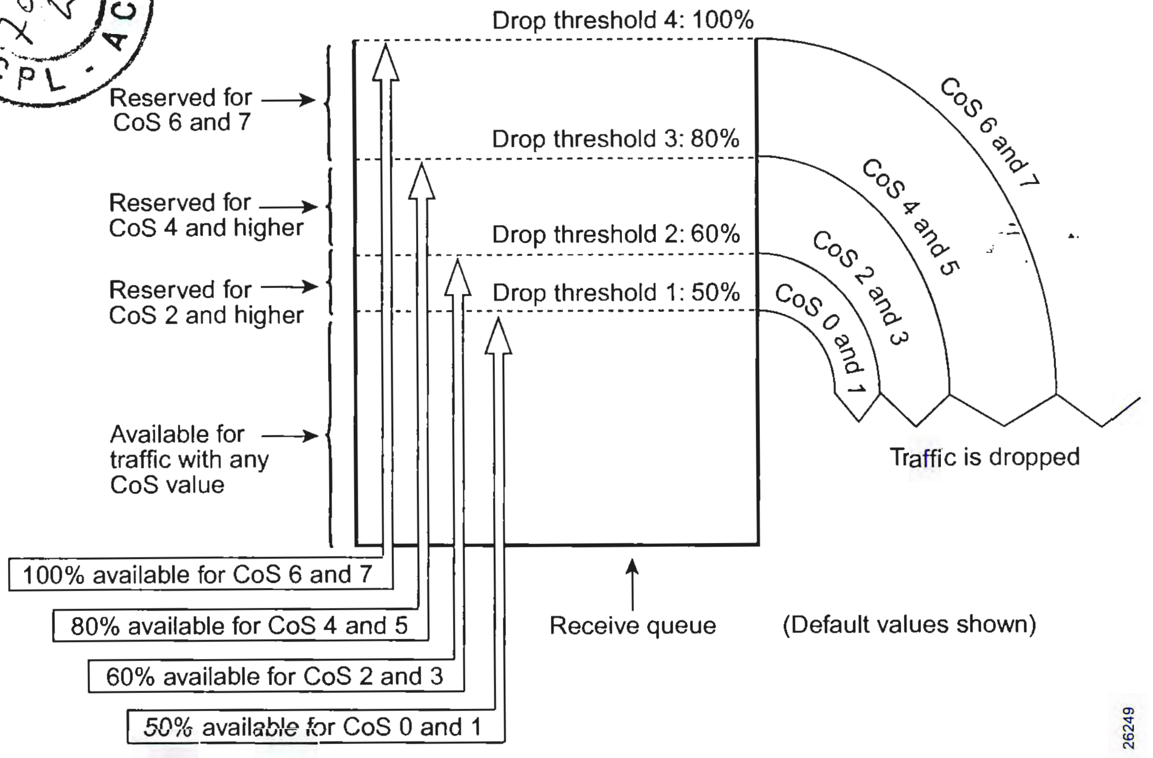
- Frames with CoS 5 go to the strict-priority receive queue (queue 2), where the switch drops incoming frames only when the strict-priority receive-queue buffer is 100 percent full.
- Frames with CoS 0, 1, 2, 3, 4, 6, or 7 go to the standard receive queue, which uses WRED-drop thresholds:
  - Using standard receive-queue WRED-drop threshold 1 for incoming frames with CoS 0, the switch starts to drop frames when the receive-queue buffer is 40 percent full and drops all frames with CoS 0 when the receive-queue buffer is 70 percent or more full.
  - Using standard receive-queue WRED-drop threshold 2 for incoming frames with CoS 1, the switch starts to drop frames when the receive-queue buffer is 40 percent full and drops all frames with CoS 1 when the receive-queue buffer is 70 percent or more full.
  - Using standard receive-queue WRED-drop threshold 3 for incoming frames with CoS 2, the switch starts to drop frames when the receive-queue buffer is 50 percent full and drops all frames with CoS 2 when the receive-queue buffer is 80 percent or more full.
  - Using standard receive-queue WRED-drop threshold 4 for incoming frames with CoS 3, the switch starts to drop frames when the receive-queue buffer is 50 percent full and drops all frames with CoS 3 when the receive-queue buffer is 80 percent or more full.
  - Using standard receive-queue WRED-drop threshold 5 for incoming frames with CoS 4, the switch starts to drop frames when the receive-queue buffer is 60 percent full and drops all frames with CoS 4 when the receive-queue buffer is 90 percent or more full.
  - Using standard receive-queue WRED-drop threshold 6 for incoming frames with CoS 6, the switch starts to drop frames when the receive-queue buffer is 60 percent full and drops all frames with CoS 6 when the receive-queue buffer is 90 percent or more full.
  - Using standard receive-queue WRED-drop threshold 7 for incoming frames with CoS 7, the switch starts to drop frames when the receive-queue buffer is 70 percent full and drops all frames with CoS 7 when the receive-queue buffer is 100 percent or more full.

  Note You can configure the standard receive queue to use both a tail-drop and a WRED-drop threshold by mapping a CoS value to the queue or to the queue and a threshold. The switch uses the tail-drop threshold for traffic carrying CoS values mapped only to the queue. The switch uses WRED-drop thresholds for traffic carrying CoS values mapped to the queue and a threshold. See the "Configuring Standard Queue WRED-Drop Thresholds" section on page 32-55.

Note The explanations in this section use default values. You can configure many of the parameters (see the "Configuring PFC QoS" section on page 32-31). All LAN ports of the same type use the same drop-threshold configuration.

Figure 32-9 illustrates the drop thresholds for a **1q4t** ingress LAN port. Drop thresholds in other configurations function similarly.

Figure 32-9 Receive Queue Drop Thresholds



Drop threshold 4: 100%
Drop threshold 3: 80%
Drop threshold 2: 60%
Drop threshold 1: 50%

PFC Marking and Policing

Note

- To mark untrusted traffic without policing in Release 12.1(12c)E1 and later releases, use the **set ip dscp** or **set ip precedence** policy map class commands (see the "Configuring Policy Map Class Actions" section on page 32-42).
- To mark untrusted traffic without policing in earlier releases, create a policer that only marks and does not police.

These sections describe PFC marking and policing:

- Internal DSCP Values, page 32-17
- Policy Maps, page 32-18
- Policers, page 32-19
- Attaching Policy Maps, page 32-21
- Egress CoS and ToS Values, page 32-21

Note Filtering for PFC QoS can use Layer 2, 3, and 4 values. Marking uses Layer 2 CoS values and Layer 3 IP precedence or DSCP values.

Internal DSCP Values

These sections describe the internal DSCP values:

- Internal DSCP Sources, page 32-17
- Egress DSCP and CoS Sources, page 32-17

Internal DSCP Sources

During processing, PFC QoS represents the priority of all traffic (including non-IP traffic) with an internal DSCP value. PFC QoS derives the internal DSCP value from the following:

- For trust-cos traffic, from received or ingress port Layer 2 CoS values

Note Traffic from an untrusted ingress LAN port has the ingress port CoS value and if traffic from an untrusted ingress Ethernet port matches a trust-cos policer, PFC QoS derives the internal DSCP value from the ingress port CoS value.

- For trust-ipprec traffic, from received IP precedence values
- For trust-dscp traffic, from received DSCP values
- For untrusted traffic, from ingress port CoS or configured DSCP values

The trust state of traffic is the trust state of the ingress LAN port unless set otherwise by a matching ACE.

Note A **trust-cos** policer cannot restore received CoS in traffic from untrusted ingress LAN ports. Traffic from untrusted ingress LAN ports always has the ingress port CoS value.

PFC QoS uses configurable mapping tables to derive the internal 6-bit DSCP value from CoS or IP precedence, which are 3-bit values (see the"Mapping Received CoS Values to Internal DSCP Values" section on page 32-64 or the "Mapping Received IP Precedence Values to Internal DSCP Values" section on page 32-65).

Egress DSCP and CoS Sources

For egress IP traffic, PFC QoS creates a ToS byte from the internal DSCP value and sends it to the egress port to be written into IP packets. For **trust-dscp** and **untrusted** IP traffic, the ToS byte includes the original 2 least-significant bits from the received ToS byte.

Note The internal DSCP value can mimic an IP precedence value (see Table 32-1 on page 32-4).

For all egress traffic, PFC QoS uses a configurable mapping table to derive a CoS value from the internal DSCP value associated with traffic (see the "Mapping Internal DSCP Values to Egress CoS Values" section on page 32-65). PFC QoS sends the CoS value to the egress LAN ports for use in scheduling and to be written into ISL and 802.1Q frames.

Policy Maps

Note

- You can globally disable marking and policing with the **mls qos queueing-only** command (see the Enabling Queueing-Only Mode, page 32-32).
- You can disable marking and policing on a per-interface basis with the **no mls qos** interface command (see the "Enabling or Disabling PFC Features on an Interface" section on page 32-49.

The PFC supports filtering, marking, and policing using policy maps (see the "Configuring a Policy Map" section on page 32-40). Each policy map can contain multiple policy-map classes. You can configure a separate policy-map class for each type of received traffic.

Policy-map classes specify filtering with the following:

- Cisco IOS access control lists (optional for IP, required for IPX and MAC-Layer filtering)
- Class-map **match** commands for Layer 3 IP precedence and DSCP values

Policy-map classes specify actions with the following:

- (Optional) Policy-map class **trust** commands. If specified, PFC QoS applies the policy-map class trust state to matched traffic. Policy-map class trust states supersede ingress LAN port trust states.

  Note If traffic matches a policy-map class that does not contain a **trust** command, the trust state remains as set on the ingress LAN port.

- (Optional) Aggregate and microflow policers, which can use bandwidth limits to either mark or drop both conforming and nonconforming traffic. See the "PFC Marking and Policing" section on page 32-16.

The PFC uses the trust state (set by the ingress LAN port configuration or by a **trust** policy-map class command) to select the Layer 2 and Layer 3 PFC QoS labels that the egress port writes into the packets and frames before it is transmitted:

- Trust IP precedence—Sets the internal DSCP value to a mapped value based on received IP precedence (see the "Mapping Received IP Precedence Values to Internal DSCP Values" section on page 32-65).
- Trust DSCP—Sets the internal DSCP value to the received DSCP value.
- Trust CoS—Sets the internal DSCP value to a mapped value based on received or port CoS. With trust CoS, note the following:
  - Received CoS is overwritten with port CoS in traffic received through ports not configured to trust CoS.
  - Received CoS is preserved only in traffic received through ports configured to trust CoS.
  - Port CoS is applied to all traffic received in untagged frames, regardless of the port trust state.
  - For information about mapping, see the "Mapping Received CoS Values to Internal DSCP Values" section on page 32-64.
- Untrusted—Sets the internal DSCP value to a configured DSCP value.

  Note With the default values, PFC QoS applies DSCP zero to traffic from ingress LAN ports configured as untrusted.

Policers

Note Policing with the **conform-action transmit** keywords supersedes the ingress LAN port trust state of matched traffic with trust DSCP or with the trust state defined by a **trust** policy-map class command (see the "Configuring the Policy Map Class Trust State" section on page 32-43).

You can create policers that do the following:

- Mark traffic
- Limit bandwidth utilization and mark traffic

  For more information, see the "Creating Named Aggregate Policers" section on page 32-33 and the "Configuring Policy Map Class Actions" section on page 32-42.

Policing rates are based on the Layer 3 packet size. You specify the bandwidth utilization limit as a committed information rate (CIR). With a PFC2, you can also specify a higher peak information rate (PIR). Packets that exceed a rate are "out of profile" or "nonconforming."

In each policer, you specify if out-of-profile packets are to be dropped or to have a new DSCP value applied to them (applying a new DSCP value is called "markdown"). Because out-of-profile packets do not retain their original priority, they are not counted as part of the bandwidth consumed by in-profile packets.

With a PFC2, if you configure a PIR, the PIR out-of-profile action cannot be less severe than the CIR out-of-profile action. For example, if the CIR out-of-profile action is to mark down the traffic, then the PIR out-of-profile action cannot be to transmit the traffic.

For all policers, PFC QoS uses a configurable global table that maps the internal DSCP value to a marked-down DSCP value (see the "Configuring DSCP Markdown Values" section on page 32-66). When markdown occurs, PFC QoS gets the marked-down DSCP value from the table. You cannot specify marked-down DSCP values in individual policers.

Note By default, the markdown table is configured so that no markdown occurs: the marked-down DSCP values are equal to the original DSCP values. To enable markdown, configure the table appropriately for your network.

You can create two kinds of policers: *aggregate* and *microflow*:

- PFC QoS applies the bandwidth limits specified in an aggregate policer cumulatively to all flows in matched traffic. You can create up to 1023 aggregate policers. You can create two types of aggregate policer: named and per port. Both types can be attached to more than one port:
  - You define per-interface aggregate policers in a policy map class with the **police** command. If you attach a per-interface aggregate policer to multiple ingress ports, it polices the matched traffic on each ingress port separately.
  - You create named aggregate policers with the **mls qos aggregate-policer** command. If you attach a named aggregate policer to multiple ingress ports, it polices the matched traffic from all the ingress ports to which it is attached.

Note Aggregate policing works independently on each DFC-equipped switching module and independently on the PFC2, which supports any non-DFC-equipped switching modules. Aggregate policing does not combine flow statistics from different DFC-equipped switching modules. You can display aggregate policing statistics for each DFC-equipped switching module and for the PFC2 and any non-DFC-equipped switching modules supported by the PFC2.

- PFC QoS applies the bandwidth limit specified in a microflow policer separately to each flow in matched traffic as follows:
  - You can create microflow policers with up to 63 different rate and burst parameter combinations.
  - You create microflow policers in a policy map class with the **police flow** command.
  - For IPX microflow policing, PFC QoS considers IPX traffic with the same source network, destination network, and destination node to be part of the same flow, including traffic with different source nodes or source sockets.
  - For MAC-Layer microflow policing, PFC QoS considers MAC-Layer traffic with the same protocol and the same source and destination MAC-Layer addresses to be part of the same flow, including traffic with different ethertypes.
  - By default, microflow policers only affect traffic routed by the MSFC. To enable microflow policing of other traffic, including traffic in bridge groups, enter the **mls qos bridged** command (see the "Enabling Microflow Policing of Bridged Traffic" section on page 32-48).

You can include both an aggregate policer and a microflow policer in each policy map class to police a flow based on both its own bandwidth utilization and on its bandwidth utilization combined with that of other flows.

Note If traffic is both aggregate and microflow policed, then the aggregate and microflow policers must both be in the same policy-map class and each must use the same **conform-action** keyword option: **drop**, **set-dscp-transmit**, **set-prec-transmit**, or **transmit**.

For example, you could create a microflow policer with a bandwidth limit suitable for individuals in a group and you could create a named aggregate policer with bandwidth limits suitable for the group as a whole. You could include both policers in policy map classes that match the group's traffic. The combination would affect individual flows separately and the group aggregately.

For policy map classes that include both an aggregate and a microflow policer, PFC QoS responds to an out-of-profile status from either policer and, as specified by the policer, applies a new DSCP value or drops the packet. If both policers return an out-of-profile status, then if either policer specifies that the packet is to be dropped, it is dropped; otherwise PFC QoS applies a marked-down DSCP value.

Note To avoid inconsistent results, ensure that all traffic policed by the same aggregate policer has the same trust state.

Attaching Policy Maps

You can configure each ingress LAN port for either physical port-based PFC QoS (default) or VLAN-based PFC QoS (see the "Enabling VLAN-Based PFC QoS on Layer 2 LAN Ports" section on page 32-50) and attach a policy map to the selected port (see the "Attaching a Policy Map to an Interface" section on page 32-47).

On ports configured for port-based PFC QoS, you can attach a policy map to the ingress LAN port as follows:

- On a nontrunk ingress LAN port configured for port-based PFC QoS, all traffic received through the port is classified, marked, and policed according to the policy map attached to the port.
- On a trunking ingress LAN port configured for port-based PFC QoS, traffic in *all VLANs* received through the port is classified, marked, and policed according to the policy map attached to the port.

On a nontrunk ingress LAN port configured for VLAN-based PFC QoS, traffic received through the port is classified, marked, and policed according to the policy map attached to the *port's* VLAN.

On a trunking ingress LAN port configured for VLAN-based PFC QoS, traffic received through the port is classified, marked, and policed according to the policy map attached to the *traffic's* VLAN.

You can attach policy maps to OSM ports.

Egress CoS and ToS Values

PFC QoS associates CoS and ToS values with traffic as specified by the trust state and policers in the policy map (see the "Internal DSCP Values" section on page 32-17). The associated CoS and ToS are used at the egress port (see the "LAN Egress Port Features" section on page 32-21).

LAN Egress Port Features

These sections describe how PFC QoS schedules traffic through the transmit queues based on CoS values and uses CoS-value-based transmit-queue drop thresholds to avoid congestion in traffic transmitted from egress LAN ports:

- Transmit Queues, page 32-21
- Scheduling and Congestion Avoidance, page 32-22
- Marking, page 32-24

Note Egress LAN port scheduling and congestion avoidance uses Layer 2 CoS values. Egress LAN port marking writes Layer 2 CoS values into trunk traffic and the Layer 3 ToS byte into all IP traffic.

Transmit Queues

Enter the **show queueing interface** {**ethernet** | **fastethernet** | **gigabitethernet** | **tengigabitethernet**} *slot/port* | **include type** command to see the queue structure of an egress LAN port.

The command displays one of the following:

- **2q2t** indicates two standard queues, each with two configurable tail-drop thresholds
- **1p2q2t** indicates one strict-priority queue and two standard queues, each with two configurable WRED-drop thresholds.

- **1p3q1t** indicates one strict-priority queue and three standard queues, each with one configurable WRED-drop threshold (on **1p3q1t** ports, each standard queue also has one nonconfigurable tail-drop threshold).
- **1p2q1t** indicates one strict-priority queue and two standard queues, each with one configurable WRED-drop threshold (on **1p2q1t** ports, each standard queue also has one nonconfigurable tail-drop threshold).

All port types have a low-priority and a high-priority standard transmit queue. **1p3q1t** ports have a medium-priority standard transmit queue. **1p2q2t, 1p3q1t** and **1p2q1t** ports have a strict-priority transmit queue in addition to the standard queues.

On **2q2t** ports, the default PFC QoS configuration allocates a minimum of 80 percent of the total transmit queue size to the low-priority standard queue and a minimum of 20 percent to the high-priority standard queue.

On **1p2q2t, 1p3q1t,** and **1p2q1t** ports, the switch services traffic in the strict-priority queue before servicing the standard queues. When the switch is servicing a standard queue, after transmitting a packet, it checks for traffic in the strict-priority queue. If the switch detects traffic in the strict-priority queue, it suspends its service of the standard queue and completes service of all traffic in the strict-priority queue before returning to the standard queue.

On **1p2q2t** ports, the default PFC QoS configuration allocates a minimum of 70 percent of the total transmit queue size to the low-priority standard queue, a minimum of 15 percent to the high-priority standard queue, and a minimum of 15 percent to the strict-priority queue.

On **1p3q1t** ports, the transmit queue size is not configurable and is allocated equally among all queues.

On **1p2q1t** ports, the default PFC QoS configuration allocates a minimum of 50 percent of the total transmit queue size to the low-priority standard queue, a minimum of 30 percent to the high-priority standard queue, and a minimum of 20 percent to the strict-priority queue.

Note Transmit-queue size is limited to the configured value (see the "Setting the Receive-Queue Size Ratio on a 1p1q0t or 1p1q8t Ingress LAN Ports" section on page 32-62), but any queue can use all available bandwidth (bandwidth is only available when there is no traffic in the other queues).

Scheduling and Congestion Avoidance

These sections describe scheduling and congestion avoidance:

- 2q2t Ports, page 32-23
- 1p2q2t Ports, page 32-23
- 1p3q1t Ports, page 32-23
- 1p2q1t Ports, page 32-24

Note The explanations in these sections use default values. You can configure many of the parameters (for more information, see the "Configuring PFC QoS" section on page 32-31). All ports of the same type use the same drop-threshold configuration.

2q2t Ports

For **2q2t** ports, each transmit queue has two tail-drop thresholds that function as follows:

- Frames with CoS 0, 1, 2, or 3 go to the low-priority transmit queue (queue 1):
  - Using transmit queue 1, tail-drop threshold 1, the switch drops frames with CoS 0 or 1 when the low-priority transmit-queue buffer is 80 percent full.
  - Using transmit queue 1, tail-drop threshold 2, the switch drops frames with CoS 2 or 3 when the low-priority transmit-queue buffer is 100 percent full.
- Frames with CoS 4, 5, 6, or 7 go to the high-priority transmit queue (queue 2):
  - Using transmit queue 2, tail-drop threshold 1, the switch drops frames with CoS 4 or 5 when the high-priority transmit-queue buffer is 80 percent full.
  - Using transmit queue 2, tail-drop threshold 2, the switch drops frames with CoS 6 or 7 when the high-priority transmit-queue buffer is 100 percent full.

1p2q2t Ports

1p2q2t ports have a strict-priority queue and two standard transmit queues. The two standard transmit queues each have two WRED-drop thresholds.

- Frames with CoS 5 go to the strict-priority transmit queue (queue 3), where the switch drops frames only when the buffer is 100 percent full.
- Frames with CoS 0, 1, 2, or 3 go to the low-priority standard transmit queue (queue 1):
  - Using standard transmit queue 1, WRED-drop threshold 1, the switch drops frames with CoS 0 or 1 when the low-priority transmit-queue buffer is 80 percent full.
  - Using standard transmit queue 1, WRED-drop threshold 2, the switch drops frames with CoS 2 or 3 when the low-priority transmit-queue buffer is 100 percent full.
- Frames with CoS 4, 6, or 7 go to the high-priority standard transmit queue (queue 2):
  - Using standard transmit queue 2, WRED-drop threshold 1, the switch drops frames with CoS 4 when the high-priority transmit-queue buffer is 80 percent full.
  - Using standard transmit queue 2, WRED-drop threshold 2, the switch drops frames with CoS 6 or 7 when the high-priority transmit-queue buffer is 100 percent full.

1p3q1t Ports

1p3q1t ports have a strict-priority queue and three standard transmit queues. The standard transmit queues each have one WRED-drop threshold and one nonconfigurable tail-drop threshold.

- Frames with CoS 5 go to the strict-priority transmit queue (queue 4), where the switch drops frames only when the buffer is 100 percent full.
- Frames with CoS 0 and 1 go to the low-priority standard transmit queue (queue 1).
- Frames with CoS 2, 3, or 4 go to the medium-priority standard transmit queue (queue 2).
- Frames with CoS 6 or 7 go to the high-priority standard transmit queue (queue 3).

Note You can configure each standard transmit queue to use both a non-configurable 100 percent tail-drop threshold and a configurable WRED-drop threshold (see the "Configuring Standard Queue WRED-Drop Thresholds" section on page 32-55).

1p2q1t Ports

1p2q1t ports have a strict-priority queue and two standard transmit queues. The standard transmit queues each have one WRED-drop threshold and one nonconfigurable tail-drop threshold.

- Frames with CoS 5 go to the strict-priority transmit queue (queue 3), where the switch drops frames only when the buffer is 100 percent full.
- The standard transmit queues have WRED-drop thresholds:
  - Frames with CoS 0, 1, 2, or 3 go to the low-priority transmit queue (queue 1), where the switch starts to drop frames when the low-priority transmit-queue buffer is 70 percent full and drops all frames with CoS 0, 1, 2, or 3 when the buffer is 100 percent full.
  - Frames with CoS 4, 6, or 7 go to the high-priority transmit queue (queue 2), where the switch starts to drop frames when the high-priority transmit-queue buffer is 70 percent full and drops all frames with CoS 4, 6, or 7 when the buffer is 100 percent full.

Note You can configure each standard transmit queue to use both the tail-drop and the WRED-drop threshold. See the "Configuring Standard Queue WRED-Drop Thresholds" section on page 32-55.

Marking

When traffic is transmitted from the switch, PFC QoS writes the ToS byte into IP packets. On LAN ports, PFC QoS also writes the CoS value that was used for scheduling and congestion avoidance into ISL and 802.1Q frames (see the "Egress CoS and ToS Values" section on page 32-21).

PFC QoS Statistics Data Export

Note Release 12.1(11b)E or later supports PFC QoS statistics data export.

The PFC QoS statistics data export feature generates per-LAN-port and per-aggregate policer utilization information and forwards this information in UDP packets to traffic monitoring, planning, or accounting applications. You can enable PFC QoS statistics data export on a per-LAN-port or on a per-aggregate policer basis. The statistics data generated per port consists of counts of the input and output packets and bytes. The aggregate policer statistics consist of counts of allowed packets and counts of packets exceeding the policed rate.

The PFC QoS statistics data collection occurs periodically at a fixed interval, but you can configure the interval at which the data is exported. PFC QoS statistics collection is enabled by default, and the data export feature is disabled by default for all ports and all aggregate policers configured on the Catalyst 6500 series switch.

Note The PFC QoS statistics data export feature is completely separate from NetFlow Data Export and does not interact with it.

PFC QoS Default Configuration

Table 32-2 shows the PFC QoS default configuration.

Table 32-2 PFC QoS Default Configuration

Feature	Default Value
PFC QoS global enable state	Disabled **Note** With PFC QoS enabled and all other PFC QoS parameters at default values, PFC QoS sets Layer 3 DSCP to zero and Layer 2 CoS to zero in all traffic transmitted from the switch.
PFC QoS queueing-only mode	Disabled
PFC QoS port enable state	Enabled when PFC QoS is globally enabled
Port CoS value	0
Microflow policing	Enabled
IntraVLAN microflow policing	Disabled
Port-based or VLAN-based PFC QoS	Port-based
CoS to DSCP map (DSCP set from CoS values)	CoS 0 = DSCP 0 CoS 1 = DSCP 8 CoS 2 = DSCP 16 CoS 3 = DSCP 24 CoS 4 = DSCP 32 CoS 5 = DSCP 40 CoS 6 = DSCP 48 CoS 7 = DSCP 56
IP precedence to DSCP map (DSCP set from IP precedence values)	IP precedence 0 = DSCP 0 IP precedence 1 = DSCP 8 IP precedence 2 = DSCP 16 IP precedence 3 = DSCP 24 IP precedence 4 = DSCP 32 IP precedence 5 = DSCP 40 IP precedence 6 = DSCP 48 IP precedence 7 = DSCP 56
DSCP to CoS map (CoS set from DSCP values)	DSCP 0–7 = CoS 0 DSCP 8–15 = CoS 1 DSCP 16–23 = CoS 2 DSCP 24–31 = CoS 3 DSCP 32–39 = CoS 4 DSCP 40–47 = CoS 5 DSCP 48–55 = CoS 6 DSCP 56–63 = CoS 7
Marked-down DSCP from DSCP map	Marked-down DSCP value equals original DSCP value (no markdown)
Policers	None
Policy maps	None

Table 32-2 PFC QoS Default Configuration (continued)

Feature	Default Value
With PFC QoS enabled	
Ingress LAN port trust state	Untrusted
2q2t transmit-queue size ratio	Low priority: 80%; high priority: 20%
1p1q0t receive-queue size ratio	Standard: 80%; strict priority: 20%
1p2q2t transmit-queue size ratio	Low priority: 70%; high priority: 15%; strict priority: 15%
1p2q1t transmit-queue size ratio	Low priority: 70%; high priority: 15%; strict priority: 15%
1p2q1t standard transmit-queue low:high priority bandwidth allocation ratio	100:255
2q2t, **1p2q2t**, and **1p2q1t** standard transmit-queue low:high priority bandwidth allocation ratio	5:255
1p3q1t standard transmit-queue low:medium:high-priority bandwidth allocation ratio	100:150:255
1q4t/2q2t receive and transmit queue CoS value/drop-threshold mapping	• Receive queue 1/drop threshold 1(50%) and transmit queue 1/drop threshold 1 (80%): CoS 0 and 1 • Receive queue 1/drop threshold 2 (60%) and transmit queue 1/drop threshold 2 (100%): CoS 2 and 3 • Receive queue 1/drop threshold 3 (80%) and transmit queue 2/drop threshold 1 (80%): CoS 4 and 5 • Receive queue 1/drop threshold 4 (100%) and transmit queue 2/drop threshold 2 (100%): CoS 6 and 7
1q2t port receive-queue CoS value/drop-threshold mapping and threshold percentages	• Receive queue 1/drop threshold 1: – CoS 0, 1, 2, 3, and 4 – Drop threshold: 80% • Receive queue 1/drop threshold 2: – CoS 5, 6, and 7 – Drop threshold: 100% (not configurable) **Note** Transmit queues same as **1p1q4t/1p2q2t**

Table 32-2 PFC QoS Default Configuration (continued)

Feature	Default Value
1p1q4t/1p2q2t port receive and transmit queue CoS value/drop-threshold mapping and threshold percentages:	• Strict-priority receive queue and strict-priority transmit queue: CoS 5 • Receive queue 1/drop threshold 1 and transmit queue 1/drop threshold 1: – CoS 0 and 1 – Transmit queue low and high WRED-drop thresholds: 40% and 70% • Receive queue 1/drop threshold 2 and transmit queue 1/drop threshold 2: – CoS 2 and 3 – Transmit queue low and high WRED-drop thresholds: 70% and 100% • Receive queue 1/drop threshold 3 and transmit queue 2/drop threshold 1: – CoS 4 and 6 – Transmit queue low and high WRED-drop thresholds: 40% and 70% • Receive queue 1/drop threshold 4 and transmit queue 2/drop threshold 2: – CoS 7 – Transmit queue low and high WRED-drop thresholds: 70% and 100%
1p1q0t receive queue CoS value mapping	• Receive queue 1 (standard) nonconfigurable 100% tail-drop threshold: CoS 0, 1, 2, 3, 4, 6, and 7 • Receive queue 2 (strict priority): CoS 5
1p3q1t transmit queue CoS value/drop-threshold mapping	• Transmit queue 1 (standard low priority) tail-drop threshold: – CoS 0 and 1 – Low and high WRED-drop threshold: 70% and 100% • Transmit queue 2 (standard medium priority) tail-drop threshold: – CoS 2, 3, and 4 – Low and high WRED-drop threshold: 70% and 100% • Transmit queue 3 (standard high priority) tail-drop threshold: – CoS 6 and 7 – Low and high WRED-drop threshold: 70% and 100% • Transmit queue 4 (strict priority): CoS 5

Table 32-2 PFC QoS Default Configuration (continued)

Feature	Default Value
1p1q8t receive queue port CoS value/drop-threshold mapping	• Receive queue 1 (standard) WRED-drop threshold: CoS 0, 1, 2, 3, 4, 6, and 7: – Drop threshold 1: CoS 0 Low WRED threshold: 40% High WRED-drop threshold: 70% – Drop threshold 2: CoS 1 Low WRED threshold: 40% High WRED-drop threshold: 70% – Drop threshold 3: CoS 2 Low WRED threshold: 50% High WRED-drop threshold: 80% – Drop threshold 4: CoS 3 Low WRED threshold: 50% High WRED-drop threshold: 80% – Drop threshold 5: CoS 4 Low WRED threshold: 60% High WRED-drop threshold: 90% – Drop threshold 6: CoS 6 Low WRED threshold: 60% High WRED-drop threshold: 90% – Drop threshold 6: CoS 7 Low WRED threshold: 70% High WRED-drop threshold: 100% • Receive queue 2 (strict priority): CoS 5
1p2q1t transmit queue port CoS value/drop-threshold mapping	• Transmit queue 1 (standard low priority) WRED-drop threshold: – CoS 0, 1, 2, and 3 – Low WRED threshold: 70% – High WRED-drop threshold: 100% • Transmit queue 2 (standard high priority) WRED-drop threshold: – CoS 4, 6, or 7 – Low WRED threshold: 70% – High WRED-drop threshold: 100% • Transmit queue 3 (strict-priority): CoS 5
PFC QoS Data Export	
Global PFC QoS data export	Disabled
Per port PFC QoS data export	Disabled
Per named aggregate policer PFC QoS data export	Disabled
Per class map policer PFC QoS data export	Disabled
PFC QoS data export time interval	300 seconds

Table 32-2 PFC QoS Default Configuration (continued)

Feature	Default Value
Export destination	Not configured
PFC QoS data export field delimiter	Pipe character (|)
With PFC QoS disabled	
Ingress LAN port trust state	**trust-dscp**
Receive-queue drop-threshold percentages	All thresholds set to 100%
Transmit-queue drop-threshold percentages	All thresholds set to 100%
Transmit-queue bandwidth allocation ratio	255:1
Transmit-queue size ratio	Low priority: 100% (other queues not used)
CoS value/drop threshold mapping	All CoS values mapped to the low-priority queue

PFC QoS Configuration Guidelines and Restrictions

Follow these guidelines and restrictions when configuring PFC QoS:

- With an MSFC2, Release 12.1(13)E and later releases support the **match protocol** class map command, which configures NBAR and sends all traffic on the port, both ingress and egress, to be processed in software on the MSFC2. To configure NBAR, refer to this publication:

  http://www.cisco.com/univercd/cc/td/doc/product/software/ios122/122newft/122t/122t8/dtnbarad.htm

  Earlier releases provide PFC QoS and Layer 3 switching in hardware, which prevents support of the **match protocol** class map command except for traffic being processed in software on the MSFC.
- PFC QoS does not support the **match cos, match any, match classmap, match destination-address, match input-interface, match mpls, match qos-group**, or **match source-address** class map commands.
- PFC QoS supports class maps that contain a ***single*** **match** command.
- PFC QoS filters only by access lists, dscp values, or IP precedence values.
- PFC QoS does not support the **class** *class_name* **destination-address, class** *class_name* **input-interface, class** *class_name* **protocol, class** *class_name* **qos-group**, or **class** *class_name* **source-address** policy map commands.
- PFC QoS does not support the **bandwidth, priority, queue-limit,** or **random-detect** policy map class commands.
- With Release 12.1(12c)E1 and later releases, PFC QoS supports the **set ip dscp** and **set ip precedence** policy map class commands (see the "Configuring Policy Map Class Actions" section on page 32-42). With Release 12.1(12c)E1 and later releases, PFC QoS does not support the **set mpls experimental** or **set qos-group** policy map class commands. With earlier releases, PFC QoS does not support any **set** policy map class commands.
- With Release 12.1(11b)E1 and later releases, OSM QoS supports the **set mpls experimental** policy map class command. Refer to the following publication for information about OSM QoS:

  http://www.cisco.com/univercd/cc/td/doc/product/core/cis7600/cfgnotes/osm_inst/index.htm
- PFC QoS does not support the **output** service-policy keyword.
- PFC QoS has the following hardware granularity for CIR and PIR rate values:

CIR and PIR Rate Value Range	Granularity
32768 to 2097152 (2 Mbps)	32768 (32 Kb)
2097153 to 4194304 (4 Mbps)	65536 (64 Kb)
4194305 to 8388608 (8 Mbps)	131072 (128 Kb)
8388609 to 16777216 (16 Mbps)	262144 (256 Kb)
16777217 to 33554432 (32 Mbps)	524288 (512 Kb)
33554433 to 67108864 (64 Mbps)	1048576 (1 Mb)
67108865 to 134217728 (128 Mbps)	2097152 (2 Mb)
134217729 to 268435456 (256 Mbps)	4194304 (4 Mb)
268435457 to 536870912 (512 Mbps)	8388608 (8 Mb)
536870913 to 1073741824 (1 Gps)	16777216 (16 Mb)
1073741825 to 2147483648 (2 Gps)	33554432 (32 Mb)
2147483649 to 4294967296 (4 Gps)	67108864 (64 Mb)

Within each range, PFC QoS programs the PFC hardware with rate values that are multiples of the granularity values.

- PFC QoS has the following hardware granularity for CIR and PIR token bucket (burst) sizes:

CIR and PIR Token Bucket Size Range	Granularity
1 to 32768 (32 KB)	1024 (1 KB)
32769 to 65536 (64 KB)	2048 (2 KB)
65537 to 131072 (128 KB)	4096 (4 KB)
131073 to 262144 (256 KB)	8196 (8 KB)
262145 to 524288 (512 KB)	16392 (16 KB)
524289 to 1048576 (1 MB)	32768 (32 KB)
1048577 to 2097152 (2 MB)	65536 (64 KB)
2097153 to 4194304 (4 MB)	131072 (128 KB)
4194305 to 8388608 (8 MB)	262144 (256 KB)
8388609 to 16777216 (16 MB)	524288 (512 KB)
16777217 to 33554432 (32 MB)	1048576 (1 MB)

Within each range, PFC QoS programs the PFC hardware with token bucket sizes that are multiples of the granularity values.

- For these commands, PFC QoS applies identical configuration to all LAN ports controlled by the same application-specific integrated circuit (ASIC):
  - rcv-queue queue-limit
  - wrr-queue queue-limit
  - wrr-queue bandwidth (except Gigabit Ethernet LAN ports)
  - priority-queue cos-map

- rcv-queue cos-map
- wrr-queue cos-map
- wrr-queue threshold
- rcv-queue threshold
- wrr-queue random-detect
- wrr-queue random-detect min-threshold
- wrr-queue random-detect max-threshold

Configuring PFC QoS

These sections describe how to configure PFC QoS on the Catalyst 6500 series switches:

- Enabling PFC QoS Globally, page 32-31
- Enabling Queueing-Only Mode, page 32-32
- Creating Named Aggregate Policers, page 32-33
- Configuring a PFC QoS Policy, page 32-35
- Enabling or Disabling Microflow Policing, page 32-48
- Enabling Microflow Policing of Bridged Traffic, page 32-48
- Enabling or Disabling PFC Features on an Interface, page 32-49
- Enabling VLAN-Based PFC QoS on Layer 2 LAN Ports, page 32-50
- Configuring the Trust State of Ethernet LAN and OSM Ingress Ports, page 32-51
- Configuring the Ingress LAN Port CoS Value, page 32-52
- Configuring LAN-Port Drop Threshold Percentages, page 32-52
- Enabling and Disabling WRED-Drop Thresholds, page 32-57
- Mapping CoS Values to LAN-Port Drop Thresholds, page 32-57
- Allocating Bandwidth Between LAN-Port Transmit Queues, page 32-62
- Setting the Receive-Queue Size Ratio on a 1p1q0t or 1p1q8t Ingress LAN Ports, page 32-62
- Setting the LAN-Port Transmit-Queue Size Ratio, page 32-63
- Configuring DSCP Value Maps, page 32-64
- Configuring PFC QoS Statistics Data Export, page 32-68

Note
- PFC QoS processes both unicast and multicast traffic.
- With Release 12.1(11b)E and later releases, when you are in configuration mode you can enter EXEC mode-level commands by entering the **do** keyword before the EXEC mode-level command.

Enabling PFC QoS Globally

To enable PFC QoS globally, perform this task:

	Command	Purpose
Step 1	`Router(config)# mls qos`	Enables PFC QoS globally on the switch.
	`Router(config)# no mls qos`	Disables PFC QoS globally on the switch.
Step 2	`Router(config)# end`	Exits configuration mode.
Step 3	`Router# show mls qos`	Verifies the configuration.

This example shows how to enable PFC QoS globally:

```
Router# configure terminal
Router(config)# mls qos
Router(config)# end
Router#
```

This example shows how to verify the configuration:

```
Router# show mls qos
  QoS is enabled globally
  Microflow QoS is enabled globally

QoS global counters:
    Total packets: 544393
    IP shortcut packets: 1410
    Packets dropped by policing: 0
    IP packets with TOS changed by policing: 467
    IP packets with COS changed by policing: 59998
    Non-IP packets with COS changed by policing: 0
```

Enabling Queueing-Only Mode

To enable queueing-only mode on the switch, perform this task:

	Command	Purpose
Step 1	`Router(config)# mls qos queueing-only`	Enables queueing-only mode on the switch.
	`Router(config)# no mls qos queueing-only`	Disables PFC QoS globally on the switch. **Note** You cannot disable queueing-only mode separately.
Step 2	`Router(config)# end`	Exits configuration mode.
Step 3	`Router# show mls qos`	Verifies the configuration.

When you enable queueing-only mode, the switch does the following:

- Disables marking and policing globally
- Configures all ports to trust Layer 2 CoS

Note The switch applies the port CoS value to untagged ingress traffic and to traffic that is received through ports that cannot be configured to trust CoS.

This example shows how to enable queueing-only mode:

```
Router# configure terminal
Router(config)# mls qos queueing-only
Router(config)# end
Router#
```

Creating Named Aggregate Policers

To create a named aggregate policer (see the "Policers" section on page 32-19), perform this task:

Command	Purpose
Router(config)# **mls qos aggregate-policer** *policer_name bits_per_second normal_burst_bytes* [*maximum_burst_bytes*] [**pir**[1] *peak_rate_bps*] [[[**conform-action** {**drop** | **set-dscp-transmit**[2] *dscp_value* | **set-prec-transmit**[2] *ip_precedence_value* | **transmit**}] **exceed-action** {**drop** | **policed-dscp** | **transmit**}] **violate-action**[1] {**drop** | **policed-dscp** | **transmit**}]	Creates a named aggregate policer.
Router(config)# **no mls qos aggregate-policer** *policer_name*	Deletes a named aggregate policer.

[1] Supported only with PFC2.

[2] With PFC2, the **set-dscp-transmit** and **set-prec-transmit** keywords are only supported for IP traffic.

Note With PFC2, aggregate policers can be applied to ingress interfaces on multiple modules, but aggregate policing works independently on each DFC-equipped switching module and independently on the PFC2, which supports any non-DFC-equipped switching modules. Aggregate policing does not combine flow statistics from different DFC-equipped switching modules. You can display aggregate policing statistics for each DFC-equipped switching module and for the PFC2 and any non-DFC-equipped switching modules supported by the PFC2.

When creating a named aggregate policer, note the following:

- Policing uses the Layer 3 packet size.
- See the "PFC QoS Configuration Guidelines and Restrictions" section on page 32-29 for information about rate and burst size granularity.
- The valid range of values for the CIR *bits_per_second* parameter is as follows:
  - Minimum—32 kilobits per second, entered as 32000
  - Maximum—4 gigabits per second, entered as 4000000000
- The *normal_burst_bytes* parameter sets the CIR token bucket size.
- The *maximum_burst_bytes* parameter sets the PIR token bucket size.
- When configuring the size of a token bucket, note the following:
  - The minimum token bucket size is 1 kilobyte, entered as 1000 (the *maximum_burst_bytes* parameter must be set larger than the *normal_burst_bytes* parameter)
  - The maximum token bucket size is approximately 32 megabytes, entered as 31250000
  - To sustain a specific rate, set the token bucket size to be at least the rate value divided by 4000, because tokens are removed from the bucket every 1/4000th of a second (0.25 ms).

  - Because the token bucket must be large enough to hold at least one frame, set the parameter larger than the maximum Layer 3 packet size of the traffic being policed.
  - For TCP traffic, configure the token bucket size as a multiple of the TCP window size, with a minimum value at least twice as large as the maximum Layer 3 packet size of the traffic being policed.

  The *maximum_burst_bytes* parameter is supported with PFC2. The *maximum_burst_bytes* parameter is not supported with PFC, but can be entered with a value equal to the *normal_burst_bytes* parameter.

- The valid range of values for the **pir** *bits_per_second* parameter is as follows:
  - Minimum—32 kilobits per second, entered as 32000 (the value cannot be smaller than the CIR *bits_per_second* parameters)
  - Maximum—4 gigabits per second, entered as 4000000000

  The **pir** *bits_per_second* parameter is supported with the PFC2. The **pir** *bits_per_second* parameter is not supported with the PFC1 but can be entered with the PFC1 if the value is equal to the CIR *bits_per_second* parameter.

- (Optional) You can specify a conform action for matched in-profile traffic as follows:
  - The default conform action is **transmit**, which sets the policy map class trust state to *trust DSCP* unless the policy map class contains a **trust** command (see the "Policy Maps" section on page 32-18 and the "Configuring Policy Map Class Actions" section on page 32-42).
  - To set PFC QoS labels in untrusted traffic, enter the **set-dscp-transmit** keyword to mark matched untrusted traffic with a new DSCP value or enter the **set-prec-transmit** keyword to mark matched untrusted traffic with a new IP precedence value (with the PFC2, the **set-dscp-transmit** and **set-prec-transmit** keywords are only supported for IP traffic). PFC QoS sets egress ToS and CoS from the configured value.
  - Enter the **drop** keyword to drop all matched traffic.

  Note When you configure **drop** as the conform action, PFC QoS configures **drop** as the exceed action and the violate action.

- (Optional) For traffic that exceeds the CIR, you can specify an exceed action as follows:
  - The default exceed action is **drop**, except with a *maximum_burst_bytes* parameter (**drop** is not supported with a *maximum_burst_bytes* parameter).

  Note When the exceed action is **drop**, PFC QoS ignores any configured violate action.

  - Enter the **policed-dscp-transmit** keyword to cause all matched out-of-profile traffic to be marked down as specified in the markdown map (see the "Configuring DSCP Markdown Values" section on page 32-66).

  Note When you create a policer that does not use the **pir** keyword and the *maximum_burst_bytes* parameter is equal to the *normal_burst_bytes* parameter (which is the case if you do not enter the *maximum_burst_bytes* parameter), the **exceed-action policed-dscp-transmit** keywords cause PFC QoS to mark traffic down as defined by the **policed-dscp max-burst** markdown map.

- (Optional) For traffic that exceeds the PIR, you can specify a violate action as follows:
  - To mark traffic without policing, enter the **transmit** keyword to transmit all matched out-of-profile traffic.
  - The default violate action is equal to the exceed action.
  - Enter the **policed-dscp-transmit** keyword to cause all matched out-of-profile traffic to be marked down as specified in the markdown map (see the "Configuring DSCP Markdown Values" section on page 32-66).
  - For marking without policing, enter the **transmit** keyword to transmit all matched out-of-profile traffic.

  The **violate-action** keyword is not supported with the PFC1, but the keyword can be entered with a PFC1 if the parameters match the **exceed-action** parameters.

This example shows how to create a named aggregate policer with a 1-Mbps rate limit and a 10-MB burst size that transmits conforming traffic and marks down out-of-profile traffic:

```
Router(config)# mls qos aggregate-policer aggr-1 1000000 10000000 conform-action transmit
exceed-action policed-dscp-transmit
Router(config)# end
Router#
```

This example shows how to verify the configuration:

```
Router# show mls qos aggregate-policer aggr-1
ag1 1000000 1000000 conform-action transmit exceed-action policed-dscp-transmit AgId=0
[pol4]
Router#
```

The output displays the following:

- The **AgId** parameter displays the hardware policer ID.
- The policy maps that use the policer are listed in the square brackets ([]).

Configuring a PFC QoS Policy

These sections describe PFC QoS policy configuration:

- PFC QoS Policy Configuration Overview, page 32-36
- Configuring MAC-Layer Named Access Lists (Optional), page 32-37
- Configuring a Class Map (Optional), page 32-38
- Verifying Class Map Configuration, page 32-39
- Configuring a Policy Map, page 32-40
- Verifying Policy Map Configuration, page 32-46
- Attaching a Policy Map to an Interface, page 32-47

Note PFC QoS policies process both unicast and multicast traffic.

PFC QoS Policy Configuration Overview

Note To mark traffic without limiting bandwidth utilization, create a policer that uses the **transmit** keywords for both conforming and nonconforming traffic.

These commands configure traffic classes and the policies to be applied to those traffic classes and attach the policies to ports:

- **access-list** (Optional for IP traffic. You can filter IP traffic with **class-map** commands.):
  - PFC QoS supports these access list types:

Protocol	Numbered Access Lists?	Extended Access Lists?	Named Access Lists?
IP	Yes: 1 to 99 1300 to 1999	Yes: 100 to 199 2000 to 2699	Yes
IPX[1]	Yes: 800 to 899	Yes: 900 to 999	Yes
MAC Layer[1]	No	No	Yes[2]

[1] Supported with Release 12.1(1)E and later.

[2] Supported with Release 12.1(1)E and later; see the "Configuring MAC-Layer Named Access Lists (Optional)" section on page 32-37.

  - In Release 12.1(19)E and later releases, PFC QoS supports time-based Cisco IOS ACLs.
  - In Release 12.1(1)E and later releases, PFC QoS supports IPX access lists that contain a *source-network* parameter and the optional *destination-network* and *destination-node* parameters. PFC QoS does not support IPX access control lists that contain other parameters (for example, *source-node*, *protocol*, *source-socket*, *destination-socket*, or *service-type*).
  - Except for MAC-Layer named access lists (see the "Configuring MAC-Layer Named Access Lists (Optional)" section on page 32-37), refer to the *Cisco IOS Security Configuration Guide*, Release 12.1, "Traffic Filtering and Firewalls," "Access Control Lists: Overview and Guidelines," at this URL:

    http://www.cisco.com/univercd/cc/td/doc/product/software/ios121/121cgcr/secur_c/scprt3/index.htm
  - See Chapter 23, "Configuring Network Security," for additional information about ACLs on the Catalyst 6500 series switches.
- **class-map** (optional)—Enter the **class-map** command to define one or more traffic classes by specifying the criteria by which traffic is classified (see the "Configuring a Class Map (Optional)" section on page 32-38).

  Note You can also create class-maps during policy map creation with the **policy-map class** command (see the "Creating a Policy Map Class and Configuring Filtering" section on page 32-41).
- **policy-map**—Enter the **policy-map** command to define the following:
  - New class maps
  - Policy map class trust mode

- Aggregate policing and marking
- Microflow policing and marking

- **service-policy**—Enter the **service-policy** command to attach a policy map to an interface.

Configuring MAC-Layer Named Access Lists (Optional)

In Release 12.1(1)E and later releases, you can configure named access lists that filter DECnet, AppleTalk, VINES, or XNS traffic based on Layer 2 addresses.

To configure a MAC-Layer named access list, perform this task:

	Command	Purpose
Step 1	`Router(config)# mac access-list extended list_name`	Configures a MAC-Layer named access list.
	`Router(config)# no mac access-list extended list_name`	Deletes a MAC-Layer named access list.
Step 2	`Router(config-ext-macl)# {permit | deny} {src-mac-mask | any} {dest-mac-mask | any} [aarp | amber | appletalk | diagnostic | decnet-iv | dec-spanning | dsm | etype-6000 | etype-8042 | lat | lavc-sca | mop-console | mop-dump | msdos | mumps | netbios | vines-ip | vines-echo | xns]`	Configures an access control entry (ACE) in a MAC-Layer named access list.
	`Router(config-ext-macl)# no {permit | deny} {src-mac-mask | any} {dest-mac-mask | any} [aarp | amber | appletalk | diagnostic | decnet-iv | dec-spanning | dsm | etype-6000 | etype-8042 | lat | lavc-sca | mop-console | mop-dump | msdos | mumps | netbios | vines-ip | vines-echo | xns]`	Deletes an ACE from a MAC-Layer named access list.

When configuring an entry in a MAC-Layer access list, note the following:

- You can enter MAC addresses as three 4-byte values in dotted hexadecimal format. For example, 0030.9629.9f84.
- You can enter MAC address masks as three 4-byte values in dotted hexadecimal format. Use 1 bits as wildcards. For example, to match an address exactly, use 0000.0000.0000 (can be entered as 0.0.0).
- Entries without a protocol parameter match any protocol.
- Access lists entries are scanned in the order you enter them. The first matching entry is used. To improve performance, place the most commonly used entries near the beginning of the access list.
- An implicit **deny any any** entry exists at the end of an access list unless you include an explicit **permit any any** entry at the end of the list.
- All new entries to an existing list are placed at the end of the list. You cannot add entries to the middle of a list.

This list shows the ethertype values matched by the protocol keywords:

- 0x0600—xns-idp—Xerox XNS IDP
- 0x0BAD—vines-ip—Banyan VINES IP
- 0x0baf—vines-echo—Banyan VINES Echo
- 0x6000—etype-6000—DEC unassigned, experimental

- 0x6001—mop-dump—DEC Maintenance Operation Protocol (MOP) Dump/Load Assistance
- 0x6002—mop-console—DEC MOP Remote Console
- 0x6003—decnet-iv—DEC DECnet Phase IV Route
- 0x6004—lat—DEC Local Area Transport (LAT)
- 0x6005—diagnostic—DEC DECnet Diagnostics
- 0x6007—lavc-sca—DEC Local-Area VAX Cluster (LAVC), SCA
- 0x6008—amber—DEC AMBER
- 0x6009—mumps—DEC MUMPS
- 0x8038—dec-spanning—DEC LANBridge Management
- 0x8039—dsm—DEC DSM/DDP
- 0x8040—netbios—DEC PATHWORKS DECnet NETBIOS Emulation
- 0x8041—msdos—DEC Local Area System Transport
- 0x8042—etype-8042—DEC unassigned
- 0x809B—appletalk—Kinetics EtherTalk (AppleTalk over Ethernet)
- 0x80F3—aarp—Kinetics AppleTalk Address Resolution Protocol (AARP)

This example shows how to create a MAC-Layer access list named **mac_layer** that denies **dec-phase-iv** traffic with source address 0000.4700.0001 and destination address 0000.4700.0009, but permits all other traffic:

```
Router(config)# mac access-list extended mac_layer
Router(config-ext-macl)# deny 0000.4700.0001 0.0.0 0000.4700.0009 0.0.0 dec-phase-iv
Router(config-ext-macl)# permit any any
```

Configuring a Class Map (Optional)

These sections describe class map configuration:

- Creating a Class Map, page 32-38
- Configuring Filtering in a Class Map, page 32-39

Note You can also create class maps during policy map creation with the **policy-map class** command (see the "Creating a Policy Map Class and Configuring Filtering" section on page 32-41).

Creating a Class Map

To create a class map, perform this task:

Command	Purpose
`Router(config)# class-map class_name`	Creates a class map.
`Router(config)# no class-map class_name`	Deletes a class map.

Configuring Filtering in a Class Map

Note Except for MAC-Layer ACLs (see the "Configuring MAC-Layer Named Access Lists (Optional)" section on page 32-37), access lists are not documented in this publication. See the reference under **access-list** in the "Configuring a PFC QoS Policy" section on page 32-35.

To configure filtering in a class map, perform one of these tasks:

Command	Purpose
Router(config-cmap)# **match access-group name** *acl_index_or_name*	(Optional) Configures the class map to filter using an ACL.
Router(config-cmap)# **no match access-group name** *acl_index_or_name*	Clears the ACL configuration from the class map.
Router (config-cmap)# **match ip precedence** *ipp_value1* [*ipp_value2* [*ipp_valueN*]]	(Optional—for IP traffic only) Configures the class map to filter on up to eight IP precedence values.
Router (config-cmap)# **no match ip precedence** *ipp_value1* [*ipp_value2* [*ipp_valueN*]]	Clears configured IP precedence values from the class map.
Router (config-cmap)# **match ip dscp** *dscp_value1* [*dscp_value2* [*dscp_valueN*]]	(Optional—for IP traffic only) Configures the class map to filter on up to eight DSCP values.
Router (config-cmap)# **no match ip dscp** *dscp_value1* [*dscp_value2* [*dscp_valueN*]]	Clears configured DSCP values from the class map.

Note

- With an MSFC2, Release 12.1(13)E and later releases support the **match protocol** class map command, which configures NBAR and sends all traffic on the port, both ingress and egress, to be processed in software on the MSFC2. To configure NBAR, refer to this publication:

  http://www.cisco.com/univercd/cc/td/doc/product/software/ios122/122newft/122t/122t8/dtnbarad.htm

  Earlier releases provide PFC QoS and Layer 3 switching in hardware, which prevents support of the **match protocol** class map command except for traffic being processed in software on the MSFC.
- PFC QoS supports class maps that contain a single **match** command.
- PFC QoS does not support the **match cos, match any, match classmap, match destination-address, match input-interface, match mpls, match qos-group**, and **match source-address** class map commands.
- Catalyst 6500 series switches do not detect the use of unsupported commands until you attach a policy map to an interface (see the "Attaching a Policy Map to an Interface" section on page 32-47).

Verifying Class Map Configuration

To verify class map configuration, perform this task:

	Command	Purpose
Step 1	Router (config-cmap)# **end**	Exits configuration mode.
Step 2	Router# **show class-map** *class_name*	Verifies the configuration.

This example shows how to create a class map named **ipp5** and how to configure filtering to match traffic with IP precedence 5:

```
Router# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Router(config)# class-map ipp5
Router(config-cmap)# match ip precedence 5
Router(config-cmap)# end
Router#
```

This example shows how to verify the configuration:

```
Router# show class-map ipp5
 Class Map match-all ipp5 (id 1)
   Match ip precedence 5

Router#
```

Configuring a Policy Map

You can attach only one policy map to an interface. Policy maps can contain one or more policy map classes, each with different policy map commands.

Configure a separate policy map class in the policy map for each type of traffic that an interface receives. Put all commands for each type of traffic in the same policy map class. PFC QoS does not attempt to apply commands from more than one policy map class to matched traffic.

These sections describe policy map configuration:

- Creating a Policy Map, page 32-40
- Creating a Policy Map Class and Configuring Filtering, page 32-41
- Configuring Policy Map Class Actions, page 32-42

Creating a Policy Map

To create a policy map, perform this task:

Command	Purpose
`Router(config)# policy-map policy_name`	Creates a policy map.
`Router(config)# no policy-map policy_name`	Deletes the policy map.

Creating a Policy Map Class and Configuring Filtering

Note

- With an MSFC2, Release 12.1(13)E and later releases support the **class** *class_name* **protocol** policy map command, which configures NBAR and sends all traffic on the port, both ingress and egress, to be processed in software on the MSFC2. To configure NBAR, refer to this publication:

  http://www.cisco.com/univercd/cc/td/doc/product/software/ios122/122newft/122t/122t8/dtnbarad.htm

  Earlier releases provide PFC QoS and Layer 3 switching in hardware, which prevents support of the **class** *class_name* **protocol** policy map command except for traffic being processed in software on the MSFC.
- PFC QoS does not support the **class** *class_name* **destination-address**, **class** *class_name* **input-interface**, **class** *class_name* **qos-group**, and **class** *class_name* **source-address** policy map commands.
- PFC QoS does not detect the use of unsupported commands until you attach a policy map to an interface (see the "Attaching a Policy Map to an Interface" section on page 32-47).

Policy maps can contain one or more policy map classes. Enter one of these **class** commands to create a policy map class and configure filtering in it.

To create a policy map class and configure it to filter with an already defined class map, perform this task:

Command	Purpose
Router(config-pmap)# **class** *class_name*	Creates a policy map class and configures it to filter with a class map (see the "Creating a Class Map" section on page 32-38). **Note** PFC QoS supports class maps that contain a single **match** command.
Router(config-pmap)# **no class** *class_name*	Clears use of the class map.

To create a policy map class and a class map simultaneously, perform this task:

Command	Purpose
Router(config-pmap)# **class** *class_name* {**access-group** *acl_index_or_name* | **dscp** *dscp_1* [*dscp_2* [*dscp_N*]] | **precedence** *ipp_1* [*ipp_2* [*ipp_N*]]}	Creates a policy map class and creates a class map and configures the policy map class to filter with the class map. **Note** This command creates a class map that can be used in other policy maps.
Router(config-pmap)# **no class** *class_name*	Clears use of the class map (does not delete the class map).

Note

- Put all trust-state and policing commands for each type of traffic in the same policy map class.
- PFC QoS does not attempt to apply commands from more than one policy map class to traffic.

Configuring Policy Map Class Actions

When configuring policy map class actions, note the following:

- For hardware-switched traffic, PFC QoS does not support the **bandwidth, priority, queue-limit**, or **random-detect** policy map class commands. You can configure these commands because they can be used for software-switched traffic.
- With Release 12.1(12c)E1 and later releases, PFC QoS does not support the **set mpls** or **set qos-group** policy map class commands. With earlier releases, PFC QoS does not support any **set** policy map class commands.
- With Release 12.1(12c)E1 and later releases, PFC QoS supports the **set ip dscp** and **set ip precedence** policy map class commands (see the "Configuring Policy Map Class Marking" section on page 32-42).
- With Release 12.1(12c)E1 and later releases, you cannot do all three of the following in a policy map class:
  - Mark traffic with the **set ip dscp** or **set ip precedence** commands
  - Configure the trust state
  - Configure policing

  In a policy map class, you can either mark untrusted traffic with the **set ip dscp** or **set ip precedence** commands or do one or both of the following:
  - Configure the trust state
  - Configure policing

Note When configure policing, you can mark traffic with policing keywords (see the "Configuring Policy Map Class Policing" section on page 32-43).

These sections describe policy map class action configuration:

- Configuring Policy Map Class Marking, page 32-42
- Configuring the Policy Map Class Trust State, page 32-43
- Configuring Policy Map Class Policing, page 32-43

Configuring Policy Map Class Marking

With Release 12.1(12c)E1 and later releases, PFC QoS supports policy map class marking for untrusted traffic with the **set ip dscp** and **set ip precedence** policy map class commands.

To configure policy map class marking for untrusted traffic, perform this task:

Command	Purpose
Router(config-pmap-c)# **set ip** {**dscp** *dscp_value* | **precedence** *ip_precedence_value*}	Configures the policy map class to mark matched untrusted traffic with the configured DSCP or IP precedence value.
Router(config-pmap-c)# **no set ip** {**dscp** *dscp_value* | **precedence** *ip_precedence_value*}	Clears the marking configuration.

Configuring the Policy Map Class Trust State

To configure the policy map class trust state, perform this task:

Command	Purpose
`Router(config-pmap-c)# trust {cos | dscp | ip-precedence}`	Configures the policy map class trust state, which selects the value that PFC QoS uses as the source of the internal DSCP value (see the "Internal DSCP Values" section on page 32-17).
`Router(config-pmap-c)# no trust`	Reverts to the default policy-map class trust state (untrusted).

When configuring the policy map class trust state, note the following:

- Enter the **no trust** command to use the trust state configured on the ingress port (this is the default).
- With the **cos** keyword, PFC QoS sets the internal DSCP value from received or ingress port CoS (see the "Mapping Received CoS Values to Internal DSCP Values" section on page 32-64).
- With the **dscp** keyword, PFC QoS uses received DSCP.
- With the **ip-precedence** keyword, PFC QoS sets DSCP from received IP precedence (see the "Mapping Received IP Precedence Values to Internal DSCP Values" section on page 32-65).

Configuring Policy Map Class Policing

When you configure policy map class policing, note the following:

- PFC QoS does not support the **set-qos-transmit** policer keyword.
- PFC QoS does not support the **set-dscp-transmit** or **set-prec-transmit** keywords as arguments to the **exceed-action** keyword.
- PFC QoS does not detect the use of unsupported keywords until you attach a policy map to an interface (see the "Attaching a Policy Map to an Interface" section on page 32-47).

These sections describe configuration of policy map class policing:

- Using a Named Aggregate Policer, page 32-43
- Configuring a Per-Interface Policer, page 32-44

Note Policing with the **conform-action transmit** keywords sets the port trust state of matched traffic to trust DSCP or to the trust state configured by a **trust** command in the policy map class.

Using a Named Aggregate Policer

To use a named aggregate policer (see the "Creating Named Aggregate Policers" section on page 32-33), perform this task:

Command	Purpose
`Router(config-pmap-c)# police aggregate` *`aggregate_name`*	Configures the policy map class to use a previously defined named aggregate policer.
`Router(config-pmap-c)# no police aggregate` *`aggregate_name`*	Clears use of the named aggregate policer.

Configuring a Per-Interface Policer

To configure a per-interface policer (see the "Policers" section on page 32-19), perform this task:

Command	Purpose
Router(config-pmap-c)# **police** [**flow**] *bits_per_second normal_burst_bytes* [*maximum_burst_bytes*] [**pir**[1] *peak_rate_bps*] [[[**conform-action** {**drop** | **set-dscp-transmit**[2] *dscp_value* | **set-prec-transmit**[2] *ip_precedence_value* | **transmit**}] **exceed-action** {**drop** | **policed-dscp** | **transmit**}] **violate-action**[1] {**drop** | **policed-dscp** | **transmit**}]	Creates a per-interface policer and configures the policy map class to use it.
Router(config-pmap-c)# **no police** [**flow**] *bits_per_second normal_burst_bytes* [*maximum_burst_bytes*] [**pir** *peak_rate_bps*] [[[**conform-action** {**drop** | **set-dscp-transmit** *dscp_value* | **set-prec-transmit** *ip_precedence_value* | **transmit**}] **exceed-action** {**drop** | **policed-dscp** | **transmit**}] **violate-action** {**drop** | **policed-dscp** | **transmit**}]	Deletes the per-interface policer from the policy map class.

[1] Supported only with PFC2. Not supported in microflow policers (the **flow** keyword configures a microflow policer).

[2] With PFC2, the **set-dscp-transmit** and **set-prec-transmit** keywords are only supported for IP traffic.

When configuring a per-interface policer, note the following:

- Policing uses the Layer 3 packet size.
- See the "PFC QoS Configuration Guidelines and Restrictions" section on page 32-29 for information about rate and burst size granularity.
- You can enter the **flow** keyword to define a microflow policer. During microflow policing, the following occurs:
  - PFC QoS considers IPX traffic with same source network, destination network, and destination node to be part of the same flow, including traffic with different source nodes or sockets.
  - PFC QoS considers MAC-Layer traffic with the same protocol and the same source and destination MAC-Layer addresses to be part of the same flow, including traffic with different ethertypes.
  - Microflow policers do not support the *maximum_burst_bytes* parameter, the **pir** *bits_per_second* keyword and parameter, or the **violate-action** keyword.
- The valid range of values for the CIR *bits_per_second* parameter is as follows:
  - Minimum—32 kilobits per second, entered as 32000
  - Maximum—4 gigabits per second, entered as 4000000000
- The *normal_burst_bytes* parameter sets the CIR token bucket size.
- The *maximum_burst_bytes* parameter sets the PIR token bucket size (not supported with the **flow** keyword)
- When configuring the size of a token bucket, note the following:
  - The minimum token bucket size is 1 kilobyte, entered as 1000 (the *maximum_burst_bytes* parameter must be set larger than the *normal_burst_bytes* parameter)
  - The maximum token bucket size is approximately 32 megabytes, entered as 31250000
  - To sustain a specific rate, set the token bucket size to be at least the rate value divided by 4000, because tokens are removed from the bucket every 1/4000th of a second (0.25 ms).

- Because the token bucket must be large enough to hold at least one frame, set the parameter larger than the maximum Layer 3 packet size of the traffic being policed.
- For TCP traffic, configure the token bucket size as a multiple of the TCP window size, with a minimum value at least twice as large as the maximum Layer 3 packet size of the traffic being policed.

The *maximum_burst_bytes* parameter is supported with the PFC2. The *maximum_burst_bytes* parameter is not supported with the PFC1, but the keyword can be entered with a value equal to the *normal_burst_bytes* parameter.

- (Not supported with the **flow** keyword.) The valid range of values for the **pir** *bits_per_second* parameter is as follows:
  - Minimum—32 kilobits per second, entered as 32000 (the value cannot be smaller than the CIR *bits_per_second* parameters)
  - Maximum—4 gigabits per second, entered as 4000000000

  The **pir** *bits_per_second* parameter is supported with the PFC2. The **pir** *bits_per_second* parameter is not supported with the PFC1, but can be entered with the PFC1 if the value is equal to the CIR *bits_per_second* parameter.
- (Optional) You can specify a conform action for matched in-profile traffic as follows:
  - The default conform action is **transmit**, which sets the policy map class trust state to *trust DSCP* unless the policy map class contains a **trust** command (see the "Policy Maps" section on page 32-18 and the "Configuring Policy Map Class Actions" section on page 32-42).
  - To set PFC QoS labels in untrusted traffic, you can enter the **set-dscp-transmit** keyword to mark matched untrusted traffic with a new DSCP value or enter the **set-prec-transmit** keyword to mark matched untrusted traffic with a new IP precedence value (with the PFC2, the **set-dscp-transmit** and **set-prec-transmit** keywords are only supported for IP traffic). PFC QoS sets egress ToS and CoS from the configured value.
  - You can enter the **drop** keyword to drop all matched traffic.
  - Ensure that aggregate and microflow policers that are applied to the same traffic each specify the same conform-action behavior.
- (Optional) For traffic that exceeds the CIR, you can specify an exceed action as follows:
  - For marking without policing, you can enter the **transmit** keyword to transmit all matched out-of-profile traffic.
  - The default exceed action is **drop**, except with a *maximum_burst_bytes* parameter (**drop** is not supported with a *maximum_burst_bytes* parameter).

Note When the exceed action is **drop**, PFC QoS ignores any configured violate action.

  - You can enter the **policed-dscp-transmit** keyword to cause all matched out-of-profile traffic to be marked down as specified in the markdown map (see the "Configuring DSCP Markdown Values" section on page 32-66).

Note When you create a policer that does not use the **pir** keyword and the *maximum_burst_bytes* parameter is equal to the *normal_burst_bytes* parameter (which is the case if you do not enter the *maximum_burst_bytes* parameter), the **exceed-action policed-dscp-transmit** keywords cause PFC QoS to mark traffic down as defined by the **policed-dscp max-burst** markdown map.

- (Optional—Not supported with the **flow** keyword) For traffic that exceeds the PIR, you can specify a violate action as follows:
  - For marking without policing, you can enter the **transmit** keyword to transmit all matched out-of-profile traffic.
  - The default violate action is equal to the exceed action.
  - You can enter the **policed-dscp-transmit** keyword to cause all matched out-of-profile traffic to be marked down as specified in the markdown map (see the "Configuring DSCP Markdown Values" section on page 32-66).

The **violate-action** keyword is not supported with the PFC1, but the keyword can be entered with the PFC1 if the parameters match the **exceed-action** parameters.

Note Aggregate policing works independently on each DFC-equipped switching module and independently on the PFC2, which supports any non-DFC-equipped switching modules. Aggregate policing does not combine flow statistics from different DFC-equipped switching modules. You can display aggregate policing statistics for each DFC-equipped switching module and for the PFC2 and any non-DFC-equipped switching modules supported by the PFC2.

This example shows how to create a policy map named **max-pol-ipp5** that uses the class-map named **ipp5**, which is configured to trust received IP precedence values and is configured with a maximum-capacity aggregate policer and with a microflow policer:

```
Router# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Router(config)# policy-map max-pol-ipp5
Router(config-pmap)# class ipp5
Router(config-pmap-c)# trust ip-precedence
Router(config-pmap-c)# police 2000000000 2000000 conform-action set-prec-transmit 6
exceed-action policed-dscp-transmit
Router(config-pmap-c)# police flow 10000000 10000 conform-action set-prec-transmit 6
exceed-action policed-dscp-transmit
Router(config-pmap-c)# end
```

Verifying Policy Map Configuration

To verify policy map configuration, perform this task:

	Command	Purpose
Step 1	`Router(config-pmap-c)# end`	Exits policy map class configuration mode. **Note** Enter additional **class** commands to create additional classes in the policy map.
Step 2	`Router# show policy-map policy_name`	Verifies the configuration.

This example shows how to verify the configuration:

```
Router# show policy-map max-pol-ipp5
 Policy Map max-pol-ipp5
  class  ipp5

  class ipp5
    police flow 10000000 10000 conform-action set-prec-transmit 6 exceed-action
policed-dscp-transmit
    trust precedence
    police 2000000000 2000000 2000000 conform-action set-prec-transmit 6 exceed-action
policed-dscp-transmit

Router#
```

Attaching a Policy Map to an Interface

Note PFC QoS does not support the **output** service-policy keyword.

To attach a policy map to an interface, perform this task:

	Command	Purpose
Step 1	`Router(config)#` **`interface`** `{{`**`vlan`** *`vlan_ID`*`} | {`*`type`*[1] *`slot/port`*`} | {`**`port-channel`** *`number`*`}}`	Selects the interface to configure.

Step 2	`Router(config-if)#` **`service-policy input`** *`policy_map_name`*
	`Router(config-if)#` **`no service-policy input`** *`policy_map_name`*
		Attaches a policy map to the input direction of the interface.
		Removes the policy map from the interface.

Step 3	`Router(config-if)#` **`end`**	Exits configuration mode.
Step 4	`Router#` **`show policy-map interface`** `{{`**`vlan`** *`vlan_ID`*`} | {`*`type`*[1] *`slot/port`*`} | {`**`port-channel`** *`number`*`}}`	Verifies the configuration.

[1] *type* = **ethernet**, **fastethernet**, **gigabitethernet**, **tengigabitethernet**, **ge-wan**, **pos**, or **atm**

Note Aggregate policing works independently on each DFC-equipped switching module and independently on the PFC2, which supports any non-DFC-equipped switching modules. Aggregate policing does not combine flow statistics from different DFC-equipped switching modules. You can display aggregate policing statistics for each DFC-equipped switching module and for the PFC2 and any non-DFC-equipped switching modules supported by the PFC2.

This example shows how to attach the policy map named **pmap1** to Fast Ethernet port 5/36:

```
Router# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Router(config)# interface fastethernet 5/36
Router(config-if)# service-policy input pmap1
Router(config-if)# end
```

This example shows how to verify the configuration:

```
Router# show policy-map interface fastethernet 5/36
 FastEthernet5/36
  service-policy input: pmap1
    class-map: cmap1 (match-all)
      0 packets, 0 bytes
      5 minute rate 0 bps
      match: ip precedence 5
  class cmap1
    police 8000 8000 conform-action transmit exceed-action drop
    class-map: cmap2 (match-any)
      0 packets, 0 bytes
      5 minute rate 0 bps
      match: ip precedence 2
        0 packets, 0 bytes
        5 minute rate 0 bps
  class cmap2
    police 8000 10000 conform-action transmit exceed-action drop
Router#
```

Enabling or Disabling Microflow Policing

To enable or disable microflow policing (see the "Policers" section on page 32-19), perform this task:

	Command	Purpose
Step 1	`Router(config)# mls qos flow-policing`	Enables microflow policing.
	`Router(config)# no mls qos flow-policing`	Disables microflow policing.
Step 2	`Router(config)# end`	Exits configuration mode.
Step 3	`Router# show mls qos`	Verifies the configuration.

This example shows how to disable microflow policing:

```
Router# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Router(config)# no mls qos flow-policing
Router(config)# end
Router#
```

This example shows how to verify the configuration:

```
Router# show mls qos | include Microflow
  Microflow QoS is disabled globally
Router#
```

Enabling Microflow Policing of Bridged Traffic

Note To apply microflow policing to multicast traffic, you must enter the **mls qos bridged** command on the Layer 3 multicast ingress interfaces.

By default, microflow policers affect only routed traffic. To enable microflow policing of bridged traffic on specified VLANs, perform this task:

	Command	Purpose
Step 1	Router(config)# **interface** {{**vlan** *vlan_ID*} | {*type*[1] *slot/port*}}	Selects the interface to configure.
Step 2	Router(config-if)# **mls qos bridged**	Enables microflow policing of bridged traffic, including bridge groups, on the VLAN.
	Router(config-if)# **no mls qos bridged**	Disables microflow policing of bridged traffic.
Step 3	Router(config-if)# **end**	Exits configuration mode.
Step 4	Router# **show mls qos**	Verifies the configuration.

[1] *type* = **ethernet**, **fastethernet**, **gigabitethernet**, or **tengigabitethernet**

This example shows how to enable microflow policing of bridged traffic on VLANs 3 through 5:

```
Router# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Router(config)# interface range vlan 3 - 5
Router(config-if)# mls qos bridged
Router(config-if)# end
Router#
```

This example shows how to verify the configuration:

```
Router# show mls qos | begin Bridged QoS
Bridged QoS is enabled on the following interfaces:
    Vl3 Vl4 Vl5
<...output truncated...>
Router#
```

Enabling or Disabling PFC Features on an Interface

You can enable or disable the PFC QoS features implemented on the PFC for traffic from an interface (see the "PFC Marking and Policing" section on page 32-16). Disabling the PFC QoS features on an interface leaves the configuration intact. The **mls qos** interface command reenables any previously configured PFC QoS features. The **mls qos** interface command does not affect the port queueing configuration.

To enable or disable PFC features for traffic from an interface, perform this task:

	Command	Purpose
Step 1	Router(config)# **interface** {{*type*[1] *slot/port*} | {**port-channel** *number*}}	Selects the interface to configure.
Step 2	Router(config-if)# **mls qos**	Enables PFC QoS on the interface.
	Router(config-if)# **no mls qos**	Disables PFC QoS on the interface.
Step 3	Router(config-if)# **end**	Exits configuration interface.
Step 4	Router# **show mls qos**	Verifies the configuration.

[1] *type* = **ethernet**, **fastethernet**, **gigabitethernet**, **tengigabitethernet**, **ge-wan**, **pos**, or **atm**

This example shows how to disable PFC QoS on the VLAN 5 interface:

```
Router# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Router(config)# interface vlan 5
Router(config-if)# no mls qos
Router(config-if)# end
Router#
```

This example shows how to verify the configuration:

```
Router# show mls qos | begin QoS is disabled
  QoS is disabled on the following interfaces:
    Vl5
<...Output Truncated...>
Router#
```

Enabling VLAN-Based PFC QoS on Layer 2 LAN Ports

Note With DFCs installed, Supervisor Engine 2 does not support VLAN-based PFC QoS.

By default, PFC QoS uses policy maps attached to LAN ports. For ports configured as Layer 2 LAN ports with the **switchport** keyword, you can configure PFC QoS to use policy maps attached to a VLAN (see the "Attaching Policy Maps" section on page 32-21). Ports not configured with the **switchport** keyword are not associated with a VLAN.

To enable VLAN-based PFC QoS on a Layer 2 LAN port, perform this task:

	Command	Purpose
Step 1	`Router(config)# interface {{type[1] slot/port}	{port-channel number}}`	Selects the interface to configure.
Step 2	`Router(config-if)# mls qos vlan-based`	Enables VLAN-based PFC QoS on a Layer 2 LAN port.
	`Router(config-if)# no mls qos vlan-based`	Disables VLAN-based PFC QoS.
Step 3	`Router(config-if)# end`	Exits configuration mode.
Step 4	`Router# show mls qos`	Verifies the configuration.

[1] *type* = **ethernet, fastethernet, gigabitethernet,** or **tengigabitethernet**

This example shows how to enable VLAN-based PFC QoS on Fast Ethernet port 5/42:

```
Router# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Router(config)# interface fastethernet 5/42
Router(config-if)# mls qos vlan-based
Router(config-if)# end
```

This example shows how to verify the configuration:

```
Router# show mls qos | begin QoS is vlan-based
  QoS is vlan-based on the following interfaces:
    Fa5/42
<...Output Truncated...>
```

Note Configuring a Layer 2 LAN port for VLAN-based PFC QoS preserves the policy map port configuration. The **no mls qos vlan-based** port command reenables any previously configured port commands.

Configuring the Trust State of Ethernet LAN and OSM Ingress Ports

By default, all ingress ports are untrusted. You can configure the ingress port trust state on all Ethernet LAN ports except non-Gigabit Ethernet **1q4t/2q2t** ports (see the "Ingress LAN Port Features" section on page 32-12). You can configure the ingress port trust state on OSM ports (see the "Ingress OSM Port Features" section on page 32-11).

To configure the trust state of an ingress port, perform this task:

	Command	Purpose
Step 1	`Router(config)# interface {{type[1] slot/port} | {port-channel number}}`	Selects the interface to configure.
Step 2	`Router(config-if)# mls qos trust [dscp | ip-precedence | cos[2]]`	Configures the trust state of the port.
	`Router(config-if)# no mls qos trust`	Reverts to the default trust state (untrusted).
Step 3	`Router(config-if)# end`	Exits configuration mode.
Step 4	`Router# show mls qos`	Verifies the configuration.

[1] *type* = **ethernet, fastethernet, gigabitethernet, tengigabitethernet, ge-wan, pos,** or **atm.**

[2] Not supported for **pos** or **atm** interface types.

When configuring the trust state of an ingress port, note the following:

- With no other keywords, the **mls qos trust** command is equivalent to **mls qos trust dscp**.
- The **mls qos trust cos** command enables receive-queue drop thresholds. To avoid dropping traffic because of inconsistent CoS values, configure ports with the **mls qos trust cos** command only when the received traffic is ISL or 802.1Q frames carrying CoS values that you know to be consistent with network policy.
- Use the **no mls qos trust** command to set the port state to untrusted.

This example shows how to configure Gigabit Ethernet port 1/1 with the **trust cos** keywords:

```
Router# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Router(config)# interface gigabitethernet 1/1
Router(config-if)# mls qos trust cos
Router(config-if)# end
Router#
```

This example shows how to verify the configuration:

```
Router# show queueing interface gigabitethernet 1/1 | include trust
  Trust state: trust COS
Router#
```

Configuring the Ingress LAN Port CoS Value

Note Whether or not PFC QoS uses the CoS value applied with the **mls qos cos** command depends on the trust state of the port and the trust state of the traffic received through the port. The **mls qos cos** command does not configure the trust state of the port or the trust state of the traffic received through the port. To use the CoS value applied with the **mls qos cos** command, configure the ingress port as trusted or configure a trust-CoS policy map that matches the ingress traffic.

You can configure the CoS value that PFC QoS assigns to untagged frames from ingress LAN ports configured as trusted and to all frames from ingress LAN ports configured as untrusted.

To configure the CoS value for an ingress LAN port, perform this task:

	Command	Purpose
Step 1	`Router(config)# `**`interface`**` {{`*`type`*[1]` `*`slot/port`*`} | {`**`port-channel`**` `*`number`*`}}`	Selects the interface to configure.
Step 2	`Router(config-if)# `**`mls qos cos`**` `*`default_cos`*	Configures the ingress LAN port CoS value.
	`Router(config-if)# `**`[no] mls qos cos`**` `*`default_cos`*	Reverts to the default port CoS value.
Step 3	`Router(config-if)# `**`end`**	Exits configuration mode.
Step 4	`Router# `**`show queueing interface {ethernet | fastethernet | gigabitethernet}`**` `*`slot/port`*	Verifies the configuration.

[1] *type* = **ethernet, fastethernet, gigabitethernet, or tengigabitethernet**

This example shows how to configure the CoS 5 as the default on Fast Ethernet port 5/24 and verify the configuration:

```
Router# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Router(config)# interface fastethernet 5/24
Router(config-if)# mls qos cos 5
Router(config-if)# end
Router# show queueing interface fastethernet 5/24 | include Default COS
  Default COS is 5
Router#
```

Configuring LAN-Port Drop Threshold Percentages

These sections describe LAN-port drop-threshold configuration:

- Configuring Tail-Drop Threshold Percentages on 1q4t/2q2t LAN Ports, page 32-53
- Configuring 1q2t and 1p1q4t Standard Receive-Queue Tail-Drop Threshold Percentages, page 32-54
- Configuring Standard Queue WRED-Drop Thresholds, page 32-55

Note Enter the **show queueing interface** {**ethernet** | **fastethernet** | **gigabitethernet** | **tengigabitethernet**} *slot/port* | **include type** command to see the queue structure of a port.

Configuring Tail-Drop Threshold Percentages on 1q4t/2q2t LAN Ports

The receive- and transmit-queue drop thresholds have this relationship:

- Receive queue 1 (standard) threshold 1 = transmit queue 1 (standard low priority) threshold 1
- Receive queue 1 (standard) threshold 2 = transmit queue 1 (standard low priority) threshold 2
- Receive queue 1 (standard) threshold 3 = transmit queue 2 (standard high priority) threshold 1
- Receive queue 1 (standard) threshold 4 = transmit queue 2 (standard high priority) threshold 2

To configure tail-drop threshold percentages for the standard receive and transmit queues on **1q4t/2q2t** LAN ports (see the "Transmit Queues" section on page 32-21), perform this task:

	Command	Purpose
Step 1	`Router(config)# interface {ethernet	fastethernet	gigabitethernet} slot/port`	Selects the interface to configure.
Step 2	`Router(config-if)# wrr-queue threshold queue_id thr1% thr2%`	Configures the receive- and transmit-queue tail-drop thresholds.
	`Router(config-if)# no wrr-queue threshold [queue_id]`	Reverts to the default receive- and transmit-queue tail-drop thresholds.
Step 3	`Router(config-if)# end`	Exits configuration mode.
Step 4	`Router# show queueing interface {ethernet	fastethernet	gigabitethernet} slot/port`	Verifies the configuration.

When configuring the receive- and transmit-queue tail-drop thresholds, note the following:

- You must use the transmit queue and threshold numbers.
- The *queue_id* is 1 for the standard low-priority queue and 2 for the standard high-priority queue.
- The percentages range from 1 to 100. A value of 10 indicates a threshold when the buffer is 10-percent full.
- Always set threshold 2 to 100 percent.

This example shows how to configure receive queue 1/threshold 1 and transmit queue 1/threshold 1 for Gigabit Ethernet port 2/1:

```
Router# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Router(config)# interface gigabitethernet 2/1
Router(config-if)# wrr-queue threshold 1 60 100
Router(config-if)# end
Router#
```

This example shows how to verify the configuration:

```
Router# show queueing interface gigabitethernet 2/1
  Transmit queues [type = 2q2t]:

<...Output Truncated...>

queue tail-drop-thresholds
    --------------------------
    1     60[1] 100[2]
    2     40[1] 100[2]

<...Output Truncated...>
```

```
Receive queues [type = 1q4t]:

<...Output Truncated...>

queue tail-drop-thresholds
--------------------------
    1     60[1] 100[2] 40[3] 100[4]
<...Output Truncated...>
Router#
```

Note Receive-queue tail-drop thresholds are supported only on ingress Gigabit Ethernet LAN ports configured to trust CoS.

Configuring 1q2t and 1p1q4t Standard Receive-Queue Tail-Drop Threshold Percentages

Note Configure **1q4t** standard receive-queue tail-drop threshold percentages with the **wrr-queue threshold** command (see the "Configuring Tail-Drop Threshold Percentages on 1q4t/2q2t LAN Ports" section on page 32-53).

To configure tail-drop threshold percentages for the standard receive queues on a **1q2t** or **1p1q4t** ingress LAN port (see the "Receive Queues" section on page 32-13), perform this task:

	Command	Purpose
Step 1	Router(config)# **interface** {**fastethernet** | **gigabitethernet**} *slot/port*	Selects the interface to configure.
Step 2	Router(config-if)# **rcv-queue threshold** *queue_id thr1% thr2%* [*thr3% thr4%*]	Configures the receive-queue tail-drop threshold percentages.
	Router(config-if)# **no rcv-queue threshold** [*queue_id*]	Reverts to the default receive-queue tail-drop threshold percentages.
Step 3	Router(config-if)# **end**	Exits configuration mode.
Step 4	Router# **show queueing interface** {**fastethernet** | **gigabitethernet**} *slot/port*	Verifies the configuration.

When configuring the receive-queue tail-drop threshold percentages, note the following:

- The *queue_id* is always 1.
- The percentages range from 1 to 100. A value of 10 indicates a threshold when the buffer is 10-percent full.
- On a **1q2t** ingress LAN port, always set threshold 2 to 100 percent.
- On a **1p1q4t** ingress LAN port, always set threshold 4 to 100 percent.

This example shows how to configure the receive-queue drop thresholds for Gigabit Ethernet port 1/1:

```
Router# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Router(config)# interface gigabitethernet 1/1
Router(config-if)# rcv-queue threshold 1 60 75 85 100
Router(config-if)# end
Router#
```

This example shows how to verify the configuration:

```
Router# show queueing interface gigabitethernet 1/1 | begin Receive queues
Receive queues [type = 1p1q4t]:
    Queue Id    Scheduling  Num of thresholds
    -----------------------------------------
       1          Standard             4
       2          Priority             1

  Trust state: trust COS

    queue tail-drop-thresholds
    --------------------------
    1     60[1] 75[2] 85[3] 100[4]
<...Output Truncated...>
Router#
```

Configuring Standard Queue WRED-Drop Thresholds

1p2q2t, **1p3q1t**, and **1p2q1t** ports have WRED-drop thresholds in their standard transmit queues.

1p1q8t ports have WRED-drop thresholds in their standard receive queue.

Note **1p3q1t** (transmit), **1p2q1t** (transmit), and **1p1q8t** (receive) ports also have nonconfigurable tail-drop thresholds (see the "1p3q1t Ports" section on page 32-23).

To configure the WRED-drop thresholds (see the "Transmit Queues" section on page 32-21), perform this task:

	Command	Purpose
Step 1	Router(config)# **interface** *type*[1] *slot/port*	Selects the interface to configure.
Step 2	Router(config-if)# **wrr-queue random-detect min-threshold** *queue_id thr1%* [*thr2%* [*thr3% thr4% thr5% thr6% thr7% thr8%*]]	Configures the low WRED-drop thresholds.
	Router(config-if)# **no wrr-queue random-detect min-threshold** [*queue_id*]	Reverts to the default low WRED-drop thresholds.
Step 3	Router(config-if)# **wrr-queue random-detect max-threshold** *queue_id thr1%* [*thr2%* [*thr3% thr4% thr5% thr6% thr7% thr8%*]]]	Configures the high WRED-drop thresholds.
	Router(config-if)# **no wrr-queue random-detect max-threshold** [*queue_id*]	Reverts to the default high WRED-drop thresholds.
Step 4	Router(config-if)# **end**	Exits configuration mode.
Step 5	Router# **show queueing interface** *type*[1] *slot/port*	Verifies the configuration.

[1] *type* = **fastethernet, gigabitethernet, or tengigabitethernet**

When configuring the WRED-drop thresholds, note the following:

- Each threshold has a low- and a high-WRED value.
- WRED values are a percentage of the queue capacity (the range is from 1 to 100).
- The low-WRED value is the traffic level under which no traffic is dropped. The low-WRED value must be lower than the high-WRED value. Configure the low-WRED value with the **min-threshold** keyword.

The high-WRED value is the traffic level above which all traffic is dropped. Configure the high-WRED value with the **max-threshold** keyword.

Note Traffic in the queue between the low- and high-WRED values has an increasing chance of being dropped as the queue fills.

- When configuring **1p2q2t** ports, note the following:
  - Queue number 1 is the low-priority standard transmit queue
  - Queue number 2 is high priority standard transmit queue
  - Each queue has two thresholds.
- When configuring **1p3q1t** ports, note the following:
  - Queue number 1 is the low-priority standard transmit queue.
  - Queue number 2 is the medium priority standard transmit queue.
  - Queue number 3 is the high priority standard transmit queue.
  - Each queue has one threshold.
  - When you configure each standard transmit queue, the single percentage that you enter sets the threshold.
- When configuring **1p1q8t** ports, note the following:
  - Queue number 1 is the single standard receive queue.
  - When you configure the single standard receive queue, note the following:

    The first percentage that you enter sets the lowest-priority threshold.

    The second percentage that you enter sets the next highest-priority threshold.

    The eighth percentage that you enter sets the highest-priority threshold.
- When configuring **1p2q1t** ports, note the following:
  - Queue number 1 is the low-priority standard transmit queue
  - Queue number 2 is high priority standard transmit queue
  - When you configure each standard transmit queue, the single percentage that you enter sets the threshold.

This example shows how to configure the low-priority transmit queue high-WRED-drop thresholds for Gigabit Ethernet port 1/1:

```
Router# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Router(config)# interface gigabitethernet 1/1
Router(config-if)# wrr-queue random-detect max-threshold 1 70 70
Router(config-if)# end
Router#
```

This example shows how to verify the configuration:

```
Router# show queueing interface gigabitethernet 1/1 | begin Transmit queues
  Transmit queues [type = 1p2q2t]:
    Queue Id    Scheduling  Num of thresholds
    -----------------------------------------
       1         WRR low             2
       2         WRR high            2
       3         Priority            1
    queue random-detect-max-thresholds
    ----------------------------------
      1     40[1]  70[2]
      2     40[1]  70[2]
<...Output Truncated...>
Router#
```

Enabling and Disabling WRED-Drop Thresholds

To enable or disable WRED-drop thresholds on **1p3q1t** or **1p2q1t** transmit queues or **1p1q8t** receive queues, perform this task:

	Command	Purpose
Step 1	`Router(config)# `**`interface`**` `*`type`*[1]` `*`slot/port`*	Selects the interface to configure.
Step 2	`Router(config-if)# `**`wrr-queue random-detect`**` `*`queue_id`*	Enables WRED-drop thresholds on queue 1, 2, or 3.
	`Router(config-if)# `**`no wrr-queue random-detect`**` [`*`queue_id`*`]`	Reverts to the default WRED-drop thresholds.
Step 3	`Router(config-if)# `**`end`**	Exits configuration mode.
Step 4	`Router# `**`show queueing interface`**` `*`type`*[1]` `*`slot/port`*	Verifies the configuration.

[1] *type* = **fastethernet** or **tengigabitethernet**

Mapping CoS Values to LAN-Port Drop Thresholds

These sections describe mapping CoS values to LAN-port drop thresholds:

- Mapping CoS Values to 1q4t/2q2t LAN Ports, page 32-57
- Mapping CoS Values on 1p1q4t/1p2q2t, 1p1q0t/1p3q1t, and 1p1q8t/1p2q1t LAN Ports, page 32-58

Mapping CoS Values to 1q4t/2q2t LAN Ports

Note Enter the **show queueing interface** {**ethernet** | **fastethernet** | **gigabitethernet** | **tengigabitethernet**} *slot/port* | **include type** command to see the queue structure of a port.

On **1q4t/2q2t** LAN ports, the receive- and transmit-queue tail-drop thresholds have this relationship:

- Receive queue 1 (standard) threshold 1 = transmit queue 1 (standard low priority) threshold 1
- Receive queue 1 (standard) threshold 2 = transmit queue 1 (standard low priority) threshold 2
- Receive queue 1 (standard) threshold 3 = transmit queue 2 (standard high priority) threshold 1
- Receive queue 1 (standard) threshold 4 = transmit queue 2 (standard high priority) threshold 2

To map CoS values to tail-drop thresholds, perform this task:

	Command	Purpose
Step 1	`Router(config)# `**`interface`**` `*`type`*[1]` `*`slot/port`*	Selects the interface to configure.
Step 2	`Router(config-if)# `**`wrr-queue cos-map`**` `*`transmit_queue_# threshold_# cos1`*` [`*`cos2`*` [`*`cos3`*` [`*`cos4`*` [`*`cos5`*` [`*`cos6`*` [`*`cos7`*` [`*`cos8`*`]]]]]]]`	Maps CoS values to a tail-drop threshold.
Step 3	`Router(config-if)# `**`no wrr-queue cos-map`**	Reverts to the default mapping.
Step 4	`Router(config-if)# `**`end`**	Exits configuration mode.
Step 5	`Router# `**`show queueing interface`**` `*`type`*[1]` `*`slot/port`*	Verifies the configuration.

[1] *type* = **ethernet**, **fastethernet**, **gigabitethernet**, or **tengigabitethernet**

When mapping CoS values to a tail-drop threshold, note the following:

- Use the transmit queue and threshold numbers.
- Queue 1 is the low-priority standard transmit queue.
- Queue 2 is the high-priority standard transmit queue.
- There are two thresholds in each queue.
- Enter up to 8 CoS values to map to the threshold.

This example shows how to map the CoS values 0 and 1 to standard transmit queue 1/threshold 1 for Fast Ethernet port 5/36:

```
Router# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Router(config)# interface fastethernet 5/36
Router(config-if)# wrr-queue cos-map 1 1 0 1
Router(config-if)# end
Router#
```

This example shows how to verify the configuration:

```
Router# show queueing interface fastethernet 5/36 | begin queue thresh cos-map
    queue thresh cos-map
    ---------------------------------------
    1      1      0 1
    1      2      2 3
    2      1      4 5
    2      2      6 7
<...Output Truncated...>
Router#
```

Mapping CoS Values on 1p1q4t/1p2q2t, 1p1q0t/1p3q1t, and 1p1q8t/1p2q1t LAN Ports

Note Enter the **show queueing interface** {**ethernet** | **fastethernet** | **gigabitethernet** | **tengigabitethernet**} *slot/port* | **include type** command to see the queue structure of a port.

These sections describe how to map CoS values:

- Mapping CoS Values to Standard Receive-Queue Tail-Drop Thresholds, page 32-59
- Mapping CoS Values to WRED-Drop Thresholds, page 32-59
- Mapping CoS Values to Strict-Priority Queues, page 32-61

Mapping CoS Values to Standard Receive-Queue Tail-Drop Thresholds

To map CoS values to the standard receive-queue tail-drop thresholds on **1q2t**, **1p1q4t**, and **1p1q0t** ingress LAN ports, perform this task:

	Command	Purpose
Step 1	Router(config)# **interface** {**fastethernet** | **gigabitethernet**} *slot/port*	Selects the interface to configure.
Step 2	Router(config-if)# **rcv-queue cos-map** *queue_# threshold_# cos1* [*cos2* [*cos3* [*cos4* [*cos5* [*cos6* [*cos7* [*cos8*]]]]]]]	Maps CoS values to the standard receive queue tail-drop thresholds. The queue number is always 1.
	Router(config-if)# **no rcv-queue cos-map**	Reverts to the default mapping.
Step 3	Router(config-if)# **end**	Exits configuration mode.
Step 4	Router# **show queueing interface** {**fastethernet** | **gigabitethernet**} *slot/port*	Verifies the configuration.

This example shows how to map the CoS values 0 and 1 to threshold 1 in the standard receive queue for Gigabit Ethernet port 1/1:

```
Router# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Router(config)# interface gigabitethernet 1/1
Router(config-if)# rcv-queue cos-map 1 1 0 1
Router(config-if)# end
Router#
```

This example shows how to verify the configuration:

```
Router# show queueing interface gigabitethernet 1/1
<...Output Truncated...>
    queue thresh cos-map
    ---------------------------------------
    1     1      0 1
    1     2      2 3
    1     3      4 5
    1     4      6 7
<...Output Truncated...>
Router#
```

Mapping CoS Values to WRED-Drop Thresholds

To map CoS values to WRED-drop thresholds, perform this task:

	Command	Purpose
Step 1	Router(config)# **interface** {**fastethernet** | **gigabitethernet**} *slot/port*	Selects the interface to configure.
Step 2	Router(config-if)# **wrr-queue cos-map** *transmit_queue_# threshold_# cos1* [*cos2* [*cos3* [*cos4* [*cos5* [*cos6* [*cos7* [*cos8*]]]]]]]	Maps CoS values to a WRED-drop threshold.
	Router(config-if)# **no wrr-queue cos-map**	Reverts to the default mapping.
Step 3	Router(config-if)# **end**	Exits configuration mode.
Step 4	Router# **show queueing interface** {**fastethernet** | **gigabitethernet**} *slot/port*	Verifies the configuration.

When associating CoS values to a WRED-drop threshold, note the following:

- On **1p2q2t** egress LAN ports:
  - Queue 1 is the low-priority standard transmit queue.
  - Queue 2 is the high-priority standard transmit queue.
  - There are two WRED-drop thresholds in each queue. Threshold 1 is low-priority and threshold 2 is high-priority.
- On **1p3q1t** egress LAN ports:
  - Queue 1 is the low-priority standard transmit queue.
  - Queue 2 is the medium-priority standard transmit queue.
  - Queue 3 is the high-priority standard transmit queue.
  - Each queue has two thresholds. Threshold 0 is the nonconfigurable 100-percent tail-drop threshold. Threshold 1 the WRED-drop threshold (see the "Enabling and Disabling WRED-Drop Thresholds" section on page 32-57 and the "Configuring Standard Queue WRED-Drop Thresholds" section on page 32-55).
- On **1p1q8t** ingress LAN ports:
  - Queue 1 is the standard queue.
  - Queue 1 has nine thresholds. Threshold 0 is the nonconfigurable 100-percent tail-drop threshold. Thresholds 1 through 8 are the WRED-drop thresholds (see the "Enabling and Disabling WRED-Drop Thresholds" section on page 32-57 and the "Configuring Standard Queue WRED-Drop Thresholds" section on page 32-55).
- On **1p2q1t** egress LAN ports:
  - Queue 1 is the standard queue.
  - Queue 1 has two thresholds. Threshold 0 is the nonconfigurable 100-percent tail-drop threshold. Threshold 1 the WRED-drop threshold (see the "Enabling and Disabling WRED-Drop Thresholds" section on page 32-57 and the "Configuring Standard Queue WRED-Drop Thresholds" section on page 32-55).
- You can enter up to 8 CoS values to map to the threshold.

This example shows how to map the CoS values 0 and 1 to standard transmit queue 1/threshold 1 for Fast Ethernet port 5/36:

```
Router# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Router(config)# interface fastethernet 5/36
Router(config-if)# wrr-queue cos-map 1 1 0 1
Router(config-if)# end
Router#
```

This example shows how to verify the configuration:

```
Router# show queueing interface fastethernet 5/36 | begin queue thresh cos-map
    queue thresh cos-map
    ---------------------------------------
    1     1      0 1
    1     2      2 3
    2     1      4 5
    2     2      6 7
<...Output Truncated...>
Router#
```

Mapping CoS Values to Strict-Priority Queues

To map CoS values to the receive and transmit strict-priority queues on **1p1q4t/1p2q2t, 1p1q0t/1p3q1t** and **1p1q8t/1p2q1t** LAN ports, perform this task:

	Command	Purpose
Step 1	`Router(config)#` **`interface`** *`type`*[1] *`slot/port`*	Selects the interface to configure.
Step 2	`Router(config-if)#` **`priority-queue cos-map`** *`queue_# cos1`* `[`*`cos2`* `[`*`cos3`* `[`*`cos4`* `[`*`cos5`* `[`*`cos6`* `[`*`cos7`* `[`*`cos8`*`]]]]]]]`	Maps CoS values to the receive and transmit strict-priority queues.
	`Router(config-if)#` **`no priority-queue cos-map`**	Reverts to the default mapping.
Step 3	`Router(config-if)#` **`end`**	Exits configuration mode.
Step 4	`Router#` **`show queueing interface`** *`type`*[1] *`slot/port`*	Verifies the configuration.

[1] *type* = **fastethernet, gigabitethernet, or tengigabitethernet**

When mapping CoS values to the strict-priority queues, note the following:

- The queue number is always 1.
- You can enter up to 8 CoS values to map to the queue.

This example shows how to map CoS value 7 to the strict-priority queues on Gigabit Ethernet port 1/1:

```
Router# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Router(config)# interface gigabitethernet 1/1
Router(config-if)# priority-queue cos-map 1 7
Router(config-if)# end
Router#
```

This example shows how to verify the configuration:

```
Router# show queueing interface gigabitethernet 1/1
<...Output Truncated...>
Transmit queues [type = 1p2q2t]:
<...Output Truncated...>
    queue thresh cos-map
    ---------------------------------------
    1     1      0 1
    1     2      2 3
    2     1      4
    2     2      6
    3     1      5 7

  Receive queues [type = 1p1q4t]:
<...Output Truncated...>
    queue thresh cos-map
    ---------------------------------------
    1     1      0 1
    1     2      2 3
    1     3      4
    1     4      6
    2     1      5 7
<...Output Truncated...>
Router#
```

Allocating Bandwidth Between LAN-Port Transmit Queues

The switch transmits frames from one standard queue at a time using a WRR algorithm. WRR uses the ratio between queue weight values to decide how much to transmit from one queue before switching to the other. The more the ratio favors a queue, the more transmit bandwidth is allocated to it.

To allocate bandwidth for an egress LAN port, perform this task:

	Command	Purpose
Step 1	`Router(config)# interface type[1] slot/port`	Selects the interface to configure.
Step 2	`Router(config-if)# wrr-queue bandwidth low_priority_queue_weight [medium_priority_queue_weight] high_priority_queue_weight`	Allocates bandwidth between standard transmit queues. The valid values for weight range from 1 to 255.
	`Router(config-if)# no wrr-queue bandwidth`	Reverts to the default bandwidth allocation.
Step 3	`Router(config-if)# end`	Exits configuration mode.
Step 4	`Router# show queueing interface type[1] slot/port`	Verifies the configuration.

[1] *type* = ethernet, fastethernet, gigabitethernet, or tengigabitethernet

This example shows how to allocate a 3-to-1 bandwidth ratio for Gigabit Ethernet port 1/2:

```
Router# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Router(config)# interface gigabitethernet 1/2
Router(config-if)# wrr-queue bandwidth 3 1
Router(config-if)# end
Router#
```

This example shows how to verify the configuration:

```
Router# show queueing interface gigabitethernet 1/2 | include bandwidth
WRR bandwidth ratios:    3[queue 1]    1[queue 2]
Router#
```

Setting the Receive-Queue Size Ratio on a 1p1q0t or 1p1q8t Ingress LAN Ports

To set the size ratio between the strict-priority and standard receive queues on a **1p1q0t** or **1p1q8t** ingress LAN ports, perform this task:

	Command	Purpose
Step 1	`Router(config)# interface {fastethernet	tengigabitethernet} slot/port`	Selects the interface to configure.
Step 2	`Router(config-if)# rcv-queue queue-limit standard_queue_weight strict_priority_queue_weight`	Sets the size ratio between the strict-priority and standard receive queues.
	`Router(config-if)# no rcv-queue queue-limit`	Reverts to the default the size ratio.
Step 3	`Router(config-if)# end`	Exits configuration mode.
Step 4	`Router# show queueing interface {fastethernet	tengigabitethernet} slot/port`	Verifies the configuration.

When setting the receive-queue size ratio, note the following:

- The **rcv-queue queue-limit** command configures ports on a per-ASIC basis.
- Estimate the mix of strict priority-to-standard traffic on your network (for example, 80 percent standard traffic and 20 percent strict-priority traffic).
- Use the estimated percentages as queue weights.
- Valid values are from 1 to 100 percent, except on **1p1q8t** ingress LAN ports, where valid values for the strict priority queue are from 3 to 100 percent.

This example shows how to set the receive-queue size ratio for Fast Ethernet port 2/2:

```
Router# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Router(config)# interface fastethernet 2/2
Router(config-if)# rcv-queue queue-limit 75 15
Router(config-if)# end
Router#
```

This example shows how to verify the configuration:

```
Router# show queueing interface fastethernet 2/2 | include queue-limit
    queue-limit ratios:     75[queue 1]  15[queue 2]
Router#
```

Setting the LAN-Port Transmit-Queue Size Ratio

To set the transmit-queue size ratio on an egress LAN port, perform this task:

	Command	Purpose
Step 1	Router(config)# **interface** *type*[1] *slot/port*	Selects the interface to configure.
Step 2	Router(config-if)# **wrr-queue queue-limit** *low_priority_queue_weight* [*medium_priority_queue_weight*] *high_priority_queue_weight*	Sets the transmit-queue size ratio between transmit queues.
	Router(config-if)# **no wrr-queue queue-limit**	Reverts to the default transmit-queue size ratio.
Step 3	Router(config-if)# **end**	Exits configuration mode.
Step 4	Router# **show queueing interface** *type*[1] *slot/port*	Verifies the configuration.

[1] *type* = **ethernet**, **fastethernet**, **gigabitethernet**, or **tengigabitethernet**

When setting the transmit-queue size ratio between transmit queues, note the following:

- Estimate the mix of low priority-to-high priority traffic on your network (for example, 80 percent low-priority traffic and 20 percent high-priority traffic).
- On **1p2q2t** egress LAN ports, PFC QoS sets the strict-priority queue size equal to the high priority queue size.
- Use the estimated percentages as queue weights.
- Valid values are from 1 to 100 percent, except on **1p2q1t** egress LAN ports, where valid values for the high priority queue are from 5 to 100 percent.

This example shows how to set the transmit-queue size ratio for Gigabit Ethernet port 1/2:

```
Router# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Router(config)# interface gigabitethernet 1/2
Router(config-if)# wrr-queue queue-limit 75 15
Router(config-if)# end
Router#
```

This example shows how to verify the configuration:

```
Router# show queueing interface gigabitethernet 1/2 | include queue-limit
    queue-limit ratios:      75[queue 1]  25[queue 2]
Router#
```

Configuring DSCP Value Maps

These sections describe how DSCP values are mapped to other values:

- Mapping Received CoS Values to Internal DSCP Values, page 32-64
- Mapping Received IP Precedence Values to Internal DSCP Values, page 32-65
- Mapping Internal DSCP Values to Egress CoS Values, page 32-65
- Configuring DSCP Markdown Values, page 32-66

Mapping Received CoS Values to Internal DSCP Values

To configure the mapping of received CoS values to the DSCP value that PFC QoS uses internally on the PFC (see the "Internal DSCP Values" section on page 32-17), perform this task:

	Command	Purpose
Step 1	`Router(config)# mls qos map cos-dscp dscp1 dscp2 dscp3 dscp4 dscp5 dscp6 dscp7 dscp8`	Configures the received CoS to internal DSCP map. You must enter 8 DSCP values to which PFC QoS maps CoS values 0 through 7.
	`Router(config)# no mls qos map cos-dscp`	Reverts to the default map.
Step 2	`Router(config)# end`	Exits configuration mode.
Step 3	`Router# show mls qos maps`	Verifies the configuration.

This example shows how to configure the received CoS to internal DSCP map:

```
Router# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Router(config)# mls qos map cos-dscp 0 1 2 3 4 5 6 7
Router(config)# end
Router#
```

This example shows how to verify the configuration:

```
Router# show mls qos maps | begin Cos-dscp map
   Cos-dscp map:
        cos:   0  1  2  3  4  5  6  7
     ----------------------------------
       dscp:   0  1  2  3  4  5  6  7
<...Output Truncated...>
Router#
```

Mapping Received IP Precedence Values to Internal DSCP Values

To configure the mapping of received IP precedence values to the DSCP value that PFC QoS uses internally on the PFC (see the "Internal DSCP Values" section on page 32-17), perform this task:

	Command	Purpose
Step 1	`Router(config)# mls qos map ip-prec-dscp dscp1 dscp2 dscp3 dscp4 dscp5 dscp6 dscp7 dscp8`	Configures the received IP precedence to internal DSCP map. You must enter 8 internal DSCP values to which PFC QoS maps received IP precedence values 0 through 7.
	`Router(config)# no mls qos map ip-prec-dscp`	Reverts to the default map.
Step 2	`Router(config)# end`	Exits configuration mode.
Step 3	`Router# show mls qos maps`	Verifies the configuration.

This example shows how to configure the received IP precedence to internal DSCP map:

```
Router# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Router(config)# mls qos map ip-prec-dscp 0 1 2 3 4 5 6 7
Router(config)# end
Router#
```

This example shows how to verify the configuration:

```
Router# show mls qos maps | begin IpPrecedence-dscp map
   IpPrecedence-dscp map:
     ipprec:   0  1  2  3  4  5  6  7
     ---------------------------------
       dscp:   0  1  2  3  4  5  6  7
<...Output Truncated...>
Router#
```

Mapping Internal DSCP Values to Egress CoS Values

To configure the mapping of the DSCP value that PFC QoS uses internally on the PFC to the CoS value used for egress LAN port scheduling and congestion avoidance (see the "Internal DSCP Values" section on page 32-17 and the "LAN Egress Port Features" section on page 32-21), perform this task:

	Command	Purpose
Step 1	`Router(config)# mls qos map dscp-cos dscp1 [dscp2 [dscp3 [dscp4 [dscp5 [dscp6 [dscp7 [dscp8]]]]]]] to cos_value`	Configures the internal DSCP to egress CoS map.
	`Router(config)# no mls qos map dscp-cos`	Reverts to the default map.
Step 2	`Router(config)# end`	Exits configuration mode.
Step 3	`Router# show mls qos maps`	Verifies the configuration.

When configuring the internal DSCP to egress CoS map, note the following:

- You can enter up to 8 DSCP values that PFC QoS maps to a CoS value.
- You can enter multiple commands to map additional DSCP values to a CoS value.
- You can enter a separate command for each CoS value.

This example shows how to configure internal DSCP values 0, 8, 16, 24, 32, 40, 48, and 54 to be mapped to egress CoS value 0:

```
Router# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Router(config)# mls qos map dscp-cos 0 8 16 24 32 40 48 54 to 0
Router(config)# end
Router#
```

This example shows how to verify the configuration:

```
Router# show mls qos map | begin Dscp-cos map
   Dscp-cos map:                                      (dscp= d1d2)
     d1 :  d2 0  1  2  3  4  5  6  7  8  9
     -------------------------------------
      0 :     00 00 00 00 00 00 00 00 00 01
      1 :     01 01 01 01 01 01 00 02 02 02
      2 :     02 02 02 02 00 03 03 03 03 03
      3 :     03 03 00 04 04 04 04 04 04 04
      4 :     00 05 05 05 05 05 05 05 00 06
      5 :     06 06 06 06 00 06 07 07 07 07
      6 :     07 07 07 07
<...Output Truncated...>
Router#
```

Note In the **Dscp-cos** display, the CoS values are shown in the body of the matrix; the first digit of the DSCP value is in the column labeled **d1** and the second digit is in the top row. In the example shown, DSCP values 41 through 47 all map to CoS 05.

Configuring DSCP Markdown Values

To configure the mapping of DSCP markdown values used by policers (see the "Policers" section on page 32-19), perform this task:

	Command	Purpose
Step 1	`Router(config)#` **`mls qos map policed-dscp {normal-burst	max-burst}`** *`dscp1 [dscp2 [dscp3 [dscp4 [dscp5 [dscp6 [dscp7 [dscp8]]]]]]]`* **`to`** *`markdown_dscp`*	Configures a DSCP markdown map.
	`Router(config)#` **`no mls qos map policed-dscp {normal-burst	max-burst}`**	Reverts to the default map.
Step 2	`Router(config)#` **`end`**	Exits configuration mode.
Step 3	`Router#` **`show mls qos maps`**	Verifies the configuration.

When configuring a DSCP markdown map, note the following:

- You can enter the **normal-burst** keyword to configure the markdown map used by the **exceed-action policed-dscp-transmit** keywords.
- You can enter the **max-burst** keyword to configure the markdown map used by the **violate-action policed-dscp-transmit** keywords.

Note When you create a policer that does not use the **pir** keyword, and the *maximum_burst_bytes* parameter is equal to the *normal_burst_bytes* parameter (which occurs if you do not enter the *maximum_burst_bytes* parameter), the **exceed-action policed-dscp-transmit** keywords cause PFC QoS to mark traffic down as defined by the **policed-dscp max-burst** markdown map.

- To avoid out-of-sequence packets, configure the markdown maps so that conforming and nonconforming traffic uses the same queue.
- You can enter up to 8 DSCP values that map to a marked-down DSCP value.
- You can enter multiple commands to map additional DSCP values to a marked-down DSCP value.
- You can enter a separate command for each marked-down DSCP value.

Note Configure marked-down DSCP values that map to CoS values consistent with the markdown penalty (see the "Mapping Internal DSCP Values to Egress CoS Values" section on page 32-65).

This example shows how to map DSCP 1 to marked-down DSCP value 0:

```
Router# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Router(config)# mls qos map policed-dscp normal-burst 1 to 0
Router(config)# end
Router#
```

This example shows how to verify the configuration:

```
Router# show mls qos map
   Normal Burst Policed-dscp map:                               (dscp= d1d2)
     d1 :  d2 0  1  2  3  4  5  6  7  8  9
     -------------------------------------
      0 :    00 01 02 03 04 05 06 07 08 09
      1 :    10 11 12 13 14 15 16 17 18 19
      2 :    20 21 22 23 24 25 26 27 28 29
      3 :    30 31 32 33 34 35 36 37 38 39
      4 :    40 41 42 43 44 45 46 47 48 49
      5 :    50 51 52 53 54 55 56 57 58 59
      6 :    60 61 62 63

   Maximum Burst Policed-dscp map:                               (dscp= d1d2)
     d1 :  d2 0  1  2  3  4  5  6  7  8  9
     -------------------------------------
      0 :    00 01 02 03 04 05 06 07 08 09
      1 :    10 11 12 13 14 15 16 17 18 19
      2 :    20 21 22 23 24 25 26 27 28 29
      3 :    30 31 32 33 34 35 36 37 38 39
      4 :    40 41 42 43 44 45 46 47 48 49
      5 :    50 51 52 53 54 55 56 57 58 59
      6 :    60 61 62 63
<...Output Truncated...>
Router#
```

Note In the **Policed-dscp** displays, the marked-down DSCP values are shown in the body of the matrix; the first digit of the original DSCP value is in the column labeled **d1** and the second digit is in the top row. In the example shown, DSCP 41 maps to DSCP 41.

Configuring PFC QoS Statistics Data Export

Note Release 12.1(11b)E and later releases support PFC QoS statistics data export.

These sections describe how to configure PFC QoS statistics data export:

- Enabling PFC QoS Statistics Data Export Globally, page 32-68
- Enabling PFC QoS Statistics Data Export for a Port, page 32-69
- Enabling PFC QoS Statistics Data Export for a Named Aggregate Policer, page 32-70
- Enabling PFC QoS Statistics Data Export for a Class Map, page 32-71
- Setting the PFC QoS Statistics Data Export Time Interval, page 32-72
- Configuring PFC QoS Statistics Data Export Destination Host and UDP Port, page 32-73
- Setting the PFC QoS Statistics Data Export Field Delimiter, page 32-75

Enabling PFC QoS Statistics Data Export Globally

To enable PFC QoS statistics data export globally, perform this task:

	Command	Purpose
Step 1	`Router(config)# mls qos statistics-export`	Enables PFC QoS statistics data export globally.
	`Router(config)# no mls qos statistics-export`	Disables PFC QoS statistics data export globally.
Step 2	`Router(config)# end`	Exits configuration mode.
Step 3	`Router# show mls qos statistics-export info`	Verifies the configuration.

This example shows how to enable PFC QoS statistics data export globally and verify the configuration:

```
Router# configure terminal
Router(config)# mls qos statistics-export
Router(config)# end
% Warning: Export destination not set.
% Use 'mls qos statistics-export destination' command to configure the export destination
Router# show mls qos statistics-export info
QoS Statistics Data Export Status and Configuration information
---------------------------------------------------------------
Export Status : enabled
Export Interval : 300 seconds
Export Delimiter : |
Export Destination : Not configured
Router#
```

Note You must enable PFC QoS statistics data export globally for other PFC QoS statistics data export configuration to take effect.

Enabling PFC QoS Statistics Data Export for a Port

To enable PFC QoS statistics data export for a port, perform this task:

	Command	Purpose
Step 1	`Router(config)# interface type[1] slot/port`	Selects the interface to configure.
Step 2	`Router(config-if)# mls qos statistics-export`	Enables PFC QoS statistics data export for the port.
	`Router(config-if)# no mls qos statistics-export`	Disables PFC QoS statistics data export for the port.
Step 3	`Router(config)# end`	Exits configuration mode.
Step 4	`Router# show mls qos statistics-export info`	Verifies the configuration.

[1] *type* = **ethernet**, **fastethernet**, **gigabitethernet**, or **tengigabitethernet**

This example shows how to enable PFC QoS statistics data export on FastEthernet port 5/24 and verify the configuration:

```
Router# configure terminal
Router(config)# interface fastethernet 5/24
Router(config-if)# mls qos statistics-export
Router(config-if)# end
Router# show mls qos statistics-export info
QoS Statistics Data Export Status and Configuration information
---------------------------------------------------------------
Export Status : enabled
Export Interval : 300 seconds
Export Delimiter : |
Export Destination : Not configured

QoS Statistics Data Export is enabled on following ports:
---------------------------------------------------------
FastEthernet5/24
Router#
```

When enabled on a port, PFC QoS statistics data export contains the following fields, separated by the delimiter character:

- Export type ("1" for a port)
- Slot/port
- Number of ingress packets
- Number of ingress bytes
- Number of egress packets
- Number of egress bytes
- Time stamp

Enabling PFC QoS Statistics Data Export for a Named Aggregate Policer

To enable PFC QoS statistics data export for a named aggregate policer, perform this task:

	Command	Purpose
Step 1	`Router(config)# mls qos statistics-export aggregate-policer aggregate_policer_name`	Enables PFC QoS statistics data export for a named aggregate policer.
	`Router(config)# no mls qos statistics-export aggregate-policer aggregate_policer_name`	Disables PFC QoS statistics data export for a named aggregate policer.
Step 2	`Router(config)# end`	Exits configuration mode.
Step 3	`Router# show mls qos statistics-export info`	Verifies the configuration.

This example shows how to enable PFC QoS statistics data export for an aggregate policer named aggr1M and verify the configuration:

```
Router# configure terminal
Router(config)# mls qos statistics-export aggregate-policer aggr1M
Router(config)# end
Router# show mls qos statistics-export info
QoS Statistics Data Export Status and Configuration information
---------------------------------------------------------------
Export Status : enabled
Export Interval : 300 seconds
Export Delimiter : |
Export Destination : Not configured

QoS Statistics Data Export is enabled on following ports:
---------------------------------------------------------
FastEthernet5/24

QoS Statistics Data export is enabled on following shared aggregate policers:
-----------------------------------------------------------------------------
aggr1M
Router#
```

When enabled for a named aggregate policer, PFC QoS statistics data export contains the following fields, separated by the delimiter character:

- Export type ("3" for an aggregate policer)
- Aggregate policer name
- Direction ("in")
- PFC or DFC slot number
- Number of in-profile packets
- Number of packets that exceed the CIR
- Number of packets that exceed the PIR
- Time stamp

Enabling PFC QoS Statistics Data Export for a Class Map

To enable PFC QoS statistics data export for a class map, perform this task:

	Command	Purpose
Step 1	Router(config)# **mls qos statistics-export class-map** *classmap_name*	Enables PFC QoS statistics data export for a class map.
	Router(config)# **no mls qos statistics-export class-map** *classmap_name*	Disables PFC QoS statistics data export for a class map.
Step 2	Router(config)# **end**	Exits configuration mode.
Step 3	Router# **show mls qos statistics-export info**	Verifies the configuration.

This example shows how to enable PFC QoS statistics data export for a class map named class3 and verify the configuration:

```
Router# configure terminal
Router(config)# mls qos statistics-export class-map class3
Router(config)# end
Router# show mls qos statistics-export info
QoS Statistics Data Export Status and Configuration information
---------------------------------------------------------------
Export Status : enabled
Export Interval : 300 seconds
Export Delimiter : |
Export Destination : Not configured

QoS Statistics Data Export is enabled on following ports:
---------------------------------------------------------
FastEthernet5/24

QoS Statistics Data export is enabled on following shared aggregate policers:
-----------------------------------------------------------------------------
aggr1M

QoS Statistics Data Export is enabled on following class-maps:
---------------------------------------------------------------
class3
Router#
```

When enabled for a class map, PFC QoS statistics data export contains the following fields, separated by the delimiter character:

- For data from a physical port:
  - Export type (“4” for a classmap and port)
  - Class map name
  - Direction (“in”)
  - Slot/port
  - Number of in-profile packets
  - Number of packets that exceed the CIR
  - Number of packets that exceed the PIR
  - Time stamp

- For data from a VLAN interface:
  - Export type ("5" for a class map and VLAN)
  - Classmap name
  - Direction ("in")
  - PFC or DFC slot number
  - VLAN ID
  - Number of in-profile packets
  - Number of packets that exceed the CIR
  - Number of packets that exceed the PIR
  - Time stamp
- For data from a port channel interface:
  - Export type ("6" for a class map and port-channel)
  - Class map name
  - Direction ("in")
  - PFC or DFC slot number
  - Port channel ID
  - Number of in-profile packets
  - Number of packets that exceed the CIR
  - Number of packets that exceed the PIR
  - Time stamp

Setting the PFC QoS Statistics Data Export Time Interval

To set the time interval for the PFC QoS statistics data export, perform this task:

	Command	Purpose
Step 1	Router(config)# **mls qos statistics-export interval** *interval_in_seconds*	Sets the time interval for the PFC QoS statistics data export. **Note** The interval needs to be short enough to avoid counter wraparound with the activity in your configuration, but because exporting PFC QoS statistic creates a significant load on the switch, be careful when decreasing the interval.
	Router(config)# **no mls qos statistics-export interval** *interval_in_seconds*	Reverts to the default time interval for the PFC QoS statistics data export.
Step 2	Router(config)# **end**	Exits configuration mode.
Step 3	Router# **show mls qos statistics-export info**	Verifies the configuration.

This example shows how to set the PFC QoS statistics data export interval and verify the configuration:

```
Router# configure terminal
Router(config)# mls qos statistics-export interval 250
Router(config)# end
Router# show mls qos statistics-export info
QoS Statistics Data Export Status and Configuration information
---------------------------------------------------------------
Export Status : enabled
Export Interval : 250 seconds
Export Delimiter : |
Export Destination : Not configured

QoS Statistics Data Export is enabled on following ports:
---------------------------------------------------------
FastEthernet5/24

QoS Statistics Data export is enabled on following shared aggregate policers:
-----------------------------------------------------------------------------
aggr1M

QoS Statistics Data Export is enabled on following class-maps:
---------------------------------------------------------------
class3
Router#
```

Configuring PFC QoS Statistics Data Export Destination Host and UDP Port

To configure the PFC QoS statistics data export destination host and UDP port number, perform this task:

	Command	Purpose
Step 1	`Router(config)# mls qos statistics-export destination {host_name | host_ip_address} {port port_number | syslog [facility facility_name] [severity severity_value]}`	Configures the PFC QoS statistics data export destination host and UDP port number.
	`Router(config)# no mls qos statistics-export destination`	Clears configured values.
Step 2	`Router(config)# end`	Exits configuration mode.
Step 3	`Router# show mls qos statistics-export info`	Verifies the configuration.

Note When the PFC QoS data export destination is a syslog server, the exported data is prefaced with a syslog header.

Table 32-3 lists the supported PFC QoS data export facility and severity parameter values.

Table 32-3 Supported PFC QoS Data Export Facility Parameter Values

Name	Definition	Name	Definition
kern	kernel messages	cron	cron/at subsystem
user	random user-level messages	local0	reserved for local use
mail	mail system	local1	reserved for local use

Table 32-3 Supported PFC QoS Data Export Facility Parameter Values (continued)

Name	Definition	Name	Definition
daemon	system daemons	local2	reserved for local use
auth	security/authentication messages	local3	reserved for local use
